If you created a key with passphrase, you may have to enter it here. However for the purpose of this example, the passphrase is blank.

Encrypting gpfdist Connections

The `gpfdists` protocol is a secure version of the `gpfdist` protocol that securely identifies the file server and the WarehousePG and encrypts the communications between them. Using `gpfdists` protects against eavesdropping and man-in-the-middle attacks.

The `gpfdists` protocol implements client/server SSL security with the following notable features:

- Client certificates are required.
- Multilingual certificates are not supported.
- A Certificate Revocation List (CRL) is not supported.
- The TLSv1 protocol is used with the `TLS_RSA_WITH_AES_128_CBC_SHA` encryption algorithm. These SSL parameters cannot be changed.
- SSL renegotiation is supported.
- The SSL ignore host mismatch parameter is set to false.
- Private keys containing a passphrase are not supported for the `gpfdist` file server (server.key) or for the WarehousePG (client.key).
- It is the user's responsibility to issue certificates that are appropriate for the operating system in use. Generally, converting certificates to the required format is supported, for example using the SSL Converter at https://www.sslshopper.com/ssl-converter.html.

A `gpfdist` server started with the `--ssl` option can only communicate with the `gpfdists` protocol. A `gpfdist` server started without the `--ssl` option can only communicate with the `gpfdist` protocol. For more detail about `gpfdist` refer to the *WarehousePG Administrator Guide*.

There are two ways to enable the `gpfdists` protocol:

- Run `gpfdist` with the `--ssl` option and then use the `gpfdists` protocol in the `LOCATION` clause of a `CREATE EXTERNAL TABLE` statement.
- Use a YAML control file with the SSL option set to true and run `gpload`. Running `gpload` starts the `gpfdist` server with the `--ssl` option and then uses the `gpfdists` protocol.

When using gpfdists, the following client certificates must be located in the `$PGDATA/gpfdists` directory on each segment:

- The client certificate file, `client.crt`
- The client private key file, `client.key`
- The trusted certificate authorities, `root.crt`

> **Important** Do not protect the private key with a passphrase. The server does not prompt for a passphrase for the private key, and loading data fails with an error if one is required.

When using `gpload` with SSL you specify the location of the server certificates in the YAML control file. When using `gpfdist` with SSL, you specify the location of the server certificates with the --ssl option.

The following example shows how to securely load data into an external table. The example creates a readable external table named `ext_expenses` from all files with the `txt` extension, using the `gpfdists` protocol. The files are formatted with a pipe (`|`) as the column delimiter and an empty space as null.

1. Run `gpfdist` with the `--ssl` option on the segment hosts.

2. Log into the database and run the following command:

```
=# CREATE EXTERNAL TABLE ext_expenses
   ( name text, date date, amount float4, category text, desc1 text )
LOCATION ('gpfdists://etlhost-1:8081/*.txt', 'gpfdists://etlhost-2:8082/*.txt')
FORMAT 'TEXT' ( DELIMITER '|' NULL ' ') ;
```

Parent topic: WarehousePG Best Practices

SHA2 algorithms were added to OpenSSL in version 0.9.8. For older versions, pgcrypto will use built-in code Any digest algorithm OpenSSL supports is automatically picked up. This is not possible with ciphers, which need to be supported explicitly. AES is included in OpenSSL since version 0.9.7. For older versions, pgcrypto will use built-in code.

6.11 Tuning SQL Queries

The WarehousePG cost-based optimizer evaluates many strategies for running a query and chooses the least costly method.

Like other RDBMS optimizers, the WarehousePG optimizer takes into account factors such as the number of rows in tables to be joined, availability of indexes, and cardinality of column data when calculating the costs of alternative execution plans. The optimizer also accounts for the location of the data, preferring to perform as much of the work as possible on the segments and to minimize the amount of data that must be transmitted between segments to complete the query.

When a query runs slower than you expect, you can view the plan the optimizer selected as well as the cost it calculated for each step of the plan. This will help you determine which steps are consuming the most resources and then modify the query or the schema to provide the optimizer with more efficient alternatives. You use the SQL `EXPLAIN` statement to view the plan for a query.

The optimizer produces plans based on statistics generated for tables. It is important to have accurate statistics to produce the best plan. See Updating Statistics with ANALYZE in this guide for information about updating statistics.

Parent topic: WarehousePG Best Practices

How to Generate Explain Plans

The `EXPLAIN` and `EXPLAIN ANALYZE` statements are useful tools to identify opportunities to improve query performance. `EXPLAIN` displays the query plan and estimated costs for a query, but does not run the query. `EXPLAIN ANALYZE` runs the query in addition to displaying the query plan. `EXPLAIN ANALYZE` discards any output from the `SELECT` statement; however, other operations in the statement are performed (for example, `INSERT`, `UPDATE`, or `DELETE`). To use `EXPLAIN ANALYZE` on a DML statement without letting the command affect the data, explicitly use `EXPLAIN ANALYZE` in a transaction (`BEGIN; EXPLAIN ANALYZE ...; ROLLBACK;`).

`EXPLAIN ANALYZE` runs the statement in addition to displaying the plan with additional information as follows:

- Total elapsed time (in milliseconds) to run the query
- Number of workers (segments) involved in a plan node operation
- Maximum number of rows returned by the segment (and its segment ID) that produced the most rows for an operation
- The memory used by the operation
- Time (in milliseconds) it took to retrieve the first row from the segment that produced the most rows, and the total time taken to retrieve all rows from that segment.

How to Read Explain Plans

An explain plan is a report detailing the steps the WarehousePG optimizer has determined it will follow to run a query. The plan is a tree of nodes, read from bottom to top, with each node passing its result to the node directly above. Each node represents a step in the plan, and one line for each node identifies the operation performed in that step—for example, a scan, join, aggregation, or sort operation. The node also identifies the method used to perform the operation. The method for a scan operation, for example, may be a sequential scan or an index scan. A join operation may perform a hash join or nested loop join.

Following is an explain plan for a simple query. This query finds the number of rows in the contributions table stored at each segment.

```
gpadmin=# EXPLAIN SELECT gp_segment_id, count(*)
                  FROM contributions
                  GROUP BY gp_segment_id;
                                  QUERY PLAN
------------------------------------------------------------------------------
 Gather Motion 2:1  (slice2; segments: 2)  (cost=0.00..431.00 rows=2 width=12)
   ->  GroupAggregate  (cost=0.00..431.00 rows=1 width=12)
         Group By: gp_segment_id
         ->  Sort  (cost=0.00..431.00 rows=1 width=12)
               Sort Key: gp_segment_id
               ->  Redistribute Motion 2:2  (slice1; segments: 2)  (cost=0.00..431.00 rows=1 width=12)
                     Hash Key: gp_segment_id
                     ->  Result  (cost=0.00..431.00 rows=1 width=12)
                           ->  GroupAggregate  (cost=0.00..431.00 rows=1 width=12)
                                 Group By: gp_segment_id
                                 ->  Sort  (cost=0.00..431.00 rows=7 width=4)
                                       Sort Key: gp_segment_id
                                       ->  Seq Scan on table1  (cost=0.00..431.00 rows=7 width=4)
 Optimizer: GPORCA
(14 rows)
```

This plan has eight nodes – Seq Scan, Sort, GroupAggregate, Result, Redistribute Motion, Sort, GroupAggregate, and finally Gather Motion. Each node contains three cost estimates: cost (in sequential page reads), the number of rows, and the width of the rows.

The cost is a two-part estimate. A cost of 1.0 is equal to one sequential disk page read. The first part of the estimate is the start-up cost, which is the cost of getting the first row. The second estimate is the total cost, the cost of getting all of the rows.

The rows estimate is the number of rows output by the plan node. The number may be lower than the actual number of rows processed or scanned by the plan node, reflecting the estimated selectivity of `WHERE` clause conditions. The total cost assumes that all rows will be retrieved, which may not always be the case (for example, if you use a `LIMIT` clause).

The width estimate is the total width, in bytes, of all the columns output by the plan node.

The cost estimates in a node include the costs of all its child nodes, so the top-most node of the plan, usually a Gather Motion, has the estimated total execution costs for the plan. This is this number that the query planner seeks to minimize.

Scan operators scan through rows in a table to find a set of rows. There are different scan operators for different types of storage. They include the following:

- Seq Scan on tables — scans all rows in the table.
- Index Scan — traverses an index to fetch the rows from the table.
- Bitmap Heap Scan — gathers pointers to rows in a table from an index and sorts by location on disk. (The operator is called a Bitmap Heap Scan, even for append-only tables.)
- Dynamic Seq Scan — chooses partitions to scan using a partition selection function.

Join operators include the following:

- Hash Join – builds a hash table from the smaller table with the join column(s) as hash key. Then scans the larger table, calculating the hash key for the join column(s) and probing the hash table to find the rows with the same hash key. Hash joins are typically the fastest joins in WarehousePG. The Hash Cond in the explain plan identifies the columns that are joined.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

- Nested Loop – iterates through rows in the larger dataset, scanning the rows in the smaller dataset on each iteration. The Nested Loop join requires the broadcast of one of the tables so that all rows in one table can be compared to all rows in the other table. It performs well for small tables or tables that are limited by using an index. It is also used for Cartesian joins and range joins. There are performance implications when using a Nested Loop join with large tables. For plan nodes that contain a Nested Loop join operator, validate the SQL and ensure that the results are what is intended. Set the `enable_nestloop` server configuration parameter to OFF (default) to favor Hash Join.
- Merge Join – sorts both datasets and merges them together. A merge join is fast for pre-ordered data, but is very rare in the real world. To favor Merge Joins over Hash Joins, set the `enable_mergejoin` system configuration parameter to ON.

Some query plan nodes specify motion operations. Motion operations move rows between segments when required to process the query. The node identifies the method used to perform the motion operation. Motion operators include the following:

- Broadcast motion – each segment sends its own, individual rows to all other segments so that every segment instance has a complete local copy of the table. A Broadcast motion may not be as optimal as a Redistribute motion, so the optimizer typically only selects a Broadcast motion for small tables. A Broadcast motion is not acceptable for large tables. In the case where data was not distributed on the join key, a dynamic redistribution of the needed rows from one of the tables to another segment is performed.
- Redistribute motion – each segment rehashes the data and sends the rows to the appropriate segments according to hash key.
- Gather motion – result data from all segments is assembled into a single stream. This is the final operation for most query plans.

Other operators that occur in query plans include the following:

- Materialize – the planner materializes a subselect once so it does not have to repeat the work for each top-level row.
- InitPlan – a pre-query, used in dynamic partition elimination, performed when the values the planner needs to identify partitions to scan are unknown until execution time.
- Sort – sort rows in preparation for another operation requiring ordered rows, such as an Aggregation or Merge Join.
- Group By – groups rows by one or more columns.
- Group/Hash Aggregate – aggregates rows using a hash.
- Append – concatenates data sets, for example when combining rows scanned from partitions in a partitioned table.
- Filter – selects rows using criteria from a `WHERE` clause.
- Limit – limits the number of rows returned.

Optimizing WarehousePG Queries

This topic describes WarehousePG features and programming practices that can be used to enhance system performance in some situations.

To analyze query plans, first identify the plan nodes where the estimated cost to perform the operation is very high. Determine if the estimated number of rows and cost seems reasonable relative to the number of rows for the operation performed.

If using partitioning, validate that partition elimination is achieved. To achieve partition elimination the query predicate (`WHERE` clause) must be the same as the partitioning criteria. Also, the `WHERE` clause must not contain an explicit value and cannot contain a subquery.

Review the execution order of the query plan tree. Review the estimated number of rows. You want the execution order to build on the smaller tables or hash join result and probe with larger tables. Optimally, the largest table is used for the final join or probe to reduce the number of rows being passed up the tree to the topmost plan nodes. If the analysis reveals that the order of execution builds and/or probes is not optimal ensure that database statistics are up to date. Running `ANALYZE` will likely address this and produce an optimal query plan.

Look for evidence of computational skew. Computational skew occurs during query execution when execution of operators such as Hash Aggregate and Hash Join cause uneven execution on the segments. More CPU and memory are used on some segments than others, resulting in less than optimal execution. The cause could be joins, sorts, or aggregations on columns that have low cardinality or non-uniform distributions. You can detect computational skew in the output of the `EXPLAIN ANALYZE` statement for a query. Each node includes a count of the maximum rows processed by any one segment and the average rows processed by all segments. If the maximum row count is much higher than the average, at least one segment has performed much more work than the others and computational skew should be suspected for that operator.

Identify plan nodes where a Sort or Aggregate operation is performed. Hidden inside an Aggregate operation is a Sort. If the Sort or Aggregate operation involves a large number of rows, there is an opportunity to improve query performance. A HashAggregate operation is preferred over Sort and Aggregate operations when a large number of rows are required to be sorted. Usually a Sort operation is chosen by the optimizer due to the SQL construct; that is, due to the way the SQL is written. Most Sort operations can be replaced with a HashAggregate if the query is rewritten. To favor a HashAggregate operation over a Sort and Aggregate operation ensure that the `enable_groupagg` server configuration parameter is set to `ON`.

When an explain plan shows a broadcast motion with a large number of rows, you should attempt to eliminate the broadcast motion. One way to do this is to use the `gp_segments_for_planner` server configuration parameter to increase the cost estimate of the motion so that alternatives are favored. The `gp_segments_for_planner` variable tells the query planner how many primary segments to use in its calculations. The default value is zero, which tells the planner to use the actual number of primary segments in estimates. Increasing the number of primary segments increases the cost of the motion, thereby favoring a redistribute motion over a broadcast motion. For example, setting `gp_segments_for_planner = 100000` tells the planner that there are 100,000 segments. Conversely, to influence the optimizer to broadcast a table and not redistribute it, set `gp_segments_for_planner` to a low number, for example 2.

WarehousePG Grouping Extensions

WarehousePG aggregation extensions to the `GROUP BY` clause can perform some common calculations in the database more efficiently than in application or procedure code:

- `GROUP BY ROLLUP(*col1*, *col2*, *col3*)`
- `GROUP BY CUBE(*col1*, *col2*, *col3*)`
- `GROUP BY GROUPING SETS((*col1*, *col2*), (*col1*, *col3*))`

A `ROLLUP` grouping creates aggregate subtotals that roll up from the most detailed level to a grand total, following a list of grouping columns (or expressions). `ROLLUP` takes an ordered list of grouping columns, calculates the standard aggregate values specified in the `GROUP BY` clause, then creates progressively higher-level subtotals, moving from right to left through the list. Finally, it creates a grand total.

A `CUBE` grouping creates subtotals for all of the possible combinations of the given list of grouping columns (or expressions). In multidimensional analysis terms, `CUBE` generates all the subtotals that could be calculated for a data cube with the specified dimensions.

You can selectively specify the set of groups that you want to create using a `GROUPING SETS` expression. This allows precise specification across multiple dimensions without computing a whole `ROLLUP` or `CUBE`.

Refer to the *WarehousePG Reference Guide* for details of these clauses.

Window Functions

Window functions apply an aggregation or ranking function over partitions of the result set—for example, `sum(population) over (partition by city)`. Window functions are powerful and, because they do all of the work in the database, they have performance advantages over front-end tools that produce similar results by retrieving detail rows from the database and reprocessing them.

- The `row_number()` window function produces row numbers for the rows in a partition, for example, `row_number() over (order by id)`.
- When a query plan indicates that a table is scanned in more than one operation, you may be able to use window functions to reduce the number of scans.
- It is often possible to eliminate self joins by using window functions.

6.12 High Availability

WarehousePG supports highly available, fault-tolerant database services when you enable and properly configure WarehousePG high availability features. To guarantee a required level of service, each component must have a standby ready to take its place if it should fail.

Parent topic: WarehousePG Best Practices

Disk Storage

With the WarehousePG "shared-nothing" MPP architecture, the coordinator host and segment hosts each have their own dedicated memory and disk storage, and each coordinator or segment instance has its own independent data directory. For both reliability and high performance, a hardware RAID storage solution with from 8 to 24 disks is recommended. A larger number of disks improves I/O throughput when using RAID 5 (or 6) because striping increases parallel disk I/O. The RAID controller can continue to function with a failed disk because it saves parity data on each disk in a way that it can reconstruct the data on any failed member of the array. If a hot spare is configured (or an operator replaces the failed disk with a new one) the controller rebuilds the failed disk automatically.

RAID 1 exactly mirrors disks, so if a disk fails, a replacement is immediately available with performance equivalent to that before the failure. With RAID 5 each I/O for data on the failed array member must be reconstructed from data on the remaining active drives until the replacement disk is rebuilt, so there is a temporary performance degradation. If the WarehousePG coordinator and segments are mirrored, you can switch any affected WarehousePG instances to their mirrors during the rebuild to maintain acceptable performance.

A RAID disk array can still be a single point of failure, for example, if the entire RAID volume fails. At the hardware level, you can protect against a disk array failure by mirroring the array, using either host operating system mirroring or RAID controller mirroring, if supported.

It is important to regularly monitor available disk space on each segment host. Query the `gp_disk_free` external table in the `gptoolkit` schema to view disk space available on the segments. This view runs the Linux `df` command. Be sure to check that there is sufficient disk space before performing operations that consume large amounts of disk, such as copying a large table.

See `gp_toolkit.gp_disk_free` in the *WarehousePG Reference Guide*.

Best Practices

- Use a hardware RAID storage solution with 8 to 24 disks.
- Use RAID 1, 5, or 6 so that the disk array can tolerate a failed disk.
- Configure a hot spare in the disk array to allow rebuild to begin automatically when disk failure is detected.
- Protect against failure of the entire disk array and degradation during rebuilds by mirroring the RAID volume.
- Monitor disk utilization regularly and add additional space when needed.
- Monitor segment skew to ensure that data is distributed evenly and storage is consumed evenly at all segments.

Coordinator Mirroring

The WarehousePG coordinator instance is clients' single point of access to the system. The coordinator instance stores the global system catalog, the set of system tables that store metadata about the database instance, but no user data. If an unmirrored coordinator instance fails or becomes inaccessible, the WarehousePG instance is effectively off-line, since the entry point to the system has been lost. For this reason, a standby coordinator must be ready to take over if the primary coordinator fails.

Coordinator mirroring uses two processes, a sender on the active coordinator host and a receiver on the mirror host, to synchronize the mirror with the coordinator. As changes are applied to the coordinator system catalogs, the active coordinator streams its write-ahead log (WAL) to the mirror so that each transaction applied on the coordinator is applied on the mirror.

The mirror is a *warm standby*. If the primary coordinator fails, switching to the standby requires an administrative user to run the `gpactivatestandby` utility on the standby host so that it begins to accept client connections. Clients must reconnect to the new coordinator and will lose any work that was not committed when the primary failed.

See "Enabling High Availability Features" in the *WarehousePG Administrator Guide* for more information.

Best Practices

- Set up a standby coordinator instance—a *mirror*—to take over if the primary coordinator fails.
- The standby can be on the same host or on a different host, but it is best practice to place it on a different host from the primary coordinator to protect against host failure.
- Plan how to switch clients to the new coordinator instance when a failure occurs, for example, by updating the coordinator address in DNS.
- Set up monitoring to send notifications in a system monitoring application or by email when the primary fails.

Segment Mirroring

WarehousePG segment instances each store and manage a portion of the database data, with coordination from the coordinator instance. If any unmirrored segment fails, the database may have to be shutdown and recovered, and transactions occurring after the most recent backup could be lost. Mirroring segments is, therefore, an essential element of a high availability solution.

A segment mirror is a hot standby for a primary segment. WarehousePG detects when a segment is unavailable and automatically activates the mirror. During normal operation, when the primary segment instance is active, data is replicated from the primary to the mirror in two ways:

- The transaction commit log is replicated from the primary to the mirror before the transaction is committed. This ensures that if the mirror is activated, the changes made by the last successful transaction at the primary are present at the mirror. When the mirror is activated, transactions in the log are applied to tables in the mirror.

- Second, segment mirroring uses physical file replication to update heap tables. WarehousePG Server stores table data on disk as fixed-size blocks packed with tuples. To optimize disk I/O, blocks are cached in memory until the cache fills and some blocks must be evicted to make room for newly updated blocks. When a block is evicted from the cache it is written to disk and replicated over the network to the mirror. Because of the caching mechanism, table updates at the mirror can lag behind the primary. However, because the transaction log is also replicated, the mirror remains consistent with the primary. If the mirror is activated, the activation process updates the tables with any unapplied changes in the transaction commit log.

When the acting primary is unable to access its mirror, replication stops and state of the primary changes to "Change Tracking." The primary saves changes that have not been replicated to the mirror in a system table to be replicated to the mirror when it is back on-line.

The coordinator automatically detects segment failures and activates the mirror. Transactions in progress at the time of failure are restarted using the new primary. Depending on how mirrors are deployed on the hosts, the database system may be unbalanced until the original primary segment is recovered. For example, if each segment host has four primary segments and four mirror segments, and a mirror is activated on one host, that host will have five active primary segments. Queries are not complete until the last segment has finished its work, so performance can be degraded until the balance is restored by recovering the original primary.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Administrators perform the recovery while WarehousePG is up and running by running the `gprecoverseg` utility. This utility locates the failed segments, verifies they are valid, and compares the transactional state with the currently active segment to determine changes made while the segment was offline. `gprecoverseg` synchronizes the changed database files with the active segment and brings the segment back online.

It is important to reserve enough memory and CPU resources on segment hosts to allow for increased activity from mirrors that assume the primary role during a failure. The formulas provided in Configuring Memory for WarehousePG for configuring segment host memory include a factor for the maximum number of primary hosts on any one segment during a failure. The arrangement of mirrors on the segment hosts affects this factor and how the system will respond during a failure. See Segment Mirroring Configurations for a discussion of segment mirroring options.

Best Practices

- Set up mirrors for all segments.
- Locate primary segments and their mirrors on different hosts to protect against host failure.
- Mirrors can be on a separate set of hosts or co-located on hosts with primary segments.
- Set up monitoring to send notifications in a system monitoring application or by email when a primary segment fails.
- Recover failed segments promptly, using the `gprecoverseg` utility, to restore redundancy and return the system to optimal balance.

Dual Clusters

For some use cases, an additional level of redundancy can be provided by maintaining two WarehousePG clusters that store the same data. The decision to implement dual clusters should be made with business requirements in mind.

There are two recommended methods for keeping the data synchronized in a dual cluster configuration. The first method is called Dual ETL. ETL (extract, transform, and load) is the common data warehousing process of cleansing, transforming, validating, and loading data into a data warehouse. With Dual ETL, the ETL processes are performed twice, in parallel on each cluster, and validated each time. Dual ETL provides for a complete standby cluster with the same data. It also provides the capability to query the data on both clusters, doubling the processing throughput. The application can take advantage of both clusters as needed and also ensure that the ETL is successful and validated on both sides.

The second mechanism for maintaining dual clusters is backup and restore. The data is backedup on the primary cluster, then the backup is replicated to and restored on the second cluster. The backup and restore mechanism has higher latency than Dual ETL, but requires less application logic to be developed. Backup and restore is ideal for use cases where data modifications and ETL are done daily or less frequently.

Best Practices

- Consider a Dual Cluster configuration to provide an additional level of redundancy and additional query processing throughput.

Backup and Restore

Backups are recommended for WarehousePG databases unless the data in the database can be easily and cleanly regenerated from source data. Backups protect from operational, software, or hardware errors.

The `gpbackup` utility makes backups in parallel across the segments, so that backups scale as the cluster grows in hardware size.

A backup strategy must consider where the backups will be written and where they will be stored. Backups can be taken to the local cluster disks, but they should not be stored there permanently. If the database and its backup are on the same storage, they can be lost simultaneously. The backup also occupies space that could be used for database storage or operations. After performing a local backup, the files should be copied to a safe, off-cluster location.

An alternative is to back up directly to an NFS mount. If each host in the cluster has an NFS mount, the backups can be written directly to NFS storage. A scale-out NFS solution is recommended to ensure that backups do not bottleneck on the IO throughput of the NFS device. Dell PowerScale (Isilon) is an example of this type of solution and can scale alongside the WarehousePG cluster.

Best Practices

- Back up WarehousePGs regularly unless the data is easily restored from sources.
- Use the `gpbackup` command to specify only the schema and tables that you want backed up. See the `gpbackup` reference for more information.
- `gpbackup` places `SHARED ACCESS` locks on the set of tables to back up. Backups with fewer tables are more efficient for selectively restoring schemas and tables, since `gprestore` does not have to search through the entire database.
- If backups are saved to local cluster storage, move the files to a safe, off-cluster location when the backup is complete. Backup files and database files that reside on the same storage can be lost simultaneously.
- If backups are saved to NFS mounts, use a scale-out NFS solution such as Dell PowerScale (Isilon) to prevent IO bottlenecks.

Detecting Failed Coordinator and Segment Instances

Recovering from system failures requires intervention from a system administrator, even when the system detects a failure and activates a standby for the failed component. In each case, the failed component must be replaced or recovered to restore full redundancy. Until the failed component is recovered, the active component lacks a standby, and the system may not be performing optimally. For these reasons, it is important to perform recovery operations promptly. Constant system monitoring ensures that administrators are aware of failures that demand their attention.

The WarehousePG server `ftsprobe` subprocess handles fault detection. `ftsprobe` connects to and scans all segments and database processes at intervals that you can configure with the `gp_fts_probe_interval` configuration parameter. If `ftsprobe` cannot connect to a segment, it marks the segment "down" in the WarehousePG cluster catalog. The segment remains down until an administrator runs the `gprecoverseg` recovery utility.

Best Practices

- Run the `gpstate` utility to see the overall state of the WarehousePG cluster.

RDBMS MIB Specification

Segment Mirroring Configurations

Segment mirroring allows database queries to fail over to a backup segment if the primary segment fails or becomes unavailable. Mirroring is required for production supported WarehousePG clusters.

A primary segment and its mirror must be on different hosts to ensure high availability. Each host in a WarehousePG cluster has the same number of primary segments and mirror segments. Multi-homed hosts should have the same numbers of primary and mirror segments on each interface. This ensures that segment hosts and network resources are equally loaded when all primary segments are operational and brings the most resources to bear on query processing.

When a segment becomes unavailable, its mirror segment on another host becomes the active primary and processing continues. The additional load on the host creates skew and degrades performance, but should allow the system to continue. A database query is not complete until all segments return results, so a single host with an additional active primary segment has the same effect as adding an additional primary segment to every host in the cluster.

The least amount of performance degradation in a failover scenario occurs when no host has more than one mirror assuming the primary role. If multiple segments or hosts fail, the amount of degradation is determined by the host or hosts with the largest number of mirrors assuming the primary role. Spreading a host's mirrors across the remaining hosts minimizes degradation when any single host fails.

It is important, too, to consider the cluster's tolerance for multiple host failures and how to maintain a mirror configuration when expanding the cluster by adding hosts. There is no mirror configuration that is ideal for every situation.

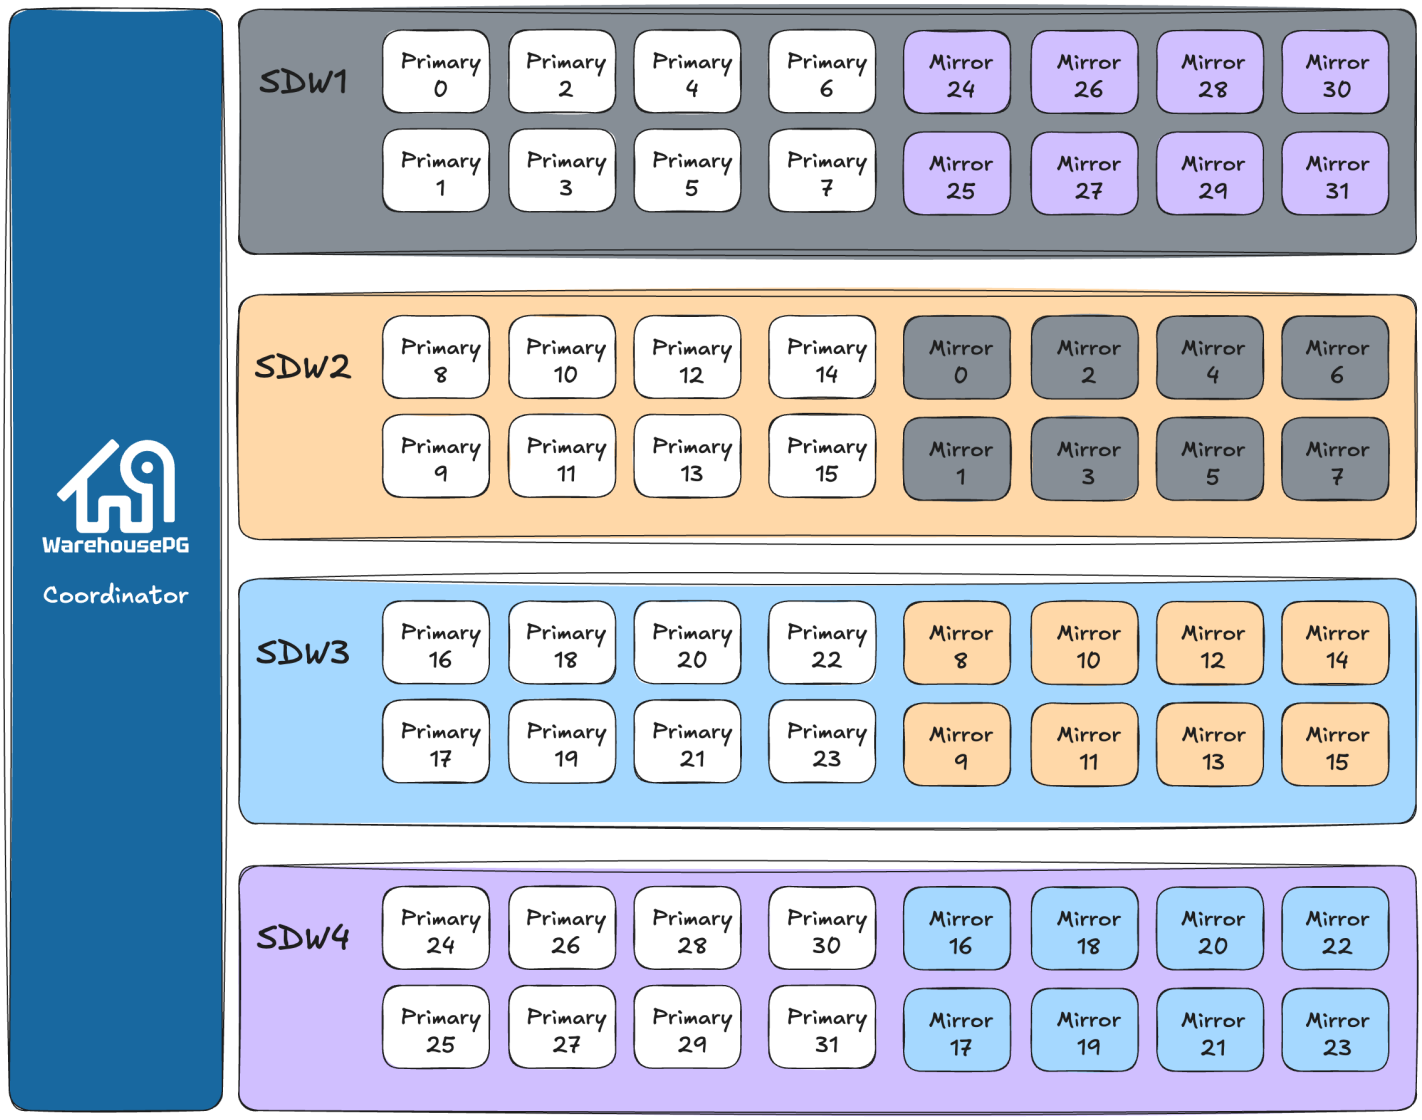
You can allow WarehousePG to arrange mirrors on the hosts in the cluster using one of two standard configurations, or you can design your own mirroring configuration.

The two standard mirroring arrangements are *group mirroring* and *spread mirroring*:

- **Group mirroring** — Each host mirrors another host's primary segments. This is the default for gpinitsystem and gpaddmirrors.
- **Spread mirroring** — Mirrors are spread across the available hosts. This requires that the number of hosts in the cluster is greater than the number of segments per host.

You can design a custom mirroring configuration and use the WarehousePG `gpaddmirrors` or gpmovemirrors utilities to set up the configuration.

Block mirroring is a custom mirror configuration that divides hosts in the cluster into equally sized blocks and distributes mirrors evenly to hosts within the block. If a primary segment fails, its mirror on another host within the same block becomes the active primary. If a segment host fails, mirror segments on each of the other hosts in the block become active.



The following sections compare the group, spread, and block mirroring configurations.

Group Mirroring

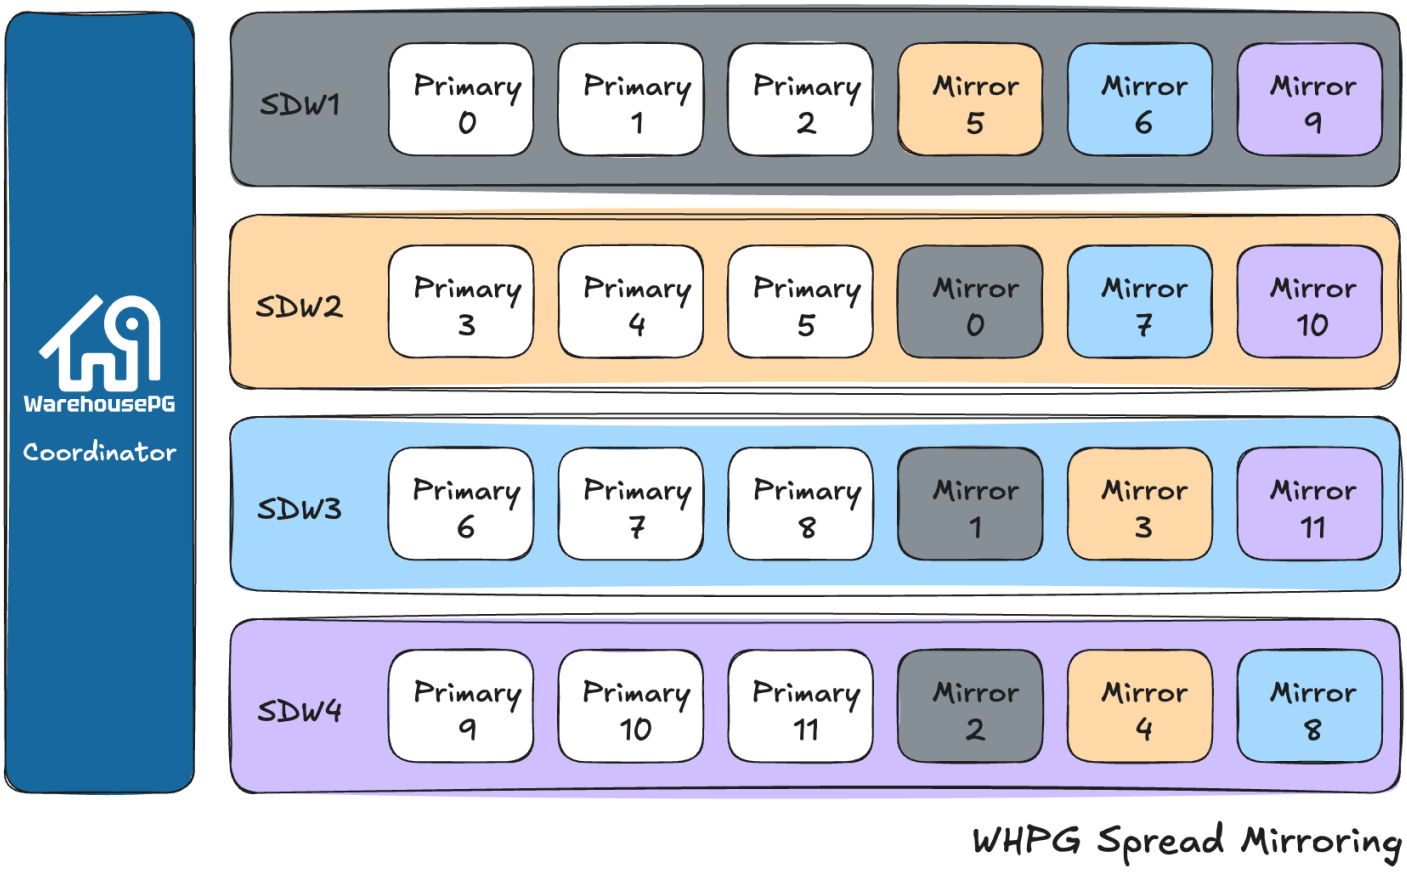
Group mirroring is easiest to set up and is the default WarehousePG mirroring configuration. It is least expensive to expand, since it can be done by adding as few as two hosts. There is no need to move mirrors after expansion to maintain a consistent mirror configuration.

The following diagram shows a group mirroring configuration with eight primary segments on four hosts.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

WHPG Group Mirroring

Unless both the primary and mirror of the same segment instance fail, up to half of your hosts can fail and the cluster will continue to run as long as resources (CPU, memory, and IO) are sufficient to meet the needs.



Any host failure will degrade performance by half or more because the host with the mirrors will have twice the number of active primaries. If your resource utilization is normally greater than 50%, you will have to adjust your workload until the failed host is recovered or replaced. If you normally run at less than 50% resource utilization the cluster can continue to operate at a degraded level of performance until the failure is corrected.

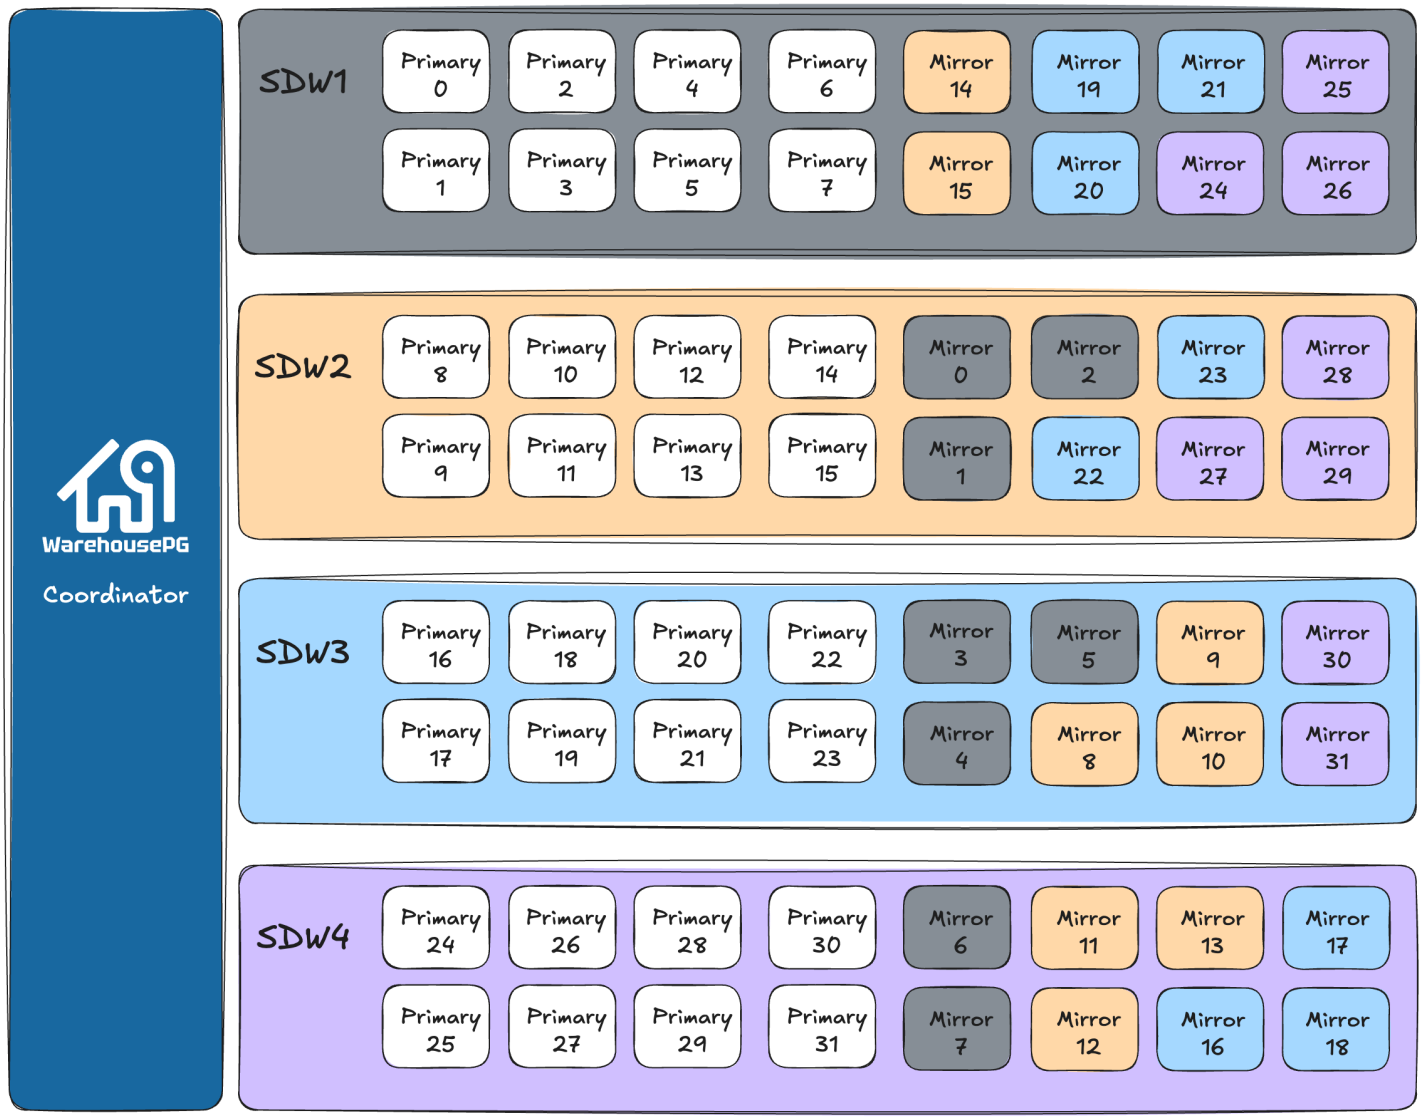
Spread Mirroring

With spread mirroring, mirrors for each host's primary segments are spread across as many hosts as there are segments per host. Spread mirroring is easy to set up when the cluster is initialized, but requires that the cluster have at least one more host than there are segments per host.

The following diagram shows the spread mirroring configuration for a cluster with three primaries on four hosts.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Expanding a cluster with spread mirroring requires more planning and may take more time. You must either add a set of hosts equal to the number of primaries per host plus one, or you can add two nodes in a group mirroring configuration and, when the expansion is complete, move mirrors to recreate the spread mirror configuration.



Spread mirroring has the least performance impact for a single failed host because each host's mirrors are spread across the maximum number of hosts. Load is increased by 1/*Nth*, where *N* is the number of primaries per host. Spread mirroring is, however, the most likely configuration to have a catastrophic failure if two or more hosts fail simultaneously.

Block Mirroring

With block mirroring, nodes are divided into blocks, for example a block of four or eight hosts, and the mirrors for segments on each host are placed on other hosts within the block. Depending on the number of hosts in the block and the number of primary segments per host, each host maintains more than one mirror for each other host's segments.

The following diagram shows a single block mirroring configuration for a block of four hosts, each with eight primary segments:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

WHPG Block Mirroring

If there are eight hosts, an additional four-host block is added with the mirrors for primary segments 32 through 63 set up in the same pattern.

A cluster with block mirroring is easy to expand because each block is a self-contained primary mirror group. The cluster is expanded by adding one or more blocks. There is no need to move mirrors after expansion to maintain a consistent mirror setup. This configuration is able to survive multiple host failures as long as the failed hosts are in different blocks.

Because each host in a block has multiple mirror instances for each other host in the block, block mirroring has a higher performance impact for host failures than spread mirroring, but a lower impact than group mirroring. The expected performance impact varies by block size and primary segments per node. As with group mirroring, if the resources are available, performance will be negatively impacted but the cluster will remain available. If resources are insufficient to accommodate the added load you must reduce the workload until the failed node is replaced.

Implementing Block Mirroring

Block mirroring is not one of the automatic options WarehousePG offers when you set up or expand a cluster. To use it, you must create your own configuration.

For a new WarehousePG cluster, you can initialize the cluster without mirrors, and then run `gpaddmirrors -i mirror_config_file` with a custom mirror configuration file to create the mirrors for each block. You must create the file system locations for the mirror segments before you run `gpaddmirrors`. See the `gpaddmirrors` reference page in the *WarehousePG Management Utility Guide* for details.

If you expand a system that has block mirroring or you want to implement block mirroring at the same time you expand a cluster, it is recommended that you complete the expansion first, using the default grouping mirror configuration, and then use the `gpmovemirrors` utility to move mirrors into the block configuration.

To implement block mirroring with an existing system that has a different mirroring scheme, you must first determine the desired location for each mirror according to your block configuration, and then determine which of the existing mirrors must be relocated. Follow these steps:

1. Run the following query to find the current locations of the primary and mirror segments:

   ```
   SELECT dbid, content, role, port, hostname, datadir FROM gp_segment_configuration WHERE content > -1 ;
   ```

   The `gp_segment_configuration` system catalog table contains the current segment configuration.

2. Create a list with the current mirror location and the desired block mirroring location, then remove any mirrors from the list that are already on the correct host.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

3. Create an input file for the `gpmovemirrors` utility with an entry for each mirror that must be moved.

   The `gpmovemirrors` input file has the following format:

   ```
   old_address|port|data_dir new_address|port|data_dir
   ```

   Where `old_address` is the host name or IP address of the segment host, port is the communication port, and `data_dir` is the segment instance data directory.

   The following example `gpmovemirrors` input file specifies three mirror segments to move.

   ```
   sdw2|50001|/data2/mirror/gpseg1 sdw3|50001|/data/mirror/gpseg1
   sdw2|50001|/data2/mirror/gpseg2 sdw4|50001|/data/mirror/gpseg2
   sdw3|50001|/data2/mirror/gpseg3 sdw1|50001|/data/mirror/gpseg3
   ```

4. Run `gpmovemirrors` with a command like the following:

   ```
   gpmovemirrors -i mirror_config_file
   ```

The `gpmovemirrors` utility validates the input file, calls `gprecoverseg` to relocate each specified mirror, and removes the original mirror. It creates a backout configuration file which can be used as input to `gpmovemirrors` to undo the changes that were made. The backout file has the same name as the input file, with the suffix `_backout_timestamp` added.

See the *WarehousePG Management Utility Reference* for complete information about the `gpmovemirrors` utility.

7.1 SQL Commands

The following SQL commands are available in WarehousePG:

- ABORT
- ALTER AGGREGATE
- ALTER COLLATION
- ALTER CONVERSION
- ALTER DATABASE
- ALTER DEFAULT PRIVILEGES
- ALTER DOMAIN
- ALTER EXTENSION
- ALTER EXTERNAL TABLE
- ALTER FOREIGN DATA WRAPPER
- ALTER FOREIGN TABLE
- ALTER FUNCTION
- ALTER GROUP
- ALTER INDEX
- ALTER LANGUAGE
- ALTER MATERIALIZED VIEW
- ALTER OPERATOR
- ALTER OPERATOR CLASS
- ALTER OPERATOR FAMILY
- ALTER POLICY
- ALTER PROCEDURE
- ALTER PROTOCOL
- ALTER RESOURCE GROUP
- ALTER RESOURCE QUEUE
- ALTER ROLE
- ALTER ROUTINE
- ALTER RULE
- ALTER SCHEMA
- ALTER SEQUENCE
- ALTER SERVER
- ALTER STATISTICS
- ALTER TABLE
- ALTER TABLESPACE
- ALTER TEXT SEARCH CONFIGURATION
- ALTER TEXT SEARCH DICTIONARY
- ALTER TEXT SEARCH PARSER
- ALTER TEXT SEARCH TEMPLATE
- ALTER TYPE
- ALTER USER
- ALTER USER MAPPING
- ALTER VIEW
- ANALYZE
- BEGIN
- CALL
- CHECKPOINT
- CLOSE
- CLUSTER
- COMMENT
- COMMIT
- COPY
- CREATE ACCESS METHOD
- CREATE AGGREGATE
- CREATE CAST
- CREATE COLLATION
- CREATE CONVERSION
- CREATE DATABASE
- CREATE DOMAIN
- CREATE EXTENSION
- CREATE EXTERNAL TABLE
- CREATE FOREIGN DATA WRAPPER
- CREATE FOREIGN TABLE
- CREATE FUNCTION
- CREATE GROUP
- CREATE INDEX
- CREATE LANGUAGE
- CREATE MATERIALIZED VIEW
- CREATE OPERATOR
- CREATE OPERATOR CLASS

7.1.1 ABORT

Terminates the current transaction.

Synopsis

```
ABORT [WORK | TRANSACTION] [AND [NO] CHAIN]
```

Description

`ABORT` rolls back the current transaction and causes all the updates made by the transaction to be discarded. This command is identical in behavior to the standard SQL commandROLLBACK, and is present only for historical reasons.

Parameters

WORK TRANSACTION Optional key words. They have no effect.

AND CHAIN If `AND CHAIN` is specified, a new transaction is immediately started with the same transaction characteristics (see SET TRANSACTION) as the just finished one. Otherwise, no new transaction is started.

Notes

Use COMMIT to successfully terminate a transaction.

Issuing `ABORT` outside of a transaction block emits a warning and otherwise has no effect.

Examples

To terminate all changes:

```
ABORT;
```

Compatibility

This command is a WarehousePG extension present for historical reasons. `ROLLBACK` is the equivalent standard SQL command.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.1.2 ALTER AGGREGATE

Changes the definition of an aggregate function

Synopsis

```
ALTER AGGREGATE <name> ( <aggregate_signature> )  RENAME TO <new_name>

ALTER AGGREGATE <name> ( <aggregate_signature> )
                 OWNER TO { <new_owner> | CURRENT_USER | SESSION_USER }

ALTER AGGREGATE <name> ( <aggregate_signature> ) SET SCHEMA <new_schema>

where <aggregate_signature> is:

* |
[ <argmode> ] [ <argname> ] <argtype> [ , ... ] |
[ [ <argmode> ] [ <argname> ] <argtype> [ , ... ] ] ORDER BY [ <argmode> ] [ <argname> ] <argtype> [ , ... ]
```

Description

`ALTER AGGREGATE` changes the definition of an aggregate function.

You must own the aggregate function to use `ALTER AGGREGATE`. To change the schema of an aggregate function, you must also have `CREATE` privilege on the new schema. To alter the owner, you must also be a direct or indirect member of the new owning role, and that role must have `CREATE` privilege on the aggregate function's schema. (These restrictions enforce that altering the owner does not do anything you could not do by dropping and recreating the aggregate function. However, a superuser can alter ownership of any aggregate function anyway.)

Parameters

name The name (optionally schema-qualified) of an existing aggregate function.

argmode The mode of an argument: `IN` or `VARIADIC`. If omitted, the default is `IN`.

argname The name of an argument. Note that `ALTER AGGREGATE` does not actually pay any attention to argument names, since only the argument data types are needed to determine the aggregate function's identity.

argtype An input data type on which the aggregate function operates. To reference a zero-argument aggregate function, write `*` in place of the list of argument specifications To reference an ordered-set aggregate function, write `ORDER BY` between the direct and aggregated argument specifications.

new_name The new name of the aggregate function.

new_owner The new owner of the aggregate function.

new_schema The new schema for the aggregate function.

Notes

The recommended syntax for referencing an ordered-set aggregate is to write `ORDER BY` between the direct and aggregated argument specifications, in the same style as inCREATE AGGREGATE. However, it will also work to omit `ORDER BY` and just run the direct and aggregated argument specifications into a single list. In this abbreviated form, if `VARIADIC "any"` was used in both the direct and aggregated argument lists, write `VARIADIC "any"` only once.

Examples

To rename the aggregate function `myavg` for type `integer` to `my_average`:

```
ALTER AGGREGATE myavg(integer) RENAME TO my_average;
```

To change the owner of the aggregate function `myavg` for type `integer` to `joe`:

```
ALTER AGGREGATE myavg(integer) OWNER TO joe;
```

To move the ordered-set aggregate `mypercentile` with direct argument of type `float8` and aggregated argument of type `integer` into schema `myschema`:

```
ALTER AGGREGATE mypercentile(float8 ORDER BY integer) SET SCHEMA myschema;
```

This will work too:

```
ALTER AGGREGATE mypercentile(float8, integer) SET SCHEMA myschema;
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Compatibility

There is no `ALTER AGGREGATE` statement in the SQL standard.

See Also

CREATE AGGREGATE, DROP AGGREGATE

Parent topic: SQL Commands

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.1.3 ALTER COLLATION

Changes the definition of a collation.

Synopsis

```
ALTER COLLATION <name> REFRESH VERSION

ALTER COLLATION <name> RENAME TO <new_name>
ALTER COLLATION <name> OWNER TO { <new_owner> | CURRENT_USER | SESSION_USER }
ALTER COLLATION <name> SET SCHEMA <new_schema>
```

Description

`ALTER COLLATION` changes the definition of a collation.

You must own the collation to use `ALTER COLLATION`. To alter the owner, you must also be a direct or indirect member of the new owning role, and that role must have `CREATE` privilege on the collation's schema. (These restrictions enforce that altering the owner doesn't do anything you couldn't do by dropping and recreating the collation. However, a superuser can alter ownership of any collation anyway.)

Parameters

name The name (optionally schema-qualified) of an existing collation.

new_name The new name of the collation.

new_owner The new owner of the collation.

new_schema The new schema for the collation.

REFRESH VERSION Update the collation's version. See the Notes below.

Notes

When using collations provided by the ICU library, the ICU-specific version of the collator is recorded in the system catalog when the collation object is created. When the collation is used, the current version is checked against the recorded version, and a warning is issued when there is a mismatch, for example:

```
WARNING:  collation "xx-x-icu" has version mismatch
DETAIL:  The collation in the database was created using version 1.2.3.4, but the operating system provides version 2.3.4.5.
HINT:  Rebuild all objects affected by this collation and run ALTER COLLATION pg_catalog."xx-x-icu" REFRESH VERSION, or build PostgreSQL with the right library
version.
```

A change in collation definitions can lead to corrupt indexes and other problems because the database system relies on stored objects having a certain sort order. Generally, this should be avoided, but it can happen in legitimate circumstances, such as when using `pg_upgrade` to upgrade to server binaries linked with a newer version of ICU. When this happens, all objects depending on the collation should be rebuilt, for example, using `REINDEX`. When that is done, the collation version can be refreshed using the command `ALTER COLLATION ... REFRESH VERSION`. This will update the system catalog to record the current collator version and will make the warning go away. Note that this does not actually check whether all affected objects have been rebuilt correctly.

The following query can be used to identify all collations in the current database that need to be refreshed and the objects that depend on them:

```
SELECT pg_describe_object(refclassid, refobjid, refobjsubid) AS "Collation",
       pg_describe_object(classid, objid, objsubid) AS "Object"
  FROM pg_depend d JOIN pg_collation c
       ON refclassid = 'pg_collation'::regclass AND refobjid = c.oid
  WHERE c.collversion <> pg_collation_actual_version(c.oid)
  ORDER BY 1, 2;
```

Examples

To rename the collation de_DE to `german`:

```
ALTER COLLATION "de_DE" RENAME TO german;
```

To change the owner of the collation `en_US` to `joe`:

```
ALTER COLLATION "en_US" OWNER TO joe;
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Compatibility

There is no `ALTER COLLATION` statement in the SQL standard.

See Also

CREATE COLLATION, DROP COLLATION

Parent topic: SQL Commands

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.1.4 ALTER CONVERSION

Changes the definition of a conversion.

Synopsis

```
ALTER CONVERSION <name> RENAME TO <new_name>

ALTER CONVERSION <name> OWNER TO { <new_owner> | CURRENT_USER | SESSION_USER }

ALTER CONVERSION <name> SET SCHEMA <new_schema>
```

Description

`ALTER CONVERSION` changes the definition of a conversion.

You must own the conversion to use `ALTER CONVERSION`. To alter the owner, you must also be a direct or indirect member of the new owning role, and that role must have `CREATE` privilege on the conversion's schema. (These restrictions enforce that altering the owner does not do anything you could not do by dropping and recreating the conversion. However, a superuser can alter ownership of any conversion anyway.)

Parameters

name The name (optionally schema-qualified) of an existing conversion.

new_name The new name of the conversion.

new_owner The new owner of the conversion.

new_schema The new schema for the conversion.

Examples

To rename the conversion `iso_8859_1_to_utf8` to `latin1_to_unicode`:

```
ALTER CONVERSION iso_8859_1_to_utf8 RENAME TO latin1_to_unicode;
```

To change the owner of the conversion `iso_8859_1_to_utf8` to `joe`:

```
ALTER CONVERSION iso_8859_1_to_utf8 OWNER TO joe;
```

Compatibility

There is no `ALTER CONVERSION` statement in the SQL standard.

See Also

CREATE CONVERSION, DROP CONVERSION

Parent topic: SQL Commands

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.1.5 ALTER DATABASE

Changes the attributes of a database.

Synopsis

```
ALTER DATABASE <name> [ [WITH] <option> [ ... ]  ]

where <option> can be:

    ALLOW_CONNECTIONS <allowconn>
    CONNECTION LIMIT <connlimit>
    IS_TEMPLATE <istemplate>

ALTER DATABASE <name> RENAME TO <new_name>

ALTER DATABASE <name> OWNER TO { <new_owner> | CURRENT_USER | SESSION_USER }

ALTER DATABASE <name> SET TABLESPACE <new_tablespace>

ALTER DATABASE <name> SET <configuration_parameter> { TO | = } { <value> | DEFAULT }
ALTER DATABASE <name> SET <configuration_parameter> FROM CURRENT
ALTER DATABASE <name> RESET <configuration_parameter>
ALTER DATABASE <name> RESET ALL
```

Description

`ALTER DATABASE` changes the attributes of a database.

The first form changes the per-database settings. (See below for details.) Only the database owner or a superuser can change these settings.

The second form changes the name of the database. Only the database owner or a superuser can rename a database; non-superuser owners must also have the `CREATEDB` privilege. You cannot rename the current database. Connect to a different database first.

The third form changes the owner of the database. To alter the owner, you must own the database and also be a direct or indirect member of the new owning role, and you must have the `CREATEDB` privilege. (Note that superusers have all these privileges automatically.)

The fourth form changes the default tablespace of the database. Only the database owner or a superuser can do this; you must also have create privilege for the new tablespace. This command physically moves any tables or indexes in the database's old default tablespace to the new tablespace. The new default tablespace must be empty for this database, and no one can be connected to the database. Note that tables and indexes in non-default tablespaces are not affected.

The remaining forms change the session default for a configuration parameter for a WarehousePG. Whenever a new session is subsequently started in that database, the specified value becomes the session default value. The database-specific default overrides whatever setting is present in the server configuration file (`postgresql.conf`). Only the database owner or a superuser can change the session defaults for a database. Certain parameters cannot be set this way, or can only be set by a superuser.

Parameters

name The name of the database whose attributes are to be altered.

allowconn If `false` , then no one can connect to this database.

connlimit The maximum number of concurrent connections allowed to this database on the coordinator. The default is `-1` , no limit. WarehousePG superusers are exempt from this limit.

istemplate If `true` , then this database can be cloned by any user with `CREATEDB` privileges; if `false` , then only superusers or the owner of the database can clone it. Note that template databases cannot be dropped.

new_name The new name of the database.

new_owner The new owner of the database.

new_tablespace The new default tablespace of the database. This form of the command cannot be executed inside a transaction block.

configuration_parameter value Set this database's session default for the specified configuration parameter to the given value. If value is `DEFAULT` or, equivalently, `RESET` is used, the database-specific setting is removed, so the system-wide default setting will be inherited in new sessions. Use `RESET ALL` to clear all database-specific settings. `SET FROM CURRENT` saves the session's current value of the parameter as the database-specific value. SeeSET and Server Configuration Parameters for more information about allowed parameter names and values.

Notes

It is also possible to tie a session default to a specific role rather than to a database; seeALTER ROLE. Role-specific settings override database-specific ones if there is a conflict.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Examples

To disable index scans by default in the `test` database:

```
ALTER DATABASE test SET enable_indexscan TO off;
```

To set the default schema search path for the `mydatabase` database:

```
ALTER DATABASE mydatabase SET search_path TO myschema, public, pg_catalog;
```

Compatibility

The `ALTER DATABASE` statement is a WarehousePG extension.

See Also

CREATE DATABASE, DROP DATABASE, SET, CREATE TABLESPACE

7.1.6 ALTER DEFAULT PRIVILEGES

Changes default access privileges.

Synopsis

```
ALTER DEFAULT PRIVILEGES
    [ FOR { ROLE | USER } <target_role> [, ...] ]
    [ IN SCHEMA <schema_name> [, ...] ]
    <abbreviated_grant_or_revoke>

where <abbreviated_grant_or_revoke> is one of:

GRANT { { SELECT | INSERT | UPDATE | DELETE | TRUNCATE | REFERENCES | TRIGGER }
    [, ...] | ALL [ PRIVILEGES ] }
    ON TABLES
    TO { [ GROUP ] <role_name> | PUBLIC } [, ...] [ WITH GRANT OPTION ]

GRANT { { USAGE | SELECT | UPDATE }
    [, ...] | ALL [ PRIVILEGES ] }
    ON SEQUENCES
    TO { [ GROUP ] <role_name> | PUBLIC } [, ...] [ WITH GRANT OPTION ]

GRANT { EXECUTE | ALL [ PRIVILEGES ] }
    ON { FUNCTIONS | ROUTINES }
    TO { [ GROUP ] <role_name> | PUBLIC } [, ...] [ WITH GRANT OPTION ]

GRANT { USAGE | ALL [ PRIVILEGES ] }
    ON TYPES
    TO { [ GROUP ] <role_name> | PUBLIC } [, ...] [ WITH GRANT OPTION ]

GRANT { USAGE | CREATE | ALL [ PRIVILEGES ] }
    ON SCHEMAS
    TO { [ GROUP ] <role_name> | PUBLIC } [, ...] [ WITH GRANT OPTION ]

REVOKE [ GRANT OPTION FOR ]
    { { SELECT | INSERT | UPDATE | DELETE | TRUNCATE | REFERENCES | TRIGGER }
    [, ...] | ALL [ PRIVILEGES ] }
    ON TABLES
    FROM { [ GROUP ] <role_name> | PUBLIC } [, ...]
    [ CASCADE | RESTRICT ]

REVOKE [ GRANT OPTION FOR ]
    { { USAGE | SELECT | UPDATE }
    [, ...] | ALL [ PRIVILEGES ] }
    ON SEQUENCES
    FROM { [ GROUP ] <role_name> | PUBLIC } [, ...]
    [ CASCADE | RESTRICT ]

REVOKE [ GRANT OPTION FOR ]
    { EXECUTE | ALL [ PRIVILEGES ] }
    ON { FUNCTIONS | ROUTINES }
    FROM { [ GROUP ] <role_name> | PUBLIC } [, ...]
    [ CASCADE | RESTRICT ]

REVOKE [ GRANT OPTION FOR ]
    { USAGE | ALL [ PRIVILEGES ] }
    ON TYPES
    FROM { [ GROUP ] <role_name> | PUBLIC } [, ...]
    [ CASCADE | RESTRICT ]

REVOKE [ GRANT OPTION FOR ]
    { USAGE | CREATE | ALL [ PRIVILEGES ] }
    ON SCHEMAS
    FROM { [ GROUP ] <role_name> | PUBLIC } [, ...]
    [ CASCADE | RESTRICT ]
```

Description

`ALTER DEFAULT PRIVILEGES` allows you to set the privileges that will be applied to objects created in the future. (It does not affect privileges assigned to already-existing objects.) Currently, only the privileges for schemas, tables (including views and foreign tables), sequences, functions, and types (including domains) can be altered. For this command, functions include aggregates and procedures. The words `FUNCTIONS` and `ROUTINES` are equivalent in this command. (`ROUTINES` is preferred going forward as the standard term for functions and procedures taken together. In earlier WarehousePG releases, only the word `FUNCTIONS` was allowed. It is not possible to set default privileges for functions and procedures separately.)

You can change default privileges only for objects that will be created by yourself or by roles that you are a member of. The privileges can be set globally (i.e., for all objects created in the current database), or just for objects created in specified schemas.

As explained under GRANT, the default privileges for any object type normally grant all grantable permissions to the object owner, and may grant some privileges to `PUBLIC` as well. However, this behavior can be changed by altering the global default privileges with `ALTER DEFAULT PRIVILEGES` .

Default privileges that are specified per-schema are added to whatever the global default privileges are for the particular object type. This means you cannot revoke privileges per-schema if they are granted globally (either by default, or according to a previous `ALTER DEFAULT PRIVILEGES` command that did not specify a schema). Per-schema `REVOKE` is only useful to reverse the effects of a previous per-schema `GRANT` .

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Parameters

target_role The name of an existing role of which the current role is a member. If `FOR ROLE` is omitted, the current role is assumed.

schema_name The name of an existing schema. If specified, the default privileges are altered for objects later created in that schema. If `IN SCHEMA` is omitted, the global default privileges are altered. `IN SCHEMA` is not allowed when setting privileges for schemas, since schemas can't be nested.

role_name The name of an existing role to grant or revoke privileges for. This parameter, and all the other parameters in abbreviated_grant_or_revoke, act as described underGRANT or REVOKE, except that one is setting permissions for a whole class of objects rather than specific named objects.

Notes

Use psql's `\ddp` command to obtain information about existing assignments of default privileges. The meaning of the privilege values is the same as explained for `\dp` under GRANT.

If you wish to drop a role for which the default privileges have been altered, it is necessary to reverse the changes in its default privileges or use `DROP OWNED BY` to get rid of the default privileges entry for the role.

Examples

Grant SELECT privilege to everyone for all tables (and views) you subsequently create in schema `myschema`, and allow role `webuser` to INSERT into them too:

```
ALTER DEFAULT PRIVILEGES IN SCHEMA myschema GRANT SELECT ON TABLES TO PUBLIC;
ALTER DEFAULT PRIVILEGES IN SCHEMA myschema GRANT INSERT ON TABLES TO webuser;
```

Undo the above, so that subsequently-created tables won't have any more permissions than normal:

```
ALTER DEFAULT PRIVILEGES IN SCHEMA myschema REVOKE SELECT ON TABLES FROM PUBLIC;
ALTER DEFAULT PRIVILEGES IN SCHEMA myschema REVOKE INSERT ON TABLES FROM webuser;
```

Remove the public EXECUTE permission that is normally granted on functions, for all functions subsequently created by role `admin`:

```
ALTER DEFAULT PRIVILEGES FOR ROLE admin REVOKE EXECUTE ON FUNCTIONS FROM PUBLIC;
```

Note however that you *cannot* accomplish that effect with a command limited to a single schema. The following command has no effect, unless it is undoing a matching `GRANT`:

```
ALTER DEFAULT PRIVILEGES IN SCHEMA public REVOKE EXECUTE ON FUNCTIONS FROM PUBLIC;
```

That's because per-schema default privileges can only add privileges to the global setting, not remove privileges granted by it.

Compatibility

There is no `ALTER DEFAULT PRIVILEGES` statement in the SQL standard.

7.1.7 ALTER DOMAIN

Changes the definition of a domain.

Synopsis

```
ALTER DOMAIN <name> { SET DEFAULT <expression> | DROP DEFAULT }

ALTER DOMAIN <name> { SET | DROP } NOT NULL

ALTER DOMAIN <name> ADD <domain_constraint> [ NOT VALID ]

ALTER DOMAIN <name> DROP CONSTRAINT [ IF EXISTS ] <constraint_name> [RESTRICT | CASCADE]

ALTER DOMAIN <name> RENAME CONSTRAINT <constraint_name> TO <new_constraint_name>

ALTER DOMAIN <name> VALIDATE CONSTRAINT <constraint_name>

ALTER DOMAIN <name> OWNER TO { <new_owner> | CURRENT_USER | SESSION_USER }

ALTER DOMAIN <name> RENAME TO <new_name>

ALTER DOMAIN <name> SET SCHEMA <new_schema>
```

Description

`ALTER DOMAIN` changes the definition of an existing domain. There are several sub-forms:

- **SET/DROP DEFAULT** — These forms set or remove the default value for a domain. Note that defaults only apply to subsequent `INSERT` commands. They do not affect rows already in a table using the domain.
- **SET/DROP NOT NULL** — These forms change whether a domain is marked to allow NULL values or to reject NULL values. You may only `SET NOT NULL` when the columns using the domain contain no null values.
- **ADD domain_constraint [NOT VALID]** — This form adds a new constraint to a domain using the same syntax as CREATE DOMAIN. When a new constraint is added to a domain, all columns using that domain will be checked against the newly-added constraint. These checks can be suppressed by adding the new constraint using the `NOT VALID` option; the constraint can later be made valid using `ALTER DOMAIN ... VALIDATE CONSTRAINT`. Newly inserted or updated rows are always checked against all constraints, even those marked `NOT VALID`. `NOT VALID` is only accepted for `CHECK` constraints.
- **DROP CONSTRAINT [IF EXISTS]** — This form drops constraints on a domain. If `IF EXISTS` is specified and the constraint does not exist, no error is thrown. In this case a notice is issued instead.
- **RENAME CONSTRAINT** — This form changes the name of a constraint on a domain.
- **VALIDATE CONSTRAINT** — This form validates a constraint previously added as `NOT VALID`, that is, it verifies that all values in table columns of the domain satisfy the specified constraint.
- **OWNER** — This form changes the owner of the domain to the specified user.
- **RENAME** — This form changes the name of the domain.
- **SET SCHEMA** — This form changes the schema of the domain. Any constraints associated with the domain are moved into the new schema as well.

You must own the domain to use `ALTER DOMAIN`. To change the schema of a domain, you must also have `CREATE` privilege on the new schema. To alter the owner, you must also be a direct or indirect member of the new owning role, and that role must have `CREATE` privilege on the domain's schema. (These restrictions enforce that altering the owner does not do anything you could not do by dropping and recreating the domain. However, a superuser can alter ownership of any domain anyway.)

Parameters

name The name (optionally schema-qualified) of an existing domain to alter.

domain_constraint New domain constraint for the domain.

constraint_name Name of an existing constraint to drop or rename.

NOT VALID Do not verify existing column data for constraint validity.

CASCADE Automatically drop objects that depend on the constraint, and in turn all objects that depend on those objects.

RESTRICT Refuse to drop the constraint if there are any dependent objects. This is the default behavior.

new_name The new name for the domain.

new_constraint_name The new name for the constraint.

new_owner The user name of the new owner of the domain.

new_schema The new schema for the domain.

Notes

Although `ALTER DOMAIN ADD CONSTRAINT` attempts to verify that existing stored data satisfies the new constraint, this check is not bulletproof, because the command cannot "see" table rows that are newly inserted or updated and not yet committed. If there is a hazard that concurrent operations might insert bad data, the way to proceed is to add the constraint using the `NOT VALID` option, commit that command, wait until all transactions started before that commit have finished, and then issue `ALTER DOMAIN VALIDATE CONSTRAINT` to search for data violating the constraint. This method is reliable because once the constraint is committed, all new transactions are guaranteed to enforce it against new values of the domain type.

Currently, `ALTER DOMAIN ADD CONSTRAINT`, `ALTER DOMAIN VALIDATE CONSTRAINT`, and `ALTER DOMAIN SET NOT NULL` will fail if the named domain or any derived domain is used within a container-type column (a composite, array, or range column) in any table in the database. They should eventually be improved to be able to verify the new constraint for such nested values.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Examples

To add a `NOT NULL` constraint to a domain:

```
ALTER DOMAIN zipcode SET NOT NULL;
```

To remove a `NOT NULL` constraint from a domain:

```
ALTER DOMAIN zipcode DROP NOT NULL;
```

To add a check constraint to a domain:

```
ALTER DOMAIN zipcode ADD CONSTRAINT zipchk CHECK (char_length(VALUE) = 5);
```

To remove a check constraint from a domain:

```
ALTER DOMAIN zipcode DROP CONSTRAINT zipchk;
```

To rename a check constraint on a domain:

```
ALTER DOMAIN zipcode RENAME CONSTRAINT zipchk TO zip_check;
```

To move the domain into a different schema:

```
ALTER DOMAIN zipcode SET SCHEMA customers;
```

Compatibility

`ALTER DOMAIN` conforms to the SQL standard, except for the `OWNER`, `RENAME`, `SET SCHEMA`, and `VALIDATE CONSTRAINT` variants, which are WarehousePG extensions. The `NOT VALID` clause of the `ADD CONSTRAINT` variant is also a WarehousePG extension.

7.1.8 ALTER EXTENSION

Change the definition of an extension.

Synopsis

```
ALTER EXTENSION <name> UPDATE [ TO <new_version> ]
ALTER EXTENSION <name> SET SCHEMA <new_schema>
ALTER EXTENSION <name> ADD <member_object>
ALTER EXTENSION <name> DROP <member_object>

where <member_object> is:

  ACCESS METHOD <object_name> |
  AGGREGATE <aggregate_name> ( <aggregate_signature> ) |
  CAST (<source_type> AS <target_type>) |
  COLLATION <object_name> |
  CONVERSION <object_name> |
  DOMAIN <object_name> |
  EVENT TRIGGER <object_name> |
  FOREIGN DATA WRAPPER <object_name> |
  FOREIGN TABLE <object_name> |
  FUNCTION <function_name> ( [ [ <argmode> ] [ <argname> ] <argtype> [, ...] ] ) |
  MATERIALIZED VIEW <object_name> |
  OPERATOR <operator_name> (<left_type>, <right_type>) |
  OPERATOR CLASS <object_name> USING <index_method> |
  OPERATOR FAMILY <object_name> USING <index_method> |
  [ PROCEDURAL ] LANGUAGE <object_name> |
  PROCEDURE <procedure_name> [ ( [ [ <argmode> ] [ <argname> ] <argtype> [, ...] ] ) ] |
  ROUTINE <routine_name> [ ( [ [ <argmode> ] [ <argname> ] <argtype> [, ...] ] ) ] |
  SCHEMA <object_name> |
  SEQUENCE <object_name> |
  SERVER <object_name> |
  TABLE <object_name> |
  TEXT SEARCH CONFIGURATION <object_name> |
  TEXT SEARCH DICTIONARY <object_name> |
  TEXT SEARCH PARSER <object_name> |
  TEXT SEARCH TEMPLATE <object_name> |
  TRANSFORM FOR <type_name> LANGUAGE <lang_name> |
  TYPE <object_name> |
  VIEW <object_name>

and <aggregate_signature> is:

* |
[ <argmode> ] [ <argname> ] <argtype> [ , ... ] |
[ [ <argmode> ] [ <argname> ] <argtype> [ , ... ] ] ORDER BY [ <argmode> ] [ <argname> ] <argtype> [ , ... ]
```

Description

`ALTER EXTENSION` changes the definition of an installed extension. There are several subforms:

UPDATE This form updates the extension to a newer version. The extension must supply a suitable update script (or series of scripts) that can modify the currently-installed version into the requested version.

SET SCHEMA This form moves the extension member objects into another schema. The extension must be*relocatable* for this command to succeed.

ADD member_object This form adds an existing object to the extension. This is mainly useful in extension update scripts. The object will subsequently be treated as a member of the extension; notably, it can only be dropped by dropping the extension.

DROP member_object This form removes a member object from the extension. This is mainly useful in extension update scripts. The object is not dropped, only disassociated from the extension.

See Packaging Related Objects into an Extension for more information about these operations.

You must own the extension to use `ALTER EXTENSION`. The `ADD` and `DROP` forms also require ownership of the object that is being added or dropped.

Parameters

name The name of an installed extension.

new_version The new version of the extension. The new_version can be either an identifier or a string literal. If not specified, `ALTER EXTENSION UPDATE` attempts to update to whatever is shown as the default version in the extension's control file.

new_schema The new schema for the extension.

object_name aggregate_name function_name operator_name procedure_name routine_name The name of an object to be added to or removed from the extension. Names of tables, aggregates, domains, foreign tables, functions, operators, operator classes, operator families, procedures, routines, sequences, text search objects, types, and views can be schema-qualified.

source_type The name of the source data type of the cast.

target_type The name of the target data type of the cast.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

argmode The mode of a function or aggregate argument: `IN`, `OUT`, `INOUT`, or `VARIADIC`. If omitted, the default is `IN`. Note that `ALTER EXTENSION` does not actually pay any attention to `OUT` arguments, since only the input arguments are needed to determine the function's identity. So it is sufficient to list the `IN`, `INOUT`, and `VARIADIC` arguments.

argname The name of a function or aggregate argument. Note that `ALTER EXTENSION` does not actually pay any attention to argument names, since only the argument data types are needed to determine the function's identity.

argtype The data type of a function, procedure, or aggregate argument.

left_type right_type The data types of the operator's arguments (optionally schema-qualified) . Specify `NONE` for the missing argument of a prefix or postfix operator.

PROCEDURAL This is a noise word.

type_name The name of the data type of the transform.

lang_name The name of the language of the transform.

Examples

To update the hstore extension to version 2.0:

```
ALTER EXTENSION hstore UPDATE TO '2.0';
```

To change the schema of the `hstore` extension to `utils`:

```
ALTER EXTENSION hstore SET SCHEMA utils;
```

To add an existing function to the `hstore` extension:

```
ALTER EXTENSION hstore ADD FUNCTION populate_record(anyelement, hstore);
```

Compatibility

`ALTER EXTENSION` is a WarehousePG extension.

7.1.9 ALTER EXTERNAL TABLE

Changes the definition of an external table.

Synopsis

```
ALTER EXTERNAL TABLE <name> <action> [, ... ]
```

where action is one of:

```
  ADD [COLUMN] <new_column> <type>
  DROP [COLUMN] <column> [RESTRICT|CASCADE]
  ALTER [COLUMN] <column> TYPE <type>
  OWNER TO <new_owner>
```

Description

`ALTER EXTERNAL TABLE` changes the definition of an existing external table. These are the supported `ALTER EXTERNAL TABLE` actions:

- **ADD COLUMN** — Adds a new column to the external table definition.
- **DROP COLUMN** — Drops a column from the external table definition. If you drop readable external table columns, it only changes the table definition in WarehousePG. The `CASCADE` keyword is required if anything outside the table depends on the column, such as a view that references the column.
- **ALTER COLUMN TYPE** — Changes the data type of a table column.
- **OWNER** — Changes the owner of the external table to the specified user.

Use the ALTER TABLE command to perform these actions on an external table:

- Set (change) the table schema.
- Rename the table.
- Rename a table column.
- Set (change) the distribution policy (writable external table only).

You must own the external table to use `ALTER EXTERNAL TABLE` or `ALTER TABLE`. To change the schema of an external table, you must also have `CREATE` privilege on the new schema. To alter the owner, you must also be a direct or indirect member of the new owning role, and that role must have `CREATE` privilege on the external table's schema. A superuser has these privileges automatically.

Changes that you make to an external table definition with either `ALTER EXTERNAL TABLE` or `ALTER TABLE` do not affect the external data.

The `ALTER EXTERNAL TABLE` and `ALTER TABLE` commands cannot modify the type of the external table (read, write, web), the table `FORMAT` information, or the location of the external data. To modify this information, you must drop and recreate the external table definition.

Parameters

name The name (possibly schema-qualified) of an existing external table definition to alter.

column Name of an existing column.

new_column Name of a new column.

type Data type of the new column, or new data type for an existing column.

new_owner The role name of the new owner of the external table.

CASCADE Automatically drop objects that depend on the dropped column, such as a view that references the column.

RESTRICT Refuse to drop the column or constraint if there are any dependent objects. This is the default behavior.

Examples

Add a new column to an external table definition:

```
ALTER EXTERNAL TABLE ext_expenses ADD COLUMN manager text;
```

Change the owner of an external table:

```
ALTER EXTERNAL TABLE ext_data OWNER TO jojo;
```

Change the data type of an external table:

```
ALTER EXTERNAL TABLE ext_leads ALTER COLUMN acct_code TYPE integer;
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Compatibility

`ALTER EXTERNAL TABLE` is a WarehousePG extension. There is no `ALTER EXTERNAL TABLE` statement in the SQL standard or regular PostgreSQL.

See Also

CREATE EXTERNAL TABLE, DROP EXTERNAL TABLE, ALTER TABLE

Parent topic: SQL Commands

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.1.10 ALTER FOREIGN DATA WRAPPER

Changes the definition of a foreign-data wrapper.

Synopsis

```
ALTER FOREIGN DATA WRAPPER <name>
    [ HANDLER <handler_function> | NO HANDLER ]
    [ VALIDATOR <validator_function> | NO VALIDATOR ]
    [ OPTIONS ( [ ADD | SET | DROP ] <option> ['<value>'] [, ... ] ) ]

ALTER FOREIGN DATA WRAPPER <name> OWNER TO { <new_owner> | CURRENT_USER | SESSION_USER }
ALTER FOREIGN DATA WRAPPER <name> RENAME TO <new_name>
```

Description

`ALTER FOREIGN DATA WRAPPER` changes the definition of a foreign-data wrapper. The first form of the command changes the support functions or generic options of the foreign-data wrapper. WarehousePG requires at least one clause. The second and third forms of the command change the owner or name of the foreign-data wrapper.

Only superusers can alter foreign-data wrappers. Additionally, only superusers can own foreign-data wrappers

Parameters

name The name of an existing foreign-data wrapper.

HANDLER handler_function Specifies a new handler function for the foreign-data wrapper.

NO HANDLER Specifies that the foreign-data wrapper should no longer have a handler function.

```
> **Note** You cannot access a foreign table that uses a foreign-data wrapper with no handler.
```

VALIDATOR validator_function Specifies a new validator function for the foreign-data wrapper.

Note that it is possible that pre-existing options of the foreign-data wrapper, or of dependent servers, user mappings, or foreign tables, may become invalid when you change the validator function. WarehousePG does not check for this. You must make sure that these options are correct before using the modified foreign-data wrapper. However, WarehousePG will check any options specified in this `ALTER FOREIGN DATA WRAPPER` command using the new validator.

NO VALIDATOR Specifies that the foreign-data wrapper should no longer have a validator function.

OPTIONS ([ADD | SET | DROP] option ['value'] [, ...]) Change the foreign-data wrapper's options `ADD`, `SET`, and `DROP` specify the action to perform. If no operation is explicitly specified, the default operation is `ADD`. Option names must be unique. WarehousePG validates names and values using the foreign-data wrapper's validator function, if any.

OWNER TO new_owner Specifies the user name of the new owner of the foreign-data wrapper. Only superusers can own foreign-data wrappers.

RENAME TO new_name Specifies the new name of the foreign-data wrapper.

Examples

Change the definition of a foreign-data wrapper named `dbi` by adding a new option named `foo`, and removing the option named `bar`:

```
ALTER FOREIGN DATA WRAPPER dbi OPTIONS (ADD foo '1', DROP 'bar');
```

Change the validator function for a foreign-data wrapper named `dbi` to `bob.myvalidator`:

```
ALTER FOREIGN DATA WRAPPER dbi VALIDATOR bob.myvalidator;
```

Compatibility

`ALTER FOREIGN DATA WRAPPER` conforms to ISO/IEC 9075-9 (SQL/MED), with the exception that the `HANDLER`, `VALIDATOR`, `OWNER TO`, and `RENAME TO` clauses are WarehousePG extensions.

See Also

CREATE FOREIGN DATA WRAPPER, DROP FOREIGN DATA WRAPPER

Parent topic: SQL Commands

7.1.11 ALTER FOREIGN TABLE

Changes the definition of a foreign table.

Synopsis

```
ALTER FOREIGN TABLE [ IF EXISTS ] [ONLY] <name> [ * ]
    <action> [, ... ]
ALTER FOREIGN TABLE [ IF EXISTS ] [ONLY] <name> [ * ]
    RENAME [ COLUMN ] <column_name> TO <new_column_name>
ALTER FOREIGN TABLE [ IF EXISTS ] <name>
    RENAME TO <new_name>
ALTER FOREIGN TABLE [ IF EXISTS ] <name>
    SET SCHEMA <new_schema>

where <action> is one of:

    ADD [ COLUMN ] <column_name> <data_type> [ COLLATE <collation> ] [ <column_constraint> [ ... ] ]
    DROP [ COLUMN ] [ IF EXISTS ] <column_name> [ RESTRICT | CASCADE ]
    ALTER [ COLUMN ] <column_name> [ SET DATA ] TYPE <data_type> [ COLLATE <collation> ]
    ALTER [ COLUMN ] <column_name> SET DEFAULT <expression>
    ALTER [ COLUMN ] <column_name> DROP DEFAULT
    ALTER [ COLUMN ] <column_name> { SET | DROP } NOT NULL
    ALTER [ COLUMN ] <column_name> SET STATISTICS <integer>
    ALTER [ COLUMN ] <column_name> SET ( <attribute_option> = <value> [, ... ] )
    ALTER [ COLUMN ] <column_name> RESET ( <attribute_option> [, ... ] )
    ALTER [ COLUMN ] <column_name> SET STORAGE { PLAIN | EXTERNAL | EXTENDED | MAIN }
    ALTER [ COLUMN ] <column_name> OPTIONS ( [ ADD | SET | DROP ] <option> ['<value>'] [, ... ])
    ADD <table_constraint> [ NOT VALID ]
    VALIDATE CONSTRAINT <constraint_name>
    DROP CONSTRAINT [ IF EXISTS ]  <constraint_name> [ RESTRICT | CASCADE ]
    DISABLE TRIGGER [ <trigger_name> | ALL | USER ]
    ENABLE TRIGGER [ <trigger_name> | ALL | USER ]
    ENABLE REPLICA TRIGGER <trigger_name>
    ENABLE ALWAYS TRIGGER <trigger_name>
    SET WITHOUT OIDS
    INHERIT <parent_table>
    NO INHERIT <parent_table>
    OWNER TO { <new_owner> | CURRENT_USER | SESSION_USER }
    OPTIONS ( [ ADD | SET | DROP ] <option> ['<value>'] [, ... ] )
```

Description

`ALTER FOREIGN TABLE` changes the definition of an existing foreign table. There are several subforms of the command:

ADD COLUMN This form adds a new column to the foreign table, using the same syntax as CREATE FOREIGN TABLE. Unlike the case when you add a column to a regular table, nothing happens to the underlying storage: this action simply declares that some new column is now accessible through the foreign table.

DROP COLUMN [IF EXISTS] This form drops a column from a foreign table. You must specify `CASCADE` if any objects outside of the table depend on the column; for example, views. If you specify `IF EXISTS` and the column does not exist, no error is thrown. In this case, WarehousePG issues a notice instead.

IF EXISTS If you specify `IF EXISTS` and the foreign table does not exist, no error is thrown. WarehousePG issues a notice instead.

SET DATA TYPE This form changes the type of a column of a foreign table. Again, this has no effect on any underlying storage: this action simply changes the type that WarehousePG believes the column to have.

SET/DROP DEFAULT These forms set or remove the default value for a column. Default values apply only in subsequent `INSERT` or `UPDATE` commands; they do not cause rows already in the table to change.

SET/DROP NOT NULL Mark a column as allowing, or not allowing, null values.

SET STATISTICS This form sets the per-column statistics-gathering target for subsequent `ANALYZE` operations. See the similar form of ALTER TABLE for more details.

SET (attribute_option = value [, ...]) RESET (attribute_option [, ...]) This form sets or resets per-attribute options. See the similar form of ALTER TABLE for more details.

SET STORAGE This form sets the storage mode for a column. See the similar form of ALTER TABLE for more details. Note that the storage mode has no effect unless the table's foreign-data wrapper chooses to pay attention to it.

ADD table_constraint [NOT VALID] This form adds a new constraint to a foreign table, using the same syntax as CREATE FOREIGN TABLE. Currently only `CHECK` constraints are supported. Unlike the case when adding a constraint to a regular table, nothing is done to verify the constraint is correct; rather, this action simply declares that some new condition should be assumed to hold for all rows in the foreign table. (See the discussion in CREATE FOREIGN TABLE.) If the constraint is marked `NOT VALID`, then it isn't assumed to hold, but is only recorded for possible future use.

VALIDATE CONSTRAINT This form marks as valid a constraint that was previously marked as `NOT VALID`. No action is taken to verify the constraint, but future queries will assume that it holds.

DROP CONSTRAINT [IF EXISTS] This form drops the specified constraint on a foreign table. If `IF EXISTS` is specified and the constraint does not exist, no error is thrown. In this case a notice is issued instead.

DISABLE/ENABLE [REPLICA | ALWAYS] TRIGGER These forms configure the firing of trigger(s) belonging to the foreign table. See the similar form of ALTER TABLE for more details.

SET WITHOUT OIDS Backward compatibility syntax for removing the oid system column. As oid system columns cannot be added anymore, this never has an effect.

INHERIT parent_table This form adds the target foreign table as a new child of the specified parent table. See the similar form of ALTER TABLE for more details.

NO INHERIT parent_table This form removes the target foreign table from the list of children of the specified parent table.

OWNER This form changes the owner of the foreign table to the specified user.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

RENAME The `RENAME` forms change the name of a foreign table or the name of an individual column in a foreign table.

SET SCHEMA This form moves the foreign table into another schema.

OPTIONS ([ADD | SET | DROP] option ['value'] [, ...]) Change options for the foreign table. `ADD`, `SET`, and `DROP` specify the action to perform. If no operation is explicitly specified, the default operation is `ADD`. Option names must be unique (although it's OK for a table option and a column option to have the same name). WarehousePG also validates names and values using the server's foreign-data wrapper.

You can combine all of the actions except `RENAME` and `SET SCHEMA` into a list of multiple alterations for WarehousePG to apply in parallel. For example, it is possible to add several columns and/or alter the type of several columns in a single command.

If the command is written as `ALTER FOREIGN TABLE IF EXISTS ...` and the foreign table does not exist, no error is thrown. A notice is issued in this case.

You must own the table to use `ALTER FOREIGN TABLE`. To change the schema of a foreign table, you must also have `CREATE` privilege on the new schema. To alter the owner, you must also be a direct or indirect member of the new owning role, and that role must have `CREATE` privilege on the table's schema. (These restrictions enforce that altering the owner doesn't do anything you couldn't do by dropping and recreating the table. However, a superuser can alter ownership of any table anyway.) To add a column or to alter a column type, you must also have `USAGE` privilege on the data type.

Parameters

name The name (possibly schema-qualified) of an existing foreign table to alter. If `ONLY` is specified before the table name, only that table is altered. If `ONLY` is not specified, the table and all its descendant tables (if any) are altered. Optionally, `*` can be specified after the table name to explicitly indicate that descendant tables are included.

column_name The name of a new or existing column.

new_column_name The new name for an existing column.

new_name The new name for the foreign table.

data_type The data type of the new column, or new data type for an existing column.

table_constraint The new table constraint for the foreign table.

constraint_name The name of an existing constraint to validate or drop.

CASCADE Automatically drop objects that depend on the dropped column or constraint (for example, views referencing the column), and in turn all objects that depend on those objects.

RESTRICT Refuse to drop the column or constraint if there are any dependent objects. This is the default behavior.

trigger_name Name of a single trigger to deactivate or enable.

ALL Deactivate or activate all triggers belonging to the foreign table. (This requires superuser privilege if any of the triggers are internally generated triggers. The core system does not add such triggers to foreign tables, but add-on code could do so.)

USER Deactivate or activate all triggers belonging to the foreign table except for internally generated triggers.

parent_table A parent table to associate or de-associate with this foreign table.

new_owner The user name of the new owner of the foreign table.

new_schema The name of the schema to which the foreign table will be moved.

Notes

The key word `COLUMN` is noise and can be omitted.

Consistency with the foreign server is not checked when a column is added or removed with `ADD COLUMN` or `DROP COLUMN`, a `NOT NULL` or `CHECK` constraint is added, or a column type is changed with `SET DATA TYPE`. It is your responsibility to ensure that the table definition matches the remote side.

Refer to CREATE FOREIGN TABLE for a further description of valid parameters.

Examples

To mark a column as not-null:

```
ALTER FOREIGN TABLE distributors ALTER COLUMN street SET NOT NULL;
```

To change the options of a foreign table:

```
ALTER FOREIGN TABLE myschema.distributors
    OPTIONS (ADD opt1 'value', SET opt2 'value2', DROP opt3 'value3');
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Compatibility

The forms `ADD`, `DROP`, and `SET DATA TYPE` conform with the SQL standard. The other forms are WarehousePG extensions of the SQL standard. The ability to specify more than one manipulation in a single `ALTER FOREIGN TABLE` command is also a WarehousePG extension.

You can use `ALTER FOREIGN TABLE ... DROP COLUMN` to drop the only column of a foreign table, leaving a zero-column table. This is an extension of SQL, which disallows zero-column foreign tables.

See Also

ALTER TABLE, CREATE FOREIGN TABLE, DROP FOREIGN TABLE

Parent topic: SQL Commands

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.1.12 ALTER FUNCTION

Changes the definition of a function.

Synopsis

```
ALTER FUNCTION <name> [ ( [ [<argmode>] [<argname>] <argtype> [, ...] ] ) ]
   <action> [, ... ] [RESTRICT]

ALTER FUNCTION <name> [ ( [ [<argmode>] [<argname>] <argtype> [, ...] ] ) ]
   RENAME TO <new_name>

    SET <configuration_parameter> FROM CURRENT
    RESET <configuration_parameter>
    RESET ALL
```

Description

`ALTER FUNCTION` changes the definition of a function.

You must own the function to use `ALTER FUNCTION`. To change a function's schema, you must also have `CREATE` privilege on the new schema. To alter the owner, you must also be a direct or indirect member of the new owning role, and that role must have `CREATE` privilege on the function's schema. (These restrictions enforce that altering the owner does not do anything you could not do by dropping and recreating the function. However, a superuser can alter ownership of any function anyway.)

Parameters

name The name (optionally schema-qualified) of an existing function. If no argument list is specified, the name must be unique in its schema.

argmode The mode of an argument: either `IN`, `OUT`, `INOUT`, or `VARIADIC`. If omitted, the default is `IN`. Note that `ALTER FUNCTION` does not actually pay any attention to `OUT` arguments, since only the input arguments are needed to determine the function's identity. So it is sufficient to list the `IN`, `INOUT`, and `VARIADIC` arguments.

argname The name of an argument. Note that ALTER FUNCTION does not actually pay any attention to argument names, since only the argument data types are needed to determine the function's identity.

argtype The data type(s) of the function's arguments (optionally schema-qualified), if any.

new_name The new name of the function.

new_owner The new owner of the function. Note that if the function is marked `SECURITY DEFINER`, it will subsequently run as the new owner.

new_schema The new schema for the function.

extension_name The name of the extension that the function is to depend on.

CALLED ON NULL INPUT RETURNS NULL ON NULL INPUT STRICT `CALLED ON NULL INPUT` changes the function so that it will be invoked when some or all of its arguments are null. `RETURNS NULL ON NULL INPUT` or `STRICT` changes the function so that it is not invoked if any of its arguments are null; instead, a null result is assumed automatically. SeeCREATE FUNCTION for more information.

IMMUTABLE STABLE VOLATILE Change the volatility of the function to the specified setting. SeeCREATE FUNCTION for details.

[EXTERNAL] SECURITY INVOKER [EXTERNAL] SECURITY DEFINER Change whether the function is a security definer or not. The key word `EXTERNAL` is ignored for SQL conformance. See CREATE FUNCTION for more information about this capability.

PARALLEL Change whether the function is deemed safe for parallelism. See CREATE FUNCTION for details.

LEAKPROOF Change whether the function is considered leakproof or not. See CREATE FUNCTION for more information about this capability.

EXECUTE ON ANY EXECUTE ON COORDINATOR EXECUTE ON ALL SEGMENTS EXECUTE ON INITPLAN The `EXECUTE ON` attributes specify where (coordinator or segment instance) a function runs when it is invoked during the query execution process.

`EXECUTE ON ANY` (the default) indicates that the function can be run on the coordinator, or any segment instance, and it returns the same result regardless of where it is run. WarehousePG determines where the function runs.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

`EXECUTE ON COORDINATOR` indicates that the function must run only on the coordinator instance.

`EXECUTE ON ALL SEGMENTS` indicates that the function must run on all primary segment instances, but not the coordinator, for each invocation. The overall result of the function is the `UNION ALL` of the results from all segment instances.

`EXECUTE ON INITPLAN` indicates that the function contains an SQL command that dispatches queries to the segment instances and requires special processing on the coordinator instance by WarehousePG when possible.

For more information about the `EXECUTE ON` attributes, see CREATE FUNCTION.

COST execution_cost Change the estimated execution cost of the function. See CREATE FUNCTION for more information.

ROWS result_rows Change the estimated number of rows returned by a set-returning function. See CREATE FUNCTION for more information.

SUPPORT support_function Set or change the planner support function to use for this function. You must be superuser to use this option. This option cannot be used to remove the support function altogether, since it must name a new support function. Use `CREATE OR REPLACE FUNCTION` if you require that.

configuration_parameter value Set or change the value of a configuration parameter when the function is called. If value is `DEFAULT` or, equivalently, `RESET` is used, the function-local setting is removed, and the function runs with the value present in its environment. Use `RESET ALL` to clear all function-local settings. `SET FROM CURRENT` saves the value of the parameter that is current when `ALTER FUNCTION` is run as the value to be applied when the function is entered. See SET for more information about allowed parameter names and values.

RESTRICT Ignored for conformance with the SQL standard.

Notes

WarehousePG has limitations on the use of functions defined as `STABLE` or `VOLATILE`. See CREATE FUNCTION for more information.

Examples

To rename the function `sqrt` for type `integer` to `square_root`:

```
ALTER FUNCTION sqrt(integer) RENAME TO square_root;
```

To change the owner of the function `sqrt` for type `integer` to `joe`:

```
ALTER FUNCTION sqrt(integer) OWNER TO joe;
```

To change the schema of the function `sqrt` for type `integer` to `maths`:

```
ALTER FUNCTION sqrt(integer) SET SCHEMA maths;
```

To mark the function `sqrt` for type `integer` as being dependent on the extension `mathlib`:

```
ALTER FUNCTION sqrt(integer) DEPENDS ON EXTENSION mathlib;
```

To adjust the search path that is automatically set for a function:

```
ALTER FUNCTION check_password(text) search_path = admin, pg_temp;
```

To disable automatic setting of `search_path` for a function:

```
ALTER FUNCTION check_password(text) RESET search_path;
```

The function will now execute with whatever search path is used by its caller.

Compatibility

This statement is partially compatible with the `ALTER FUNCTION` statement in the SQL standard. The standard allows more properties of a function to be modified, but does not provide the ability to rename a function, make a function a security definer, attach configuration parameter values to a function, or change the owner, schema, or volatility of a function. The standard also requires the `RESTRICT` key word, which is optional in WarehousePG.

7.1.13 ALTER GROUP

Changes a role name or membership.

Synopsis

```
ALTER GROUP <role_specification> ADD USER <user_name> [, ... ]

ALTER GROUP <role_specification> DROP USER <user_name> [, ... ]

where <role_specification> can be:

    <role_name>
  | CURRENT_USER
  | SESSION_USER

ALTER GROUP <group_name> RENAME TO <new_name>
```

Description

`ALTER GROUP` changes the attributes of a user group. This is an obsolete command, though still accepted for backwards compatibility, because users and groups are superseded by the more general concept of roles.

The first two variants add users to a group or remove them from a group. (Any role can play the part of either a "user" or "group" for this purpose. These variants are effectively equivalent to granting or revoking membership in the role named as the "group"; so, the preferred way to do this is to use GRANT or REVOKE.

The third variant changes the name of the group. This is exactly equivalent to renaming the role withALTER ROLE.

Parameters

group_name The name of the group (role) to modify.

user_name Users (roles) that are to be added to or removed from the group. The users (roles) must already exist; `ALTER GROUP` does not create or drop users.

new_name The new name of the group.

Examples

To add users to a group:

```
ALTER GROUP staff ADD USER karl, john;
```

To remove a user from a group:

```
ALTER GROUP workers DROP USER beth;
```

Compatibility

There is no `ALTER GROUP` statement in the SQL standard.

7.1.14 ALTER INDEX

Changes the definition of an index.

Synopsis

```
ALTER INDEX [ IF EXISTS ] <name> RENAME TO <new_name>
ALTER INDEX [ IF EXISTS ] <name> SET TABLESPACE <tablespace_name>
ALTER INDEX <name> ATTACH PARTITION <index_name>
ALTER INDEX <name DEPENDS ON EXTENSION <extension_name>
ALTER INDEX [ IF EXISTS ] <name> SET ( <storage_parameter> [= <value>] [, ...] )
ALTER INDEX [ IF EXISTS ] <name> RESET ( <storage_parameter>  [, ...] )
ALTER INDEX [ IF EXISTS ] <name> ALTER [ COLUMN ] <column_number>
    SET STATISTICS <integer>
ALTER INDEX ALL IN TABLESPACE <name> [ OWNED BY <role_name> [, ... ] ]
    SET TABLESPACE <new_tablespace> [ NOWAIT ]
```

Description

`ALTER INDEX` changes the definition of an existing index. There are several subforms described below. Note that the lock level required may differ for each subform. An `ACCESS EXCLUSIVE` lock is held unless explicitly noted. When multiple subcommands are listed, the lock held will be the strictest one required from any subcommand.

RENAME Changes the name of the index. If the index is associated with a table constraint (either `UNIQUE`, `PRIMARY KEY`, or `EXCLUDE`), the constraint is renamed as well. There is no effect on the stored data. Renaming an index acquires a `SHARE UPDATE EXCLUSIVE` lock.

SET TABLESPACE Changes the index's tablespace to the specified tablespace and moves the data file(s) associated with the index to the new tablespace. To change the tablespace of an index, you must own the index and have `CREATE` privilege on the new tablespace. All indexes in the current database in a tablespace can be moved by using the `ALL IN TABLESPACE` form, which will lock all indexes to be moved and then move each one. This form also supports `OWNED BY`, which will only move indexes owned by the roles specified. If the `NOWAIT` option is specified then the command will fail if it is unable to acquire all of the locks required immediately. Note that system catalogs will not be moved by this command, use `ALTER DATABASE` or explicit `ALTER INDEX` invocations instead if desired. See also CREATE TABLESPACE.

ATTACH PARTITION Causes the named index to become attached to the altered index. The named index must be on a partition of the table containing the index being altered, and have an equivalent definition. An attached index cannot be dropped by itself, and will automatically be dropped if its parent index is dropped.

DEPENDS ON EXTENSION This form marks the index as dependent on the extension, such that if the extension is dropped, the index will automatically be dropped as well.

SET (storage_parameter [= value][, ...]) Changes one or more index-method-specific storage parameters for the index. See CREATE INDEX for details on the available parameters. Note that the index contents will not be modified immediately by this command; depending on the parameter you might need to rebuild the index with REINDEX to get the desired effects.

RESET (storage_parameter [, ...]) Resets one or more index-method-specific storage parameters for the index to their defaults. As with `SET`, a `REINDEX` may be needed to update the index entirely.

ALTER [COLUMN] column_number SET STATISTICS integer This form sets the per-column statistics-gathering target for subsequent `ANALYZE` operations, though can be used only on index columns that are defined as an expression. Since expressions lack a unique name, we refer to them using the ordinal number of the index column. The target can be set in the range 0 to 10000; alternatively, set it to `-1` to revert to using the system default statistics target (default_statistics_target).

Parameters

IF EXISTS Do not throw an error if the index does not exist. WarehousePG issues a notice in this case.

column_number The ordinal number refers to the ordinal (left-to-right) position of the index column.

name The name (optionally schema-qualified) of an existing index to alter.

new_name New name for the index.

tablespace_name The tablespace to which the index will be moved.

storage_parameter The name of an index-method-specific storage parameter.

value The new value for an index-method-specific storage parameter. This might be a number or a word depending on the parameter.

Notes

These operations are also possible using ALTER TABLE. `ALTER INDEX` is in fact just an alias for the forms of `ALTER TABLE` that apply to indexes.

There was formerly an `ALTER INDEX OWNER` variant, but this is now ignored (with a warning). An index cannot have an owner different from its table's owner. Changing the table's owner automatically changes the index as well.

Changing any part of a system catalog index is not permitted.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Examples

To rename an existing index:

```
ALTER INDEX distributors RENAME TO suppliers;
```

To move an index to a different tablespace:

```
ALTER INDEX distributors SET TABLESPACE fasttablespace;
```

To change an index's fill factor (assuming that the index method supports it):

```
ALTER INDEX distributors SET (fillfactor = 75);
REINDEX INDEX distributors;
```

Set the statistics-gathering target for an expression index:

```
CREATE INDEX coord_idx ON measured (x, y, (z + t));
ALTER INDEX coord_idx ALTER COLUMN 3 SET STATISTICS 1000;
```

Compatibility

`ALTER INDEX` is a WarehousePG extension to the SQL standard.

7.1.15 ALTER LANGUAGE

Changes the definition of a procedural language.

Synopsis

```
ALTER [ PROCEDURAL ] LANGUAGE <name> RENAME TO <new_name>
ALTER [ PROCEDURAL ] LANGUAGE <name> OWNER TO { <new_owner> | CURRENT_USER | SESSION_USER }
```

Description

`ALTER LANGUAGE` changes the definition of a procedural language for a specific database. Definition changes supported include renaming the language or assigning a new owner. You must be superuser or the owner of the language to use `ALTER LANGUAGE`.

Parameters

name Name of a language.

new_name The new name of the language.

new_owner The new owner of the language.

Compatibility

There is no `ALTER LANGUAGE` statement in the SQL standard.

See Also

CREATE LANGUAGE, DROP LANGUAGE

7.1.16 ALTER MATERIALIZED VIEW

Changes the definition of a materialized view.

Synopsis

```
ALTER MATERIALIZED VIEW [ IF EXISTS ] <name> <action> [, ... ]
ALTER MATERIALIZED VIEW <name>
    DEPENDS ON EXTENSION <extension_name>
ALTER MATERIALIZED VIEW [ IF EXISTS ] <name>
    RENAME [ COLUMN ] <column_name> TO <new_column_name>
ALTER MATERIALIZED VIEW [ IF EXISTS ] <name>
    RENAME TO <new_name>
ALTER MATERIALIZED VIEW [ IF EXISTS ] <name>
    SET SCHEMA <new_schema>
ALTER MATERIALIZED VIEW ALL IN TABLESPACE <name> [ OWNED BY <role_name> [, ... ] ]
    SET TABLESPACE <new_tablespace> [ NOWAIT ]

where <action> is one of:

    ALTER [ COLUMN ] <column_name> SET STATISTICS <integer>
    ALTER [ COLUMN ] <column_name> SET ( <attribute_option> = <value> [, ... ] )
    ALTER [ COLUMN ] <column_name> RESET ( <attribute_option> [, ... ] )
    ALTER [ COLUMN ] <column_name> SET STORAGE { PLAIN | EXTERNAL | EXTENDED | MAIN }
    CLUSTER ON <index_name>
    SET WITHOUT CLUSTER
    SET TABLESPACE <new_tablespace>
    SET ( <storage_paramete>r = <value> [, ... ] )
    RESET ( <storage_parameter> [, ... ] )
    OWNER TO { <new_owner> | CURRENT_USER | SESSION_USER }
```

Description

`ALTER MATERIALIZED VIEW` changes various auxiliary properties of an existing materialized view.

You must own the materialized view to use `ALTER MATERIALIZED VIEW`. To change a materialized view's schema, you must also have `CREATE` privilege on the new schema. To alter the owner, you must also be a direct or indirect member of the new owning role, and that role must have `CREATE` privilege on the materialized view's schema. (These restrictions enforce that altering the owner doesn't do anything you couldn't do by dropping and recreating the materialized view. However, a superuser can alter ownership of any view anyway.)

The `DEPENDS ON EXTENSION` form marks the materialized view as dependent on an extension, such that the materialized view will automatically be dropped if the extension is dropped.

The statement subforms and actions available for `ALTER MATERIALIZED VIEW` are a subset of those available for `ALTER TABLE`, and have the same meaning when used for materialized views. See the descriptions for ALTER TABLE for details.

Parameters

name The name (optionally schema-qualified) of an existing materialized view.

column_name Name of a new or existing column.

extension_name The name of the extension that the materialized view is to depend on.

new_column_name New name for an existing column.

new_owner The user name of the new owner of the materialized view.

new_name The new name for the materialized view.

new_schema The new schema for the materialized view.

Examples

To rename the materialized view `foo` to `bar`:

```
ALTER MATERIALIZED VIEW foo RENAME TO bar;
```

Compatibility

`ALTER MATERIALIZED VIEW` is a WarehousePG extension of the SQL standard.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.1.17 ALTER OPERATOR

Changes the definition of an operator.

Synopsis

```
ALTER OPERATOR <name> ( {<left_type> | NONE} , {<right_type> | NONE} )
   OWNER TO { <new_owner> | CURRENT_USER | SESSION_USER }

ALTER OPERATOR <name> ( {<left_type> | NONE} , {<right_type> | NONE} )
    SET SCHEMA <new_schema>

ALTER OPERATOR name ( { <left_type> | NONE } , { <right_type> | NONE } )
    SET ( {  RESTRICT = { <res_proc> | NONE }
           | JOIN = { <join_proc> | NONE }
         } [, ... ] )
```

Description

`ALTER OPERATOR` changes the definition of an operator.

You must own the operator to use `ALTER OPERATOR`. To alter the owner, you must also be a direct or indirect member of the new owning role, and that role must have `CREATE` privilege on the operator's schema. (These restrictions enforce that altering the owner does not do anything you could not do by dropping and recreating the operator. However, a superuser can alter ownership of any operator anyway.)

Parameters

name The name (optionally schema-qualified) of an existing operator.

left_type The data type of the operator's left operand; write `NONE` if the operator has no left operand.

right_type The data type of the operator's right operand; write `NONE` if the operator has no right operand.

new_owner The new owner of the operator.

new_schema The new schema for the operator.

res_proc The restriction selectivity estimator function for this operator; write `NONE` to remove the existing selectivity estimator.

join_proc The join selectivity estimator function for this operator; write `NONE` to remove the existing selectivity estimator.

Examples

Change the owner of a custom operator `a @@ b` for type `text`:

```
ALTER OPERATOR @@ (text, text) OWNER TO joe;
```

Change the restriction and join selectivity estimator functions of a custom operator `a && b` for type `int[]`:

```
ALTER OPERATOR && (_int4, _int4) SET (RESTRICT = _int_contsel, JOIN = _int_contjoinsel);
```

Compatibility

There is no `ALTER OPERATOR` statement in the SQL standard.

See Also

CREATE OPERATOR, DROP OPERATOR

Parent topic: SQL Commands

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.1.18 ALTER OPERATOR CLASS

Changes the definition of an operator class.

Synopsis

```
ALTER OPERATOR CLASS <name> USING <index_method> RENAME TO <new_name>

ALTER OPERATOR CLASS <name> USING <index_method> OWNER TO { <new_owner> | CURRENT_USER | SESSION_USER }

ALTER OPERATOR CLASS <name> USING <index_method> SET SCHEMA <new_schema>
```

Description

`ALTER OPERATOR CLASS` changes the definition of an operator class.

You must own the operator class to use `ALTER OPERATOR CLASS`. To alter the owner, you must also be a direct or indirect member of the new owning role, and that role must have `CREATE` privilege on the operator class's schema. (These restrictions enforce that altering the owner does not do anything you could not do by dropping and recreating the operator class. However, a superuser can alter ownership of any operator class anyway.)

Parameters

name The name (optionally schema-qualified) of an existing operator class.

index_method The name of the index method this operator class is for.

new_name The new name of the operator class.

new_owner The new owner of the operator class

new_schema The new schema for the operator class.

Compatibility

There is no `ALTER OPERATOR CLASS` statement in the SQL standard.

See Also

CREATE OPERATOR CLASS, DROP OPERATOR CLASS, ALTER OPERATOR FAMILY

Parent topic: SQL Commands

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.1.19 ALTER OPERATOR FAMILY

Changes the definition of an operator family.

Synopsis

```
ALTER OPERATOR FAMILY <name> USING <index_method> ADD
  {  OPERATOR <strategy_number> <operator_name> ( <op_type>, <op_type> ) [ FOR SEARCH | FOR ORDER BY <sort_family_name> ]
    | FUNCTION <support_number> [ ( <op_type> [ , <op_type> ] ) ] <function_name> ( <argument_type> [, ...] )
  } [, ... ]

ALTER OPERATOR FAMILY <name> USING <index_method> DROP
  {  OPERATOR <strategy_number> ( <op_type> [ , <op_type> ] )
    | FUNCTION <support_number> ( <op_type> [ , <op_type> ] )
  } [, ... ]

ALTER OPERATOR FAMILY <name> USING <index_method> RENAME TO <new_name>

ALTER OPERATOR FAMILY <name> USING <index_method> OWNER TO { <new_owner> | CURRENT_USER | SESSION_USER }

ALTER OPERATOR FAMILY <name> USING <index_method> SET SCHEMA <new_schema>
```

Description

`ALTER OPERATOR FAMILY` changes the definition of an operator family. You can add operators and support functions to the family, remove them from the family, or change the family's name or owner.

When operators and support functions are added to a family with `ALTER OPERATOR FAMILY`, they are not part of any specific operator class within the family, but are just "loose" within the family. This indicates that these operators and functions are compatible with the family's semantics, but are not required for correct functioning of any specific index. (Operators and functions that are so required should be declared as part of an operator class, instead; see CREATE OPERATOR CLASS.) You can drop loose members of a family from the family at any time, but members of an operator class cannot be dropped without dropping the whole class and any indexes that depend on it. Typically, single-data-type operators and functions are part of operator classes because they are needed to support an index on that specific data type, while cross-data-type operators and functions are made loose members of the family.

You must be a superuser to use `ALTER OPERATOR FAMILY`. (This restriction is made because an erroneous operator family definition could confuse or even crash the server.)

`ALTER OPERATOR FAMILY` does not presently check whether the operator family definition includes all the operators and functions required by the index method, nor whether the operators and functions form a self-consistent set. It is the user's responsibility to define a valid operator family.

Parameters

name The name (optionally schema-qualified) of an existing operator family.

index_method The name of the index method this operator family is for.

strategy_number The index method's strategy number for an operator associated with the operator family.

operator_name The name (optionally schema-qualified) of an operator associated with the operator family.

op_type In an `OPERATOR` clause, the operand data type(s) of the operator, or `NONE` to signify a left-unary or right-unary operator. Unlike the comparable syntax in `CREATE OPERATOR CLASS`, the operand data types must always be specified. In an `ADD FUNCTION` clause, the operand data type(s) the function is intended to support, if different from the input data type(s) of the function. For B-tree comparison functions and hash functions it is not necessary to specify op_type since the function's input data type(s) are always the correct ones to use. For B-tree sort support functions and all functions in GiST, SP-GiST, and GIN operator classes, it is necessary to specify the operand data type(s) the function is to be used with. In a `DROP FUNCTION` clause, the operand data type(s) the function is intended to support must be specified.

sort_family_name The name (optionally schema-qualified) of an existing `btree` operator family that describes the sort ordering associated with an ordering operator.

If neither `FOR SEARCH` nor `FOR ORDER BY` is specified, `FOR SEARCH` is the default.

support_number The index method's support function number for a function associated with the operator family.

function_name The name (optionally schema-qualified) of a function that is an index method support function for the operator family. If no argument list is specified, the name must be unique in its schema.

argument_type The parameter data type(s) of the function.

new_name The new name of the operator family.

new_owner The new owner of the operator family.

new_schema The new schema for the operator family.

The `OPERATOR` and `FUNCTION` clauses can appear in any order.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Notes

Notice that the `DROP` syntax only specifies the "slot" in the operator family, by strategy or support number and input data type(s). The name of the operator or function occupying the slot is not mentioned. Also, for `DROP FUNCTION` the type(s) to specify are the input data type(s) the function is intended to support; for `GiST`, `SP_GiST`, and `GIN` indexes this might have nothing to do with the actual input argument types of the function.

Because the index machinery does not check access permissions on functions before using them, including a function or operator in an operator family is tantamount to granting public execute permission on it. This is usually not an issue for the sorts of functions that are useful in an operator family.

The operators should not be defined by SQL functions. A SQL function is likely to be inlined into the calling query, which will prevent the optimizer from recognizing that the query matches an index.

Before WarehousePG 6.0, the `OPERATOR` clause could include a `RECHECK` option. This option is no longer supported. WarehousePG now determines whether an index operator is "lossy" on-the-fly at run time. This allows more efficient handling of cases where an operator might or might not be lossy.

Examples

The following example command adds cross-data-type operators and support functions to an operator family that already contains B-tree operator classes for data types `int4` and `int2`.:

```
ALTER OPERATOR FAMILY integer_ops USING btree ADD

  -- int4 vs int2
  OPERATOR 1 < (int4, int2) ,
  OPERATOR 2 <= (int4, int2) ,
  OPERATOR 3 = (int4, int2) ,
  OPERATOR 4 >= (int4, int2) ,
  OPERATOR 5 > (int4, int2) ,
  FUNCTION 1 btint42cmp(int4, int2) ,

  -- int2 vs int4
  OPERATOR 1 < (int2, int4) ,
  OPERATOR 2 <= (int2, int4) ,
  OPERATOR 3 = (int2, int4) ,
  OPERATOR 4 >= (int2, int4) ,
  OPERATOR 5 > (int2, int4) ,
  FUNCTION 1 btint24cmp(int2, int4) ;
```

To remove these entries:

```
ALTER OPERATOR FAMILY integer_ops USING btree DROP

  -- int4 vs int2
  OPERATOR 1 (int4, int2) ,
  OPERATOR 2 (int4, int2) ,
  OPERATOR 3 (int4, int2) ,
  OPERATOR 4 (int4, int2) ,
  OPERATOR 5 (int4, int2) ,
  FUNCTION 1 (int4, int2) ,

  -- int2 vs int4
  OPERATOR 1 (int2, int4) ,
  OPERATOR 2 (int2, int4) ,
  OPERATOR 3 (int2, int4) ,
  OPERATOR 4 (int2, int4) ,
  OPERATOR 5 (int2, int4) ,
  FUNCTION 1 (int2, int4) ;
```

Compatibility

There is no `ALTER OPERATOR FAMILY` statement in the SQL standard.

7.1.20 ALTER POLICY

Changes the definition of a row-level security policy.

Synopsis

```
ALTER POLICY <name> ON <table_name> RENAME TO <new_name>

ALTER POLICY <name ON table_name>
    [ TO { <role_name> | PUBLIC | CURRENT_USER | SESSION_USER } [, ...] ]
    [ USING ( <using_expression> ) ]
    [ WITH CHECK ( <check_expression> ) ]
```

Description

`ALTER POLICY` changes the definition of an existing row-level security policy. Note that `ALTER POLICY` only allows the set of roles to which the policy applies and the `USING` and `WITH CHECK` expressions to be modified. To change other properties of a policy, such as the command to which it applies or whether it is permissive or restrictive, the policy must be dropped and recreated.

To use `ALTER POLICY`, you must own the table to which the policy applies.

In the second form of `ALTER POLICY`, the role list, using_expression, and check_expression are replaced independently if specified. When one of those clauses is omitted, the corresponding part of the policy is unchanged.

Parameters

name The name of an existing policy to alter.

table_name The name (optionally schema-qualified) of the table that the policy is on.

new_name The new name for the policy.

role_name The role(s) to which the policy applies. Multiple roles can be specified at one time. To apply the policy to all roles, use `PUBLIC`.

using_expression The `USING` expression for the policy. See CREATE POLICY for details.

check_expression The `WITH CHECK` expression for the policy. See CREATE POLICY for details.

Compatibility

`ALTER POLICY` is a WarehousePG extension to the SQL standard.

7.1.21 ALTER PROCEDURE

Changes the definition of a procedure.

Synopsis

```
ALTER PROCEDURE <name> [ ( [ [<argmode>] [<argname>] <argtype> [, ...] ] ) ]
   <action> [, ... ] [RESTRICT]

ALTER PROCEDURE <name> [ ( [ [<argmode>] [<argname>] <argtype> [, ...] ] ) ]
   RENAME TO <new_name>

ALTER PROCEDURE <name> [ ( [ [<argmode>] [<argname>] <argtype> [, ...] ] ) ]
   OWNER TO { <new_owner> | CURRENT_USER | SESSION_USER }

ALTER PROCEDURE <name> [ ( [ [<argmode>] [<argname>] <argtype> [, ...] ] ) ]
   SET SCHEMA <new_schema>

ALTER PROCEDURE <name> [ ( [ [<argmode>] [<argname>] <argtype> [, ...] ] ) ]
   DEPENDS ON EXTENSION <extension_name>

where <action> is one of:

    { [EXTERNAL] SECURITY INVOKER | [EXTERNAL] SECURITY DEFINER }
    SET <configuration_parameter> { TO | = } { <value> | DEFAULT }
    SET <configuration_parameter> FROM CURRENT
    RESET <configuration_parameter>
    RESET ALL
```

Description

`ALTER PROCEDURE` changes the definition of a procedure.

You must own the procedure to use `ALTER PROCEDURE`. To change a procedure's schema, you must also have `CREATE` privilege on the new schema. To alter the owner, you must also be a direct or indirect member of the new owning role, and that role must have `CREATE` privilege on the procedure's schema. (These restrictions enforce that altering the owner doesn't do anything you couldn't do by dropping and recreating the procedure. However, a superuser can alter ownership of any procedure anyway.)

Parameters

name The name (optionally schema-qualified) of an existing procedure. If no argument list is specified, the name must be unique in its schema.

argmode The mode of an argument: `IN` or `VARIADIC`. If omitted, the default is `IN`.

argname The name of an argument. Note that `ALTER PROCEDURE` does not actually pay any attention to argument names, since only the argument data types are needed to determine the function's identity.

argtype The data type(s) of the procedure's arguments (optionally schema-qualified), if any.

new_name The new name of the procedure.

new_owner The new owner of the procedure. Note that if the procedure is marked `SECURITY DEFINER`, it will subsequently run as the new owner.

new_schema The new schema for the procedure.

extension_name The name of the extension that the procedure is to depend on.

[EXTERNAL] SECURITY INVOKER [EXTERNAL] SECURITY DEFINER Change whether the procedure is a security definer or not. The key word `EXTERNAL` is ignored for SQL conformance. See CREATE PROCEDURE for more information about this capability.

configuration_parameter value Set or change the value of a configuration parameter when the procedure is called. If value is `DEFAULT` or, equivalently, `RESET` is used, the procedure-local setting is removed, and the procedure runs with the value present in its environment. Use `RESET ALL` to clear all procedure-local settings. `SET FROM CURRENT` saves the value of the parameter that is current when `ALTER PROCEDURE` is run as the value to be applied when the procedure is entered. See SET for more information about allowed parameter names and values.

RESTRICT Ignored for conformance with the SQL standard.

Notes

WarehousePG has limitations on the use of functions defined as `STABLE` or `VOLATILE`. See CREATE FUNCTION for more information.

Examples

To rename the procedure `insert_data` with two arguments of type `integer` to `insert_record`:

```
ALTER PROCEDURE insert_data(integer, integer) RENAME TO insert_record;
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

To change the owner of the procedure `insert_data` with two arguments of type `integer` to `joe`:

```
ALTER PROCEDURE insert_data(integer, integer) OWNER TO joe;
```

To change the schema of the procedure `insert_data` with two arguments of type `integer` to `accounting`:

```
ALTER PROCEDURE insert_data(integer, integer) SET SCHEMA accounting;
```

To mark the procedure `insert_data(integer, integer)` as being dependent on the extension `myext`:

```
ALTER PROCEDURE insert_data(integer, integer) DEPENDS ON EXTENSION myext;
```

To adjust the search path that is automatically set for a procedure:

```
ALTER PROCEDURE check_password(text) SET search_path = admin, pg_temp;
```

To disable automatic setting of `search_path` for a procedure:

```
ALTER PROCEDURE check_password(text) RESET search_path;
```

The procedure will now execute with whatever search path is used by its caller.

Compatibility

This statement is partially compatible with the `ALTER PROCEDURE` statement in the SQL standard. The standard allows more properties of a procedure to be modified, but does not provide the ability to rename a procedure, make a procedure a security definer, attach configuration parameter values to a procedure, or change the owner, schema, or volatility of a procedure. The standard also requires the `RESTRICT` key word, which is optional in WarehousePG.

7.1.22 ALTER PROTOCOL

Changes the definition of a protocol.

Synopsis

```
ALTER PROTOCOL <name> RENAME TO <newname>

ALTER PROTOCOL <name> OWNER TO <newowner>
```

Description

`ALTER PROTOCOL` changes the definition of a protocol. Only the protocol name or owner can be altered.

You must own the protocol to use `ALTER PROTOCOL`. To alter the owner, you must also be a direct or indirect member of the new owning role, and that role must have `CREATE` privilege on schema of the protocol.

These restrictions are in place to ensure that altering the owner only makes changes that could by made by dropping and recreating the protocol. Note that a superuser can alter ownership of any protocol.

Parameters

name The name (optionally schema-qualified) of an existing protocol.

newname The new name of the protocol.

newowner The new owner of the protocol.

Examples

To rename the protocol `GPDBauth` to `GPDB_authentication`:

```
ALTER PROTOCOL GPDBauth RENAME TO GPDB_authentication;
```

To change the owner of the `GPDB_authentication` protocol to `joe`:

```
ALTER PROTOCOL GPDB_authentication OWNER TO joe;
```

Compatibility

There is no `ALTER PROTOCOL` statement in the SQL standard.

7.1.23 ALTER RESOURCE GROUP

Changes the limits of a resource group, or renames it.

Synopsis

```
ALTER RESOURCE GROUP <name> SET <group_attribute> <value>
```

where group_attribute is one of:

```
[ CONCURRENCY=<integer> ]
CPU_MAX_PERCENT=<integer> | CPUSET=<coordinator_cores>;<segment_cores>
[ CPU_WEIGHT=<integer> ]
[ MEMORY_QUOTA=<integer> ]
[ MIN_COST=<integer> ]
[ IO_LIMIT=' <tablespace_io_limit_spec> [; ...] ' ]
[ NAME <new_name> ]
```

Where `<tablespace_io_limit_spec>` is:

```
<tablespace_name> | <oid> : <io_limit_option_spec> [, ...]
```

Where `<io_limit_option_spec>` is:

```
wbps=<io_limit_option_value>
| rbps=<io_limit_option_value>
| wiops=<io_limit_option_value>
| riops=<io_limit_option_value>
```

Where `<io_limit_option_vlaue>` is:

```
<integer> | max
```

Description

`ALTER RESOURCE GROUP` changes the limits of a resource group. Only a superuser can alter a resource group.

You can set or reset the concurrency limit of a resource group that you create for roles to control the maximum number of active concurrent statements in that group. You can also reset the memory or CPU resources of a resource group to control the amount of memory or CPU resources that all queries submitted through the group can consume on each segment host.

When you alter the CPU resource management mode or limit of a resource group, the new mode or limit is immediately applied.

When you alter a memory quota of a resource group that you create for roles, the new resource limit is immediately applied if current resource usage is less than or equal to the new value and there are no running transactions in the resource group. If the current resource usage exceeds the new memory quota value, or if there are running transactions in other resource groups that hold some of the resource, then WarehousePG defers assigning the new limit until resource usage falls within the range of the new value.

When you increase the memory quota of a resource group that you create for external components, the new resource limit is phased in as system memory resources become available. If you decrease the memory quota of a resource group that you create for external components, the behavior is component-specific.

You can alter one limit type in a single `ALTER RESOURCE GROUP` call.

Parameters

- `name`

  The name of the resource group to alter.

- `CONCURRENCY` *integer*

  The maximum number of concurrent transactions, including active and idle transactions, that are permitted for this resource group. The `CONCURRENCY` value must be an integer in the range [0 .. `max_connections`]. The default `CONCURRENCY` value for resource groups defined for roles is 20.

  You must set `CONCURRENCY` to `0` for resource groups that you create for external components.

  > **Note** You cannot set the `CONCURRENCY` value for the `admin_group` to `0`.

- `CPU_MAX_PERCENT` *integer*

  The percentage of the maximum available CPU resources that the resource group can use. The value range is `1-100`.

- `CPU_WEIGHT` *integer*

  The scheduling priority of the current group. The value range is `1-500`, the default is `100`.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

- `CPUSET` *\<coordinator_cores>;\<segment_cores>*

  Identifies the CPU cores to reserve for this resource group on the coordinator host and on segment hosts. The CPU cores that you specify must be available in the system and cannot overlap with any CPU cores that you specify for other resource groups.

  > **Note** You must specify either `CPU_MAX_PERCENT` or `CPUSET` when you create a resource group, but not both.

  Specify cores as a comma-separated list of single core numbers or core number intervals. Define the coordinator host cores first, followed by segment host cores, and separate the two with a semicolon. You must enclose the full core configuration in single quotes. For example, `'1;1,3-4'` configures core 1 for the coordinator host, and cores 1, 3, and 4 for the segment hosts.

  > **Note** You can configure `CPUSET` for a resource group only after you have enabled resource group-based resource management for your WarehousePG cluster.

- `IO_LIMIT` *'\<tablespace_io_limit_spec> [; ...]'*

  Optional. The maximum read/write sequential disk I/O throughput, and the maximum read/write I/O operations per second for the queries assigned to a specific resource group.

  Where `<tablespace_io_limit_spec>` is:

  ```
  <tablespace_name> | <oid> : <io_limit_option_spec> [, ...]
  ```

  Where `<io_limit_option_spec>` is:

  ```
  wbps=<io_limit_option_value>
  | rbps=<io_limit_option_value>
  | wiops=<io_limit_option_value>
  | riops=<io_limit_option_value>
  ```

  Where `<io_limit_option_value>` is:

  ```
  <integer> | max
  ```

  When you use this parameter, specify:

  - The tablespace name or the tablespace object ID (OID) you set the limits for. Use `*` to set limits for all tablespaces.
  - The values for `rbps` and `wbps` to limit the maximum read and write sequential disk I/O throughput in the resource group, in MB/S. The default value is `max`, which means there is no limit.
  - The values for `riops` and `wiops` to limit the maximum read and write I/O operations per second in the resource group. The default value is `max`, which means there is no limit.

  If `IO_LIMIT` is not set, the default value for `rbps`, `wbps`, `riops`, and `wiops` is `max`, which means there are no disk I/O limits. In this scenario, the `gp_toolkit.gp_resgroup_config` system view displays its value as `-1`.

  > **Note** The parameter `IO_LIMIT` is only available when you use Linux Control Groups v2. See Configuring and Using Resource Groups for more information.

- `MEMORY_QUOTA` *integer*

  The maximum available memory, in MB, to reserve for this resource group. This value determines the total amount of memory that all worker processes within a resource group can consume on a segment host during query execution.

  The minimum memory quantity you can specify for a resource group is `0`. The default value is `-1`.

  When you specify a `MEMORY_QUOTA` of `-1`, `MEMORY_QUOTA` takes the value of the `statement_mem` server configuration parameter.

  > **Note** If the server configuration parameter `gp_resgroup_memory_query_fixed_mem` is set, its value overrides at the session level the value of `MEMORY_QUOTA`.

- `MIN_COST` *integer*

  The limit on the cost of the query plan generated by a query in this resource group. When the query plan cost of the query is less than this value, the query is unassigned from the resource group to which it belongs, allowing low-cost queries to execute without resource constraints.

  The value range is `0-500`. The default value is `0`, which means that the cost is not used to bypass the query.

- `NAME` *new_name*

  The new name for the resource group. The name must be unique among all resource groups. You can't rename the default resource groups `admin_group`, `default_group`, and `system_group`, and you can't use `none` as a new name.

Notes

Use CREATE ROLE or ALTER ROLE to assign a specific resource group to a role (user).

You cannot submit an `ALTER RESOURCE GROUP` command in an explicit transaction or sub-transaction.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Examples

Change the active transaction limit for a resource group:

```
ALTER RESOURCE GROUP rgroup1 SET CONCURRENCY 13;
```

Update the CPU limit for a resource group:

```
ALTER RESOURCE GROUP rgroup2 SET CPU_MAX_PERCENT 45;
```

Update the memory quota for a resource group:

```
ALTER RESOURCE GROUP rgroup3 SET MEMORY_QUOTA 300;
```

Reserve CPU core 1 for a resource group on the coordinator host and all segment hosts:

```
ALTER RESOURCE GROUP rgroup5 SET CPUSET '1;1';
```

Set disk I/O limits for tablespaces `tablespace1` and a tablespace with oid 1663:

```
ALTER RESOURCE GROUP admin_group SET IO_LIMIT 'tablespace1:wbps=2000,wiops=2000;1663:rbps=2024,riops=2024';
```

Rename a resource group:

```
ALTER RESOURCE GROUP rgroup1 SET NAME rgroup1_renamed;
```

Compatibility

The `ALTER RESOURCE GROUP` statement is a WarehousePG extension. This command does not exist in standard PostgreSQL.

7.1.24 ALTER RESOURCE QUEUE

Changes the limits of a resource queue.

Synopsis

```
ALTER RESOURCE QUEUE <name> WITH ( <queue_attribute>=<value> [, ... ] )
```

where queue_attribute is:

```
   ACTIVE_STATEMENTS=<integer>
   MEMORY_LIMIT='<memory_units>'
   MAX_COST=<float>
   COST_OVERCOMMIT={TRUE|FALSE}
   MIN_COST=<float>
   PRIORITY={MIN|LOW|MEDIUM|HIGH|MAX}
```

```
ALTER RESOURCE QUEUE <name> WITHOUT ( <queue_attribute> [, ... ] )
```

where queue_attribute is:

```
   ACTIVE_STATEMENTS
   MEMORY_LIMIT
   MAX_COST
   COST_OVERCOMMIT
   MIN_COST
```

> **Note** A resource queue must have either an `ACTIVE_STATEMENTS` or a `MAX_COST` value. Do not remove both these `queue_attributes` from a resource queue.

Description

`ALTER RESOURCE QUEUE` changes the limits of a resource queue. Only a superuser can alter a resource queue. A resource queue must have either an `ACTIVE_STATEMENTS` or a `MAX_COST` value (or it can have both). You can also set or reset priority for a resource queue to control the relative share of available CPU resources used by queries associated with the queue, or memory limit of a resource queue to control the amount of memory that all queries submitted through the queue can consume on a segment host.

`ALTER RESOURCE QUEUE WITHOUT` removes the specified limits on a resource that were previously set. A resource queue must have either an `ACTIVE_STATEMENTS` or a `MAX_COST` value. Do not remove both these `queue_attributes` from a resource queue.

Parameters

name The name of the resource queue whose limits are to be altered.

ACTIVE_STATEMENTS integer The number of active statements submitted from users in this resource queue allowed on the system at any one time. The value for `ACTIVE_STATEMENTS` should be an integer greater than 0. To reset `ACTIVE_STATEMENTS` to have no limit, enter a value of `-1`.

MEMORY_LIMIT 'memory_units' Sets the total memory quota for all statements submitted from users in this resource queue. Memory units can be specified in kB, MB or GB. The minimum memory quota for a resource queue is 10MB. There is no maximum; however the upper boundary at query execution time is limited by the physical memory of a segment host. The default value is no limit (`-1`).

MAX_COST float The total query optimizer cost of statements submitted from users in this resource queue allowed on the system at any one time. The value for `MAX_COST` is specified as a floating point number (for example 100.0) or can also be specified as an exponent (for example 1e+2). To reset `MAX_COST` to have no limit, enter a value of `-1.0`.

COST_OVERCOMMIT boolean If a resource queue is limited based on query cost, then the administrator can allow cost overcommit (`COST_OVERCOMMIT=TRUE`, the default). This means that a query that exceeds the allowed cost threshold will be allowed to run but only when the system is idle. If `COST_OVERCOMMIT=FALSE` is specified, queries that exceed the cost limit will always be rejected and never allowed to run.

MIN_COST float Queries with a cost under this limit will not be queued and run immediately. Cost is measured in units of disk page fetches; 1.0 equals one sequential disk page read. The value for `MIN_COST` is specified as a floating point number (for example 100.0) or can also be specified as an exponent (for example 1e+2). To reset `MIN_COST` to have no limit, enter a value of `-1.0`.

PRIORITY={MIN|LOW|MEDIUM|HIGH|MAX} Sets the priority of queries associated with a resource queue. Queries or statements in queues with higher priority levels will receive a larger share of available CPU resources in case of contention. Queries in low-priority queues may be delayed while higher priority queries are run.

Notes

GPORCA and the Postgres-based planner utilize different query costing models and may compute different costs for the same query. The WarehousePG resource queue resource management scheme neither differentiates nor aligns costs between GPORCA and the Postgres-based planner; it uses the literal cost value returned from the optimizer to throttle queries.

When resource queue-based resource management is active, use the `MEMORY_LIMIT` and `ACTIVE_STATEMENTS` limits for resource queues rather than configuring cost-based limits. Even when using GPORCA, WarehousePG may fall back to using the Postgres-based planner for certain queries, so using cost-based limits can lead to unexpected results.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Examples

Change the active query limit for a resource queue:

```
ALTER RESOURCE QUEUE myqueue WITH (ACTIVE_STATEMENTS=20);
```

Change the memory limit for a resource queue:

```
ALTER RESOURCE QUEUE myqueue WITH (MEMORY_LIMIT='2GB');
```

Reset the maximum and minimum query cost limit for a resource queue to no limit:

```
ALTER RESOURCE QUEUE myqueue WITH (MAX_COST=-1.0,
  MIN_COST= -1.0);
```

Reset the query cost limit for a resource queue to 310 (or 30000000000.0) and do not allow overcommit:

```
ALTER RESOURCE QUEUE myqueue WITH (MAX_COST=3e+10,
  COST_OVERCOMMIT=FALSE);
```

Reset the priority of queries associated with a resource queue to the minimum level:

```
ALTER RESOURCE QUEUE myqueue WITH (PRIORITY=MIN);
```

Remove the `MAX_COST` and `MEMORY_LIMIT` limits from a resource queue:

```
ALTER RESOURCE QUEUE myqueue WITHOUT (MAX_COST, MEMORY_LIMIT);
```

Compatibility

The `ALTER RESOURCE QUEUE` statement is a WarehousePG extension. This command does not exist in standard PostgreSQL.

See Also

CREATE RESOURCE QUEUE, DROP RESOURCE QUEUE, CREATE ROLE, ALTER ROLE

Parent topic: SQL Commands

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.1.25 ALTER ROLE

Changes a database role (user or group).

Synopsis

```
ALTER ROLE <role_specification> [ WITH ] <option> [ ... ]

where <option> can be:

    SUPERUSER | NOSUPERUSER
  | CREATEDB | NOCREATEDB
  | CREATEROLE | NOCREATEROLE
  | CREATEEXTTABLE | NOCREATEEXTTABLE  [ ( attribute='value' [, ...] )
     where attributes and values are:
       type='readable'|'writable'
       protocol='gpfdist'|'http'
  | INHERIT | NOINHERIT
  | LOGIN | NOLOGIN
  | REPLICATION | NOREPLICATION
  | BYPASSRLS | NOBYPASSRLS
  | CONNECTION LIMIT <connlimit>
  | [ ENCRYPTED ] PASSWORD '<password>' | PASSWORD NULL
  | VALID UNTIL '<timestamp>'
  | [ DENY <deny_point> ]
  | [ DENY BETWEEN <deny_point> AND <deny_point>]
  | [ DROP DENY FOR <deny_point> ]

ALTER ROLE <name> RENAME TO <new_name>

ALTER ROLE { <role_specification> | ALL } [ IN DATABASE <database_name> ] SET <configuration_parameter> { TO | = } { <value> | DEFAULT }
ALTER ROLE { <role_specification> | ALL } [ IN DATABASE <database_name> ] SET <configuration_parameter> FROM CURRENT
ALTER ROLE { <role_specification> | ALL } [ IN DATABASE <database_name> ] RESET <configuration_parameter>
ALTER ROLE { <role_specification> | ALL } [ IN DATABASE <database_name> ] RESET ALL

ALTER ROLE <role_specification> RESOURCE QUEUE {<queue_name> | NONE}
ALTER ROLE <role_specification> RESOURCE GROUP {<group_name> | NONE}

where <role_specification> can be:

    <role_name>
  | CURRENT_USER
  | SESSION_USER
```

Description

`ALTER ROLE` changes the attributes of a WarehousePG role. There are several variants of this command.

WITH option Changes many of the role attributes that can be specified in CREATE ROLE. (All of the possible attributes are covered, execept that there are no options for adding or removing memberships; use GRANT and REVOKE for that.) Attributes not mentioned in the command retain their previous settings. Database superusers can change any of these settings for any role. Roles having `CREATEROLE` privilege can change any of these settings except `SUPERUSER`, `REPLICATION`, and `BYPASSRLS`, but only for non-superuser and non-replication roles. Ordinary roles can only change their own password.

RENAME Changes the name of the role. Database superusers can rename any role. Roles having `CREATEROLE` privilege can rename non-superuser roles. The current session user cannot be renamed (connect as a different user to rename a role). Because MD5-encrypted passwords use the role name as cryptographic salt, renaming a role clears its password if the password is MD5-encrypted.

SET | RESET Changes a role's session default for a specified configuration parameter, either for all databases or, when the `IN DATABASE` clause is specified, only for sessions in the named database. If `ALL` is specified instead of a role name, this changes the setting for all roles. Using `ALL` with `IN DATABASE` is effectively the same as using the command `ALTER DATABASE ... SET ...`.

```
Whenever the role subsequently starts a new session, the specified value becomes the session default, overriding whatever setting is present in the server configuration file \(`postgresql.conf`\) or has been received from the `postgres` command line. This only happens at login time; running [SET ROLE](SET_ROLE.html) or [SET SESSION AUTHORIZATION](SET_SESSION_AUTHORIZATION.html) does not cause new configuration values to be set. Settings set for all databases are overridden by database-specific settings attached to a role. Settings for specific databases or specific roles override settings for all roles.

Superusers can change anyone's session defaults. Roles having `CREATEROLE` privilege can change defaults for non-superuser roles. Ordinary roles can only set defaults for themselves. Certain configuration variables cannot be set this way, or can only be set if a superuser issues the command. Only superusers can change a setting for all roles in all databases.
```

RESOURCE QUEUE Assigns the role to a resource queue. The role would then be subject to the limits assigned to the resource queue when issuing queries. Specify `NONE` to assign the role to the default resource queue. A role can belong to only one resource queue. For a role without `LOGIN` privilege, resource queues have no effect. See CREATE RESOURCE QUEUE for more information.

RESOURCE GROUP Assigns a resource group to the role. The role would then be subject to the concurrent transaction, memory, and CPU limits configured for the resource group. You can assign a single resource group to one or more roles. You cannot assign a resource group that you create for an external component to a role. See CREATE RESOURCE GROUP for additional information.

Parameters

name The name of the role whose attributes are to be altered.

CURRENT_USER Alter the current user instead of an explicitly identified role.

SESSION_USER Alter the current session user instead of an explicitly identified role.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

SUPERUSER NOSUPERUSER CREATEDB NOCREATEDB CREATEROLE NOCREATEROLE INHERIT NOINHERIT LOGIN NOLOGIN REPLICATION NOREPLICATION BYPASSRLS NOBYPASSRLS CONNECTION LIMIT connlimit [ENCRYPTED] PASSWORD 'password' PASSWORD NULL VALID UNTIL 'timestamp' These clauses alter attributes originally set by `CREATE ROLE`. For more information, see the CREATE ROLE reference page.

new_name The new name of the role.

database_name The name of the database in which to set the configuration parameter.

configuration_parameter value Set this role's session default for the specified configuration parameter to the given value. If value is `DEFAULT` or, equivalently, `RESET` is used, the role-specific parameter setting is removed, so the role will inherit the system-wide default setting in new sessions. Use `RESET ALL` to clear all role-specific settings. `SET FROM CURRENT` saves the session's current value of the parameter as the role-specific value. If `IN DATABASE` is specified, the configuration parameter is set or removed for the given role and database only.

Role-specific variable settings take effect only at login; SET ROLE and SET SESSION AUTHORIZATION do not process role-specific variable settings.

See SET and Server Configuration Parameters for more information about allowed parameter names and values.

group_name The name of the resource group to assign to this role. Specifying the group_name `NONE` removes the role's current resource group assignment and assigns a default resource group based on the role's capability. `SUPERUSER` roles are assigned the `admin_group` resource group, while the `default_group` resource group is assigned to non-admin roles.

You cannot assign a resource group that you create for an external component to a role.

queue_name The name of the resource queue to which the user-level role is to be assigned. Only roles with `LOGIN` privilege can be assigned to a resource queue. To unassign a role from a resource queue and put it in the default resource queue, specify `NONE`. A role can belong only to one resource queue.

Notes

Use CREATE ROLE to add a new role, and DROP ROLE to remove a role.

`ALTER ROLE` cannot change a role's memberships; use GRANT and REVOKE to do that.

You must exercise caution when specifying an unencrypted password with this command. The password will be transmitted to the server in clear text, and it might also be logged in the client's command history or the server log. The psql command-line client contains a meta-command `\password` that can be used to change a role's password without exposing the clear text password.

It is also possible to tie a session default to a specific database rather than to a role; see ALTER DATABASE. If there is a conflict, database-role-specific settings override role-specific ones, which in turn override database-specific ones.

Examples

Change the password for a role:

```
ALTER ROLE daria WITH PASSWORD 'passwd123';
```

Remove a role's password:

```
ALTER ROLE daria WITH PASSWORD NULL;
```

Change a password expiration date, specifying that the password should expire at midday on 4th May 2022 using the time zone which is one hour ahead of UTC:

```
ALTER ROLE scott VALID UNTIL 'May 4 12:00:00 2022 +1';
```

Make a password valid forever:

```
ALTER ROLE luke VALID UNTIL 'infinity';
```

Give a role the ability to create other roles and new databases:

```
ALTER ROLE joelle CREATEROLE CREATEDB;
```

Give a role a non-default setting of the `maintenance_work_mem` parameter:

```
ALTER ROLE admin SET maintenance_work_mem = 100000;
```

Give a role a non-default, database-specific setting of the `client_min_messages` parameter:

```
ALTER ROLE fred IN DATABASE devel SET client_min_messages = DEBUG;
```

Assign a role to a resource queue:

```
ALTER ROLE sammy RESOURCE QUEUE poweruser;
```

Give a role permission to create writable external tables:

```
ALTER ROLE load CREATEEXTTABLE (type='writable');
```

Alter a role so it does not allow login access on Sundays:

```
ALTER ROLE user3 DENY DAY 'Sunday';
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Alter a role to remove the constraint that does not allow login access on Sundays:

```
ALTER ROLE user3 DROP DENY FOR DAY 'Sunday';
```

Assign a new resource group to a role:

```
ALTER ROLE parttime_user RESOURCE GROUP rg_light;
```

Compatibility

The `ALTER ROLE` statement is a WarehousePG extension.

See Also

CREATE ROLE, DROP ROLE, ALTER DATABASE, SET, CREATE RESOURCE GROUP, CREATE RESOURCE QUEUE, GRANT, REVOKE

Parent topic: SQL Commands

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.1.26 ALTER ROUTINE

Changes the definition of a routine.

Synopsis

```
ALTER ROUTINE <name> [ ( [ [<argmode>] [<argname>] <argtype> [, ...] ] ) ]
   <action> [, ... ] [RESTRICT]

ALTER ROUTINE <name> [ ( [ [<argmode>] [<argname>] <argtype> [, ...] ] ) ]
   RENAME TO <new_name>

ALTER ROUTINE <name> [ ( [ [<argmode>] [<argname>] <argtype> [, ...] ] ) ]
   OWNER TO { <new_owner> | CURRENT_USER | SESSION_USER }

ALTER ROUTINE <name> [ ( [ [<argmode>] [<argname>] <argtype> [, ...] ] ) ]
   SET SCHEMA <new_schema>

ALTER ROUTINE <name> [ ( [ [<argmode>] [<argname>] <argtype> [, ...] ] ) ]
   DEPENDS ON EXTENSION <extension_name>

where <action> is one of (depending on the type of routine):

    { IMMUTABLE | STABLE | VOLATILE }
    [ NOT ] LEAKPROOF
    { [EXTERNAL] SECURITY INVOKER | [EXTERNAL] SECURITY DEFINER }
    PARALLEL { UNSAFE | RESTRICTED | SAFE }
    EXECUTE ON { ANY | COORDINATOR | ALL SEGMENTS | INITPLAN }
    COST <execution_cost>
    ROWS <result_rows>
    SET <configuration_parameter> { TO | = } { <value> | DEFAULT }
    SET <configuration_parameter> FROM CURRENT
    RESET <configuration_parameter>
    RESET ALL
```

Description

`ALTER ROUTINE` changes the definition of a routine, which can be an aggregate function, a normal function, or a procedure. Refer to ALTER AGGREGATE, ALTER FUNCTION, and ALTER PROCEDURE for the description of the parameters, more examples, and further details.

Examples

To rename the routine `foo` for type `integer` to `foobar`:

```
ALTER ROUTINE foo(integer) RENAME TO foobar;
```

This command will work independent of whether `foo` is an aggregate, function, or procedure.

Compatibility

This statement is partially compatible with the `ALTER ROUTINE` statement in the SQL standard. Refer to ALTER FUNCTION and ALTER PROCEDURE for more details. Allowing routine names to refer to aggregate functions is a WarehousePG extension.

7.1.27 ALTER SCHEMA

Changes the definition of a schema.

Synopsis

```
ALTER SCHEMA <name> RENAME TO <new_name>

ALTER SCHEMA <name> OWNER TO { <new_owner> | CURRENT_USER | SESSION_USER }
```

Description

`ALTER SCHEMA` changes the definition of a schema.

You must own the schema to use `ALTER SCHEMA`. To rename a schema you must also have the `CREATE` privilege for the database. To alter the owner, you must also be a direct or indirect member of the new owning role, and you must have the `CREATE` privilege for the database. Note that superusers have all these privileges automatically.

Parameters

name The name of an existing schema.

new*name The new name of the schema. The new name cannot begin with `pg`*, as such names are reserved for system schemas.

new_owner The new owner of the schema.

Compatibility

There is no `ALTER SCHEMA` statement in the SQL standard.

7.1.28 ALTER SEQUENCE

Changes the definition of a sequence generator.

Synopsis

```
ALTER SEQUENCE [ IF EXISTS ] <name>
     [ AS <data_type> ]
     [INCREMENT [ BY ] <increment>]
     [MINVALUE <minvalue> | NO MINVALUE]
     [MAXVALUE <maxvalue> | NO MAXVALUE]
     [START [ WITH ] <start> ]
     [RESTART [ [ WITH ] <restart>] ]
     [CACHE <cache>] [[ NO ] CYCLE]
     [OWNED BY {<table_name.column_name> | NONE}]

ALTER SEQUENCE [ IF EXISTS ] <name> OWNER TO { <new_owner> | CURRENT_USER | SESSION_USER }

ALTER SEQUENCE [ IF EXISTS ] <name> RENAME TO <new_name>

ALTER SEQUENCE [ IF EXISTS ] <name> SET SCHEMA <new_schema>
```

Description

`ALTER SEQUENCE` changes the parameters of an existing sequence generator. Any parameters not specifically set in the `ALTER SEQUENCE` command retain their prior settings.

You must own the sequence to use `ALTER SEQUENCE`. To change a sequence's schema, you must also have `CREATE` privilege on the new schema. Note that superusers have all these privileges automatically.

To alter the owner, you must be a direct or indirect member of the new owning role, and that role must have `CREATE` privilege on the sequence's schema. (These restrictions enforce that altering the owner does not do anything you could not do by dropping and recreating the sequence. However, a superuser can alter ownership of any sequence anyway.)

Parameters

name The name (optionally schema-qualified) of a sequence to be altered.

IF EXISTS Do not throw an error if the sequence does not exist. WarehousePG issues a notice in this case.

data_type The optional clause `AS data_type` changes the data type of the sequence. Valid types are `smallint`, `integer`, and `bigint`.

Changing the data type automatically changes the minimum and maximum values of the sequence if and only if the previous minimum and maximum values were the minimum or maximum value of the old data type (in other words, if the sequence had been created using `NO MINVALUE` or `NO MAXVALUE`, implicitly or explicitly). Otherwise, the minimum and maximum values are preserved, unless new values are given as part of the same command. If the minimum and maximum values do not fit into the new data type, WarehousePG generates an error.

increment The clause `INCREMENT BY increment` is optional. A positive value will make an ascending sequence, a negative one a descending sequence. If unspecified, the old increment value will be maintained.

minvalue NO MINVALUE The optional clause `MINVALUE minvalue` determines the minimum value a sequence can generate. If `NO MINVALUE` is specified, the defaults of `1` and the minimum value of the data type for ascending and descending sequences, respectively, will be used. If neither option is specified, the current minimum value will be maintained.

maxvalue NO MAXVALUE The optional clause `MAXVALUE maxvalue` determines the maximum value for the sequence. If `NO MAXVALUE` is specified, the defaults of the maximum value of the data type and `-1` for ascending and descending sequences, respectively, will be used. If neither option is specified, the current maximum value will be maintained.

start The optional clause `START WITH start` changes the recorded start value of the sequence. This has no effect on the *current* sequence value; it simply sets the value that future `ALTER SEQUENCE RESTART` commands will use.

restart The optional clause `RESTART [ WITH restart ]` changes the current value of the sequence. This is equivalent to calling the `setval(sequence, start_val, is_called)` function with `is_called = false`. The specified value will be returned by the *next* call of the `nextval(sequence)` function. Writing `RESTART` with no restart value is equivalent to supplying the start value that was recorded by `CREATE SEQUENCE` or last set by `ALTER SEQUENCE START WITH`. In contrast to a `setval()` call, a `RESTART` operation on a sequence is transactional and blocks concurrent transactions from obtaining numbers from the same sequence. If that's not the desired mode of operation, `setval()` should be used

cache The clause `CACHE cache` enables sequence numbers to be preallocated and stored in memory for faster access. The minimum value is 1 (only one value can be generated at a time, i.e., no cache). If unspecified, the old cache value will be maintained.

> **Note** When operating with a cache of sequence numbers (`cache > 1`), WarehousePG may discard some cached sequence values. If you require consecutive values, you must explicitly set `CACHE 1` when you create or alter the sequence.

CYCLE The optional `CYCLE` key word may be used to enable the sequence to wrap around when the `maxvalue` or `minvalue` has been reached by an ascending or descending sequence. If the limit is reached, the next number generated will be the respective `minvalue` or `maxvalue`.

NO CYCLE If the optional `NO CYCLE` key word is specified, any calls to `nextval()` after the sequence has reached its maximum value will return an error. If neither `CYCLE` or `NO CYCLE` are specified, the old cycle behavior will be maintained.

OWNED BY table_name.column_name OWNED BY NONE The `OWNED BY` option causes the sequence to be associated with a specific table column, such that if that column (or its whole table) is dropped, the sequence will be automatically dropped as well. If specified, this association replaces any previously specified association for the sequence. The specified table must have the same owner and be in the same schema as the sequence. Specifying `OWNED BY NONE` removes any existing table column association.

new_owner The user name of the new owner of the sequence.

new_name The new name for the sequence.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

new_schema The new schema for the sequence.

Notes

`ALTER SEQUENCE` will not immediately affect `nextval()` results in backends, other than the current one, that have preallocated (cached) sequence values. They will use up all cached values prior to noticing the changed sequence generation parameters. The current backend will be affected immediately.

`ALTER SEQUENCE` blocks concurrent `nextval()` and `setval()` calls.

For historical reasons, `ALTER TABLE` can be used with sequences too; but the only variants of `ALTER TABLE` that are allowed with sequences are equivalent to the forms shown above.

Examples

Restart a sequence called `serial` at `105`:

```
ALTER SEQUENCE serial RESTART WITH 105;
```

Compatibility

`ALTER SEQUENCE` conforms to the SQL standard, except for the `AS`, `START WITH`, `OWNED BY`, `OWNER TO`, `RENAME TO`, and `SET SCHEMA` clauses, which are WarehousePG extensions.

7.1.29 ALTER SERVER

Changes the definition of a foreign server.

Synopsis

```
ALTER SERVER <name> [ VERSION '<new_version>' ]
    [ OPTIONS ( [ ADD | SET | DROP ] <option> ['<value>'] [, ... ] ) ]

ALTER SERVER <name> OWNER TO { <new_owner> | CURRENT_USER | SESSION_USER }

ALTER SERVER <name> RENAME TO <new_name>
```

Description

`ALTER SERVER` changes the definition of a foreign server. The first form of the command changes the version string or the generic options of the server. WarehousePG requires at least one clause. The second and third forms of the command change the owner or the name of the server.

To alter the server, you must be the owner of the server. To alter the owner you must:

- Own the server.
- Be a direct or indirect member of the new owning role.
- Have `USAGE` privilege on the server's foreign-data wrapper.

Superusers automatically satisfy all of these criteria.

Parameters

name The name of an existing server.

new_version The new server version.

OPTIONS ([ADD | SET | DROP] option ['value'] [, ...]) Change the server's options `ADD`, `SET`, and `DROP` specify the action to perform. Option names must be unique. WarehousePG validates names and values using the server's foreign-data wrapper library. Use `ADD` to define an option that is not currently set. Use `SET` to change the value of an option that you previously defined. If you do not explicitly specify an action, the default operation is `ADD`.

new_owner Specifies the new owner of the foreign server.

new_name Specifies the new name of the foreign server.

Examples

Change the definition of a server named `foo` by adding connection options:

```
ALTER SERVER foo OPTIONS (host 'foo', dbname 'foodb');
```

Change the option named `host` for a server named `foo`, and set the server version:

```
ALTER SERVER foo VERSION '9.1' OPTIONS (SET host 'baz');
```

Compatibility

`ALTER SERVER` conforms to ISO/IEC 9075-9 (SQL/MED). The `OWNER TO` and `RENAME` forms are WarehousePG extensions.

7.1.30 ALTER STATISTICS

Changes the definition of an extended statistics object.

Synopsis

```
ALTER STATISTICS <name> RENAME TO <new_name>

ALTER STATISTICS <name> OWNER TO { <new_owner> | CURRENT_USER | SESSION_USER }

ALTER STATISTICS <name> SET SCHEMA <new_schema>
```

Description

`ALTER STATISTICS` changes the parameters of an existing extended statistics object. Any parameters not specifically set in the `ALTER STATISTICS` command retain their prior settings.

You must own the statistics object to use `ALTER STATISTICS`. To change a statistics object's schema, you must also have `CREATE` privilege on the new schema. To alter the owner, you must also be a direct or indirect member of the new owning role, and that role must have `CREATE` privilege on the statistics object's schema. (These restrictions enforce that altering the owner doesn't do anything you couldn't do by dropping and recreating the statistics object. However, a superuser can alter ownership of any statistics object anyway.)

Parameters

name The name (optionally schema-qualified) of the statistics object to be altered.

new_owner The user name of the new owner of the statistics object.

new_name The new name for the statistics object.

new_schema The new schema for the statistics object.

Compatibility

There is no `ALTER STATISTICS` statement in the SQL standard.

[ TABLESPACE <tablespace> ]
```

Description

`ALTER TABLE` changes the definition of an existing table. There are several subforms described below. Note that the lock level required may differ for each subform.*An `ACCESS EXCLUSIVE` lock is acquired unless explicitly noted.* When multiple subcommands are provided, WarehousePG acquires the strictest lock required by any subcommand.

ADD COLUMN [IF NOT EXISTS] Adds a new column to the table, using the same syntax asCREATE TABLE. If `IF NOT EXISTS` is specified and a column already exists with this name, no error is thrown.

DROP COLUMN [IF EXISTS] Drops a column from a table. Note that if you drop table columns that are being used as the WarehousePG distribution key, the distribution policy for the table will be changed tc `DISTRIBUTED RANDOMLY` . Indexes and table constraints involving the column are automatically dropped as well. Multivariate statistics referencing the dropped column will also be removed if the removal of the column would cause the statistics to contain data for only a single column. You need to specify `CASCADE` if anything outside of the table depends on the column, such as views. If `IF EXISTS` is specified and the column does not exist, no error is thrown; WarehousePG issues a notice instead.

SET DATA TYPE This form changes the data type of a column of a table. Note that you cannot alter column data types that are being used as distribution or partitioning keys. Indexes and simple table constraints involving the column will be automatically converted to use the new column type by reparsing the originally supplied expression. The optional `COLLATE` clause specifies a collation for the new column; if omitted, the collation is the default for the new column type. The optional `USING` clause specifies how to compute the new column value from the old. If omitted, the default conversion is the same as an assignment cast from old data type to new. A `USING` clause must be provided if there is no implicit or assignment cast from old to new type.

> **Note** The WarehousePG query optimizer (GPORCA) supports collation only when all columns in the query use the same collation. If columns in the query use different collations, then WarehousePG uses the Postgres-based planner.

Changing a column data type may or may not require a table rewrite. For information about table rewrites performed by `ALTER TABLE` , see Notes.

SET DEFAULT DROP DEFAULT Sets or removes the default value for a column. Default values apply only in subsequent `INSERT` or `UPDATE` commands; they do not cause rows already in the table to change.

SET NOT NULL DROP NOT NULL Changes whether a column is marked to allow null values or to reject null values.

`SET NOT NULL` may only be applied to a column provided none of the records in the table contain a `NULL` value for the column. This is typically checked during the `ALTER TABLE` by scanning the entire table; however, if a valid `CHECK` constraint is found which proves no `NULL` can exist, then WarehousePG skips the table scan.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

If this table is a partition, you cannot `DROP NOT NULL` on a column if it is marked `NOT NULL` in the parent table. To drop the `NOT NULL` constraint from all the partitions, perform `DROP NOT NULL` on the parent table. Even if there is no `NOT NULL` constraint on the parent, such a constraint can still be added to individual partitions, if desired; that is, the children can disallow nulls even if the parent allows them, but not the other way around.

ADD GENERATED { ALWAYS | BY DEFAULT } AS IDENTITY SET GENERATED { ALWAYS | BY DEFAULT } DROP IDENTITY [IF EXISTS] These forms change whether a column is an identity column or change the generation attribute of an existing identity column. See CREATE TABLE for details.

If `DROP IDENTITY IF EXISTS` is specified and the column is not an identity column, no error is thrown. In this case WarehousePG issues a notice instead.

SET sequence_option RESTART These forms alter the sequence that underlies an existing identity column. sequence_option is an option supported by ALTER SEQUENCE such as `INCREMENT BY`.

SET STATISTICS Sets the per-column statistics-gathering target for subsequent ANALYZE operations. The target can be set in the range 0 to 10000, or set to -1 to revert to using the system default statistics target (default_statistics_target. When set to 0, no statistics are collected.

`SET STATISTICS` acquires a `SHARE UPDATE EXCLUSIVE` lock.

SET (attribute_option = value [, ...]) RESET (attribute_option [, ...]) Sets or resets per-attribute options. Currently, the only defined per-attribute options are `n_distinct` and `n_distinct_inherited`, which override the number-of-distinct-values estimates made by subsequent ANALYZE operations. `n_distinct` affects the statistics for the table itself, while `n_distinct_inherited` affects the statistics gathered for the table plus its inheritance children. When set to a positive value, `ANALYZE` assumes that the column contains exactly the specified number of distinct non-null values. When set to a negative value, which must be greater than or equal to -1, `ANALYZE` assumes that the number of distinct non-null values in the column is linear in the size of the table; the exact count is to be computed by multiplying the estimated table size by the absolute value of the given number. For example, a value of -1 implies that all values in the column are distinct, while a value of -0.5 implies that each value appears twice on the average. This can be useful when the size of the table changes over time, since the multiplication by the number of rows in the table is not performed until query planning time. Specify the value 0 to revert to estimating the number of distinct values normally.

Changing per-attribute options acquires a `SHARE UPDATE EXCLUSIVE` lock.

Do not use this form of `SET` to set attribute encoding options for appendoptimized, column-oriented tables. Instead, use `ALTER COLUMN ... SET ENCODING ...`.

SET STORAGE This form sets the storage mode for a column. This controls whether this column is held inline or in a secondary TOAST table, and whether the data should be compressed or not. `PLAIN` must be used for fixed-length values such as integer and is inline, uncompressed. `MAIN` is for inline, compressible data. `EXTERNAL` is for external, uncompressed data, and `EXTENDED` is for external, compressed data. `EXTENDED` is the default for most data types that support non- `PLAIN` storage. Use of `EXTERNAL` will make substring operations on very large text and bytea values run faster, at the penalty of increased storage space. Note that `SET STORAGE` doesn't itself change anything in the table, it just sets the strategy to be pursued during future table updates.

SET ENCODING (storage_directive> [, ...]) This form sets column encoding options for append-optimized, column-oriented tables.

ADD table_constraint [NOT VALID] Adds a new constraint to a table using the same syntax asCREATE TABLE. The `NOT VALID` option is currently allowed only for foreign key and `CHECK` constraints.

Normally, this form causes a scan of the table to verify that all existing rows in the table satisfy the new constraint. If the constraint is marked `NOT VALID`, WarehousePG skips the potentially-lengthy initial check to verify that all rows in the table satisfy the constraint. The constraint will still be enforced against subsequent inserts or updates (that is, they'll fail unless there is a matching row in the referenced table, in the case of foreign keys; and they'll fail unless the new row matches the specified check constraints). But the database will not assume that the constraint holds for all rows in the table, until it is validated by using the `VALIDATE CONSTRAINT` option. See the Notes for more information about using the `NOT VALID` option.

Most forms of `ADD <table_constraint>` require an `ACCESS EXCLUSIVE` lock.

Additional restrictions apply when unique or primary key constraints are added to partitioned tables; see CREATE TABLE.

ADD table_constraint_using_index This form adds a new `PRIMARY KEY` or `UNIQUE` constraint to a table based on an existing unique index. All the columns of the index will be included in the constraint.

The index cannot have expression columns nor be a partial index. Also, it must be a b-tree index with default sort ordering. These restrictions ensure that the index is equivalent to one that would be built by a regular `ADD PRIMARY KEY` or `ADD UNIQUE` command.

If `PRIMARY KEY` is specified, and the index's columns are not already marked `NOT NULL`, then this command attempts to `ALTER COLUMN SET NOT NULL` against each such column. That requires a full table scan to verify the column(s) contain no nulls. In all other cases, this is a fast operation.

If a constraint name is provided then WarehousePG renames the index to match the constraint name. Otherwise the constraint will be named the same as the index.

After this command is executed, the index is "owned" by the constraint, in the same way as if the index had been built by a regular `ADD PRIMARY KEY` or `ADD UNIQUE` command. In particular, dropping the constraint will make the index disappear too.

This form is not currently supported on partitioned tables.

ALTER CONSTRAINT This form alters the attributes of a constraint that was previously created. Currently only foreign key constraints may be altered, which WarehousePG will accept, but not enforce.

VALIDATE CONSTRAINT This form validates a foreign key constraint that was previously created as `NOT VALID`, by scanning the table to ensure there are no rows for which the constraint is not satisfied. Nothing happens if the constraint is already marked valid. The advantage of separating validation from initial creation of the constraint is that validation requires a lesser lock on the table than constraint creation does.

This command acquires a `SHARE UPDATE EXCLUSIVE` lock.

DROP CONSTRAINT [IF EXISTS] Drops the specified constraint on a table, along with any index underlying the constraint. If `IF EXISTS` is specified and the constraint does not exist, no error is thrown. WarehousePG issues a notice in this case instead.

DISABLE ROW LEVEL SECURITY ENABLE ROW LEVEL SECURITY These forms control the application of row security policies belonging to the table. If enabled and no policies exist for the table, then WarehousePG applies a default-deny policy. Note that policies can exist for a table even if row level security is disabled - in this case, the policies will NOT be applied and the policies will be ignored. See also CREATE POLICY.

NO FORCE ROW LEVEL SECURITY FORCE ROW LEVEL SECURITY These forms control the application of row security policies belonging to the table when the user is the table owner. If enabled, row level security policies will be applied when the user is the table owner. If disabled (the default) then row level security will not be applied when the user is the table owner. See also CREATE POLICY.

CLUSTER ON Selects the default index for future CLUSTER operations. It does not actually re-cluster the table.

Changing cluster options acquires a `SHARE UPDATE EXCLUSIVE` lock.

REPACK BY COLUMNS Physically reorders a table based on one or more columns to improve physical correlation. You specify one or more columns, and an optional column order. If not specified, the default is `ASC`. The command is equivalent to the CLUSTER command, but it uses the provided column list instead of an index to determine the sorting order.

The command is especially useful for tables that are loaded in small batches. You may combine `REPACK BY COLUMNS` with most other `ALTER TABLE` commands that do not require a rewrite of the table. You may use `REPACK BY COLUMNS` to add compression or change the existing compression settings of a table while physically reordering the table, which results in better compression and storage. See Examples for more details.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

SET WITHOUT CLUSTER Removes the most recently used CLUSTER index specification from the table. This affects future cluster operations that do not specify an index.

Changing cluster options acquires a `SHARE UPDATE EXCLUSIVE` lock.

SET TABLESPACE Changes the table's tablespace to the specified tablespace and moves the data file(s) associated with the table to the new tablespace. Indexes on the table, if any, are not moved; but they can be moved separately with additional `SET TABLESPACE` commands. When applied to a partitioned table, nothing is moved, but any partitions created afterwards with `CREATE TABLE ... PARTITION OF` will use that tablespace, unless the `TABLESPACE` clause is used to override it.

All tables in the current database in a tablespace can be moved by using the `ALL IN TABLESPACE` form, which will lock all tables to be moved first and then move each one. This form also supports `OWNED BY`, which will only move tables owned by the roles specified. If the `NOWAIT` option is specified then the command will fail if it is unable to acquire all of the locks required immediately. Note that system catalogs are not moved by this command, use `ALTER DATABASE` or explicit `ALTER TABLE` invocations instead if desired. The `information_schema` relations are not considered part of the system catalogs and will be moved. See also CREATE TABLESPACE.

If changing the tablespace of a partitioned table, all child tables will also be moved to the new tablespace.

SET { LOGGED | UNLOGGED } This form changes the table from unlogged to logged or vice-versa. It cannot be applied to a temporary table.

SET (storage_\parameter [= value][, ...]) This form changes one or more table-level options. See Storage Parameters in the `CREATE TABLE` reference for details on the available parameters. Note that for heap tables, the table contents will not be modified immediately by this command; depending on the parameter, you may need to rewrite the table to get the desired effects. That can be done with VACUUM FULL, CLUSTER or one of the forms of `ALTER TABLE` that forces a table rewrite, see Notes. For append-optimized column-oriented tables, changing a storage parameter always results in a table rewrite. For planner-related parameters, changes take effect from the next time the table is locked, so currently executing queries are not affected.

WarehousePG takes a `SHARE UPDATE EXCLUSIVE` lock when setting `fillfactor`, toast and autovacuum storage parameters, and the planner parameter `parallel_workers`.

RESET (storage_parameter [, ...]) This form resets one or more table level options to their defaults. As with `SET`, a table rewrite might be required to update the table entirely.

SET WITH (`<set_with_parameter>` = `<value>` [, ...]) You can use this form of the command to reorganize the table, or to set the table access method and also optionally set storage parameters.

> **Note: Note:** Although you can specify the table's access method using the `appendoptimized` and `orientation` storage parameters, it is recommended to use use `SET ACCESS METHOD <access_method>` instead.

INHERIT parent_table Adds the target table as a new child of the specified parent table. Queries against the parent will include records of the target table. To be added as a child, the target table must already contain all of the same columns as the parent (it could have additional columns, too). The columns must have matching data types, and if they have `NOT NULL` constraints in the parent then they must also have `NOT NULL` constraints in the child.

There must also be matching child-table constraints for all `CHECK` constraints of the parent, except those marked non-inheritable (that is, created with `ALTER TABLE ... ADD CONSTRAINT ... NO INHERIT`) in the parent, which are ignored; all child-table constraints matched must not be marked non-inheritable. `UNIQUE`, `PRIMARY KEY`, and `FOREIGN KEY` constraints are not currently considered.

NO INHERIT parent_table This form removes the target table from the list of children of the specified parent table. Queries against the parent table will no longer include records drawn from the target table.

OF type_name This form links the table to a composite type as though `CREATE TABLE OF` had formed it. The table's list of column names and types must precisely match that of the composite type. The table must not inherit from any other table. These restrictions ensure that `CREATE TABLE OF` would permit an equivalent table definition.

NOT OF This form dissociates a typed table from its type.

OWNER TO Changes the owner of the table, sequence, view, materialized view, or foreign table to the specified user.

RENAME Changes the name of a table (or an index, sequence, view, materialized view, or foreign table), the name of an individual column in a table, or the name of a constraint of the table. When renaming a constraint that has an underlying index, the index is renamed as well. There is no effect on the stored data.

SET SCHEMA Moves the table into another schema. Associated indexes, constraints, and sequences owned by table columns are moved as well.

SET DISTRIBUTED Changes the distribution policy of a table. Changing a hash distribution policy, or changing to or from a replicated policy, will cause the table data to be physically redistributed on disk, which can be resource intensive. If you declare the same hash distribution policy or change from hash to random distribution, data will not be redistributed unless you declare `SET WITH (reorganize=true)`.

: While WarehousePG permits changing the distribution policy of a writable external table, the operation never results in physical redistribution of the external data.

ATTACH PARTITION partition_name { FOR VALUES partition_bound_spec | DEFAULT } This form of the *modern partitioning syntax* attaches an existing table (which might itself be partitioned) as a partition of the target table. The table can be attached as a partition for specific values using `FOR VALUES` or as a default partition by using `DEFAULT`. For each index in the target table, a corresponding one will be created in the attached table; or, if an equivalent index already exists, it will be attached to the target table's index, as if you had run `ALTER INDEX ATTACH PARTITION`. Note that if the existing table is a foreign table, WarehousePG does not permit attaching the table as a partition of the target table if there are `UNIQUE` indexes on the target table. (See also CREATE FOREIGN TABLE.)

A partition using `FOR VALUES` uses the same syntax for partition_bound_spec> as CREATE TABLE. The partition bound specification must correspond to the partitioning strategy and partition key of the target table. The table to be attached must have all the same columns as the target table and no more; moreover, the column types must also match. Also, it must have all of the `NOT NULL` and `CHECK` constraints of the target table. Currently `FOREIGN KEY` constraints are not considered. `UNIQUE` and `PRIMARY KEY` constraints from the parent table will be created in the partition, if they don't already exist. If any of the `CHECK` constraints of the table being attached are marked `NO INHERIT`, the command will fail; such constraints must be recreated without the `NO INHERIT` clause.

If the new partition is a regular table, WarehousePG performs a full table scan to check that existing rows in the table do not violate the partition constraint. It is possible to avoid this scan by adding a valid `CHECK` constraint to the table that allows only rows satisfying the desired partition constraint before running this command. The `CHECK` constraint will be used to determine that the table need not be scanned to validate the partition constraint. This does not work, however, if any of the partition keys is an expression and the partition does not accept `NULL` values. If attaching a list partition that will not accept `NULL` values, also add a `NOT NULL` constraint to the partition key column, unless it's an expression.

If the new partition is a foreign table, nothing is done to verify that all of the rows in the foreign table obey the partition constraint. (See the discussion in CREATE FOREIGN TABLE about constraints on the foreign table.)

When a table has a default partition, defining a new partition changes the partition constraint for the default partition. The default partition can't contain any rows that would need to be moved to the new partition, and will be scanned to verify that none are present. This scan, like the scan of the new partition, can be avoided if an appropriate `CHECK` constraint is present. Also like the scan of the new partition, it is always skipped when the default partition is a foreign table.

Attaching a partition acquires a `SHARE UPDATE EXCLUSIVE` lock on the parent table, in addition to the `ACCESS EXCLUSIVE` locks on the table being attached and on the default partition (if any). You can run `SELECT` and `INSERT` queries in parallel with `ATTACH PARTITION`. You can also run `UPDATE` queries in parallel with `ATTACH PARTITION` when the parent table is a heap table and the Global Deadlock Detector is enabled (the gp_enable_global_deadlock_detector server configuration paramer is set to `on`).

Additional locks must also be held on all sub-partitions if the table being attached is itself a partitioned table. Likewise if the default partition is itself a partitioned table. The locking of the sub-partitions can be avoided by adding a `CHECK` constraint as described in Partitioning Large Tables.

DETACH PARTITION partition_name This form of the *modern partitioning syntax* detaches the specified partition of the target table. The detached partition continues to exist as a standalone table, but no longer has any ties to the table from which it was detached. Any indexes that were attached to the target table's indexes are detached.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

ALTER PARTITION | DROP PARTITION | RENAME PARTITION | TRUNCATE PARTITION | ADD PARTITION | SPLIT PARTITION | EXCHANGE PARTITION | SET SUBPARTITION TEMPLATE These forms of the *classic partitioning syntax* change the structure of a partitioned table. You must go through the parent table to alter one of its child tables.

> **Note** If you add a partition to a table that has sub-partition encodings, the new partition inherits the storage directives for the sub-partitions. For more information about the precedence of compression settings, seeUsing Compression.

You can combine all forms of `ALTER TABLE` that act on a single table into a list of multiple alterations to apply together, except `RENAME`, `SET SCHEMA`, `ATTACH PARTITION`, and `DETACH PARTITION`. For example, it is possible to add several columns and/or alter the type of several columns in a single command. This is particularly useful with large tables, since only one pass over the table need be made.

You must own the table to use `ALTER TABLE`. To change the schema or tablespace of a table, you must also have `CREATE` privilege on the new schema or tablespace. To add the table as a new child of a parent table, you must own the parent table as well. Also, to attach a table as a new partition of the table, you must own the table being attached. To alter the owner, you must also be a direct or indirect member of the new owning role, and that role must have `CREATE` privilege on the table's schema. To add a column or alter a column type or use the `OF` clause, you must also have `USAGE` privilege on the data type. A superuser has these privileges automatically.

You can't use `ALTER TABLE ... SET DISTRIBUTED` to change a table to `COORDINATOR ONLY` distribution, nor can you change a `COORDINATOR ONLY` table to any other distribution using `ALTER TABLE`. The `COORDINATOR ONLY` distribution policy must be defined at the time of table creation. If you need to change the distribution of a coordinator-only table, you must drop the table and recreate it using the desired distribution policy.

> **Note** Memory usage increases significantly when a table has many partitions, if a table has compression, or if the blocksize for a table is large. If the number of relations associated with the table is large, this condition can force an operation on the table to use more memory. For example, if the table is an append-optimized column-oriented table and has a large number of columns, each column is a relation. An operation that accesses all of the columns in the table allocates associated buffers. If the table has 40 columns and 100 partitions, and the columns are compressed and the blocksize is 2 MB (with a system factor of 3), the system attempts to allocate 24 GB, that is (40 ×100) × (2 ×3) MB or 24 GB.

Parameters

IF EXISTS Do not throw an error if the table does not exist. WarehousePG issues a notice in this case.

name The name (possibly schema-qualified) of an existing table to alter. If `ONLY` is specified, only that table is altered. If `ONLY` is not specified, the table and all of its descendant tables (if any) are updated. You can optionally specify `*` after the table name to explicitly indicate that descendant tables are included.

```
> **Note** Adding or dropping a column, or changing a column's type, in a parent or descendant table only is not permitted. The parent table and its descendents must always have the same columns and types.
```

column_name Name of a new or existing column. Note that WarehousePG distribution key columns must be treated with special care. Altering or dropping these columns can change the distribution policy for the table.

new_column_name New name for an existing column.

new_name New name for the table.

type Data type of the new column, or new data type for an existing column. If changing the data type of a WarehousePG distribution key column, you are only allowed to change it to a compatible type (for example, `text` to `varchar` is OK, but `text` to `int` is not).

table_constraint New table constraint for the table. Note that foreign key constraints are currently not supported in WarehousePG. Also a table is only allowed one unique constraint and the uniqueness must be within the WarehousePG distribution key.

constraint_name Name of an existing constraint to drop.

ENCODING (<storage_directive> [,...]) The `ENCODING` clause is valid only for append-optimized, column-oriented tables.

When you add a column to an append-optimized, column-oriented table, WarehousePG sets each data compression parameter for the column (`compresstype`, `compresslevel`, and `blocksize`) based on the following setting, in order of preference.

```
1.  The compression parameter setting specified in the `ALTER TABLE` command `ENCODING` clause.
2.  The table's data compression setting specified in the `WITH` clause when the table was created.
3.  The compression parameter setting specified in the server configuration parameter [gp\_default\_storage\_option](../config_params/guc-list.html).
4.  The default compression parameter value.
```

For more information about the supported `ENCODING` storage directives, refer to CREATE TABLE.

CASCADE Automatically drop objects that depend on the dropped column or constraint (for example, views referencing the column), and in turn all objects that depend on those objects.

RESTRICT Refuse to drop the column or constraint if there are any dependent objects. This is the default behavior.

index_name The name of an existing index.

storage_parameter The name of a table storage parameter. Refer to the Storage Parameters section on the `CREATE TABLE` reference page for a list of parameters.

value The new value for the a table storage parameter. This might be a number or a word, depending on the parameter.

parent_table A parent table to associate or de-associate with this table.

new_owner The role name of the new owner of the table.

new_tablespace The name of the tablespace to which the table will be moved.

new_schema The name of the schema to which the table will be moved.

partition_name The name of the table to attach as a new partition or to detach from this table.

partition_bound_spec The partition bound specification for a new partition. Refer to CREATE TABLE for more details on the syntax of the same.

access_method The method to use for accessing the table. Refer to Choosing the Storage Model for more information on the table storage models and access methods available in WarehousePG. Set to `heap` to access the table as a heap-storage table, `ao_row` to access the table as an append-optimized table with row-oriented storage (AO), or `ao_column` to access the table as an append-optimized table with column-oriented storage (AO/CO).

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

> **Note: Note:** Although you can specify the table's access method using `SET <storage_parameter>`, the recommendation is to use `SET ACCESS METHOD <access_method>` instead.

SET WITH (reorganize=true|false) Use `reorganize=true` when the hash distribution policy has not changed or when you have changed from a hash to a random distribution, and you want to redistribute the data anyway. If you are setting the distribution policy, you must specify the `WITH (reorganize=<value>)` clause before the `DISTRIBUTED ...` clause.
Any attempt to reorganize an external table fails with an error.

Classic Partitioning Syntax Parameters

Descriptions of additional parameters that are specific to the *classic partitioning syntax* follow.

ALTER [DEFAULT] PARTITION If altering a partition deeper than the first level of partitions, use `ALTER PARTITION` clauses to specify which sub-partition in the hierarchy you want to alter. For each partition level in the table hierarchy that is above the target partition, specify the partition that is related to the target partition in an `ALTER PARTITION` clause.

DROP [DEFAULT] PARTITION Drops the specified partition. If the partition has sub-partitions, the sub-partitions are automatically dropped as well.

TRUNCATE [DEFAULT] PARTITION Truncates the specified partition. If the partition has sub-partitions, the sub-partitions are automatically truncated as well.

RENAME [DEFAULT] PARTITION Changes the partition name of a partition (not the relation name). Partitioned tables are created using the naming convention: `<` parentname `>_<` level `>_prt_<` partition_name `>`.

ADD DEFAULT PARTITION Adds a default partition to an existing partition design. When data does not match to an existing partition, it is inserted into the default partition. Partition designs that do not have a default partition will reject incoming rows that do not match to an existing partition. Default partitions must be given a name.

ADD PARTITION partition_element - Using the existing partition type of the table (range or list), defines the boundaries of new partition you are adding. `ADD PARTITION` acquires an `ACCESS EXCLUSIVE` lock on the parent table.

name - A name for this new partition.

VALUES - For list partitions, defines the value(s) that the partition will contain.

START - For range partitions, defines the starting range value for the partition. By default, start values are `INCLUSIVE`. For example, if you declared a start date of `2016-01-01`', then the partition would contain all dates greater than or equal to '`2016-01-01`'. The data type of the `START` expression must support a suitable `+` operator, for example `timestamp` or `integer` (not `float` or `text`) if it is defined with the `EXCLUSIVE` keyword. Typically the data type of the `START` expression is the same type as the partition key column. If that is not the case, then you must explicitly cast to the intended data type.

END - For range partitions, defines the ending range value for the partition. By default, end values are `EXCLUSIVE`. For example, if you declared an end date of `2016-02-01`', then the partition would contain all dates less than but not equal to '`2016-02-01`'. The data type of the `END` expression must support a suitable `+` operator, for example `timestamp` or `integer` (not `float` or `text`) if it is defined with the `INCLUSIVE` keyword. Typically the data type of the `END` expression is the same type as the partition key column. If that is not the case, then you must explicitly cast to the intended data type.

WITH - Sets the table storage options for a partition. For example, you may want older partitions to be append-optimized tables and newer partitions to be regular heap tables. SeeCREATE TABLE for a description of the storage options.

TABLESPACE - The name of the tablespace in which the partition is to be created.

subpartition_spec - Only allowed on partition designs that were created without a sub-partition template. Declares a sub-partition specification for the new partition you are adding. If the partitioned table was originally defined using a sub-partition template, then the template will be used to generate the sub-partitions automatically.

EXCHANGE [DEFAULT] PARTITION Exchanges another table into the partition hierarchy into the place of an existing partition. In a multi-level partition design, you can only exchange the lowest level partitions (those that contain data).

WITH TABLE table_name - The name of the table you are swapping into the partition design. You can exchange a table where the table data is stored in the database. For example, the table is created with the `CREATE TABLE` command. The table must have the same number of columns, column order, column names, column types, and distribution policy as the parent table.

With the `EXCHANGE PARTITION` clause, you can also exchange a readable external table (created with the `CREATE EXTERNAL TABLE` command) into the partition hierarchy in the place of an existing leaf partition.

Exchanging a leaf partition with an external table is not supported if the partitioned table contains a column with a check constraint or a `NOT NULL` constraint.

You cannot exchange a partition with a replicated table. Exchanging a partition with a partitioned table or a child partition of a partitioned table is not supported.

WITH | **WITHOUT VALIDATION** - No-op (always validate the data against the partition constraint).

SET SUBPARTITION TEMPLATE Modifies the sub-partition template for an existing partition. After a new sub-partition template is set, all new partitions added will have the new sub-partition design (existing partitions are not modified).

SPLIT DEFAULT PARTITION Splits a default partition. In a multi-level partition, only a range partition can be split, not a list partition, and you can only split the lowest level default partitions (those that contain data). Splitting a default partition creates a new partition containing the values specified and leaves the default partition containing any values that do not match to an existing partition.

AT - For list partitioned tables, specifies a single list value that should be used as the criteria for the split.

START - For range partitioned tables, specifies a starting value for the new partition.

END - For range partitioned tables, specifies an ending value for the new partition.

INTO - Allows you to specify a name for the new partition. When using the `INTO` clause to split a default partition, the second partition name specified should always be that of the existing default partition. If you do not know the name of the default partition, you can look it up using the pg_partitions view.

SPLIT PARTITION Splits an existing partition into two partitions. In a multi-level partition, only a range partition can be split, not a list partition, and you can only split the lowest level partitions (those that contain data).

AT - Specifies a single value that should be used as the criteria for the split. The partition will be divided into two new partitions with the split value specified being the starting range for the latter partition.

INTO - Allows you to specify names for the two new partitions created by the split.

partition_name The given name of a partition. You can obtain the table names of the leaf partitions of a partitioned table using the `pg_partition_tree() function.

FOR ('value') Specifies a partition by declaring a value that falls within the partition boundary specification. If the value declared with `FOR` matches to both a partition and one of its sub-partitions (for example, if the value is a date and the table is partitioned by month and then by day), then `FOR` will operate on the first level where a match is found (for example, the monthly partition). If your intent is to operate on a sub-partition, you must declare so as follows:
`ALTER TABLE name ALTER PARTITION FOR ('2016-10-01') DROP PARTITION FOR ('2016-10-01');`

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Notes

The key word `COLUMN` is noise and can be omitted.

When a column is added with `ADD COLUMN`, all existing rows in the table are initialized with the column's default value, or `NULL` if no `DEFAULT` clause is specified. Adding a column with a non-null default or changing the type of an existing column will require the entire table and indexes to be rewritten. As an exception, if the `USING` clause does not change the column contents and the old type is either binary coercible to the new type or an unconstrained domain over the new type, a table rewrite is not needed, but any indexes on the affected columns must still be rebuilt. Table and/or index rebuilds may take a significant amount of time for a large table; and will temporarily require as much as double the disk space.

Adding a `CHECK` or `NOT NULL` constraint requires scanning the table to verify that existing rows meet the constraint, but does not require a table rewrite.

Similarly, when attaching a new partition it may be scanned to verify that existing rows meet the partition constraint.

WarehousePG provides the option to specify multiple changes in a single `ALTER TABLE` so that multiple table scans or rewrites can be combined into a single pass over the table.

Scanning a large table to verify a new check constraint can take a long time, and other updates to the table are locked out until the `ALTER TABLE ADD CONSTRAINT` command is committed. The main purpose of the `NOT VALID` constraint option is to reduce the impact of adding a constraint on concurrent updates. With `NOT VALID`, the `ADD CONSTRAINT` command does not scan the table and can be committed immediately. After that, a `VALIDATE CONSTRAINT` command can be issued to verify that existing rows satisfy the constraint. The validation step does not need to lock out concurrent updates, since it knows that other transactions will be enforcing the constraint for rows that they insert or update; only pre-existing rows need to be checked. Hence, validation acquires only a `SHARE UPDATE EXCLUSIVE` lock on the table being altered. In addition to improving concurrency, it can be useful to use `NOT VALID` and `VALIDATE CONSTRAINT` in cases where the table is known to contain pre-existing violations. Once the constraint is in place, no new violations can be inserted, and you can correct the existing problems until `VALIDATE CONSTRAINT` finally succeeds.

The `DROP COLUMN` form does not physically remove the column, but simply makes it invisible to SQL operations. Subsequent insert and update operations in the table will store a null value for the column. Thus, dropping a column is quick but it will not immediately reduce the on-disk size of your table, as the space occupied by the dropped column is not reclaimed. The space will be reclaimed over time as existing rows are updated. If you drop the system `oid` column, however, the table is rewritten immediately.

To force immediate reclamation of space occupied by a dropped column, you can run one of the forms of `ALTER TABLE` that performs a rewrite of the whole table. This results in reconstructing each row with the dropped column replaced by a null value.

This table lists the `ALTER TABLE` operations that require a table rewrite when performed on tables defined with the specified type of table storage.

Operation (See Note)	Append-Optimized, Column-Oriented	Append-Optimized	Heap
`ALTER COLUMN TYPE`	No	Yes	Yes
`ADD COLUMN`	No	No	No
`ALTER COLUMN SET ENCODING`	No	N/A	N/A

> **Important** The forms of `ALTER TABLE` that perform a table rewrite are not MVCC-safe. After a table rewrite, the table will appear empty to concurrent transactions if they are using a snapshot taken before the rewrite occurred. See MVCC Caveats for more details.

Take special care when altering or dropping columns that are part of the WarehousePG distribution key as this can change the distribution policy for the table.

The `USING` option of `SET DATA TYPE` can actually specify any expression involving the old values of the row; that is, it can refer to other columns as well as the one being converted. This allows very general conversions to be done with the `SET DATA TYPE` syntax. Because of this flexibility, the `USING` expression is not applied to the column's default value (if any); the result might not be a constant expression as required for a default. This means that when there is no implicit or assignment cast from old to new type, `SET DATA TYPE` might fail to convert the default even though a `USING` clause is supplied. In such cases, drop the default with `DROP DEFAULT`, perform the `ALTER TYPE`, and then use `SET DEFAULT` to add a suitable new default. Similar considerations apply to indexes and constraints involving the column.

If a table has any descendant tables, it is not permitted to add, rename, or change the type of a column in the parent table without doing the same to the descendants. This ensures that the descendants always have columns matching the parent. Similarly, a `CHECK` constraint cannot be renamed in the parent without also renaming it in all descendants, so that `CHECK` constraints also match between the parent and its descendants. (That restriction does not apply to index-based constraints, however.) Also, because selecting from the parent also selects from its descendants, a constraint on the parent cannot be marked valid unless it is also marked valid for those descendants. In all of these cases, `ALTER TABLE ONLY` will be rejected.

A recursive `DROP COLUMN` operation will remove a descendant table's column only if the descendant does not inherit that column from any other parents and never had an independent definition of the column. A nonrecursive `DROP COLUMN` (`ALTER TABLE ONLY ... DROP COLUMN`) never removes any descendant columns, but instead marks them as independently defined rather than inherited. A nonrecursive `DROP COLUMN` command will fail for a partitioned table, because all partitions of a table must have the same columns as the partitioning root.

The actions for identity columns (`ADD GENERATED`, `SET` etc., `DROP IDENTITY`), as well as the actions `CLUSTER`, `OWNER`, and `TABLESPACE` never recurse to descendant tables; that is, they always act as though `ONLY` were specified. Adding a constraint recurses only for `CHECK` constraints that are not marked `NO INHERIT`.

WarehousePG does not currently support foreign key constraints. For a unique constraint to be enforced in WarehousePG, the table must be hash-distributed (not `DISTRIBUTED RANDOMLY`), and all of the distribution key columns must be the same as the initial columns of the unique constraint columns.

WarehousePG does not permit changing any part of a system catalog table.

Refer to CREATE TABLE for a further description of valid parameters.

Be aware of the following when altering partitioned tables using the *classic syntax*:

- The table name specified in the `ALTER TABLE` command must be the actual table name of the partition, not the partition alias that is specified in the classic syntax.
- Use the `pg_partition_tree()` function to view the structure of a partitioned table. This function returns the partition hierarchy, and can help you identify the particular partitions you may want to alter.
- These `ALTER PARTITION` operations are supported if no data is changed on a partitioned table that contains a leaf partition that has been exchanged to use an external table. Otherwise, an error is returned.
    - Adding or dropping a column.
    - Changing the data type of column.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

- These `ALTER PARTITION` operations are not supported for a partitioned table that contains a leaf partition that has been exchanged to use an external table:
    - Setting a sub-partition template.
    - Altering the partition properties.
    - Creating a default partition.
    - Setting a distribution policy.
    - Setting or dropping a `NOT NULL` constraint of column.
    - Adding or dropping constraints.
    - Splitting an external partition.

Examples

Add a column of type `varchar` to a table:

```
ALTER TABLE distributors ADD COLUMN address varchar(30);
```

To drop a column from a table:

```
ALTER TABLE distributors DROP COLUMN address RESTRICT;
```

To change the types of two existing columns in one operation:

```
ALTER TABLE distributors
    ALTER COLUMN address TYPE varchar(80),
    ALTER COLUMN name TYPE varchar(100);
```

To change an integer column containing Unix timestamps to `timestamp with time zone` via a `USING` clause:

```
ALTER TABLE foo
    ALTER COLUMN foo_timestamp SET DATA TYPE timestamp with time zone
    USING
        timestamp with time zone 'epoch' + foo_timestamp * interval '1 second';
```

The same, when the column has a default expression that won't automatically cast to the new data type:

```
ALTER TABLE foo
    ALTER COLUMN foo_timestamp DROP DEFAULT,
    ALTER COLUMN foo_timestamp TYPE timestamp with time zone
    USING
        timestamp with time zone 'epoch' + foo_timestamp * interval '1 second',
    ALTER COLUMN foo_timestamp SET DEFAULT now();
```

Rename an existing column:

```
ALTER TABLE distributors RENAME COLUMN address TO city;
```

Rename an existing table:

```
ALTER TABLE distributors RENAME TO suppliers;
```

To rename an existing constraint:

```
ALTER TABLE distributors RENAME CONSTRAINT zipchk TO zip_check;
```

Add a not-null constraint to a column:

```
ALTER TABLE distributors ALTER COLUMN street SET NOT NULL;
```

Rename an existing constraint:

```
ALTER TABLE distributors RENAME CONSTRAINT zipchk TO zip_check;
```

To remove a not-null constraint from a column:

```
ALTER TABLE distributors ALTER COLUMN street DROP NOT NULL;
```

Add a check constraint to a table and all of its children:

```
ALTER TABLE distributors ADD CONSTRAINT zipchk CHECK
  (char_length(zipcode) = 5);
```

To add a check constraint only to a table and not to its children:

```
ALTER TABLE distributors ADD CONSTRAINT zipchk CHECK (char_length(zipcode) = 5)
  NO INHERIT;
```

(The check constraint will not be inherited by future children, either.)

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Remove a check constraint from a table and all of its children:

```
ALTER TABLE distributors DROP CONSTRAINT zipchk;
```

Remove a check constraint from one table only:

```
ALTER TABLE ONLY distributors DROP CONSTRAINT zipchk;
```

(The check constraint remains in place for any child tables that inherit `distributors`.)

To add a (multicolumn) unique constraint to a table:

```
ALTER TABLE distributors ADD CONSTRAINT dist_id_zipcode_key UNIQUE (dist_id, zipcode);
```

To add an automatically named primary key constraint to a table, noting that a table can only ever have one primary key:

```
ALTER TABLE distributors ADD PRIMARY KEY (dist_id);
```

To move a table to a different tablespace:

```
ALTER TABLE distributors SET TABLESPACE fasttablespace;
```

Move a table to a different schema:

```
ALTER TABLE myschema.distributors SET SCHEMA yourschema;
```

Change a table's access method to `ao_row`:

```
ALTER TABLE distributors SET ACCESS METHOD ao_row;
```

Change a table's `blocksize` to `32768`:

```
ALTER TABLE distributors SET (blocksize = 32768);
```

Change a table's access method to `ao_row`, compression type to `zstd` and compression level to `4`:

```
ALTER TABLE sales SET ACCESS METHOD ao_row with (compresstype=zstd,compresslevel=4);
```

Alternatively, you can perform the same operation using `SET WITH`:

```
ALTER TABLE sales SET WITH (appendoptimized=true, compresstype=zstd, compresslevel=4);
```

Change access method for all existing partitions of a table:

```
ALTER TABLE sales SET ACCESS METHOD ao_row;
```

Change all future partitions of a table to have an access method of `heap`, leaving the access method of current partitions as is:

```
ALTER TABLE ONLY sales SET ACCESS METHOD heap;
```

Add a column and change the table's access method:

```
ALTER TABLE distributors SET ACCESS METHOD ao_row, ADD column j int;
```

Add a column and change table storage parameters:

```
ALTER TABLE distributors SET (compresslevel=7), ADD COLUMN k int;
```

Change the distribution policy of a table to replicated:

```
ALTER TABLE myschema.distributors SET DISTRIBUTED REPLICATED;
```

Change the distribution policy of a table to random and force a table rewrite:

```
ALTER TABLE distributors SET WITH (REORGANIZE=true) SET DISTRIBUTED RANDOMLY;
```

Set compression for a table and physically reorder the table by column `i`:

```
ALTER TABLE distributors
    REPACK BY COLUMNS (i),
    SET (compresstype=zstd, compresslevel=3);
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Modern Syntax Partioning Examples

Attach a partition to a range-partitioned table:

```
ALTER TABLE measurement
    ATTACH PARTITION measurement_y2016m07 FOR VALUES FROM ('2016-07-01') TO ('2016-08-01');
```

Attach a partition to a list-partitioned table:

```
ALTER TABLE cities
    ATTACH PARTITION cities_ab FOR VALUES IN ('a', 'b');
```

Attach a partition to a hash-partitioned table:

```
ALTER TABLE orders
    ATTACH PARTITION orders_p4 FOR VALUES WITH (MODULUS 4, REMAINDER 3);
```

Attach a default partition to a partitioned table:

```
ALTER TABLE cities
    ATTACH PARTITION cities_partdef DEFAULT;
```

Detach a partition from a partitioned table:

```
ALTER TABLE measurement
    DETACH PARTITION measurement_y2015m12;
```

Classic Syntax Partioning Examples

Add a new partition to a partitioned table:

```
ALTER TABLE sales ADD PARTITION
            START (date '2017-02-01') INCLUSIVE
            END (date '2017-03-01') EXCLUSIVE;
```

Add a default partition to an existing partition design:

```
ALTER TABLE sales ADD DEFAULT PARTITION other;
```

Rename a partition:

```
ALTER TABLE sales RENAME PARTITION FOR ('2016-01-01') TO
jan08;
```

Exchange a table into your partition design:

```
ALTER TABLE sales EXCHANGE PARTITION FOR ('2016-01-01') WITH
TABLE jan08;
```

Split the default partition (where the existing default partition's name is `other`) to add a new monthly partition for January 2017:

```
ALTER TABLE sales SPLIT DEFAULT PARTITION
  START ('2017-01-01') INCLUSIVE
  END ('2017-02-01') EXCLUSIVE
INTO (PARTITION jan09, PARTITION other);
```

Split a monthly partition into two with the first partition containing dates January 1-15 and the second partition containing dates January 16-31:

```
ALTER TABLE sales SPLIT PARTITION FOR ('2016-01-01')
AT ('2016-01-16')
INTO (PARTITION jan081to15, PARTITION jan0816to31);
```

For a multi-level partitioned table that consists of three levels, year, quarter, and region, exchange a leaf partition `region` with the table `region_new`.

```
ALTER TABLE sales ALTER PARTITION year_1 ALTER PARTITION quarter_4 EXCHANGE PARTITION region WITH TABLE region_new ;
```

In the previous command, the two `ALTER PARTITION` clauses identify which `region` partition to exchange. Both clauses are required to identify the specific partition to exchange.

Compatibility

The forms `ADD` (without `USING INDEX`), `DROP [COLUMN]`, `DROP IDENTITY`, `RESTART`, `SET DEFAULT`, `SET DATA TYPE` (without `USING`), `SET GENERATED`, and `SET <sequence_option>` conform with the SQL standard. The other forms are WarehousePG extensions of the SQL standard. Also, the ability to specify more than one manipulation in a single `ALTER TABLE` command is an extension.

`ALTER TABLE DROP COLUMN` can be used to drop the only column of a table, leaving a zero-column table. This is an extension of SQL, which disallows zero-column tables.

7.1.32 ALTER TABLESPACE

Changes the definition of a tablespace.

Synopsis

```
ALTER TABLESPACE <name> RENAME TO <new_name>

ALTER TABLESPACE <name> OWNER TO { <new_owner> | CURRENT_USER | SESSION_USER }

ALTER TABLESPACE <name> SET ( <tablespace_option> = <value> [, ... ] )

ALTER TABLESPACE <name> RESET ( <tablespace_option> [, ... ] )
```

Description

`ALTER TABLESPACE` changes the definition of a tablespace.

You must own the tablespace to use `ALTER TABLESPACE`. To alter the owner, you must also be a direct or indirect member of the new owning role. (Note that superusers have these privileges automatically.)

Parameters

name The name of an existing tablespace.

new*name The new name of the tablespace. The new name cannot begin with `pg* or* gp_ `*(reserved for system tablespaces).

new_owner The new owner of the tablespace.

tablespace_parameter A tablespace parameter to set or reset. Currently, the only available parameters are `seq_page_cost` and `random_page_cost`. Setting either value for a particular tablespace will override the planner's usual estimate of the cost of reading pages from tables in that tablespace, as established by the configuration parameters of the same name (see seq_page_cost, random_page_cost). This may be useful if one tablespace is located on a disk which is faster or slower than the remainder of the I/O subsystem.

Examples

Rename tablespace `index_space` to `fast_raid`:

```
ALTER TABLESPACE index_space RENAME TO fast_raid;
```

Change the owner of tablespace `index_space`:

```
ALTER TABLESPACE index_space OWNER TO mary;
```

Compatibility

There is no `ALTER TABLESPACE` statement in the SQL standard.

7.1.33 ALTER TEXT SEARCH CONFIGURATION

Changes the definition of a text search configuration.

Synopsis

```
ALTER TEXT SEARCH CONFIGURATION <name>
    ADD MAPPING FOR <token_type> [, ... ] WITH <dictionary_name> [, ... ]
ALTER TEXT SEARCH CONFIGURATION <name>
    ALTER MAPPING FOR <token_type> [, ... ] WITH <dictionary_name> [, ... ]
ALTER TEXT SEARCH CONFIGURATION <name>
    ALTER MAPPING REPLACE <old_dictionary> WITH <new_dictionary>
ALTER TEXT SEARCH CONFIGURATION <name>
    ALTER MAPPING FOR <token_type> [, ... ] REPLACE <old_dictionary> WITH <new_dictionary>
ALTER TEXT SEARCH CONFIGURATION <name>
    DROP MAPPING [ IF EXISTS ] FOR <token_type> [, ... ]
ALTER TEXT SEARCH CONFIGURATION <name> RENAME TO <new_name>
ALTER TEXT SEARCH CONFIGURATION <name> OWNER TO { <new_owner> | CURRENT_USER | SESSION_USER }
ALTER TEXT SEARCH CONFIGURATION <name> SET SCHEMA <new_schema>
```

Description

`ALTER TEXT SEARCH CONFIGURATION` changes the definition of a text search configuration. You can modify its mappings from token types to dictionaries, or change the configuration's name or owner.

You must be the owner of the configuration to use `ALTER TEXT SEARCH CONFIGURATION`.

Parameters

name The name (optionally schema-qualified) of an existing text search configuration.

token_type The name of a token type that is emitted by the configuration's parser.

dictionary_name The name of a text search dictionary to be consulted for the specified token type(s). If multiple dictionaries are listed, they are consulted in the specified order.

old_dictionary The name of a text search dictionary to be replaced in the mapping.

new_dictionary The name of a text search dictionary to be substituted for old_dictionary.

new_name The new name of the text search configuration.

new_owner The new owner of the text search configuration.

new_schema The new schema for the text search configuration.

The `ADD MAPPING FOR` form installs a list of dictionaries to be consulted for the specified token type(s); it is an error if there is already a mapping for any of the token types. The `ALTER MAPPING FOR` form does the same, but first removing any existing mapping for those token types. The `ALTER MAPPING REPLACE` forms substitute new_dictionary for old_dictionary anywhere the latter appears. This is done for only the specified token types when `FOR` appears, or for all mappings of the configuration when it doesn't. The `DROP MAPPING` form removes all dictionaries for the specified token type(s), causing tokens of those types to be ignored by the text search configuration. It is an error if there is no mapping for the token types, unless `IF EXISTS` appears.

Examples

The following example replaces the `english` dictionary with the `swedish` dictionary anywhere that `english` is used within `my_config`.

```
ALTER TEXT SEARCH CONFIGURATION my_config
  ALTER MAPPING REPLACE english WITH swedish;
```

Compatibility

There is no `ALTER TEXT SEARCH CONFIGURATION` statement in the SQL standard.

See Also

CREATE TEXT SEARCH CONFIGURATION, DROP TEXT SEARCH CONFIGURATION

7.1.34 ALTER TEXT SEARCH DICTIONARY

Changes the definition of a text search dictionary.

Synopsis

```
ALTER TEXT SEARCH DICTIONARY <name> (
    <option> [ = <value> ] [, ... ]
)
ALTER TEXT SEARCH DICTIONARY <name> RENAME TO <new_name>
ALTER TEXT SEARCH DICTIONARY <name> OWNER TO { <new_owner> | CURRENT_USER | SESSION_USER }
ALTER TEXT SEARCH DICTIONARY <name> SET SCHEMA <new_schema>
```

Description

`ALTER TEXT SEARCH DICTIONARY` changes the definition of a text search dictionary. You can change the dictionary's template-specific options, or change the dictionary's name or owner.

You must be the owner of the dictionary to use `ALTER TEXT SEARCH DICTIONARY`.

Parameters

name The name (optionally schema-qualified) of an existing text search dictionary.

option The name of a template-specific option to be set for this dictionary.

value The new value to use for a template-specific option. If the equal sign and value are omitted, then any previous setting for the option is removed from the dictionary, allowing the default to be used.

new_name The new name of the text search dictionary.

new_owner The new owner of the text search dictionary.

new_schema The new schema for the text search dictionary.

Template-specific options can appear in any order.

Examples

The following example command changes the stop word list for a Snowball-based dictionary. Other parameters remain unchanged.

```
ALTER TEXT SEARCH DICTIONARY my_dict ( StopWords = newrussian );
```

The following example command changes the language option to `dutch`, and removes the stop word option entirely:

```
ALTER TEXT SEARCH DICTIONARY my_dict ( language = dutch, StopWords );
```

The following example command "updates" the dictionary's definition without actually changing anything:

```
ALTER TEXT SEARCH DICTIONARY my_dict ( dummy );
```

(The reason this works is that the option removal code doesn't complain if there is no such option.) This trick is useful when changing configuration files for the dictionary: the `ALTER` will force existing database sessions to re-read the configuration files, which they would otherwise never do if they had read them earlier.

Compatibility

There is no `ALTER TEXT SEARCH DICTIONARY` statement in the SQL standard.

See Also

CREATE TEXT SEARCH DICTIONARY, DROP TEXT SEARCH DICTIONARY

7.1.35 ALTER TEXT SEARCH PARSER

Changes the definition of a text search parser.

Synopsis

```
ALTER TEXT SEARCH PARSER <name> RENAME TO <new_name>
ALTER TEXT SEARCH PARSER <name> SET SCHEMA <new_schema>
```

Description

`ALTER TEXT SEARCH PARSER` changes the definition of a text search parser. Currently, the only supported functionality is to change the parser's name.

You must be a superuser to use `ALTER TEXT SEARCH PARSER`.

Parameters

name The name (optionally schema-qualified) of an existing text search parser.

new_name The new name of the text search parser.

new_schema The new schema for the text search parser.

Compatibility

There is no `ALTER TEXT SEARCH PARSER` statement in the SQL standard.

See Also

CREATE TEXT SEARCH PARSER, DROP TEXT SEARCH PARSER

Parent topic: SQL Commands

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.1.36 ALTER TEXT SEARCH TEMPLATE

Changes the definition of a text search template.

Synopsis

```
ALTER TEXT SEARCH TEMPLATE <name> RENAME TO <new_name>
ALTER TEXT SEARCH TEMPLATE <name> SET SCHEMA <new_schema>
```

Description

`ALTER TEXT SEARCH TEMPLATE` changes the definition of a text search parser. Currently, the only supported functionality is to change the template's name.

You must be a superuser to use `ALTER TEXT SEARCH TEMPLATE`.

Parameters

name The name (optionally schema-qualified) of an existing text search template.

new_name The new name of the text search template.

new_schema The new schema for the text search template.

Compatibility

There is no `ALTER TEXT SEARCH TEMPLATE` statement in the SQL standard.

See Also

CREATE TEXT SEARCH TEMPLATE, DROP TEXT SEARCH TEMPLATE

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.1.37 ALTER TYPE

Changes the definition of a data type.

Synopsis

```
ALTER TYPE <name> <action> [, ... ]
ALTER TYPE <name> OWNER TO { <new_owner> | CURRENT_USER | SESSION_USER }
ALTER TYPE <name> RENAME ATTRIBUTE <attribute_name> TO <new_attribute_name> [ CASCADE | RESTRICT ]
ALTER TYPE <name> RENAME TO <new_name>
ALTER TYPE <name> SET SCHEMA <new_schema>
ALTER TYPE <name> ADD VALUE [ IF NOT EXISTS ] <new_enum_value> [ { BEFORE | AFTER } <neighbor_enum_value> ]
ALTER TYPE <name> RENAME VALUE <existing_enum_value> to <new_enum_value>
ALTER TYPE <name> SET DEFAULT ENCODING ( <storage_directive> )

where <action> is one of:

  ADD ATTRIBUTE <attribute_name> <data_type> [ COLLATE <collation> ] [ CASCADE | RESTRICT ]
  DROP ATTRIBUTE [ IF EXISTS ] <attribute_name> [ CASCADE | RESTRICT ]
  ALTER ATTRIBUTE <attribute_name> [ SET DATA ] TYPE <data_type> [ COLLATE <collation> ] [ CASCADE | RESTRICT ]

where <storage_directive> is:

   COMPRESSTYPE={ZLIB | ZSTD | RLE_TYPE | NONE}
   COMPRESSLEVEL={0-19}
   BLOCKSIZE={8192-2097152}
```

Description

`ALTER TYPE` changes the definition of an existing type. There are several subforms:

`ADD ATTRIBUTE` Adds a new attribute to a composite type, using the same syntax as CREATE TYPE.

`DROP ATTRIBUTE [ IF EXISTS ]` Drops an attribute from a composite type. If `IF EXISTS` is specified and the attribute does not exist, no error is thrown. In this case WarehousePG issues a notice instead.

`SET DATA TYPE` Changes the type of an attribute of a composite type.

`OWNER` Changes the owner of the type.

`RENAME` Changes the name of the type or the name of an individual attribute of a composite type.

`SET SCHEMA` Moves the type into another schema.

`ADD VALUE [ IF NOT EXISTS ] [ BEFORE | AFTER ]` Adds a new value to an enum type. The new value's place in the enum's ordering can be specified as being `BEFORE` or `AFTER` one of the existing values. Otherwise, the new item is added at the end of the list of values.

If `IF NOT EXISTS` is specified, it is not an error if the type already contains the new value; WarehousePG issues a notice but takes no other action. Otherwise, an error will occur if the new value is already present.

`RENAME VALUE` Renames a value of an enum type. The value's place in the enum's ordering is not affected. An error will occur if the specified value is not present or the new name is already present.

The `ADD ATTRIBUTE`, `DROP ATTRIBUTE`, and `ALTER ATTRIBUTE` actions can be combined into a list of multiple alterations to apply in parallel. For example, it is possible to add several attributes and/or alter the type of several attributes in a single command.

You can change the name, the owner, and the schema of a type. You can also add or update storage options for a scalar type.

> **Note** WarehousePG does not support adding storage options for row or composite types.

You must own the type to use `ALTER TYPE`. To change the schema of a type, you must also have `CREATE` privilege on the new schema. To alter the owner, you must also be a direct or indirect member of the new owning role, and that role must have `CREATE` privilege on the type's schema. (These restrictions enforce that altering the owner does not do anything that could be done by dropping and recreating the type. However, a superuser can alter ownership of any type.) To add an attribute or alter an attribute type, you must also have `USAGE` privilege on the data type.

Parameters

name The name (optionally schema-qualified) of an existing type to alter.

new_name The new name for the type.

new_owner The user name of the new owner of the type.

new_schema The new schema for the type.

attribute_name The name of the attribute to add, alter, or drop.

new_attribute_name The new name of the attribute to be renamed.

data_type The data type of the attribute to add, or the new type of the attribute to alter.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

new_enum_value The new value to be added to an enum type's list of values. Like all enum literals, it must be quoted.

neighbor_enum_value The existing enum value that the new value should be added immediately before or after in the enum type's sort ordering. Like all enum literals, it must be quoted.

existing_enum_value The existing enum value that should be renamed. Like all enum literals, it must be quoted.

CASCADE Automatically propagate the operation to typed tables of the type being altered, and their descendants.

RESTRICT Refuse the operation if the type being altered is the type of a typed table. This is the default.

storage_directive Identifies default storage options for the type when specified in a table column definition. Options include `COMPRESSTYPE`, `COMPRESSLEVEL`, and `BLOCKSIZE`.

COMPRESSTYPE — Set to `ZLIB` (the default), `ZSTD` or `RLE_TYPE` to specify the type of compression used.

COMPRESSLEVEL — For Zstd compression, set to an integer value from 1 (fastest compression) to 19 (highest compression ratio). For zlib compression, the valid range is from 1 to 9. For `RLE_TYPE`, the compression level can be set to an integer value from 1 (fastest compression) to 6 (highest compression ratio). The default compression level is 1.

BLOCKSIZE — Set to the size, in bytes, for each block in the column. The `BLOCKSIZE` must be between 8192 and 2097152 bytes, and be a multiple of 8192. The default block size is 32768.

```
> **Note** storage\_directives defined at the table- or column-level override the default storage options defined for a type.
```

Notes

If `ALTER TYPE ... ADD VALUE` (the form that adds a new value to an enum type) is executed inside a transaction block, the new value cannot be used until after the transaction has been committed.

Comparisons involving an added enum value will sometimes be slower than comparisons involving only original members of the enum type. This will usually only occur if `BEFORE` or `AFTER` is used to set the new value's sort position somewhere other than at the end of the list. However, sometimes it will happen even though the new value is added at the end (this occurs if the OID counter "wrapped around" since the original creation of the enum type). The slowdown is usually insignificant; but if it matters, optimal performance can be regained by dropping and recreating the enum type, or by dumping and reloading the database.

Examples

To rename the data type named `electronic_mail`:

```
ALTER TYPE electronic_mail RENAME TO email;
```

To change the owner of the user-defined type `email` to `joe`:

```
ALTER TYPE email OWNER TO joe;
```

To change the schema of the user-defined type `email` to `customers`:

```
ALTER TYPE email SET SCHEMA customers;
```

To set or alter the compression type and compression level of the user-defined type named `int33`:

```
ALTER TYPE int33 SET DEFAULT ENCODING (compresstype=zlib, compresslevel=7);
```

To add a new attribute to a type:

```
ALTER TYPE compfoo ADD ATTRIBUTE f3 int;
```

To add a new value to an enum type in a particular sort position:

```
ALTER TYPE colors ADD VALUE 'orange' AFTER 'red';
```

To rename an enum value:

```
ALTER TYPE colors RENAME VALUE 'purple' TO 'mauve';
```

Compatibility

The variants to add and drop attributes are part of the SQL standard; the other variants are WarehousePG extensions.

See Also

CREATE TYPE, DROP TYPE

Parent topic: SQL Commands

7.1.38 ALTER USER

Changes the definition of a database role.

Synopsis

```
ALTER USER <role_specification> [WITH] <option> [ ... ]

where option can be:

      SUPERUSER | NOSUPERUSER
    | CREATEDB | NOCREATEDB
    | CREATEROLE | NOCREATEROLE
    | CREATEEXTTABLE | NOCREATEEXTTABLE
      [ ( <attribute>='<value>'[, ...] ) ]
           where <attributes> and <value> are:
           type='readable'|'writable'
           protocol='gpfdist'|'http'
    | INHERIT | NOINHERIT
    | LOGIN | NOLOGIN
    | REPLICATION | NOREPLICATION
    | BYPASSRLS | NOBYPASSRLS
    | CONNECTION LIMIT <connlimit>
    | [ENCRYPTED ] PASSWORD '<password>' | PASSWORD NULL
    | VALID UNTIL '<timestamp>'
    | [ DENY <deny_point> ]
    | [ DENY BETWEEN <deny_point> AND <deny_point>]
    | [ DROP DENY FOR <deny_point> ]

ALTER USER <name> RENAME TO <new_name>

ALTER USER <name> RESOURCE QUEUE {<queue_name> | NONE}

ALTER USER <name> RESOURCE GROUP {<group_name> | NONE}

ALTER USER { <role_specification> | ALL } [ IN DATABASE <database_name> ] SET <configuration_parameter> {TO | =} {<value> | DEFAULT}
ALTER USER { <role_specification> | ALL } [ IN DATABASE <database_name> ] SET <configuration_parameter> FROM CURRENT
ALTER USER { <role_specification> | ALL } [ IN DATABASE <database_name> ] RESET <configuration_parameter>
ALTER USER { <role_specification> | ALL } [ IN DATABASE <database_name> ] RESET ALL

where <role_specification> can be:

    role_name
  | CURRENT_USER
  | SESSION_USER
```

Description

`ALTER USER` is an alias for ALTER ROLE.

Compatibility

The `ALTER USER` statement is a WarehousePG extension. The SQL standard leaves the definition of users to the implementation.

See Also

ALTER ROLE

Parent topic: SQL Commands

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.1.39 ALTER USER MAPPING

Changes the definition of a user mapping for a foreign server.

Synopsis

```
ALTER USER MAPPING FOR { <user_name> | USER | CURRENT_USER | SESSION_USER | PUBLIC }
    SERVER <server_name>
    OPTIONS ( [ ADD | SET | DROP ] <option> ['<value>'] [, ... ] )
```

Description

`ALTER USER MAPPING` changes the definition of a user mapping for a foreign server.

The owner of a foreign server can alter user mappings for that server for any user. Also, a user granted `USAGE` privilege on the server can alter a user mapping for their own user name.

Parameters

user_name User name of the mapping. `CURRENT_USER` and `USER` match the name of the current user. `PUBLIC` is used to match all present and future user names in the system.

server_name Server name of the user mapping.

OPTIONS ([ADD | SET | DROP] option ['value'] [, ...]) Change options for the user mapping. The new options override any previously specified options `ADD`, `SET`, and `DROP` specify the action to perform. If no operation is explicitly specified, the default operation is `ADD`. Option names must be unique. WarehousePG validates names and values using the server's foreign-data wrapper.

Examples

Change the password for user mapping `bob`, server `foo`:

```
ALTER USER MAPPING FOR bob SERVER foo OPTIONS (SET password 'public');
```

Compatibility

`ALTER USER MAPPING` conforms to ISO/IEC 9075-9 (SQL/MED). There is a subtle syntax issue: The standard omits the `FOR` key word. Since both `CREATE USER MAPPING` and `DROP USER MAPPING` use `FOR` in analogous positions, WarehousePG diverges from the standard here in the interest of consistency and interoperability.

See Also

CREATE USER MAPPING, DROP USER MAPPING

Parent topic: SQL Commands

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.1.40 ALTER VIEW

Changes properties of a view.

Synopsis

```
ALTER VIEW [ IF EXISTS ] <name> ALTER [ COLUMN ] <column_name> SET DEFAULT <expression>

ALTER VIEW [ IF EXISTS ] <name> ALTER [ COLUMN ] <column_name> DROP DEFAULT

ALTER VIEW [ IF EXISTS ] <name> OWNER TO { <new_owner> | CURRENT_USER | SESSION_USER }

ALTER VIEW [ IF EXISTS ] <name> RENAME TO <new_name>

ALTER VIEW [ IF EXISTS ] <name> SET SCHEMA <new_schema>

ALTER VIEW [ IF EXISTS ] <name> SET ( <view_option_name> [= <view_option_value>] [, ... ] )

ALTER VIEW [ IF EXISTS ] <name> RESET ( <view_option_name> [, ... ] )
```

Description

`ALTER VIEW` changes various auxiliary properties of a view. (If you want to modify the view's defining query, use `CREATE OR REPLACE VIEW`).

You must own the view to use `ALTER VIEW`. To change a view's schema you must also have `CREATE` privilege on the new schema. To alter the owner, you must also be a direct or indirect member of the new owning role, and that role must have `CREATE` privilege on the view's schema. These restrictions enforce that altering the owner does not do anything you could not do by dropping and recreating the view. However, a superuser can alter ownership of any view.

Parameters

name The name (optionally schema-qualified) of an existing view.

IF EXISTS Do not throw an error if the view does not exist. WarehousePG issues a notice in this case.

SET/DROP DEFAULT These forms set or remove the default value for a column. A view column's default value is substituted into any `INSERT` or `UPDATE` command whose target is the view, before applying any rules or triggers for the view. The view's default will therefore take precedence over any default values from underlying relations.

new_owner The user name of the new owner of the view.

new_name The new name of the view.

new_schema The new schema for the view.

SET (view_option_name [= view_option_value][, ...]) RESET (view_option_name [, ...]) Sets or resets a view option. Currently supported options are:

```
check\_option \(string\)
Changes the check option of the view. The value must be `local` or `cascaded`.

security\_barrier \(boolean\)
Changes the security-barrier property of the view. The value must be a Boolean value, such as `true` or `false`.
```

Notes

For historical reasons, `ALTER TABLE` can be used with views, too; however, the only variants of `ALTER TABLE` that are allowed with views are equivalent to the statements shown above.

Examples

To rename the view `foo` to `bar`:

```
ALTER VIEW foo RENAME TO bar;
```

To attach a default column value to an updatable view:

```
CREATE TABLE base_table (id int, ts timestamptz);
CREATE VIEW a_view AS SELECT * FROM base_table;
ALTER VIEW a_view ALTER COLUMN ts SET DEFAULT now();
INSERT INTO base_table(id) VALUES(1);  -- ts will receive a NULL
INSERT INTO a_view(id) VALUES(2);  -- ts will receive the current time
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Compatibility

`ALTER VIEW` is a WarehousePG extension of the SQL standard.

7.1.41 ANALYZE

Collects statistics about a database.

Synopsis

```
ANALYZE [VERBOSE] [SKIP_LOCKED] [<table> [ (<column> [, ...] ) ]]

ANALYZE [VERBOSE] [SKIP_LOCKED] {<root_partition_table_name>|<leaf_partition_table_name>} [ (<column> [, ...] )]

ANALYZE [VERBOSE] [SKIP_LOCKED] ROOTPARTITION {ALL | <root_partition_table_name> [ (<column> [, ...] )]}
```

Description

`ANALYZE` collects statistics about the contents of tables in the database, and stores the results in the system table*pg_statistic*. Subsequently, WarehousePG uses these statistics to help determine the most efficient execution plans for queries. For information about the table statistics that are collected, see Notes.

With no parameter, `ANALYZE` collects statistics for every table in the current database. You can specify a table name to collect statistics for a single table. You can specify a set of column names in a specific table, in which case the statistics only for those columns from that table are collected.

`ANALYZE` does not collect statistics on external tables.

For partitioned tables, `ANALYZE` collects additional statistics, HyperLogLog (HLL) statistics, on the leaf partitions. HLL statistics are used are used to derive number of distinct values (NDV) for queries against partitioned tables.

- When aggregating NDV estimates across multiple leaf partitions, HLL statistics generate a more accurate NDV estimates than the standard table statistics.
- When updating HLL statistics, `ANALYZE` operations are required only on leaf partitions that have changed. For example, `ANALYZE` is required if the leaf partition data has changed, or if the leaf partition has been exchanged with another table. For more information about updating partitioned table statistics, see Notes.

> **Important** If you intend to run queries on partitioned tables with GPORCA enabled (the default), then you must collect statistics on the root partition of the partitioned table with the `ANALYZE` or `ANALYZE ROOTPARTITION` command. For information about collecting statistics on partitioned tables and when the `ROOTPARTITION` keyword is required, see Notes. For information about GPORCA, see Overview of GPORCA in the *WarehousePG Administrator Guide*.

> **Note** You can also use the WarehousePG utility `analyzedb` to update table statistics. The `analyzedb` utility can update statistics for multiple tables concurrently. The utility can also check table statistics and update statistics only if the statistics are not current or do not exist. For information about the utility, see the *WarehousePG Utility Guide*.

Parameters

{ root_partition_table_name | leaf_partition_table_name } [(column [, ...])] Collect statistics for partitioned tables including HLL statistics. HLL statistics are collected only on leaf partitions.

`ANALYZE root\_partition\_table\_name` , collects statistics on all leaf partitions and the root partition.

`ANALYZE leaf\_partition\_table\_name` , collects statistics on the leaf partition.

By default, if you specify a leaf partition, and all other leaf partitions have statistics, `ANALYZE` updates the root partition statistics. If not all leaf partitions have statistics, `ANALYZE` logs information about the leaf partitions that do not have statistics. For information about when root partition statistics are collected, see Notes.

ROOTPARTITION [ALL] Collect statistics only on the root partition of partitioned tables based on the data in the partitioned table. If possible, `ANALYZE` uses leaf partition statistics to generate root partition statistics. Otherwise, `ANALYZE` collects the statistics by sampling leaf partition data. Statistics are not collected on the leaf partitions, the data is only sampled. HLL statistics are not collected.

For information about when the `ROOTPARTITION` keyword is required, see Notes.

When you specify `ROOTPARTITION` , you must specify either `ALL` or the name of a partitioned table.

If you specify `ALL` with `ROOTPARTITION` , WarehousePG collects statistics for the root partition of all partitioned tables in the database. If there are no partitioned tables in the database, a message stating that there are no partitioned tables is returned. For tables that are not partitioned tables, statistics are not collected.

If you specify a table name with `ROOTPARTITION` and the table is not a partitioned table, no statistics are collected for the table and a warning message is returned.

The `ROOTPARTITION` clause is not valid with `VACUUM ANALYZE` . The command `VACUUM ANALYZE ROOTPARTITION` returns an error.

If all the leaf partitions have statistics, performing `ANALYZE ROOTPARTITION` to generate root partition statistics should be quick (a few seconds depending on the number of partitions and table columns). If some of the leaf partitions do not have statistics, then all the table data is sampled to generate root partition statistics. Sampling table data takes longer and results in lower quality root partition statistics.

For the partitioned table *sales_curr_yr*, this example command collects statistics only on the root partition of the partitioned table. `ANALYZE ROOTPARTITION sales_curr_yr;`

This example `ANALYZE` command collects statistics on the root partition of all the partitioned tables in the database.

```
```
ANALYZE ROOTPARTITION ALL;
```
```

VERBOSE Enables display of progress messages. When specified, `ANALYZE` emits this information

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
-   The table that is being processed.
-   The query that is run to generate the sample table.
-   The column for which statistics is being computed.
-   The queries that are issued to collect the different statistics for a single column.
-   The statistics that are collected.
```

SKIP_LOCKED Specifies that `ANALYZE` should not wait for any conflicting locks to be released when beginning work on a relation: if it cannot lock a relation immediately without waiting, it skips the relation. Note that even with this option, `ANALYZE` may still block when opening the relation's indexes or when acquiring sample rows from partitions, table inheritance children, and some types of foreign tables. Also, while `ANALYZE` ordinarily processes all partitions of specified partitioned tables, this option will cause `ANALYZE` to skip all partitions if there is a conflicting lock on the partitioned table.

table The name (possibly schema-qualified) of a specific table to analyze. If omitted, all regular tables (but not foreign tables) in the current database are analyzed.

column The name of a specific column to analyze. Defaults to all columns.

Notes

Foreign tables are analyzed only when explicitly selected. Not all foreign data wrappers support `ANALYZE`. If the table's wrapper does not support `ANALYZE`, the command prints a warning and does nothing.

It is a good idea to run `ANALYZE` periodically, or just after making major changes in the contents of a table. Accurate statistics helps WarehousePG choose the most appropriate query plan, and thereby improve the speed of query processing. A common strategy for read-mostly databases is to run VACUUM and `ANALYZE` once a day during a low-usage time of day. (This will not be sufficient if there is heavy update activity.) You can check for tables with missing statistics using the `gp_stats_missing` view, which is in the `gp_toolkit` schema:

```
SELECT * from gp_toolkit.gp_stats_missing;
```

`ANALYZE` requires `SHARE UPDATE EXCLUSIVE` lock on the target table. This lock conflicts with these locks: `SHARE UPDATE EXCLUSIVE`, `SHARE`, `SHARE ROW EXCLUSIVE`, `EXCLUSIVE`, `ACCESS EXCLUSIVE`.

If you run `ANALYZE` on a table that does not contain data, statistics are not collected for the table. For example, if you perform a `TRUNCATE` operation on a table that has statistics, and then run `ANALYZE` on the table, the statistics do not change.

For a partitioned table, specifying which portion of the table to analyze, the root partition or sub-partitions (leaf partitions) can be useful if the partitioned table has a large number of partitions that have been analyzed and only a few leaf partitions have changed.

> **Note** When you create a partitioned table with the `CREATE TABLE` command, WarehousePG creates the table that you specify (the root partition or parent table), and also creates a hierarchy of tables based on the partition hierarchy that you specified (the child tables).

- When you run `ANALYZE` on the root partitioned table, statistics are collected for all the leaf partitions. Leaf partitions are the lowest-level tables in the hierarchy of child tables created by WarehousePG for use by the partitioned table.
- When you run `ANALYZE` on a leaf partition, statistics are collected only for that leaf partition and the root partition. If data in the leaf partition has changed (for example, you made significant updates to the leaf partition data or you exchanged the leaf partition), then you can run ANALYZE on the leaf partition to collect table statistics. By default, if all other leaf partitions have statistics, the command updates the root partition statistics.

  For example, if you collected statistics on a partitioned table with a large number partitions and then updated data in only a few leaf partitions, you can run `ANALYZE` only on those partitions to update statistics on the partitions and the statistics on the root partition.
- When you run `ANALYZE` on a child table that is not a leaf partition, statistics are not collected.

  For example, you can create a partitioned table with partitions for the years 2006 to 2016 and sub-partitions for each month in each year. If you run `ANALYZE` on the child table for the year 2013 no statistics are collected. If you run `ANALYZE` on the leaf partition for March of 2013, statistics are collected only for that leaf partition.

For a partitioned table that contains a leaf partition that has been exchanged to use an external table, `ANALYZE` does not collect statistics for the external table partition:

- If `ANALYZE` is run on an external table partition, the partition is not analyzed.
- If `ANALYZE` or `ANALYZE ROOTPARTITION` is run on the root partition, external table partitions are not sampled and root table statistics do not include external table partition.
- If the `VERBOSE` clause is specified, an informational message is displayed: `skipping external table`.

The WarehousePG server configuration parameter optimizer_analyze_root_partition determines when statistics are collected on a root partitioned table. If the parameter is `on` (the default), the `ROOTPARTITION` keyword is not required to collect statistics on the root partition when you run `ANALYZE`. Root partition statistics are collected when you run `ANALYZE` on the root partition, or when you run `ANALYZE` on a leaf partition of the partitioned table and the other leaf partitions have statistics. If the parameter is `off`, you must run `ANALZYE ROOTPARTITION` to collect root partition statistics.

The statistics collected by `ANALYZE` usually include a list of some of the most common values in each column and a histogram showing the approximate data distribution in each column. One or both of these may be omitted if `ANALYZE` deems them uninteresting (for example, in a unique-key column, there are no common values) or if the column data type does not support the appropriate operators.

For large tables, `ANALYZE` takes a random sample of the table contents, rather than examining every row. This allows even very large tables to be analyzed in a small amount of time. Note, however, that the statistics are only approximate, and will change slightly each time `ANALYZE` is run, even if the actual table contents did not change. This may result in small changes in the planner's estimated costs shown by `EXPLAIN`. In rare situations, this non-determinism will cause the query optimizer to choose a different query plan between runs of `ANALYZE`. To avoid this, raise the amount of statistics collected by `ANALYZE` by adjusting the default_statistics_target configuration parameter, or on a column-by-column basis by setting the per-column statistics target with `ALTER TABLE ... ALTER COLUMN ... SET (n_distinct ...)` (see `ALTER TABLE`). The target value sets the maximum number of entries in the most-common-value list and the maximum number of bins in the histogram. The default target value is 100, but this can be adjusted up or down to trade off accuracy of planner estimates against the time taken for `ANALYZE` and the amount of space occupied in `pg_statistic`. In particular, setting the statistics target to zero deactivates collection of statistics for that column. It may be useful to do that for columns that are never used as part of the `WHERE`, `GROUP BY`, or `ORDER BY` clauses of queries, since the planner will have no use for statistics on such columns.

The largest statistics target among the columns being analyzed determines the number of table rows sampled to prepare the statistics. Increasing the target causes a proportional increase in the time and space needed to do `ANALYZE`.

One of the values estimated by `ANALYZE` is the number of distinct values that appear in each column. Because only a subset of the rows are examined, this estimate can sometimes be quite inaccurate, even with the largest possible statistics target. If this inaccuracy leads to bad query plans, a more accurate value can be determined manually and then installed with `ALTER TABLE ... ALTER COLUMN ... SET STATISTICS DISTINCT` (see ALTER TABLE).

When WarehousePG performs an `ANALYZE` operation to collect statistics for a table and detects that all the sampled table data pages are empty (do not contain valid data), WarehousePG displays a message that a `VACUUM FULL` operation should be performed. If the sampled pages are empty, the table statistics will be inaccurate. Pages become empty after a large number of changes to the table, for example deleting a large number of rows. A `VACUUM FULL` operation removes the empty pages and allows an `ANALYZE` operation to collect accurate statistics.

If there are no statistics for the table, the server configuration parameter gp_enable_relsize_collection controls whether the Postgres-based planner uses a default statistics file or estimates the size of a table using the `pg_relation_size` function. By default, the Postgres-based planner uses the default statistics file to estimate the number of rows if statistics are not available.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Examples

Collect statistics for the table `mytable`:

```
ANALYZE mytable;
```

Compatibility

There is no `ANALYZE` statement in the SQL standard.

See Also

ALTER TABLE, EXPLAIN, VACUUM, analyzedb.

7.1.42 BEGIN

Starts a transaction block.

Synopsis

```
BEGIN [WORK | TRANSACTION] [<transaction_mode>]

where <transaction_mode> is:

   ISOLATION LEVEL {READ UNCOMMITTED | READ COMMITTED | REPEATABLE READ | SERIALIZABLE}
   READ WRITE | READ ONLY
   [NOT] DEFERRABLE
```

Description

`BEGIN` initiates a transaction block, that is, all statements after a `BEGIN` command will be run in a single transaction until an explicit COMMIT or ROLLBACK is given. By default (without `BEGIN`), WarehousePG runs transactions in "autocommit" mode, that is, each statement is run in its own transaction and a commit is implicitly performed at the end of the statement (if execution was successful, otherwise a rollback is done).

Statements are run more quickly in a transaction block, because transaction start/commit requires significant CPU and disk activity. Execution of multiple statements inside a transaction is also useful to ensure consistency when making several related changes: other sessions will be unable to see the intermediate states wherein not all the related updates have been done.

If the isolation level, read/write mode, or deferrable mode is specified, the new transaction has those characteristics, as if SET TRANSACTION was run.

Parameters

WORK TRANSACTION Optional key words. They have no effect.

Refer to SET TRANSACTION for information on the meaning of the other parameters to this statement.

Notes

START TRANSACTION has the same functionality as `BEGIN`.

Use COMMIT or ROLLBACK to terminate a transaction block.

Issuing `BEGIN` when already inside a transaction block will provoke a warning message. The state of the transaction is not affected. To nest transactions within a transaction block, use savepoints (seeSAVEPOINT).

For reasons of backwards compatibility, the commas between successive transaction_modes can be omitted.

Examples

To begin a transaction block:

```
BEGIN;
```

Compatibility

`BEGIN` is a WarehousePG language extension. It is equivalent to the SQL-standard command START TRANSACTION, whose reference page contains additional compatibility information.

The `DEFERRABLE` transaction_mode is a WarehousePG language extension.

Incidentally, the `BEGIN` key word is used for a different purpose in embedded SQL. You are advised to be careful about the transaction semantics when porting database applications.

See Also

COMMIT, ROLLBACK, SAVEPOINT, START TRANSACTION

7.1.43 CALL

Invokes a procedure.

Synopsis

```
CALL <name> ( [ <argument> ] [, ...] )
```

Description

`CALL` executes a procedure.

If the procedure has any output parameters, then a result row will be returned, containing the values of those parameters.

Parameters

name The name (optionally schema-qualified) of the procedure.

argument An input argument for the procedure call.

Notes

The user must have `EXECUTE` privilege on the procedure in order to be allowed to invoke it.

To call a function (not a procedure), use SELECT instead.

If `CALL` is invoked in a transaction block, then the called procedure cannot run transaction control statements. Transaction control statements are only allowed if `CALL` is invoked in its own transaction.

PL/pgSQL handles output parameters in `CALL` commands differently; refer to Calling a Procedure in the PostgreSQL documentation for more information.

Examples

```
CALL do_db_maintenance();
```

Compatibility

`CALL` conforms to the SQL standard.

See Also

CREATE PROCEDURE

Parent topic: SQL Commands

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.1.44 CHECKPOINT

Forces a write-ahead log checkpoint.

Synopsis

```
CHECKPOINT
```

Description

A checkpoint is a point in the write-ahead log sequence at which all data files have been updated to reflect the information in the log. All data files will be flushed to disk.

The `CHECKPOINT` command forces an immediate checkpoint when the command is issued, without waiting for a regular checkpoint scheduled by the system. `CHECKPOINT` is not intended for use during normal operation.

If run during recovery, the `CHECKPOINT` command will force a restartpoint rather than writing a new checkpoint.

Only superusers may call `CHECKPOINT`.

Compatibility

The `CHECKPOINT` command is a WarehousePG extension.

Parent topic: SQL Commands

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.1.45 CLOSE

Closes a cursor.

Synopsis

```
CLOSE { <cursor_name> | ALL }
```

Description

`CLOSE` frees the resources associated with an open cursor. After the cursor is closed, no subsequent operations are allowed on it. A cursor should be closed when it is no longer needed.

Every non-holdable open cursor is implicitly closed when a transaction is terminated by `COMMIT` or `ROLLBACK`. A holdable cursor is implicitly closed if the transaction that created it is prematurely ended via `ROLLBACK`. If the creating transaction successfully commits, the holdable cursor remains open until an explicit `CLOSE` is run, or the client disconnects.

Parameters

cursor_name The name of an open cursor to close.

ALL Close all open cursors.

Notes

WarehousePG does not have an explicit `OPEN` cursor statement. A cursor is considered open when it is declared. Use theDECLARE statement to declare (and open) a cursor.

You can see all available cursors by querying the pg_cursors system view.

If a cursor is closed after a savepoint which is later rolled back, the `CLOSE` is not rolled back; that is, the cursor remains closed.

Examples

Close the cursor `portala`:

```
CLOSE portala;
```

Compatibility

`CLOSE` is fully conforming with the SQL standard. `CLOSE ALL` is a WarehousePG extension.

DECLARE, FETCH, MOVE, RETRIEVE

Parent topic: SQL Commands

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.1.46 CLUSTER

Physically reorders a table on disk according to an index.

Synopsis

```
CLUSTER <indexname> ON <table_name>

CLUSTER [VERBOSE] <table_name> [ USING <index_name> ]

CLUSTER [VERBOSE]
```

Description

`CLUSTER` instructs WarehousePG to order the table specified by `<table_name>` based on the index specified by `<index_name>`. The index must already have been defined on `<table_name>`.

WarehousePG supports `CLUSTER` operations on append-optimized tables only for B-tree indexes.

> **Note** WarehousePG 7 does not support `CLUSTER`ing a partitioned table.

When a table is clustered, it is physically reordered on disk based on the index information. Clustering is a one-time operation: when the table is subsequently updated, the changes are not clustered. That is, no attempt is made to store new or updated rows according to their index order. If you wish, you can periodically recluster by issuing the command again. Setting the table's `FILLFACTOR` storage parameter to less than 100% can aid in preserving cluster ordering during updates, because updated rows are kept on the same page if enough space is available there.

When a table is clustered using this command, WarehousePG remembers on which index it was clustered. The form `CLUSTER <table_name>` reclusters the table on the same index that it was clustered before. You can use the `CLUSTER` or `SET WITHOUT CLUSTER` forms of ALTER TABLE to set the index to use for future cluster operations, or to clear any previous setting. `CLUSTER` without any parameter reclusters all previously clustered tables in the current database that the calling user owns, or all tables if called by a superuser. This form of `CLUSTER` cannot be run inside a transaction block.

When a table is being clustered, an `ACCESS EXCLUSIVE` lock is acquired on it. This prevents any other database operations (both reads and writes) from operating on the table until the `CLUSTER` is finished.

Parameters

index_name The name of an index.

`VERBOSE` Prints a progress report as each table is clustered.

table_name The name (optionally schema-qualified) of a table.

Notes

If the records you need are distributed randomly on disk, then the database has to seek across the disk to get the records requested. If those records are stored more closely together, then the fetching from disk is more sequential. In cases where you are accessing single rows randomly within a table, the actual order of the data in the table is unimportant. However, if you tend to access some data more than others, and there is an index that groups them together, you will benefit from using `CLUSTER`. If you are requesting a range of indexed values from a table, or a single indexed value that has multiple rows that match, `CLUSTER` will help because once the index identifies the table page for the first row that matches, all other rows that match are probably already on the same table page, and so you save disk accesses and speed up the query. A good example for a clustered index is on a date column where the data is ordered sequentially by date. A query against a specific date range will result in an ordered fetch from the disk, which leverages faster sequential access.

`CLUSTER` can re-sort the table using either an index scan on the specified index, or (if the index is a b-tree) a sequential scan followed by sorting. It will attempt to choose the method that will be faster, based on planner cost parameters and available statistical information.

When an index scan is used, a temporary copy of the table is created that contains the table data in the index order. Temporary copies of each index on the table are created as well. Therefore, you need free space on disk at least equal to the sum of the table size and the index sizes.

When a sequential scan and sort is used, a temporary sort file is also created, so that the peak temporary space requirement is as much as double the table size, plus the index sizes. This method is often faster than the index scan method, but if the disk space requirement is intolerable, you can deactivate this choice by temporarily setting the enable_sort configuration parameter to `off`.

It is advisable to set the maintenance_work_mem configuration parameter to a reasonably large value (but not more than the amount of RAM you can dedicate to the `CLUSTER` operation) before clustering.

Because the query optimizer records statistics about the ordering of tables, it is advisable to run ANALYZE on the newly clustered table. Otherwise, the planner may make poor query plan choices.

Because `CLUSTER` remembers which indexes are clustered, you can cluster the tables you want clustered manually the first time, then set up a periodic maintenance script that runs `CLUSTER` without any parameters, so that the desired tables are periodically reclustered.

Examples

Cluster the table `employees` on the basis of its index `emp_ind`:

```
CLUSTER emp_ind ON emp;
```

Cluster the `employees` table using the same index that was used before:

```
CLUSTER employees;
```

Cluster all tables in the database that have previously been clustered:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
CLUSTER;
```

Compatibility

There is no `CLUSTER` statement in the SQL standard.

where <aggregate_signature> is:

* |
[ <argmode> ] [ <argname> ] <argtype> [ , ... ] |
[ [ <argmode> ] [ <argname> ] <argtype> [ , ... ] ] ORDER BY [ <argmode> ] [ <argname> ] <argtype> [ , ... ]
```

Description

`COMMENT` stores a comment about a database object. Only one comment string is stored for each object, so to modify a comment, issue a new `COMMENT` command for the same object. To remove a comment, specify `NULL` in place of the text string. Comments are automatically dropped when the object is dropped.

WarehousePG acquires a `SHARE UPDATE EXCLUSIVE` lock on the object to be commented.

For most kinds of object, only the object's owner can set the comment. Roles don't have owners, so the rule for `COMMENT ON ROLE` is that you must be superuser to comment on a superuser role, or have the `CREATEROLE` privilege to comment on non-superuser roles. Likewise, access methods don't have owners either; you must be superuser to comment on an access method. Of course, a superuser can comment on anything.

You can view comments using the `psql` meta-commands `\dd`, `\d+`, and `\l+`. Other user interfaces to retrieve comments can be built atop the same built-in functions that `psql` uses, namely `obj_description()`, `col_description()`, and `shobj_description()`.

Parameters

object_name relation_name.column_name aggregate_name constraint_name function_name operator_name policy_name procedure_name routine_name rule_name trigger_name The name of the object to be commented. Names of tables, aggregates, collations, conversions, domains, foreign tables, functions, indexes, operators, operator classes, operator families, procedures, routines, sequences, statistics, text search objects, types, views, and materialized views can be schema-qualified. When commenting on a column, relation_name must refer to a table, view, materialized view, composite type, or foreign table.

```
> **Note** WarehousePG does not support triggers.
```

table_name domain_name When creating a comment on a constraint, a trigger, a rule, or a policy, these parameters specify the name of the table or domain on which that object is defined.

source_type The name of the source data type of the cast.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

target_type The name of the target data type of the cast.

argmode The mode of a function or aggregate argument: either `IN`, `OUT`, `INOUT`, or `VARIADIC`. If omitted, the default is `IN`. Note that `COMMENT` does not actually pay any attention to `OUT` arguments, since only the input arguments are needed to determine the function's identity. It is sufficient to list the `IN`, `INOUT`, and `VARIADIC` arguments.

argname The name of a function, procedure, or aggregate argument. Note that `COMMENT` does not actually pay any attention to argument names, since only the argument data types are needed to determine the function's identity.

argtype The data type of a function, procedure, or aggregate argument.

left_type right_type The data type(s) of the operator's arguments (optionally schema-qualified). Specify `NONE` for the missing argument of a prefix or postfix operator.

PROCEDURAL WarehousePG ignores this noise word.

type_name The name of the data type of the transform.

lang_name The name of the language of the transform.

string_literal The new comment contents, written as a string literal.

NULL Specify `NULL` to drop the comment.

Notes

There is presently no security mechanism for viewing comments: any user connected to a database can see all of the comments for objects in that database. For shared objects such as databases, roles, and tablespaces, comments are stored globally so any user connected to any database in the cluster can see all the comments for shared objects.

> **Caution** Do not put security-critical information in comments.

Examples

Attach a comment to the table `mytable`:

```
COMMENT ON TABLE mytable IS 'This is my table.';
```

Remove it again:

```
COMMENT ON TABLE mytable IS NULL;
```

More examples:

```
COMMENT ON ACCESS METHOD gin IS 'GIN index access method';
COMMENT ON AGGREGATE my_aggregate (double precision) IS 'Computes sample variance';
COMMENT ON CAST (text AS int4) IS 'Allow casts from text to int4';
COMMENT ON COLLATION "fr_CA" IS 'Canadian French';
COMMENT ON COLUMN my_table.my_column IS 'Employee ID number';
COMMENT ON CONVERSION my_conv IS 'Conversion to UTF8';
COMMENT ON CONSTRAINT bar_col_cons ON bar IS 'Constrains column col';
COMMENT ON CONSTRAINT dom_col_constr ON DOMAIN dom IS 'Constrains col of domain';
COMMENT ON DATABASE my_database IS 'Development Database';
COMMENT ON DOMAIN my_domain IS 'Email Address Domain';
COMMENT ON EVENT TRIGGER cancel_ddl IS 'Cancels all DLL commands';
COMMENT ON EXTENSION hstore IS 'implements the hstore data type';
COMMENT ON FOREIGN DATA WRAPPER mywrapper IS 'my foreign data wrapper';
COMMENT ON FOREIGN TABLE my_foreign_table IS 'Employee Information in other database';
COMMENT ON FUNCTION my_function (timestamp) IS 'Returns Roman Numeral';
COMMENT ON INDEX my_index IS 'Enforces uniqueness on employee ID';
COMMENT ON LANGUAGE plpython IS 'Python support for stored procedures';
COMMENT ON MATERIALIZED VIEW my_matview IS 'Summary of order history';
COMMENT ON OPERATOR ^ (text, text) IS 'Performs intersection of two texts';
COMMENT ON OPERATOR - (NONE, integer) IS 'Unary minus';
COMMENT ON OPERATOR CLASS int4_ops USING btree IS '4 byte integer operators for btrees';
COMMENT ON OPERATOR FAMILY integer_ops USING btree IS 'all integer operators for btrees';
COMMENT ON POLICY my_policy ON mytable IS 'Filter rows by users';
COMMENT ON PROCEDURE my_proc (integer, integer) IS 'Runs a report';
COMMENT ON ROLE my_role IS 'Administration group for finance tables';
COMMENT ON ROUTINE my_routine (integer, integer) IS 'Runs a routine (which is a function or procedure)';
COMMENT ON RULE my_rule ON my_table IS 'Logs updates of employee records';
COMMENT ON SCHEMA my_schema IS 'Departmental data';
COMMENT ON SEQUENCE my_sequence IS 'Used to generate primary keys';
COMMENT ON SERVER myserver IS 'my foreign server';
COMMENT ON STATISTICS my_statistics IS 'Improves planner row estimations';
COMMENT ON TABLE my_schema.my_table IS 'Employee Information';
COMMENT ON TABLESPACE my_tablespace IS 'Tablespace for indexes';
COMMENT ON TEXT SEARCH CONFIGURATION my_config IS 'Special word filtering';
COMMENT ON TEXT SEARCH DICTIONARY swedish IS 'Snowball stemmer for Swedish language';
COMMENT ON TEXT SEARCH PARSER my_parser IS 'Splits text into words';
COMMENT ON TEXT SEARCH TEMPLATE snowball IS 'Snowball stemmer';
COMMENT ON TRANSFORM FOR hstore LANGUAGE plpythonu IS 'Transform between hstore and Python dict';
COMMENT ON TRIGGER my_trigger ON my_table IS 'Used for RI';
COMMENT ON TYPE complex IS 'Complex number data type';
COMMENT ON VIEW my_view IS 'View of departmental costs';
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Compatibility

There is no `COMMENT` command in the SQL standard.

Parent topic: SQL Commands

7.1.48 COMMIT

Commits the current transaction.

Synopsis

```
COMMIT [WORK | TRANSACTION] [AND [NO] CHAIN]
```

Description

`COMMIT` commits the current transaction. All changes made by the transaction become visible to others and are guaranteed to be durable if a crash occurs.

Parameters

WORK TRANSACTION Optional key words. They have no effect.

AND CHAIN If `AND CHAIN` is specified, a new transaction is immediately started with the same transaction characteristics (see SET TRANSACTION) as the just finished one. Otherwise, no new transaction is started.

Notes

Use ROLLBACK to prematurely end a transaction.

Issuing `COMMIT` when not inside a transaction does no harm, but it will provoke a warning message. `COMMIT AND CHAIN` when not inside a transaction is an error.

Examples

To commit the current transaction and make all changes permanent:

```
COMMIT;
```

Compatibility

The command `COMMIT` conforms to the SQL standard. The form `COMMIT TRANSACTION` is a WarehousePG extension.

7.1.49 COPY

Copies data between a file and a table.

Synopsis

```
COPY <table_name> [(<column_name> [, ...])]
     FROM {'<filename>' | PROGRAM '<command>' | STDIN}
     [ [ WITH ] ( <option> [, ...] ) ]
     [ WHERE <condition> ]
     [ ON SEGMENT ]

COPY { <table_name> [(<column_name> [, ...])] | (<query>)}
     TO {'<filename>' | PROGRAM '<command>' | STDOUT}
     [ [ WITH ] ( <option> [, ...] ) ]
     [ ON SEGMENT ]

where <option> can be one of:

FORMAT <format_name>
FREEZE [ <boolean> ]
DELIMITER '<delimiter_character>'
NULL '<null_string>'
HEADER [ <boolean> ]
QUOTE '<quote_character>'
ESCAPE '<escape_character>'
FORCE_QUOTE { ( <column_name> [, ...] ) | * }
FORCE_NOT_NULL ( <column_name> [, ...] )
FORCE_NULL ( <column_name> [, ...] )
ENCODING '<encoding_name>'
FILL MISSING FIELDS
LOG ERRORS [ SEGMENT REJECT LIMIT <count> [ ROWS | PERCENT ] ]
IGNORE EXTERNAL PARTITIONS
```

Description

`COPY` moves data between WarehousePG tables and standard file-system files. `COPY TO` copies the contents of a table *to* a file (or multiple files based on the segment ID if copying `ON SEGMENT`), while `COPY FROM` copies data *from* a file to a table (appending the data to whatever is in the table already). `COPY TO` can also copy the results of a `SELECT` query.

If a list of columns is specified, `COPY TO` copies only the data in the specified columns to the file. For COPY FROM, each field in the file is inserted, in order, into the specified column. Table columns not specified in the `COPY FROM` column list will receive their default values.

`COPY` with a file name instructs the WarehousePG coordinator host to directly read from or write to a file. The file must be accessible by the operating system user running WarehousePG (typically `gpadmin`) on the coordinator host and the name must be specified from the viewpoint of the server. When `PROGRAM` is specified, the server runs the given command and reads from the standard output of the program, or writes to the standard input of the program. The command must be specified from the viewpoint of the server, and be executable by the `gpadmin` user. When `STDIN` or `STDOUT` is specified, data is transmitted via the connection between the client and the coordinator. `STDIN` and `STDOUT` cannot be used with the `ON SEGMENT` clause.

When `COPY` is used with the `ON SEGMENT` clause, the `COPY TO` causes segments to create individual segment-oriented files, which remain on the segment hosts. The filename argument for `ON SEGMENT` takes the string literal `<SEGID>` (required) and uses either the absolute path or the `<SEG_DATA_DIR>` string literal. When the `COPY` operation is run, the segment IDs and the paths of the segment data directories are substituted for the string literal values.

Using `COPY TO` with a replicated table (`DISTRIBUTED REPLICATED`) as source creates a file with rows from a single segment so that the target file contains no duplicate rows. Using `COPY TO` with the `ON SEGMENT` clause with a replicated table as source creates target files on segment hosts containing all table rows.

The `ON SEGMENT` clause allows you to copy table data to files on segment hosts for use in operations such as migrating data between clusters or performing a backup. Segment data created by the `ON SEGMENT` clause can be restored by tools such as `gpfdist`, which is useful for high speed data loading.

> **Caution** Use of the `ON SEGMENT` clause is recommended for expert users only.

If `SEGMENT REJECT LIMIT` is provided, then a `COPY FROM` operation will operate in single row error isolation mode. In this release, single row error isolation mode only applies to rows in the input file with format errors — for example, extra or missing attributes, attributes of a wrong data type, or invalid client encoding sequences. Constraint errors such as violation of a `NOT NULL`, `CHECK`, or `UNIQUE` constraint will still be handled in 'all-or-nothing' input mode. The user can specify the number of error rows acceptable (on a per-segment basis), after which the entire `COPY FROM` operation will be cancelled and no rows will be loaded. The count of error rows is per-segment, not per entire load operation. If the per-segment reject limit is not reached, then all rows not containing an error will be loaded and any error rows discarded. To keep error rows for further examination, specify the `LOG ERRORS` clause to capture error log information. The error information and the row is stored internally in WarehousePG.

Parameters

table_name The name (optionally schema-qualified) of an existing table.

column_name An optional list of columns to be copied. If no column list is specified, all columns of the table except generated columns will be copied.

When copying in text format, the default, a row of data in a column of type `bytea` can be up to 256MB.

query A SELECT, VALUES, INSERT, UPDATE, or DELETE command whose results are to be copied. Note that parentheses are required around the query. For `INSERT`, `UPDATE`, and `DELETE` queries a `RETURNING` clause must be provided, and the target relation must not have a conditional rule, nor an `ALSO` rule, nor an `INSTEAD` rule that expands to multiple statements.

filename The path name of the input or output file. An input file name can be an absolute or relative path, but an output file name must be an absolute path. Windows users might need to use an `E''` string and double any backslashes used in the path name.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

PROGRAM 'command' Specify a command to run. In `COPY FROM`, the input is read from standard output of the command, and in `COPY TO`, the output is written to the standard input of the command. The command must be specified from the viewpoint of the WarehousePG coordinator host system, and must be executable by the WarehousePG administrator operating system user (`gpadmin`).

The command is invoked by a shell. When passing arguments to the shell command that come from an untrusted source, strip or escape any special characters that have a special meaning for the shell. For security reasons, it is best to use a fixed command string, or at least avoid passing any user input in the string.

When `ON SEGMENT` is specified, the command must be executable on all WarehousePG primary segment hosts by the WarehousePG administrator user (`gpadmin`). The command is run by each WarehousePG segment instance. The `<SEGID>` is required in the command.

See the `ON SEGMENT` clause for information about command syntax requirements and the data that is copied when the clause is specified.

STDIN Specifies that input comes from the client application. The `ON SEGMENT` clause is not supported with `STDIN`.

STDOUT Specifies that output goes to the client application. The `ON SEGMENT` clause is not supported with `STDOUT`.

boolean Specifies whether the selected option should be turned on or off. You can specify `TRUE`, `ON`, or `1` to enable the option, and `FALSE`, `OFF`, or `0` to deactivate it. The boolean value can also be omitted, in which case `TRUE` is assumed.

FORMAT Selects the data format to be read or written: `text`, `csv` (Comma Separated Values), or `binary`. The default is `text`. See File Formats for more information.

FREEZE Requests copying the data with rows already frozen, just as they would be after running the `VACUUM FREEZE` command. This is intended as a performance option for initial data loading. Rows will be frozen only if the table being loaded has been created or truncated in the current subtransaction, there are no cursors open, and there are no older snapshots held by this transaction. It is not currently possible to perform a `COPY FREEZE` on a partitioned table.

Note that all other sessions will immediately be able to see the data once it has been successfully loaded. This violates the normal rules of MVCC visibility and users specifying this option should be aware of the potential problems this might cause.

DELIMITER Specifies the character that separates columns within each row (line) of the file. The default is a tab character in `text` format, a comma in `CSV` format. This must be a single one-byte character. This option is not allowed when using `binary` format.

NULL Specifies the string that represents a null value. The default is `\N` (backslash-N) in `text` format, and an unquoted empty string in `CSV` format. You might prefer an empty string even in `text` format for cases where you don't want to distinguish nulls from empty strings. This option is not allowed when using `binary` format.

```
> **Note** When using `COPY FROM`, WarehousePG stores any data item that matches this string as a null value, so be sure that you use the same string that you specified in `COPY TO`.
```

HEADER Specifies that a file contains a header line with the names of each column in the file. On output, the first line contains the column names from the table, and on input, the first line is ignored. This option is allowed only when using `CSV` format.

QUOTE Specifies the quoting character to be used when a data value is quoted. The default is double-quote. This must be a single one-byte character. This option is allowed only when using `CSV` format.

ESCAPE Specifies the character that should appear before a data character that matches the `QUOTE` value. The default is the same as the `QUOTE` value (so that the quoting character is doubled if it appears in the data). This must be a single one-byte character. This option is allowed only when using `CSV` format.

FORCE_QUOTE Forces quoting to be used for all non-`NULL` values in each specified column. `NULL` output is never quoted. If `*` is specified, non-`NULL` values will be quoted in all columns. This option is allowed only in `COPY TO`, and only when using `CSV` format.

FORCE_NOT_NULL Do not match the specified columns' values against the null string. In the default case where the null string is empty, this means that empty values will be read as zero-length strings rather than nulls, even when they are not quoted. This option is allowed only in `COPY FROM`, and only when using `CSV` format.

FORCE_NULL Match the specified columns' values against the null string, even if it has been quoted, and if a match is found set the value to `NULL`. In the default case where the null string is empty, this converts a quoted empty string into `NULL`. This option is allowed only in `COPY FROM`, and only when using `CSV` format.

ENCODING 'encoding_name' Specifies that the file is encoded in the encoding_name. If this option is omitted, the current client encoding is used. See theNotes below for more details.

WHERE The optional `WHERE` clause has the general form:

```
WHERE condition
```

where condition is any expression that evaluates to a result of type `boolean`. Any row that does not satisfy this condition will not be inserted to the table. A row satisfies the condition if it returns `true` when the actual row values are substituted for any variable references. Currently, subqueries are not allowed in `WHERE` expressions, and the evaluation does not see any changes made by the `COPY` itself (this matters when the expression contains calls to `VOLATILE` functions).

ON SEGMENT Specify individual, segment data files on the segment hosts. Each file contains the table data that is managed by the primary segment instance. For example, when copying data to files from a table with a `COPY TO...ON SEGMENT` command, the command creates a file on the segment host for each segment instance on the host. Each file contains the table data that is managed by the segment instance.

The `COPY` command does not copy data from or to mirror segment instances and segment data files.

The keywords `STDIN` and `STDOUT` are not supported with `ON SEGMENT`.

The `<SEG_DATA_DIR>` and `<SEGID>` string literals are used to specify an absolute path and file name with the following syntax:

```
COPY <table> [TO|FROM] <SEG_DATA_DIR>/<gpdumpname><SEGID>_<suffix> ON SEGMENT;
```

`<SEG\_DATA\_DIR\>` The string literal representing the absolute path of the segment instance data directory for `ON SEGMENT` copying. The angle brackets (`<` and `>`) are part of the string literal used to specify the path. `COPY` replaces the string literal with the segment path(s) when `COPY` is run. An absolute path can be used in place of the `<SEG_DATA_DIR>` string literal.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
`<SEGID\>`
The string literal representing the content ID number of the segment instance to be copied when copying `ON SEGMENT`. `<SEGID>` is a required part of the file
name when `ON SEGMENT` is specified. The angle brackets are part of the string literal used to specify the file name.
With `COPY TO`, the string literal is replaced by the content ID of the segment instance when the `COPY` command is run.
With `COPY FROM`, specify the segment instance content ID in the name of the file and place that file on the segment instance host. There must be a file for each
primary segment instance on each host. When the `COPY FROM` command is run, the data is copied from the file to the segment instance.
```

When the `PROGRAM command` clause is specified, the `<SEGID>` string literal is required in the command, the `<SEG_DATA_DIR>` string literal is optional. See Examples.

For a `COPY FROM...ON SEGMENT` command, the table distribution policy is checked when data is copied into the table. By default, an error is returned if a data row violates the table distribution policy. You can deactivate the distribution policy check with the server configuration parameter `gp_enable_segment_copy_checking`. See Notes.

NEWLINE Specifies the newline used in your data files — `LF` (Line feed, 0x0A), `CR` (Carriage return, 0x0D), or `CRLF` (Carriage return plus line feed, 0x0D 0x0A). If not specified, a WarehousePG segment will detect the newline type by looking at the first row of data it receives and using the first newline type encountered.

FILL MISSING FIELDS In `COPY FROM` more for both `TEXT` and `CSV`, specifying `FILL MISSING FIELDS` will set missing trailing field values to `NULL` (instead of reporting an error) when a row of data has missing data fields at the end of a line or row. Blank rows, fields with a `NOT NULL` constraint, and trailing delimiters on a line will still report an error.

LOG ERRORS This is an optional clause that can precede a `SEGMENT REJECT LIMIT` clause to capture error log information about rows with formatting errors.

Error log information is stored internally and is accessed with the WarehousePG built-in SQL function `gp_read_error_log()`.

See Notes for information about the error log information and built-in functions for viewing and managing error log information.

SEGMENT REJECT LIMIT count [ROWS | PERCENT] Runs a `COPY FROM` operation in single row error isolation mode. If the input rows have format errors they will be discarded provided that the reject limit count is not reached on any WarehousePG segment instance during the load operation. The reject limit count can be specified as number of rows (the default) or percentage of total rows (1-100). If `PERCENT` is used, each segment starts calculating the bad row percentage only after the number of rows specified by the parameter gp_reject_percent_threshold has been processed. The default for `gp_reject_percent_threshold` is 300 rows. Constraint errors such as violation of a `NOT NULL`, `CHECK`, or `UNIQUE` constraint will still be handled in 'all-or-nothing' input mode. If the limit is not reached, all good rows will be loaded and any error rows discarded.

> **Note** WarehousePG limits the initial number of rows that can contain formatting errors if the `SEGMENT REJECT LIMIT` is not triggered first or is not specified. If the first 1000 rows are rejected, the `COPY` operation is stopped and rolled back.

The limit for the number of initial rejected rows can be changed with the WarehousePG server configuration parameter gp_initial_bad_row_limit server configuration parameter documentation for information about the parameter.

IGNORE EXTERNAL PARTITIONS When copying data from partitioned tables, data are not copied from leaf partitions that are external tables. A message is added to the log file when data are not copied.

If this clause is not specified and WarehousePG attempts to copy data from a leaf partition that is an external table, an error is returned.

See the Notes for information about specifying an SQL query to copy data from leaf child partitions that are external tables.

Outputs

On successful completion, a `COPY` command returns a command tag of the form, where `<count>` identifies the number of rows copied:

```
COPY <count>
```

`psql` prints this command tag only if the command was not `COPY ... TO STDOUT`, or the equivalent `psql` meta-command `\copy ... to stdout`. This is to prevent confusing the command tag with the data that was just printed.

If running a `COPY FROM` command in single row error isolation mode, WarehousePG returns the following notice message if any rows were not loaded due to format errors. `<count>` identifies the number of formatting errors and `<n>` identfies the minimum number of rows rejected:

```
NOTICE: found <count> data formatting errors (<n> or more input rows), rejected related input data
```

Notes

`COPY TO` can only be used with plain tables, not with external tables or views, and does not copy rows from child tables or child partitions. For example, `COPY <table> TO` copies the same rows as `SELECT * FROM ONLY <table>`. However, you can write `COPY (SELECT * FROM <viewname>) TO ...` to dump all of the rows in an inheritance hierarchy, partitioned table, or view.

Similarly, to copy data from a partitioned table with a leaf partition that is an external table, use an SQL query to select the data to copy. For example, if the table `my_sales` contains a leaf partition that is an external table, this command `COPY my_sales TO stdout` returns an error. This command sends the data to `stdout`:

```
COPY (SELECT * from my_sales ) TO stdout;
```

`COPY FROM` can be used with plain, foreign, or partitioned tables or with views that have INSTEAD OF INSERT triggers.

You must have `SELECT` privilege on the table whose values are read by `COPY TO`, and `INSERT` privilege on the table into which values are inserted by `COPY FROM`. It is sufficient to have column privileges on the columns listed in the command.

If row-level security is enabled for the table, the relevant `SELECT` policies will apply to `COPY <table> TO` statements. Currently, `COPY FROM` is not supported for tables with row-level security. Use equivalent `INSERT` statements instead.

Files named in a `COPY` command are read or written directly by the database server, not by the client application. Therefore, they must reside on or be accessible to the WarehousePG coordinator host machine, not the client. They must be accessible to and readable or writable by the WarehousePG cluster user (the user ID the server runs as), not the client. Only database superusers are permitted to name files with `COPY`, because this allows reading or writing any file that the server has privileges to access.

Do not confuse `COPY` with the `psql` instruction `\copy`. `\copy` invokes `COPY FROM STDIN` or `COPY TO STDOUT`, and then fetches/stores the data in a file accessible to the `psql` client. Thus, file accessibility and access rights depend on the client rather than the server when `\copy` is used.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Always specify the file name used in `COPY` as an absolute path. This is enforced by the server in the case of `COPY TO`, but for `COPY FROM` you do have the option of reading from a file specified by a relative path. The path will be interpreted relative to the working directory of the server process (normally the cluster's data directory), not the client's working directory

Executing a command with `PROGRAM` might be restricted by the operating system's access control mechanisms.

`COPY FROM` will invoke any triggers and check constraints on the destination table. However, it will not invoke rules. Note that in this release, violations of constraints are not evaluated for single row error isolation mode.

For identity columns, the `COPY FROM` command will always write the column values provided in the input data, like the `INSERT` option `OVERRIDING SYSTEM VALUE`.

`COPY` input and output is affected by `DateStyle`. To ensure portability to other WarehousePG installations that might use non-default `DateStyle` settings, set `DateStyle` to `ISO` before using `COPY TO`. It is also a good idea to avoid dumping data with `IntervalStyle` set to `sql_standard`, because negative interval values might be misinterpreted by a server that has a different setting for `IntervalStyle`.

Input data is interpreted according to `ENCODING` option or the current client encoding, and output data is encoded in `ENCODING` or the current client encoding, even if the data does not pass through the client but is read from or written to a file directly by the server.

By default, `COPY` stops operation at the first error. This should not lead to problems in the event of a `COPY TO`, but the target table will already have received earlier rows in a `COPY FROM`. These rows will not be visible or accessible, but they still occupy disk space. This may amount to a considerable amount of wasted disk space if the failure happened well into a large `COPY FROM` operation. You may choose to invoke `VACUUM` to recover the wasted space. Another option would be to use single row error isolation mode to filter out error rows while still loading good rows.

`FORCE_NULL` and `FORCE_NOT_NULL` can be used simultaneously on the same column. This results in converting quoted null strings to null values and unquoted null strings to empty strings.

The `BINARY` keyword causes all data to be stored/read as binary format rather than as text. It is somewhat faster than the normal text mode, but a binary-format file is less portable across machine architectures and WarehousePG versions. Also, you cannot run `COPY FROM` in single row error isolation mode if the data is in binary format.

When copying XML data from a file in text mode, the server configuration parameter xmloption affects the validation of the XML data that is copied. If the value is `content` (the default), XML data is validated as an XML content fragment. If the parameter value is `document`, XML data is validated as an XML document. If the XML data is not valid, `COPY` returns an error.

When a `COPY FROM...ON SEGMENT` command is run, the server configuration parameter gp_enable_segment_copy_checking controls whether WarehousePG checks the table distribution policy (from the table `DISTRIBUTED` clause) when data is copied into the table. The default is to check the distribution policy. An error is returned if the row of data violates the distribution policy for the segment instance.

Data from a table that is generated by a `COPY TO...ON SEGMENT` command can be used to restore table data with `COPY FROM...ON SEGMENT`. However, data restored to the segments is distributed according to the table distribution policy at the time the files were generated with the `COPY TO` command. The `COPY` command might return table distribution policy errors, if you attempt to restore table data and the table distribution policy was changed after the `COPY FROM...ON SEGMENT` was run.

> **Note** If you run `COPY FROM...ON SEGMENT` and the server configuration parameter `gp_enable_segment_copy_checking` is `false`, manual redistribution of table data might be required. See the `ALTER TABLE` clause `WITH REORGANIZE`.

When you specify the `LOG ERRORS` clause, WarehousePG captures errors that occur while reading the external table data. You can view and manage the captured error log data.

- Use the built-in SQL function `gp_read_error_log('table\_name')`. It requires `SELECT` privilege on table_name. This example displays the error log information for data loaded into table `ext_expenses` with a `COPY` command:

  ```
  SELECT * from gp_read_error_log('ext_expenses');
  ```

  For information about the error log format, see Viewing Bad Rows in the Error Log in the *WarehousePG Administrator Guide*.

  The function returns `FALSE` if table_name does not exist.

- If error log data exists for the specified table, the new error log data is appended to existing error log data. The error log information is not replicated to mirror segments.

- Use the built-in SQL function `gp_truncate_error_log('table\_name')` to delete the error log data for table_name. It requires the table owner privilege This example deletes the error log information captured when moving data into the table `ext_expenses`:

  ```
  SELECT gp_truncate_error_log('ext_expenses');
  ```

  The function returns `FALSE` if table_name does not exist.

  Specify the `*` wildcard character to delete error log information for existing tables in the current database. Specify the string `*.*` to delete all database error log information, including error log information that was not deleted due to previous database issues. If `*` is specified, database owner privilege is required. If `*.*` is specified, operating system super-user privilege is required.

When a WarehousePG user who is not a superuser runs a `COPY` command, the command can be controlled by a resource queue. The resource queue must be configured with the `ACTIVE_STATEMENTS` parameter that specifies a maximum limit on the number of queries that can be run by roles assigned to that queue. WarehousePG does not apply a cost value or memory value to a `COPY` command, resource queues with only cost or memory limits do not affect the running of `COPY` commands.

A non-superuser can run only these types of `COPY` commands:

- `COPY FROM` command where the source is `stdin`
- `COPY TO` command where the destination is `stdout`

For information about resource queues, refer to Using Resource Queues in the *WarehousePG Administrator Guide*.

File Formats

The file formats supported by `COPY` include text, CSV, and binary.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Text Format

When the `text` format is used, the data read or written is a text file with one line per table row. Columns in a row are separated by the delimiter_character (tab by default). The column values themselves are strings generated by the output function, or acceptable to the input function, of each attribute's data type. The specified null string is used in place of columns that are null. `COPY FROM` will raise an error if any line of the input file contains more or fewer columns than are expected.

Backslash characters (`\`) can be used in the `COPY` data to quote data characters that might otherwise be taken as row or column delimiters. In particular, the following characters*must* be preceded by a backslash if they appear as part of a column value: backslash itself, newline, carriage return, and the current delimiter character.

The specified null string is sent by `COPY TO` without adding any backslashes; conversely, `COPY FROM` matches the input against the null string before removing backslashes. Therefore, a null string such as `\N` cannot be confused with the actual data value `\N` (which would be represented as `\\N`).

The following special backslash sequences are recognized by `COPY FROM` :

Sequence	Represents
\b	Backspace (ASCII 8)
\f	Form feed (ASCII 12)
\n	Newline (ASCII 10)
\r	Carriage return (ASCII 13)
\t	Tab (ASCII 9)
\v	Vertical tab (ASCII 11)
\digits	Backslash followed by one to three octal digits specifies the byte with that numeric code
\xdigits	Backslash x followed by one or two hex digits specifies the byte with that numeric code

`COPY TO` will never emit an octal or hex-digits backslash sequence, but it does use the other sequences listed above for those control characters.

Any other backslashed character that is not mentioned in the above table will be taken to represent itself. However, beware of adding backslashes unnecessarily, since that might accidentally produce a string matching the end-of-data marker (`\.`) or the null string (`\N` by default). These strings will be recognized before any other backslash processing is done.

Ensure that applications generating `COPY` data convert data newlines and carriage returns to the `\n` and `\r` sequences respectively. It is currently possible to represent a data carriage return by a backslash and carriage return, and to represent a data newline by a backslash and newline. However, these representations might not be accepted in future releases, and they are also highly vulnerable to corruption if the `COPY` file is transferred across different machines (for example, from Unix to Windows or vice versa).

All backslash sequences are interpreted after encoding conversion. The bytes specified with the octal and hex-digit backslash sequences must form valid characters in the database encoding.

`COPY TO` will terminate each row with a Unix-style newline (`\n`). Servers running on Microsoft Windows instead output carriage return/newline (`\r\n`), but only for `COPY` to a server file; for consistency across platforms, `COPY TO STDOUT` always sends `\n` regardless of server platform. `COPY FROM` can handle lines ending with newlines, carriage returns, or carriage return/newlines. To reduce the risk of error due to un-backslashed newlines or carriage returns that were meant as data, `COPY FROM` issues a warning if the line endings in the input are not all alike.

To summarize, two reserved characters have special meaning to `COPY` :

- The designated delimiter character (tab by default), which is used to separate fields in the data file.
- A UNIX-style line feed (`\n` or `0x0a`), which is used to designate a new row in the data file.

By default, the escape character for a text-format file is a `\\` (backslash). If you want to use a different escape character, you can do so using the `ESCAPE` clause. Make sure to choose an escape character that is not used anywhere in your data file as an actual data value. You can also deactivate escaping in text-formatted files by using `ESCAPE 'OFF'` .

If your data contains either of these characters, you must escape the character so `COPY` treats it as data and not as a field separator or new row. The following characters must also be preceded by the escape character if they appear as part of a column value: the escape character itself, newline, carriage return, and the current delimiter character.

For example, suppose you have a table with three columns and you want to load the following three fields using `COPY` .

- percentage sign = %
- vertical bar = |
- backslash = \

Your designated delimiter_character is `|` (pipe character), and your designated escape character is `*` (asterisk). The formatted row in your data file would appear as follows:

```
percentage sign = % | vertical bar = *| | backslash = \
```

Notice how the pipe character that is part of the data has been escaped using the asterisk character (*). Also notice that we do not need to escape the backslash since we are using an alternative escape character.

CSV Format

This format option is used for importing and exporting the Comma Separated Value (CSV) file format used by many other programs, such as spreadsheets. Instead of the escaping rules used by WarehousePG standard text format, it produces and recognizes the common CSV escaping mechanism.

The values in each record are separated by the `DELIMITER` character. If the value contains the delimiter character, the `QUOTE` character, the `ESCAPE` character (which is double quote by default), the `NULL` string, a carriage return, or line feed character, then the whole value is prefixed and suffixed by the `QUOTE` character. You can also use `FORCE_QUOTE` to force quotes when outputting non- `NULL` values in specific columns.

The CSV format has no standard way to distinguish a `NULL` value from an empty string. WarehousePG `COPY` handles this by quoting. A `NULL` is output as the `NULL` parameter string and is not quoted, while a non- `NULL` value matching the `NULL` string is quoted. For example, with the default settings, a `NULL` is written as an unquoted empty string, while an empty string data value is written with double quotes (`""`). Reading values follows similar rules. You can use `FORCE_NOT_NULL` to prevent `NULL` input comparisons for specific columns. You can also use `FORCE_NULL` to convert quoted null string data values to `NULL` .

Because backslash is not a special character in the `CSV` format, `\.` , the end-of-data marker, could also appear as a data value. To avoid any misinterpretation, a `\.` data value appearing as a lone entry on a line is automatically quoted on output, and on input, if quoted, is not interpreted as the end-of-data marker. If you are loading a file created by another application that has a single unquoted column and might have a value of `\.` , you might need to quote that value in the input file.

> **Note** In `CSV` format, all characters are significant. A quoted value surrounded by white space, or any characters other than `DELIMITER` , will include those characters. This can cause errors if you import data from a system

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

> that pads CSV lines with white space out to some fixed width. If such a situation arises you might need to preprocess the CSV file to remove the trailing white space, before importing the data into WarehousePG.

`CSV` format will both recognize and produce CSV files with quoted values containing embedded carriage returns and line feeds. The files are not strictly one line per table row like text-format files.

> **Note** Many programs produce strange CSV files, so the file format is more a convention than a standard. You might encounter some files that cannot be imported using this mechanism, and `COPY` might produce files that other programs cannot process.

Binary Format

The `binary` format option causes all data to be stored/read as binary format rather than as text. It is somewhat faster than the text and `CSV` formats, but a binary-format file is less portable across machine architectures and WarehousePG versions. Also, the binary format is very data type specific; for example it will not work to output binary data from a `smallint` column and read it into an `integer` column, even though that would work fine in text format.

The binary file format consists of a file header, zero or more tuples containing the row data, and a file trailer. Headers and data are in network byte order.

File Header

The file header consists of 15 bytes of fixed fields, followed by a variable-length header extension area. The fixed fields are:

Signature 11-byte sequence `PGCOPY\\n\\377\\r\\n\\0` — note that the zero byte is a required part of the signature. (The signature is designed to allow easy identification of files that have been munged by a non-8-bit-clean transfer. This signature will be changed by end-of-line-translation filters, dropped zero bytes, dropped high bits, or parity changes.)

Flags field 32-bit integer bit mask to denote important aspects of the file format. Bits are numbered from 0 (LSB) to 31 (MSB). Note that this field is stored in network byte order (most significant byte first), as are all the integer fields used in the file format. Bits 16-31 are reserved to denote critical file format issues; a reader should cancel if it finds an unexpected bit set in this range. Bits 0-15 are reserved to signal backwards-compatible format issues; a reader should simply ignore any unexpected bits set in this range. Currently only one flag is defined, and the rest must be zero. Bit 16: 1 if data has OIDs, 0 if not. WarehousePG no longer supports OID system columns, but the format still contains the indicator.

Header extension area length 32-bit integer, length in bytes of remainder of header, not including self. Currently, this is zero, and the first tuple follows immediately. Future changes to the format might allow additional data to be present in the header. A reader should silently skip over any header extension data it does not know how to parse. The header extension area is envisioned to contain a sequence of self-identifying chunks. The flags field is not intended to tell readers what is in the extension area.

Tuples

Each tuple begins with a 16-bit integer count of the number of fields in the tuple. (All tuples in a table will have the same count, but that might not always be true.) Then, repeated for each field in the tuple, there is a 32-bit length word followed by that many bytes of field data. (The length word does not include itself, and can be zero.) As a special case, -1 indicates a NULL field value. No value bytes follow in the NULL case.

There is no alignment padding or any other extra data between fields.

All data values in a binary-format file are assumed to be in binary format (format code one). It is anticipated that a future extension may add a header field that allows per-column format codes to be specified.

If OIDs are included in the file, the OID field immediately follows the field-count word. It is a normal field except that it is not included in the field-count. Note that WarehousePG no longer supports OID system columns.

File Trailer

The file trailer consists of a 16-bit integer word containing `-1`. This is easily distinguished from a tuple's field-count word. A reader should report an error if a field-count word is neither `-1` nor the expected number of columns. This provides an extra check against somehow getting out of sync with the data.

Examples

Copy a table to the client using the vertical bar (`|`) as the field delimiter:

```
COPY country TO STDOUT (DELIMITER '|');
```

Copy data from a file into the `country` table:

```
COPY country FROM '/home/usr1/sql/country_data';
```

Copy into a file just the countries whose names start with 'A':

```
COPY (SELECT * FROM country WHERE country_name LIKE 'A%') TO '/home/usr1/sql/a_list_countries.copy';
```

To copy into a compressed file, you can pipe the output through an external compression program:

```
COPY country TO PROGRAM 'gzip > /usr1/proj/bray/sql/country_data.gz';
```

WarehousePG-specific examples START

Copy data from a file into the `sales` table using single row error isolation mode and log errors:

```
COPY sales FROM '/home/usr1/sql/sales_data' LOG ERRORS
   SEGMENT REJECT LIMIT 10 ROWS;
```

To copy segment data for later use, use the `ON SEGMENT` clause. Use of the `COPY ... TO ... ON SEGMENT` command takes the form:

```
COPY <table> TO '<SEG_DATA_DIR>/<gpdumpname><SEGID>_<suffix>' ON SEGMENT;
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

The `<SEGID>` is required. However, you can substitute an absolute path for the `<SEG_DATA_DIR>` string literal in the path.

When you pass in the string literal `<SEG_DATA_DIR>` and `<SEGID>` to `COPY`, `COPY` will fill in the appropriate values when the operation is run.

For example, if you have `mytable` with the segments and mirror segments like this:

```
contentid | dbid | file segment location
    0     |  1   | /home/usr1/data1/gpsegdir0
    0     |  3   | /home/usr1/data_mirror1/gpsegdir0
    1     |  4   | /home/usr1/data2/gpsegdir1
    1     |  2   | /home/usr1/data_mirror2/gpsegdir1
```

running the command:

```
COPY mytable TO '<SEG_DATA_DIR>/mytable_backup<SEGID>.txt' ON SEGMENT;
```

would result in the following files:

```
/home/usr1/data1/gpsegdir0/mytable_backup0.txt
/home/usr1/data2/gpsegdir1/mytable_backup1.txt
```

The content ID in the first column is the identifier inserted into the file path (for example, `gpsegdir0/mytable_backup0.txt` above) Files are created on the segment hosts, rather than on the coordinator, as they would be in a standard `COPY` operation. No data files are created for the mirror segments when using `ON SEGMENT` copying.

If an absolute path is specified, instead of `<SEG_DATA_DIR>`, such as in the statement

```
COPY mytable TO '/tmp/gpdir/mytable_backup_<SEGID>.txt' ON SEGMENT;
```

files would be placed in `/tmp/gpdir` on every segment. The `gpfdist` tool can also be used to restore data files generated with `COPY TO` with the `ON SEGMENT` option if redistribution is necessary.

> **Note** Tools such as `gpfdist` can be used to restore data. The backup/restore tools will not work with files that were manually generated with `COPY TO ON SEGMENT`.

This example uses a `SELECT` statement to copy data to files on each segment:

```
COPY (SELECT * FROM testtbl) TO '/tmp/mytst<SEGID>' ON SEGMENT;
```

This example copies the data from the `lineitem` table and uses the `PROGRAM` clause to add the data to the `/tmp/lineitem_program.csv` file with `cat` utility. The file is placed on the WarehousePG coordinator.

```
COPY lineitem TO PROGRAM 'cat > /tmp/lineitem.csv' CSV;
```

This example uses the `PROGRAM` and `ON SEGMENT` clauses to copy data to files on the segment hosts. On the segment hosts, the `COPY` command replaces `<SEGID>` with the segment content ID to create a file for each segment instance on the segment host.

```
COPY lineitem TO PROGRAM 'cat > /tmp/lineitem_program<SEGID>.csv' ON SEGMENT CSV;
```

This example uses the `PROGRAM` and `ON SEGMENT` clauses to copy data from files on the segment hosts. The `COPY` command replaces `<SEGID>` with the segment content ID when copying data from the files. On the segment hosts, there must be a file for each segment instance where the file name contains the segment content ID on the segment host.

```
COPY lineitem_4 FROM PROGRAM 'cat /tmp/lineitem_program<SEGID>.csv' ON SEGMENT CSV;
```

WarehousePG-specific examples END

Compatibility

There is no `COPY` statement in the SQL standard.

The following syntax was used in earlier versions of WarehousePG and is still supported:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
COPY <table_name> [(<column_name> [, ...])] FROM {'<filename>' | PROGRAM '<command>' | STDIN}
     [ [WITH]
       [ON SEGMENT]
       [BINARY]
       [DELIMITER [ AS ] '<delimiter_character>']
       [NULL [ AS ] '<null string>']
       [HEADER]
       [ESCAPE [ AS ] '<escape>' | 'OFF']
       [NEWLINE [ AS ] 'LF' | 'CR' | 'CRLF']
       [CSV [QUOTE [ AS ] '<quote>']
            [FORCE NOT NULL <column_name> [, ...]]
       [FILL MISSING FIELDS]
       [[LOG ERRORS]
       SEGMENT REJECT LIMIT <count> [ROWS | PERCENT] ]

COPY { <table_name> [(<column_name> [, ...])] | (<query>)} TO {'<filename>' | PROGRAM '<command>' | STDOUT}
      [ [WITH]
        [ON SEGMENT]
        [BINARY]
        [DELIMITER [ AS ] 'delimiter_character']
        [NULL [ AS ] 'null string']
        [HEADER]
        [ESCAPE [ AS ] '<escape>' | 'OFF']
        [CSV [QUOTE [ AS ] 'quote']
             [FORCE QUOTE <column_name> [, ...]] | * ]
      [IGNORE EXTERNAL PARTITIONS ]
```

Note that in this syntax, `BINARY` and `CSV` are treated as independent keywords, not as arguments of a `FORMAT` option.

7.1.50 CREATE ACCESS METHOD

Defines a new access method.

Synopsis

```
CREATE ACCESS METHOD <name>
    TYPE <access_method_type>
    HANDLER <handler_function>
```

Description

`CREATE ACCESS METHOD` creates a new access method.

The access method name must be unique within the database.

Only superusers can define new access methods.

Parameters

name The name of the access method to create.

access_method_type The type of access method to define. Only `TABLE` and `INDEX` types are supported at present.

handler_function handler_function is the name (possibly schema-qualified) of a previously registered function that represents the access method. The handler function must be declared to take a single argument of type `internal`, and its return type depends on the type of access method; for `TABLE` access methods, it must be `table_am_handler` and for `INDEX` access methods, it must be `index_am_handler`. The C-level API that the handler function must implement varies depending on the type of access method. The table access method API is described in Table Access Method Interface Definition in the PostgreSQL documentation. The index access method API is described in Index Access Method Interface Definition.

Examples

Create an index access method `heptree` with handler function `heptree_handler`:

```
CREATE ACCESS METHOD heptree TYPE INDEX HANDLER
heptree_handler;
```

Compatibility

`CREATE ACCESS METHOD` is a WarehousePG extension.

    [ , MINITCOND = <minitial_condition> ]
    [ , SORTOP = <sort_operator> ]
    [ , REPSAFE = <boolean> ]
  )
```

Description

`CREATE AGGREGATE` defines a new aggregate function. `CREATE OR REPLACE AGGREGATE` will either define a new aggregate function or replace an existing definition. Some basic and commonly-used aggregate functions such as `count()`, `min()`, `max()`, `sum()`, `avg()` and so on are already provided in WarehousePG. If you define new types or need an aggregate function not already provided, you can use `CREATE AGGREGATE` to provide the desired features.

When replacing an existing definition, the argument types, result type, and number of direct arguments may not be changed. Also, the new definition must be of the same kind (ordinary aggregate, ordered-set aggregate, or hypothetical-set aggregate) as the old one.

If a schema name is given (for example, `CREATE AGGREGATE myschema.myagg ...`) then the aggregate function is created in the specified schema. Otherwise it is created in the current schema.

An aggregate function is identified by its name and input data type(s). Two aggregate functions in the same schema can have the same name if they operate on different input types. The name and input data type(s) of an aggregate function must also be distinct from the name and input data type(s) of every ordinary function in the same schema. This behavior is identical to overloading of ordinary function names. See CREATE FUNCTION.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

A simple aggregate function is made from one or two ordinary functions; a state transition function sfunc, and an optional final calculation function ffunc.

These functions are used as follows:

```
sfunc( internal-state, next-data-values ) ---> next-internal-state
ffunc( internal-state ) ---> aggregate-value
```

WarehousePG creates a temporary variable of data type state_data_type to hold the current internal state of the aggregate function. At each input row, the aggregate argument value(s) are calculated and the state transition function is invoked with the current state value and the new argument value(s) to calculate a new internal state value. After all the rows have been processed, the final function is invoked once to calculate the aggregate's return value. If there is no final function then the ending state value is returned as-is.

An aggregate function can provide an initial condition, that is, an initial value for the internal state value. This is specified and stored in the database as a value of type `text`, but it must be a valid external representation of a constant of the state value data type. If it is not supplied then the state value starts out null.

If the state transition function is declared `STRICT`, then it cannot be called with null inputs. With such a transition function, aggregate execution behaves as follows. Rows with any null input values are ignored (the function is not called and the previous state value is retained). If the initial state value is null, then at the first row with all non-null input values, the first argument value replaces the state value, and the transition function is invoked at subsequent rows with all non-null input values. This is useful for implementing aggregates like `max()`. Note that this behavior is only available when state_data_type is the same as the first arg_data_type. When these types are different, you must supply a non-null initial condition or use a nonstrict transition function.

If the state transition function is not declared `STRICT`, then it will be called unconditionally at each input row, and must deal with null inputs and null state values for itself. This allows the aggregate author to have full control over the aggregate's handling of null values.

If the final function is declared `STRICT`, then it will not be called when the ending state value is null; instead a null result will be returned automatically. (This is the normal behavior of `STRICT` functions.) In any case the final function has the option of returning a null value. For example, the final function for `avg()` returns null when it sees there were zero input rows.

Sometimes it is useful to declare the final function as taking not just the state value, but extra parameters corresponding to the aggregate's input values. The main reason for doing this is if the final function is polymorphic and the state value's data type would be inadequate to pin down the result type. These extra parameters are always passed as `NULL` (and so the final function must not be strict when the `FINALFUNC_EXTRA` option is used), but nonetheless they are valid parameters. The final function could for example make use of `get_fn_expr_argtype` to identify the actual argument type in the current call.

An aggregate can optionally support *moving-aggregate mode*, as described in Moving-Aggregate Mode in the PostgreSQL documentation. This requires specifying the `MSFUNC`, `MINVFUNC`, and `MSTYPE` functions, and optionally the `MSSPACE`, `MFINALFUNC`, `MFINALFUNC_EXTRA`, `MFINALFUNC_MODIFY`, and `MINITCOND` functions. Except for `MINVFUNC`, these functions work like the corresponding simple-aggregate functions without `M`; they define a separate implementation of the aggregate that includes an inverse transition function.

The syntax with `ORDER BY` in the parameter list creates a special type of aggregate called an *ordered-set aggregate*; or if `HYPOTHETICAL` is specified, then a *hypothetical-set aggregate* is created. These aggregates operate over groups of sorted values in order-dependent ways, so that specification of an input sort order is an essential part of a call. Also, they can have *direct* arguments, which are arguments that are evaluated only once per aggregation rather than once per input row. Hypothetical-set aggregates are a subclass of ordered-set aggregates in which some of the direct arguments are required to match, in number and data types, the aggregated argument columns. This allows the values of those direct arguments to be added to the collection of aggregate-input rows as an additional "hypothetical" row.

An aggregate can optionally support partial aggregation. This requires specifying the `COMBINEFUNC` parameter. If the state_data_type is internal, it's usually also appropriate to provide the `SERIALFUNC` and `DESERIALFUNC` parameters so that parallel aggregation is possible. Note that the aggregate must also be marked `PARALLEL SAFE` to enable parallel aggregation.

Aggregates that behave like `min()` or `max()` can sometimes be optimized by looking into an index instead of scanning every input row. If this aggregate can be so optimized, indicate it by specifying a*sort operator*. The basic requirement is that the aggregate must yield the first element in the sort ordering induced by the operator; in other words:

```
SELECT agg(col) FROM tab;
```

must be equivalent to:

```
SELECT col FROM tab ORDER BY col USING sortop LIMIT 1;
```

Further assumptions are that the aggregate function ignores null inputs, and that it delivers a null result if and only if there were no non-null inputs. Ordinarily, a data type's `<` operator is the proper sort operator for `min()`, and `>` is the proper sort operator for `max()`. Note that the optimization will never actually take effect unless the specified operator is the "less than" or "greater than" strategy member of a B-tree index operator class.

To be able to create an aggregate function, you must have `USAGE` privilege on the argument types, the state type(s), and the return type, as well as `EXECUTE` privilege on the supporting functions.

You can specify `combinefunc` as a method for optimizing aggregate execution. By specifying `combinefunc`, the aggregate can be run in parallel on segments first and then on the coordinator. When a two-level execution is performed, the `sfunc` is run on the segments to generate partial aggregate results, and `combinefunc` is run on the coordinator to aggregate the partial results from segments. If single-level aggregation is performed, all the rows are sent to the coordinator and the `sfunc` is applied to the rows.

Single-level aggregation and two-level aggregation are equivalent execution strategies. Either type of aggregation can be implemented in a query plan. When you implement the functions `combinefunc` and `sfunc`, you must ensure that the invocation of the `sfunc` on the segment instances followed by `combinefunc` on the coordinator produce the same result as single-level aggregation that sends all the rows to the coordinator and then applies only the `sfunc` to the rows.

Parameters

name The name (optionally schema-qualified) of the aggregate function to create.

argmode The mode of an argument: `IN` or `VARIADIC`. (Aggregate functions do not support `OUT` arguments.) If omitted, the default is `IN`. Only the last argument can be marked `VARIADIC`.

argname The name of an argument. This is currently only useful for documentation purposes. If omitted, the argument has no name.

arg_data_type An input data type on which this aggregate function operates. To create a zero-argument aggregate function, write `*` in place of the list of argument specifications. (An example of such an aggregate is `count(*)`.)

base_type In the old syntax for `CREATE AGGREGATE`, the input data type is specified by a `basetype` parameter rather than being written next to the aggregate name. Note that this syntax allows only one input parameter. To define a zero-argument aggregate function with this syntax, specify the `basetype` as `"ANY"` (not `*`). Ordered-set aggregates cannot be defined with the old syntax.

sfunc The name of the state transition function to be called for each input row. For a normal N-argument aggregate function, the state transition function `sfunc` must take N+1 arguments, the first being of type state_data_type and the rest matching the declared input data type(s) of the aggregate. The function must return a value of type state_data_type. This function takes the current state value and the current input data value(s), and returns the next state value.

For ordered-set (including hypothetical-set) aggregates, the state transition function receives only the current state value and the aggregated arguments, not the direct arguments. Otherwise it is the same.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

state_data_type The data type for the aggregate's state value.

state_data_size The approximate average size (in bytes) of the aggregate's state value. If this parameter is omitted or is zero, a default estimate is used based on the state_data_type. The planner uses this value to estimate the memory required for a grouped aggregate query. The planner will consider using hash aggregation for such a query only if the hash table is estimated to fit in work_mem; therefore, large values of this parameter discourage use of hash aggregation.

ffunc The name of the final function called to compute the aggregate result after all input rows have been traversed. The function must take a single argument of type state_data_type. The return data type of the aggregate is defined as the return type of this function. If `ffunc` is not specified, then the ending state value is used as the aggregate result, and the return type is state_data_type.

For ordered-set (including hypothetical-set) aggregates, the final function receives not only the final state value, but also the values of all the direct arguments.

If `FINALFUNC_EXTRA` is specified, then in addition to the final state value and any direct arguments, the final function receives extra NULL values corresponding to the aggregate's regular (aggregated) arguments. This is mainly useful to allow correct resolution of the aggregate result type when a polymorphic aggregate is being defined.

FINALFUNC_MODIFY = { READ_ONLY | SHAREABLE | READ_WRITE } This option specifies whether the final function is a pure function that does not modify its arguments. `READ_ONLY` indicates it does not; the other two values indicate that it may change the transition state value. See Notes below for more detail. The default is `READ_ONLY`, except for ordered-set aggregates, for which the default is `READ_WRITE`.

combinefunc The combinefunc function may optionally be specified to allow the aggregate function to support partial aggregation. If provided, the combinefunc must combine two state_data_type values, each containing the result of aggregation over some subset of the input values, to produce a new state_data_type that represents the result of aggregating over both sets of inputs. This function can be thought of as an sfunc, where instead of acting upon an individual input row and adding it to the running aggregate state, it adds another aggregate state to the running state. The combinefunc must be declared as taking two arguments of the state_data_type and returning a value of the state_data_type. Optionally this function may be "strict". In this case the function will not be called when either of the input states are null; the other state will be taken as the correct result. For aggregate functions whose state_data_type is `internal`, the combinefunc must not be strict. In this case the combinefunc must ensure that null states are handled correctly and that the state being returned is properly stored in the aggregate memory context. In WarehousePG, if the result of the aggregate function is computed in a segmented fashion, the combine function is invoked on the individual internal states in order to combine them into an ending internal state. Note that this function is also called in hash aggregate mode within a segment. Therefore, if you call this aggregate function without a combine function, hash aggregate is never chosen. Since hash aggregate is efficient, consider defining a combine function whenever possible.

serialfunc An aggregate function whose state_data_type is `internal` can participate in parallel aggregation only if it has a serialfunc function, which must serialize the aggregate state into a `bytea` value for transmission to another process. This function must take a single argument of type `internal` and return type `bytea`. A corresponding deserialfunc is also required.

deserialfunc Deserialize a previously serialized aggregate state back into state_data_type. This function must take two arguments of types `bytea` and `internal`, and produce a result of type `internal`. (Note: the second, `internal` argument is unused, but is required for type safety reasons.)

initial_condition The initial setting for the state value. This must be a string constant in the form accepted for the data type state_data_type. If not specified, the state value starts out null.

msfunc The name of the forward state transition function to be called for each input row in moving-aggregate mode. This is exactly like the regular transition function, except that its first argument and result are of type mstate_data_type, which might be different from state_data_type.

minvfunc The name of the inverse state transition function to be used in moving-aggregate mode. This function has the same argument and result types as msfunc, but it is used to remove a value from the current aggregate state, rather than add a value to it. The inverse transition function must have the same strictness attribute as the forward state transition function.

mstate_data_type The data type for the aggregate's state value, when using moving-aggregate mode.

mstate_data_size The approximate average size (in bytes) of the aggregate's state value, when using moving-aggregate mode. This works the same as state_data_size.

mffunc The name of the final function called to compute the aggregate's result after all input rows have been traversed, when using moving-aggregate mode. This works the same as ffunc, except that its first argument's type is mstate_data_type and extra dummy arguments are specified by writing `MFINALFUNC_EXTRA`. The aggregate result type determined by mffunc or mstate_data_type must match that determined by the aggregate's regular implementation.

MFINALFUNC_MODIFY = { READ_ONLY | SHAREABLE | READ_WRITE } This option is like `FINALFUNC_MODIFY`, but it describes the behavior of the moving-aggregate final function.

minitial_condition The initial setting for the state value, when using moving-aggregate mode. This works the same as initial_condition.

sort_operator The associated sort operator for a `min()`- or `max()`-like aggregate. This is just an operator name (possibly schema-qualified). The operator is assumed to have the same input data types as the aggregate (which must be a single-argument normal aggregate).

PARALLEL = { SAFE | RESTRICTED | UNSAFE } The meanings of `PARALLEL SAFE`, `PARALLEL RESTRICTED`, and `PARALLEL UNSAFE` are the same as in CREATE FUNCTION. An aggregate will not be considered for parallelization if it is marked `PARALLEL UNSAFE` (which is the default!) or `PARALLEL RESTRICTED`. Note that the parallel-safety markings of the aggregate's support functions are not consulted by the planner, only the marking of the aggregate itself.

REPSAFE = boolean Specifies whether or not the aggregate can be safely executed on replicated slices. An order-agnostic aggregate would be considered safe in this context. The default value is `false`. Setting `REPSAFE = true` instructs the optimizer to perform additional optimizations that specifically suppress certain broadcast motions.

```
> **Caution** Incorrectly setting `REPSAFE = true` for an order-dependent aggregate may produce incorrect results.
```

HYPOTHETICAL For ordered-set aggregates only, this flag specifies that the aggregate arguments are to be processed according to the requirements for hypothetical-set aggregates: that is, the last few direct arguments must match the data types of the aggregated (`WITHIN GROUP`) arguments. The `HYPOTHETICAL` flag has no effect on run-time behavior, only on parse-time resolution of the data types and collations of the aggregate's arguments.

The parameters of `CREATE AGGREGATE` can be written in any order, not just the order illustrated above.

Notes

The ordinary functions used to define a new aggregate function must be defined first.

If the value of the WarehousePG server configuration parameter `gp_enable_multiphase_agg` is `off`, only single-level aggregation is performed by the Postgres-based planner. There is no equivalent parameter for GPORCA.

Any compiled code (shared library files) for custom functions must be placed in the same location on every host in your WarehousePG cluster (coordinator and all segments). This location must also be in the `LD_LIBRARY_PATH` so that the server can locate the files.

In previous versions of WarehousePG, there was a concept of ordered aggregates. Since version 6, any aggregate can be called as an ordered aggregate, using the syntax:

```
name ( arg [ , ... ] [ORDER BY sortspec [ , ...]] )
```

The `ORDERED` keyword is accepted for backwards compatibility, but is ignored.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

In previous versions of WarehousePG, the `COMBINEFUNC` option was called `PREFUNC`. It is still accepted for backwards compatibility, as a synonym for `COMBINEFUNC`.

Example

The following simple example creates an aggregate function that computes the sum of two columns.

Before creating the aggregate function, create two functions that are used as the `sfunc` and `combinefunc` functions of the aggregate function.

This function is specified as the `sfunc` function in the aggregate function.

```
CREATE FUNCTION mysfunc_accum(numeric, numeric, numeric)
  RETURNS numeric
   AS 'select $1 + $2 + $3'
   LANGUAGE SQL
   RETURNS NULL ON NULL INPUT;
```

This function is specified as the `combinefunc` function in the aggregate function.

```
CREATE FUNCTION mycombine_accum(numeric, numeric )
  RETURNS numeric
   AS 'select $1 + $2'
   LANGUAGE SQL
   RETURNS NULL ON NULL INPUT;
```

This `CREATE AGGREGATE` command creates the aggregate function that adds two columns.

```
CREATE AGGREGATE agg_twocols(numeric, numeric) (
   SFUNC = mysfunc_accum,
   STYPE = numeric,
   COMBINEFUNC = mycombine_accum,
   INITCOND = 0 );
```

The following commands create a table, adds some rows, and runs the aggregate function.

```
CREATE TABLE t1 (a int, b int) DISTRIBUTED BY (a);
INSERT INTO t1 VALUES
   (10, 1),
   (20, 2),
   (30, 3);
SELECT agg_twocols(a, b) FROM t1;
```

Refer to User-Defined Aggregates in the PostgreSQL documentation for more examples of creating aggregates.

Compatibility

`CREATE AGGREGATE` is a WarehousePG language extension. The SQL standard does not provide for user-defined aggregate functions.

7.1.52 CREATE CAST

Defines a new cast.

Synopsis

```
CREATE CAST (<sourcetype> AS <targettype>)
       WITH FUNCTION <funcname> (<argtype> [, ...])
       [AS ASSIGNMENT | AS IMPLICIT]

CREATE CAST (<sourcetype> AS <targettype>)
       WITHOUT FUNCTION
       [AS ASSIGNMENT | AS IMPLICIT]

CREATE CAST (<sourcetype> AS <targettype>)
       WITH INOUT
       [AS ASSIGNMENT | AS IMPLICIT]
```

Description

`CREATE CAST` defines a new cast. A cast specifies how to perform a conversion between two data types. For example,

```
SELECT CAST(42 AS float8);
```

converts the integer constant `42` to type `float8` by invoking a previously specified function, in this case `float8(int4)`. If no suitable cast has been defined, the conversion fails.

Two types may be binary coercible, which means that the types can be converted into one another without invoking any function. This requires that corresponding values use the same internal representation. For instance, the types `text` and `varchar` are binary coercible in both directions. Binary coercibility is not necessarily a symmetric relationship. For example, the cast from `xml` to `text` can be performed for free in the present implementation, but the reverse direction requires a function that performs at least a syntax check. (Two types that are binary coercible both ways are also referred to as binary compatible.)

You can define a cast as an *I/O conversion cast* by using the `WITH INOUT` syntax. An I/O conversion cast is performed by invoking the output function of the source data type, and passing the resulting string to the input function of the target data type. In many common cases, this feature avoids the need to write a separate cast function for conversion. An I/O conversion cast acts the same as a regular function-based cast; only the implementation is different.

By default, a cast can be invoked only by an explicit cast request, that is an explicit `CAST(x AS` typename `)` or `x:: typename` construct.

If the cast is marked `AS ASSIGNMENT` then it can be invoked implicitly when assigning a value to a column of the target data type. For example, supposing that `foo.f1` is a column of type `text`, then:

```
INSERT INTO foo (f1) VALUES (42);
```

will be allowed if the cast from type `integer` to type `text` is marked `AS ASSIGNMENT`, otherwise not. The term *assignment cast* is typically used to describe this kind of cast.

If the cast is marked `AS IMPLICIT` then it can be invoked implicitly in any context, whether assignment or internally in an expression. The term *implicit cast* is typically used to describe this kind of cast. For example, consider this query:

```
SELECT 2 + 4.0;
```

The parser initially marks the constants as being of type `integer` and `numeric`, respectively. There is no `integer + numeric` operator in the system catalogs, but there is a `numeric + numeric` operator. This query succeeds if a cast from `integer` to `numeric` exists (it does) and is marked `AS IMPLICIT`, which in fact it is. The parser applies only the implicit cast and resolves the query as if it had been written as the following:

```
SELECT CAST ( 2 AS numeric ) + 4.0;
```

The catalogs also provide a cast from `numeric` to `integer`. If that cast were marked `AS IMPLICIT`, which it is not, then the parser would be faced with choosing between the above interpretation and the alternative of casting the `numeric` constant to `integer` and applying the `integer + integer` operator. Lacking any knowledge of which choice to prefer, the parser would give up and declare the query ambiguous. The fact that only one of the two casts is implicit is the way in which we teach the parser to prefer resolution of a mixed `numeric`-and-`integer` expression as `numeric`; the parser has no built-in knowledge about that.

It is wise to be conservative about marking casts as implicit. An overabundance of implicit casting paths can cause WarehousePG to choose surprising interpretations of commands, or to be unable to resolve commands at all because there are multiple possible interpretations. A good general rule is to make a cast implicitly invokable only for information-preserving transformations between types in the same general type category. For example, the cast from `int2` to `int4` can reasonably be implicit, but the cast from `float8` to `int4` should probably be assignment-only. Cross-type-category casts, such as `text` to `int4`, are best made explicit-only.

> **Note** Sometimes it is necessary for usability or standards-compliance reasons to provide multiple implicit casts among a set of types, resulting in ambiguity that cannot be avoided as described above. The parser uses a fallback heuristic based on type categories and preferred types that helps to provide desired behavior in such cases. See CREATE TYPE for more information.

To be able to create a cast, you must own the source or the target data type and have `USAGE` privilege on the other type. To create a binary-coercible cast, you must be superuser. (This restriction is made because an erroneous binary-coercible cast conversion can easily crash the server.)

Parameters

sourcetype The name of the source data type of the cast.

targettype The name of the target data type of the cast.

funcname(argtype [, ...]) The function used to perform the cast. The function name may be schema-qualified. If it is not, WarehousePG looks for the function in the schema search path. The function's result data type must match the target type of the cast.

Cast implementation functions may have one to three arguments. The first argument type must be identical to or binary-coercible from the cast's source type. The second argument, if present, must be type `integer`; it receives the type modifier associated with the destination type, or `-1` if there is none. The third argument, if present, must be type `boolean`; it receives `true` if the cast is an explicit cast, `false` otherwise. The SQL specification demands different behaviors for explicit and implicit casts in some cases. This argument is supplied for functions that must implement such casts. It is not recommended that you design your own data types this way.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

The return type of a cast function must be identical to or binary-coercible to the cast's target type.

Ordinarily a cast must have different source and target data types. However, you are permitted to declare a cast with identical source and target types if it has a cast implementation function that takes more than one argument. This is used to represent type-specific length coercion functions in the system catalogs. The named function is used to coerce a value of the type to the type modifier value given by its second argument.

When a cast has different source and target types and a function that takes more than one argument, the cast converts from one type to another and applies a length coercion in a single step. When no such entry is available, coercion to a type that uses a type modifier involves two steps, one to convert between data types and a second to apply the modifier.

A cast to or from a domain type currently has no effect. Casting to or from a domain uses the casts associated with its underlying type.

WITHOUT FUNCTION Indicates that the source type is binary-coercible to the target type, so no function is required to perform the cast.

WITH INOUT Indicates that the cast is an I/O conversion cast, performed by invoking the output function of the source data type, and passing the resulting string to the input function of the target data type.

AS ASSIGNMENT Indicates that the cast may be invoked implicitly in assignment contexts.

AS IMPLICIT Indicates that the cast may be invoked implicitly in any context.

Notes

Note that in this release of WarehousePG, user-defined functions used in a user-defined cast must be defined as `IMMUTABLE`. Any compiled code (shared library files) for custom functions must be placed in the same location on every host in your WarehousePG cluster (coordinator and all segments). This location must also be in the `LD_LIBRARY_PATH` so that the server can locate the files.

Remember that if you want to be able to convert types both ways you need to declare casts both ways explicitly.

It is normally not necessary to create casts between user-defined types and the standard string types (`text`, `varchar`, and `char(*n*)`, as well as user-defined types that are defined to be in the string category). WarehousePG provides automatic I/O conversion casts for these. The automatic casts to string types are treated as assignment casts, while the automatic casts from string types are explicit-only. You can override this behavior by declaring your own cast to replace an automatic cast, but usually the only reason to do so is if you want the conversion to be more easily invokable than the standard assignment-only or explicit-only setting. Another possible reason is that you want the conversion to behave differently from the type's I/O function - think twice before doing this. (A small number of the built-in types do indeed have different behaviors for conversions, mostly because of requirements of the SQL standard.)

It is recommended that you follow the convention of naming cast implementation functions after the target data type, as the built-in cast implementation functions are named. Many users are used to being able to cast data types using a function-style notation, that is `typename(x)`.

There are two cases in which a function-call construct is treated as a cast request without having matched it to an actual function. If a function call `*name\(x\)*` does not exactly match any existing function, but `*name*` is the name of a data type and `pg_cast` provides a binary-coercible cast to this type from the type of `*x*`, then the call will be construed as a binary-coercible cast. WarehousePG makes this exception so that binary-coercible casts can be invoked using functional syntax, even though they lack any function. Likewise, if there is no `pg_cast` entry but the cast would be to or from a string type, the call is construed as an I/O conversion cast. This exception allows I/O conversion casts to be invoked using functional syntax.

There is an exception to the exception above: I/O conversion casts from composite types to string types cannot be invoked using functional syntax, but must be written in explicit cast syntax (either `CAST` or :: notation). This exception exists because after the introduction of automatically-provided I/O conversion casts, it was found to be too easy to accidentally invoke such a cast when you intended a function or column reference.

Examples

To create an assignment cast from type `bigint` to type `int4` using the function `int4(bigint)` (This cast is already predefined in the system.):

```
CREATE CAST (bigint AS int4) WITH FUNCTION int4(bigint) AS ASSIGNMENT;
```

Compatibility

The `CREATE CAST` command conforms to the SQL standard, except that SQL does not make provisions for binary-coercible types or extra arguments to implementation functions. `AS IMPLICIT` is a WarehousePG extension, too.

7.1.53 CREATE COLLATION

Defines a new collation.

Synopsis

```
CREATE COLLATION [ IF NOT EXISTS ] <name> (
    [ LOCALE = <locale>, ]
    [ LC_COLLATE = <lc_collate>, ]
    [ LC_CTYPE = <lc_ctype>, ]
    [ PROVIDER = <provider>, ]
    [ DETERMINISTIC = <boolean>, ]
    [ VERSION = <version> ])

CREATE COLLATION [ IF NOT EXISTS ] <name> FROM <existing_collation>
```

Description

`CREATE COLLATION` defines a new collation using the specified operating system locale settings, or by copying an existing collation.

To be able to create a collation, you must have `CREATE` privilege on the destination schema.

Parameters

IF NOT EXISTS Do not throw an error if a collation with the same name already exists. A notice is issued in this case. Note that there is no guarantee that the existing collation is anything like the one that would have been created.

name The name of the collation. The collation name can be schema-qualified. If it is not, the collation is defined in the current schema. The collation name must be unique within that schema. (The system catalogs can contain collations with the same name for other encodings, but these are ignored if the database encoding does not match.)

locale This is a shortcut for setting `LC_COLLATE` and `LC_CTYPE` at once. If you specify this, you cannot specify either of those parameters.

lc_collate Use the specified operating system locale for the `LC_COLLATE` locale category.

lc_ctype Use the specified operating system locale for the `LC_CTYPE` locale category.

provider Specifies the provider to use for locale services associated with this collation. Possible values are: `icu` , `libc` . `libc` is the default. The available choices depend on the operating system and build options.

DETERMINISTIC Specifies whether the collation should use deterministic comparisons. The default is `true` . A deterministic comparison considers strings that are not byte-wise equal to be unequal even if they are considered logically equal by the comparison. WarehousePG breaks ties using a byte-wise comparison. Comparison that is not deterministic can make the collation be, say, case- or accent-insensitive. For that, you need to choose an appropriate `LC_COLLATE` setting and set the collation to not deterministic here. Nondeterministic collations are only supported with the `icu` provider.

version Specifies the version string to store with the collation. Normally, this should be omitted, which will cause the version to be computed from the actual version of the collation as provided by the operating system. This option is intended to be used by `pg_upgrade` for copying the version from an existing installation. See also ALTER COLLATION for how to handle collation version mismatches.

existing_collation The name of an existing collation to copy. The new collation will have the same properties as the existing one, but it will be an independent object.

Notes

`CREATE COLLATION` takes a `SHARE ROW EXCLUSIVE` lock, which is self-conflicting, on the `pg_collation` system catalog, so only one `CREATE COLLATION` command can run at a time.

Use DROP COLLATION to remove user-defined collations.

See Collation Support in the PostgreSQL documentation for more information about collation support in WarehousePG.

When using the `libc` collation provider, the, locale must be applicable to the current database encoding. See CREATE DATABASE for the precise rules.

Examples

To create a collation from the operating system locale `fr_FR.utf8` (assuming the current database encoding is `UTF8`):

```
CREATE COLLATION french (LOCALE = 'fr_FR.utf8');
```

To create a collation using the `icu` provider using German phone book sort order:

```
CREATE COLLATION german_phonebook (provider = icu, locale = 'de-u-co-phonebk');
```

To create a collation from an existing collation:

```
CREATE COLLATION german FROM "de_DE";
```

This can be convenient to be able to use operating-system-independent collation names in applications.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Compatibility

There is a `CREATE COLLATION` statement in the SQL standard, but it is limited to copying an existing collation. The syntax to create a new collation is a WarehousePG extension.

See Also

ALTER COLLATION, DROP COLLATION

Parent topic: SQL Commands

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.1.54 CREATE CONVERSION

Defines a new encoding conversion.

Synopsis

```
CREATE [DEFAULT] CONVERSION <name>
     FOR <source_encoding> TO <dest_encoding> FROM <function_name>
```

Description

`CREATE CONVERSION` defines a new conversion between character set encodings. Also, conversions that are marked `DEFAULT` can be used for automatic encoding conversion between client and server. For this purpose, two conversions, from encoding A to B *and* from encoding B to A, must be defined.

To create a conversion, you must have `EXECUTE` privilege on the function and `CREATE` privilege on the destination schema.

Parameters

DEFAULT Indicates that this conversion is the default for this particular source to destination encoding. There should be only one default encoding in a schema for the encoding pair.

name The name of the conversion. The conversion name may be schema-qualified. If it is not, the conversion is defined in the current schema. The conversion name must be unique within a schema.

source_encoding The source encoding name.

dest_encoding The destination encoding name.

function_name The function used to perform the conversion. The function name may be schema-qualified. If it is not, the function will be looked up in the path. The function must have the following signature:

```
conv_proc(
    integer,  -- source encoding ID
    integer,  -- destination encoding ID
    cstring,  -- source string (null terminated C string)
    internal, -- destination (fill with a null terminated C string)
    integer   -- source string length
) RETURNS void;
```

Notes

Use DROP CONVERSION to remove a user-defined conversion.

The privileges required to create a conversion might change in a feature release.

Note that in this release of WarehousePG, user-defined functions used in a user-defined conversion must be defined as `IMMUTABLE`. Any compiled code (shared library files) for custom functions must be placed in the same location on every host in your WarehousePG cluster (coordinator and all segments). This location must also be in the `LD_LIBRARY_PATH` so that the server can locate the files.

Examples

To create a conversion from encoding `UTF8` to `LATIN1` using `myfunc`:

```
CREATE CONVERSION myconv FOR 'UTF8' TO 'LATIN1' FROM myfunc;
```

Compatibility

`CREATE CONVERSION` is a WarehousePG extension. There is no `CREATE CONVERSION` statement in the SQL standard, but there is a `CREATE TRANSLATION` statement that is very similar in purpose and syntax.

See Also

ALTER CONVERSION, CREATE FUNCTION, DROP CONVERSION

Parent topic: SQL Commands

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.1.55 CREATE DATABASE

Creates a new database.

Synopsis

```
CREATE DATABASE name
    [ [WITH] [OWNER [=] <user_name>]
          [TEMPLATE [=] <template>]
          [ENCODING [=] <encoding>]
          [LC_COLLATE [=] <lc_collate>]
          [LC_CTYPE [=] <lc_ctype>]
          [TABLESPACE [=] <tablespace_name>]
          [ALLOW_CONNECTIONS [=] <allowconn>]
          [CONNECTION LIMIT [=] <connlimit> ]
          [IS_TEMPLATE [=] <istemplate> ] ]
```

Description

`CREATE DATABASE` creates a new database.

To create a database, you must be a superuser or have the special `CREATEDB` privilege. See CREATE ROLE.

The creator becomes the owner of the new database by default. Superusers can create databases owned by other users by using the `OWNER` clause. They can even create databases owned by users with no special privileges. Non-superusers with `CREATEDB` privilege can only create databases owned by themselves.

By default, the new database will be created by cloning the standard system database `template1`. A different template can be specified by writing `TEMPLATE name`. In particular, by writing `TEMPLATE template0`, you can create a clean database containing only the standard objects predefined by WarehousePG. This is useful if you wish to avoid copying any installation-local objects that may have been added to `template1`.

Parameters

name The name of a database to create.

user_name The name of the database user who will own the new database, or `DEFAULT` to use the default owner (the user running the command). To create a database owned by another role, you must be a direct or indirect member of that role, or be a superuser.

template The name of the template from which to create the new database, or `DEFAULT` to use the default template (template1).

encoding Character set encoding to use in the new database. Specify a string constant (such as `'SQL_ASCII'`), an integer encoding number, or `DEFAULT` to use the default encoding (namely, the encoding of the template database). For more information, see Character Set Support. Refer to the Notes for additional restrictions.

lc_collate The collation order (`LC_COLLATE`) to use in the new database. This affects the sort order applied to strings, e.g. in queries with `ORDER BY`, as well as the order used in indexes on text columns. The default is to use the collation order of the template database. See the Notes for additional restrictions.

lc_ctype The character classification (`LC_CTYPE`) to use in the new database. This affects the categorization of characters, e.g. lower, upper, and digit. The default is to use the character classification of the template database. See the Notes for additional restrictions.

tablespace_name The name of the tablespace that will be associated with the new database, or `DEFAULT` to use the template database's tablespace. This tablespace will be the default tablespace used for objects created in this database. See CREATE TABLESPACE for more information.

allowconn If `false`, then no one can connect to this database. The default is `true`, allowing connections (except as restricted by other mechanisms, such as `GRANT/REVOKE CONNECT`).

connlimit The maximum number of concurrent connections allowed to this database on the coordinator. The default is `-1`, no limit. WarehousePG superusers are exempt from this limit.

istemplate If `true`, then this database can be cloned by any user with `CREATEDB` privileges; if `false` (the default), then only superusers or the owner of the database can clone it. Note that template databases cannot be dropped.

Optional parameters can be written in any order, not only the order illustrated above.

Notes

`CREATE DATABASE` cannot be run inside a transaction block.

Errors along the line of “could not initialize database directory” are most likely related to insufficient permissions on the data directory, a full disk, or other file system problems.

Use DROP DATABASE to remove a database.

The program createdb is a wrapper program around this command, provided for convenience.

Database-level configuration parameters (set via ALTER DATABASE and database-level permissions (set via GRANT) are not copied from the template database.

Although it is possible to copy a database other than `template1` by specifying its name as the template, this is not (yet) intended as a general-purpose `“COPY DATABASE”` facility. The principal limitation is that no other sessions can be connected to the template database while it is being copied. `CREATE DATABASE` will fail if any other connection exists when it starts; otherwise, new connections to the template database are locked out until `CREATE DATABASE` completes.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

The character set encoding specified for the new database must be compatible with the chosen locale settings (`LC_COLLATE` and `LC_CTYPE`). If the locale is `C` (or equivalently `POSIX`), then all encodings are allowed, but for other locale settings there is only one encoding that will work properly. `CREATE DATABASE` will allow superusers to specify `SQL_ASCII` encoding regardless of the locale settings, but this choice is deprecated and may result in misbehavior of character-string functions if data that is not encoding-compatible with the locale is stored in the database.

The encoding and locale settings must match those of the template database, except when `template0` is used as template. This is because other databases might contain data that does not match the specified encoding, or might contain indexes whose ordering is affected by `LC_COLLATE` and `LC_CTYPE`. Copying such data would result in a database that is corrupt according to the new settings. `template0`, however, is known to not contain any data or indexes that would be affected.

The `CONNECTION LIMIT` option is enforced approximately; if two new sessions start at about the same time when just one connection "slot" remains for the database, it is possible that both will fail. Also, the limit is not enforced against superusers or background worker processes.

Examples

To create a new database:

```
CREATE DATABASE gpdb;
```

To create a database `sales` owned by user `salesapp` with a default tablespace of `salesspace`:

```
CREATE DATABASE sales OWNER salesapp TABLESPACE salesspace;
```

To create a database `music` with a different locale:

```
CREATE DATABASE music
    LC_COLLATE 'sv_SE.utf8' LC_CTYPE 'sv_SE.utf8'
    TEMPLATE template0;
```

In this example, the `TEMPLATE template0` clause is required if the specialized locale is different from the one in `template1`. (If it is not, then specifying the locale explicitly is redundant.)

To create a database `music2` with a different locale and a different character set encoding:

```
CREATE DATABASE music2
    LC_COLLATE 'sv_SE.iso885915' LC_CTYPE 'sv_SE.iso885915'
    ENCODING LATIN9
    TEMPLATE template0;
```

The specified locale and encoding settings must match, or an error will be reported.

Note that locale names are specific to the operating system, so that the above commands might not work in the same way everywhere.

Compatibility

There is no `CREATE DATABASE` statement in the SQL standard. Databases are equivalent to catalogs, whose creation is implementation-defined.

7.1.56 CREATE DOMAIN

Defines a new domain.

Synopsis

```
CREATE DOMAIN <name> [AS] <data_type>
       [ COLLATE <collation> ]
       [ DEFAULT <expression> ]
       [ <constraint> [ ... ] ]

where <constraint> is:

[ CONSTRAINT <constraint_name> ]
{ NOT NULL | NULL | CHECK (<expression>)  }
```

Description

`CREATE DOMAIN` creates a new domain. A domain is essentially a data type with optional constraints (restrictions on the allowed set of values). The user who defines a domain becomes its owner.

If a schema name is given (for example, `CREATE DOMAIN myschema.mydomain ...`) then the domain is created in the specified schema. Otherwise it is created in the current schema. The domain name must be unique among the data types and domains existing in its schema.

Domains are useful for abstracting common constraints on fields into a single location for maintenance. For example, several tables might contain email address columns, all requiring the same `CHECK` constraint to verify the address syntax. Define a domain rather than setting up each table's constraint individually.

To be able to create a domain, you must have `USAGE` privilege on the underlying type.

Parameters

name The name (optionally schema-qualified) of a domain to be created.

data_type The underlying data type of the domain. This may include array specifiers.

collation An optional collation for the domain. If no collation is specified, the domain has the same collation behavior as its underlying data type. The underlying type must be collatable if `COLLATE` is specified.

DEFAULT expression Specifies a default value for columns of the domain data type. The value is any variable-free expression (but subqueries are not allowed). The data type of the default expression must match the data type of the domain. If no default value is specified, then the default value is the null value. The default expression will be used in any insert operation that does not specify a value for the column. If a default value is defined for a particular column, it overrides any default associated with the domain. In turn, the domain default overrides any default value associated with the underlying data type.

CONSTRAINT constraint_name An optional name for a constraint. If not specified, the system generates a name.

NOT NULL Values of this domain are prevented from being null (but see the Notes below).

NULL Values of this domain are allowed to be null. This is the default. This clause is only intended for compatibility with nonstandard SQL databases. Its use is discouraged in new applications.

CHECK (expression) `CHECK` clauses specify integrity constraints or tests which values of the domain must satisfy. Each constraint must be an expression producing a Boolean result. It should use the key word `VALUE` to refer to the value being tested. Expressions evaluating to TRUE or UNKNOWN succeed. If the expression produces a FALSE result, an error is reported and the value is not allowed to be converted to the domain type. Currently, `CHECK` expressions cannot contain subqueries nor refer to variables other than `VALUE`. When a domain has multiple `CHECK` constraints, they will be tested in alphabetical order by name. (WarehousePG versions before 7.0 did not honor any particular firing order for `CHECK` constraints.)

Notes

Domain constraints, particularly `NOT NULL`, are checked when converting a value to the domain type. It is possible for a column that is nominally of the domain type to read as null despite there being such a constraint. For example, this can happen in an outer-join query, if the domain column is on the nullable side of the outer join. A more subtle example is:

```
INSERT INTO tab (domcol) VALUES ((SELECT domcol FROM tab WHERE false));
```

The empty scalar sub-SELECT will produce a null value that is considered to be of the domain type, so no further constraint checking is applied to it, and the insertion will succeed.

It is very difficult to avoid such problems, because of SQL's general assumption that a null value is a valid value of every data type. Best practice therefore is to design a domain's constraints so that a null value is allowed, and then to apply column `NOT NULL` constraints to columns of the domain type as needed, rather than directly to the domain type.

Greeplum Database assumes that `CHECK` constraints' conditions are immutable, that is, they will always give the same result for the same input value. This assumption is what justifies examining `CHECK` constraints only when a value is first converted to be of a domain type, and not at other times. (This is essentially the same as the treatment of table `CHECK` constraints.)

An example of a common way to break this assumption is to reference a user-defined function in a `CHECK` expression, and then change the behavior of that function. WarehousePG does not disallow that, but it will not notice if there are stored values of the domain type that now violate the `CHECK` constraint. That would cause a subsequent database dump and restore to fail. The recommended way to handle such a change is to drop the constraint (using `ALTER DOMAIN`), adjust the function definition, and re-add the constraint, thereby rechecking it against stored data.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Examples

This example creates the `us_postal_code` data type and then uses the type in a table definition. A regular expression test is used to verify that the value looks like a valid US postal code.

```
CREATE DOMAIN us_postal_code AS TEXT
CHECK(
   VALUE ~ '^\d{5}$'
OR VALUE ~ '^\d{5}-\d{4}$'
);

CREATE TABLE us_snail_addy (
  address_id SERIAL PRIMARY KEY,
  street1 TEXT NOT NULL,
  street2 TEXT,
  street3 TEXT,
  city TEXT NOT NULL,
  postal us_postal_code NOT NULL
);
```

Compatibility

`CREATE DOMAIN` conforms to the SQL standard.

7.1.57 CREATE EXTENSION

Registers an extension in a WarehousePG.

Synopsis

```
CREATE EXTENSION [ IF NOT EXISTS ] <extension_name>
  [ WITH ] [ SCHEMA <schema_name> ]
           [ VERSION <version> ]
           [ FROM <old_version> ]
           [ CASCADE ]
```

Description

`CREATE EXTENSION` loads a new extension into the current database. There must not be an extension of the same name already loaded.

Loading an extension essentially amounts to running the extension script file. The script typically creates new SQL objects such as functions, data types, operators, and index support methods. `CREATE EXTENSION` additionally records the identities of all of the created objects, so that they can be dropped again if `DROP EXTENSION` is issued.

Loading an extension requires the same privileges that would be required to create its component objects. For most extensions this means superuser or database owner privileges are required. The user who runs `CREATE EXTENSION` becomes the owner of the extension for purposes of later privilege checks, as well as the owner of any objects created by the extension script.

Parameters

IF NOT EXISTS Do not throw an error if an extension with the same name already exists. WarehousePG issues a notice in this case. Note that there is no guarantee that the existing extension is anything like the one that would have been created from the currently-available script file.

extension_name The name of the extension to be installed. WarehousePG will create the extension using details from the file `SHAREDIR/extension/<extension_name>.control`. `SHAREDIR` is the installation shared-data directory, for example `/usr/edb/whpg7/share/postgresql`. The command `pg_config --sharedir` displays the directory.

schema_name The name of the schema in which to install the extension objects, given that the extension allows its contents to be relocated. The named schema must already exist. If not specified, and the extension's control file does not specify a schema either, the current default object creation schema is used. If the extension specifies a schema parameter in its control file, then that schema cannot be overridden with a `SCHEMA` clause. Normally, an error is raised if a `SCHEMA` clause is given and it conflicts with the extension's `schema` parameter. However, if the `CASCADE` clause is also given, then schema_name is ignored when it conflicts. The given schema_name is used for installation of any needed extensions that do not a specify schema in their control files. Remember that the extension itself is not considered to be within any schema: extensions have unqualified names that must be unique database-wide. But objects belonging to the extension can be within schemas.

version The version of the extension to install. This can be written as either an identifier or a string literal. The default version is whatever is specified in the extension's control file.

old_version Specify `FROM old_version` only if you are attempting to install an extension that replaces an *old-style* module that is a collection of objects that is not packaged into an extension. This option causes `CREATE EXTENSION` to run an alternative installation script that absorbs the existing objects into the extension, instead of creating new objects. Ensure that `SCHEMA` specifies the schema containing these pre-existing objects. The value to use for old_version is determined by the extension's author, and might vary if there is more than one version of the old-style module that can be upgraded into an extension.

CASCADE Automatically install any extensions that this extension depends on that are not already installed. Dependent extensions are checked recursively and those dependencies are also installed automatically. If the `SCHEMA` clause is specified, the schema applies to the extension and all dependent extensions that are installed. Other options that are specified are not applied to the automatically-installed dependent extensions; in particular, their default versions are always selected.

Notes

Before you can use `CREATE EXTENSION` to load an extension into a database, the extension's supporting files must be installed. The supporting files must be installed in the same location on all WarehousePG hosts. For information about creating new extensions, see the PostgreSQL Packaging Related Objects into an Extension documentation.

The extensions currently available for loading can be identified from the pg_available_extensions or pg_available_extension_versions system views.

> **Note:** Installing an extension as superuser requires trusting that the extension's author wrote the extension installation script in a secure fashion. It is not terribly difficult for a malicious user to create trojan-horse objects that will compromise later execution of a carelessly-written extension script, allowing that user to acquire superuser privileges. However, trojan-horse objects are only hazardous if they are in the `search_path` during script execution, meaning that they are in the extension's installation target schema or in the schema of some extension it depends on. Therefore, a good rule of thumb when dealing with extensions whose scripts have not been carefully vetted is to install them only into schemas for which `CREATE` privilege has not been and will not be granted to any untrusted users. Likewise for any extensions they depend on.
>
> The extensions supplied with WarehousePG are believed to be secure against installation-time attacks of this sort, except for a few that depend on other extensions. As stated in the documentation for those extensions, they should be installed into secure schemas, or installed into the same schemas as the extensions they depend on, or both.

Examples

Install the `hstore` extension into the current database, placing its objects in schema `addons`:

```
CREATE EXTENSION hstore SCHEMA addons;
```

Another way to accomplish the same thing:

```
SET search_path = addons;
CREATE EXTENSION hstore;
```

    [ DISTRIBUTED BY ({<column> [<opclass>]}, [ ... ] ) | DISTRIBUTED RANDOMLY ]
```

Description

`CREATE EXTERNAL TABLE` or `CREATE EXTERNAL WEB TABLE` creates a new readable external table definition in WarehousePG. Readable external tables are typically used for fast, parallel data loading. Once an external table is defined, you can query its data directly (and in parallel) using SQL commands. For example, you can select, join, or sort external table data. You can also create views for external tables. DML operations (`UPDATE`, `INSERT`, `DELETE`, or `TRUNCATE`) are not allowed on readable external tables, and you cannot create indexes on readable external tables.

`CREATE WRITABLE EXTERNAL TABLE` or `CREATE WRITABLE EXTERNAL WEB TABLE` creates a new writable external table definition in WarehousePG. Writable external tables are typically used for unloading data from the database into a set of files or named pipes. Writable external web tables can also be used to output data to an executable program. Once a writable external table is defined, data can be selected from database tables and inserted into the writable external table. Writable external tables only allow `INSERT` operations – `SELECT`, `UPDATE`, `DELETE` or `TRUNCATE` are not allowed.

The main difference between regular external tables and external web tables is their data sources. Regular readable external tables access static flat files, whereas external web tables access dynamic data sources – either on a web server or by running OS commands or scripts.

See Working with External Data for detailed information about working with external tables.

Parameters

READABLE | WRITABLE

Specifies the type of external table, readable being the default. Readable external tables are used for loading data into WarehousePG. Writable external tables are used for unloading data.

WEB

Creates a readable or writable external web table definition in WarehousePG. There are two forms of readable external web tables – those that access files via the `http://` protocol or those that access data by running OS commands. Writable external web tables output data to an executable program that can accept an input stream of data. External web tables are not rescannable during query execution.

The `s3` protocol does not support external web tables. You can, however, create an external web table that runs a third-party tool to read data from or write data to S3 directly.

TEMPORARY | TEMP

If specified, creates a temporary readable or writable external table definition in WarehousePG. Temporary external tables exist in a special schema; you cannot specify a schema name when you create the table. Temporary external tables are automatically dropped at the end of a session.

An existing permanent table with the same name is not visible to the current session while the temporary table exists, unless you reference the permanent table with its schema-qualified name.

table_name

The name of the new external table.

column_name

The name of a column to create in the external table definition. Unlike regular tables, external tables do not have column constraints or default values, so do not specify those.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

LIKE other_table

The `LIKE` clause specifies a table from which the new external table automatically copies all column names, data types and WarehousePG distribution policy. If the original table specifies any column constraints or default column values, those will not be copied over to the new external table definition.

data_type

The data type of the column.

LOCATION ('protocol://[host[:port]]/path/file' [, ...])

If you use the `pxf` protocol to access an external data source, refer to pxf:// Protocol for information about the `pxf` protocol.

If you use the `s3` protocol to read or write to S3, refer to s3:// Protocol for additional information about the `s3` protocol `LOCATION` clause syntax.

For readable external tables, specifies the URI of the external data source(s) to be used to populate the external table or web table. Regular readable external tables allow the `gpfdist` or `file` protocols. External web tables allow the `http` protocol. If `port` is omitted, port `8080` is assumed for `http` and `gpfdist` protocols. If using the `gpfdist` protocol, the `path` is relative to the directory from which `gpfdist` is serving files (the directory specified when you started the `gpfdist` program). Also, `gpfdist` can use wildcards or other C-style pattern matching (for example, a whitespace character is `[[:space:]]`) to denote multiple files in a directory. For example:

```
'gpfdist://filehost:8081/*'
'gpfdist://coordinatorhost/my_load_file'
'file://seghost1/dbfast1/external/myfile.txt'
'http://intranet.example.com/finance/expenses.csv'
```

For writable external tables, specifies the URI location of the `gpfdist` process or S3 protocol that will collect data output from the WarehousePG segments and write it to one or more named files. For `gpfdist` the `path` is relative to the directory from which `gpfdist` is serving files (the directory specified when you started the `gpfdist` program). If multiple `gpfdist` locations are listed, the segments sending data will be evenly divided across the available output locations. For example:

```
'gpfdist://outputhost:8081/data1.out',
'gpfdist://outputhost:8081/data2.out'
```

With two `gpfdist` locations listed as in the above example, half of the segments would send their output data to the `data1.out` file and the other half to the `data2.out` file.

With the option `#transform=trans_name`, you can specify a transform to apply when loading or extracting data. The trans_name is the name of the transform in the YAML configuration file you specify with the you run the `gpfdist` utility. For information about specifying a transform, see gpfdist in the *WarehousePG Utility Guide*.

ON COORDINATOR

Restricts all table-related operations to the WarehousePG coordinator segment. Permitted only on readable and writable external tables created with the `s3` or custom protocols. The `gpfdist`, `gpfdists`, `pxf`, and `file` protocols do not support `ON COORDINATOR`.

> **Note**
>
> Be aware of potential resource impacts when reading from or writing to external tables you create with the `ON COORDINATOR` clause. You may encounter performance issues when you restrict table operations solely to the WarehousePG coordinator segment.

EXECUTE 'command' [ON ...]

Allowed for readable external web tables or writable external tables only. For readable external web tables, specifies the OS command to be run by the segment instances. The command can be a single OS command or a script. The `ON` clause is used to specify which segment instances will run the given command.

- ON ALL is the default. The command will be run by every active (primary) segment instance on all segment hosts in the WarehousePG cluster. If the command runs a script, that script must reside in the same location on all of the segment hosts and be executable by the WarehousePG superuser (`gpadmin`).
- ON COORDINATOR runs the command on the coordinator host only.

  > **Note**
  >
  > Logging is not supported for external web tables when the `ON COORDINATOR` clause is specified.

- ON number means the command will be run by the specified number of segments. The particular segments are chosen randomly at runtime by the WarehousePG cluster. If the command runs a script, that script must reside in the same location on all of the segment hosts and be executable by the WarehousePG superuser (`gpadmin`).
- HOST means the command will be run by one segment on each segment host (once per segment host), regardless of the number of active segment instances per host.
- HOST segment_hostname means the command will be run by all active (primary) segment instances on the specified segment host.
- SEGMENT segment_id means the command will be run only once by the specified segment. You can determine a segment instance's ID by looking at the content number in the system catalog tablegp_segment_configuration. The content ID of the WarehousePG coordinator is always `-1`.

For writable external tables, the command specified in the `EXECUTE` clause must be prepared to have data piped into it. Since all segments that have data to send will write their output to the specified command or program, the only available option for the `ON` clause is `ON ALL`.

FORMAT 'TEXT | CSV' (options)

When the `FORMAT` clause identfies delimited text (`TEXT`) or comma separated values (`CSV`) format, formatting options are similar to those available with the PostgreSQL COPY command. If the data in the file does not use the default column delimiter, escape character, null string and so on, you must specify the additional formatting options so that the data in the external file is read correctly by WarehousePG. For information about using a custom format, see Loading and Unloading Data in the *WarehousePG Administrator Guide*.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

If you use the `pxf` protocol to access an external data source, refer to Accessing External Data with PXF for information about using PXF.

FORMAT 'CUSTOM' (formatter=formatter_specification)

Specifies a custom data format. The formatter_specification specifies the function to use to format the data, followed by comma-separated parameters to the formatter function. The length of the formatter specification, the string including `Formatter=`, can be up to approximately 50K bytes.

If you use the `pxf` protocol to access an external data source, refer to Accessing External Data with PXF for information about using PXF.

For general information about using a custom format, see "Loading and Unloading Data" in the *WarehousePG Administrator Guide*.

DELIMITER

Specifies a single ASCII character that separates columns within each row (line) of data. The default is a tab character in `TEXT` mode, a comma in `CSV` mode. In `TEXT` mode for readable external tables, the delimiter can be set to `OFF` for special use cases in which unstructured data is loaded into a single-column table.

For the `s3` protocol, the delimiter cannot be a newline character (`\n`) or a carriage return character (`\r`).

NULL

Specifies the string that represents a `NULL` value. The default is `\N` (backslash-N) in `TEXT` mode, and an empty value with no quotations in `CSV` mode. You might prefer an empty string even in `TEXT` mode for cases where you do not want to distinguish `NULL` values from empty strings. When using external and web tables, any data item that matches this string will be considered a `NULL` value.

As an example for the `text` format, this `FORMAT` clause can be used to specify that the string of two single quotes (`''`) is a `NULL` value.

```
FORMAT 'text' (delimiter ',' null '\'\'\'\'' )
```

ESCAPE

Specifies the single character that is used for C escape sequences (such as `\n`, `\t`, `\100`, and so on) and for escaping data characters that might otherwise be taken as row or column delimiters. Make sure to choose an escape character that is not used anywhere in your actual column data. The default escape character is a `\` (backslash) for text-formatted files and a `"` (double quote) for csv-formatted files, however it is possible to specify another character to represent an escape. It is also possible to deactivate escaping in text-formatted files by specifying the value `'OFF'` as the escape value. This is very useful for data such as text-formatted web log data that has many embedded backslashes that are not intended to be escapes.

NEWLINE

Specifies the newline used in your data files – `LF` (Line feed, 0x0A), `CR` (Carriage return, 0x0D), or `CRLF` (Carriage return plus line feed, 0x0D 0x0A). If not specified, a WarehousePG segment will detect the newline type by looking at the first row of data it receives and using the first newline type encountered.

HEADER

For readable external tables, specifies that the first line in the data file(s) is a header row (contains the names of the table columns) and should not be included as data for the table. If using multiple data source files, all files must have a header row.

For the `s3` protocol, the column names in the header row cannot contain a newline character (`\n`) or a carriage return (`\r`).

The `pxf` protocol does not support the `HEADER` formatting option.

QUOTE

Specifies the quotation character for `CSV` mode. The default is double-quote (`"`).

FORCE NOT NULL

In `CSV` mode, processes each specified column as though it were quoted and hence not a `NULL` value. For the default null string in `CSV` mode (nothing between two delimiters), this causes missing values to be evaluated as zero-length strings.

FORCE QUOTE

In `CSV` mode for writable external tables, forces quoting to be used for all non-`NULL` values in each specified column. If `*` is specified then non-`NULL` values will be quoted in all columns. `NULL` output is never quoted.

FILL MISSING FIELDS

In both `TEXT` and `CSV` mode for readable external tables, specifying `FILL MISSING FIELDS` will set missing trailing field values to `NULL` (instead of reporting an error) when a row of data has missing data fields at the end of a line or row. Blank rows, fields with a `NOT NULL` constraint, and trailing delimiters on a line will still report an error.

OPTIONS key 'value'[, key' value' ...]

Optional. Specifies parameters and values as key-value pairs that are set to a custom data access protocol when the protocol is used as a external table protocol for an external table. It is the responsibility of the custom data access protocol to process and validate the key-value pairs.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

ENCODING 'encoding'

Character set encoding to use for the external table. Specify a string constant (such as `'SQL_ASCII'`), an integer encoding number, or `DEFAULT` to use the default server encoding. See Character Set Support.

LOG ERRORS [PERSISTENTLY]

This is an optional clause that can precede a `SEGMENT REJECT LIMIT` clause to log information about rows with formatting errors. The error log data is stored internally. If error log data exists for a specified external table, new data is appended to existing error log data. The error log data is not replicated to mirror segments.

The data is deleted when the external table is dropped unless you specify the keyword `PERSISTENTLY`. If the keyword is specified, the log data persists after the external table is dropped.

The error log data is accessed with the WarehousePG built-in SQL function `gp_read_error_log()`, or with the SQL function `gp_read_persistent_error_log()` if the `PERSISTENTLY` keyword is specified.

If you use the `PERSISTENTLY` keyword, you must install the functions that manage the persistent error log information.

See Notes for information about the error log information and built-in functions for viewing and managing error log information.

SEGMENT REJECT LIMIT count [ROWS | PERCENT]

Runs a `COPY FROM` operation in single row error isolation mode. If the input rows have format errors they will be discarded provided that the reject limit count is not reached on any WarehousePG segment instance during the load operation. The reject limit count can be specified as number of rows (the default) or percentage of total rows (1-100). If `PERCENT` is used, each segment starts calculating the bad row percentage only after the number of rows specified by the parameter `gp_reject_percent_threshold` has been processed. The default for `gp_reject_percent_threshold` is 300 rows. Constraint errors such as violation of a `NOT NULL`, `CHECK`, or `UNIQUE` constraint will still be handled in "all-or-nothing" input mode. If the limit is not reached, all good rows will be loaded and any error rows discarded.

> **Note**
>
> When reading an external table, WarehousePG limits the initial number of rows that can contain formatting errors if the `SEGMENT REJECT LIMIT` is not triggered first or is not specified. If the first 1000 rows are rejected, the `COPY` operation is stopped and rolled back.

You can change the limit for the number of initial rejected rows with the WarehousePG server configuration parameter gp_initial_bad_row_limit.

```
DISTRIBUTED BY \(\{column \[opclass\]\}, \[ ... \] \)
DISTRIBUTED RANDOMLY
```

Used to declare the WarehousePG distribution policy for a writable external table. By default, writable external tables are distributed randomly. If the source table you are exporting data from has a hash distribution policy, defining the same distribution key column(s) and operator class(es), `oplcass`, for the writable external table will improve unload performance by eliminating the need to move rows over the interconnect. When you issue an unload command such as `INSERT INTO wex_table SELECT * FROM source_table`, the rows that are unloaded can be sent directly from the segments to the output location if the two tables have the same hash distribution policy.

Examples

Start the `gpfdist` file server program in the background on port `8081` serving files from directory `/var/data/staging`:

```
gpfdist -p 8081 -d /var/data/staging -l /home/<gpadmin>/log &
```

Create a readable external table named `ext_customer` using the `gpfdist` protocol and any text formatted files (`*.txt`) found in the `gpfdist` directory. The files are formatted with a pipe (`|`) as the column delimiter and an empty space as `NULL`. Also access the external table in single row error isolation mode:

```
CREATE EXTERNAL TABLE ext_customer
   (id int, name text, sponsor text)
   LOCATION ( 'gpfdist://filehost:8081/*.txt' )
   FORMAT 'TEXT' ( DELIMITER '|' NULL ' ')
   LOG ERRORS SEGMENT REJECT LIMIT 5;
```

Create the same readable external table definition as above, but with CSV formatted files:

```
CREATE EXTERNAL TABLE ext_customer
   (id int, name text, sponsor text)
   LOCATION ( 'gpfdist://filehost:8081/*.csv' )
   FORMAT 'CSV' ( DELIMITER ',' );
```

Create a readable external table named `ext_expenses` using the `file` protocol and several CSV formatted files that have a header row:

```
CREATE EXTERNAL TABLE ext_expenses (name text, date date,
amount float4, category text, description text)
LOCATION (
'file://seghost1/dbfast/external/expenses1.csv',
'file://seghost1/dbfast/external/expenses2.csv',
'file://seghost2/dbfast/external/expenses3.csv',
'file://seghost2/dbfast/external/expenses4.csv',
'file://seghost3/dbfast/external/expenses5.csv',
'file://seghost3/dbfast/external/expenses6.csv'
)
FORMAT 'CSV' ( HEADER );
```

Create a readable external web table that runs a script once per segment host:

```
CREATE EXTERNAL WEB TABLE log_output (linenum int, message
text)  EXECUTE '/var/load_scripts/get_log_data.sh' ON HOST
 FORMAT 'TEXT' (DELIMITER '|');
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Create a writable external table named `sales_out` that uses `gpfdist` to write output data to a file named `sales.out`. The files are formatted with a pipe (`|`) as the column delimiter and an empty space as `NULL`.

```
CREATE WRITABLE EXTERNAL TABLE sales_out (LIKE sales)
   LOCATION ('gpfdist://etl1:8081/sales.out')
   FORMAT 'TEXT' ( DELIMITER '|' NULL ' ')
   DISTRIBUTED BY (txn_id);
```

Create a writable external web table that pipes output data received by the segments to an executable script named `to_adreport_etl.sh`:

```
CREATE WRITABLE EXTERNAL WEB TABLE campaign_out
(LIKE campaign)
 EXECUTE '/var/unload_scripts/to_adreport_etl.sh'
 FORMAT 'TEXT' (DELIMITER '|');
```

Use the writable external table defined above to unload selected data:

```
INSERT INTO campaign_out SELECT * FROM campaign WHERE customer_id=123;
```

Notes

When you specify the `LOG ERRORS` clause, WarehousePG captures errors that occur while reading the external table data. For information about the error log format, see Viewing Bad Rows in the Error Log.

You can view and manage the captured error log data. The functions to manage log data depend on whether the data is persistent (the `PERSISTENTLY` keyword is used with the `LOG ERRORS` clause).

- Functions that manage non-persistent error log data from external tables that were defined without the `PERSISTENTLY` keyword.
    - The built-in SQL function `gp_read_error_log('table_name')` displays error log information for an external table. This example displays the error log data from the external table `ext_expenses`.

      ```
      SELECT * from gp_read_error_log('ext_expenses');
      ```

      The function returns no data if you created the external table with the `LOG ERRORS PERSISTENTLY` clause, or if the external table does not exist.
    - The built-in SQL function `gp_truncate_error_log('table_name')` deletes the error log data for table_name. This example deletes the error log data captured from the external table `ext_expenses`:

      ```
      SELECT gp_truncate_error_log('ext_expenses');
      ```

      Dropping the table also deletes the table's log data. The function does not truncate log data if the external table is defined with the `LOG ERRORS PERSISTENTLY` clause.

      The function returns `FALSE` if the table does not exist.
- Functions that manage persistent error log data from external tables that were defined with the `PERSISTENTLY` keyword.
    - The SQL function `gp_read_persistent_error_log('table_name')` displays persistent log data for an external table.

      The function returns no data if you created the external table without the `PERSISTENTLY` keyword. The function returns persistent log data for an external table even after the table has been dropped.
    - The SQL function `gp_truncate_persistent_error_log('table_name')` truncates persistent log data for a table.

      For persistent log data, you must manually delete the data. Dropping the external table does not delete persistent log data.
- These items apply to both non-persistent and persistent error log data and the related functions.
    - The `gp_read_*` functions require `SELECT` privilege on the table.
    - The `gp_truncate_*` functions require owner privilege on the table.
    - You can use the `*` wildcard character to delete error log information for existing tables in the current database. Specify the string `*.*` to delete all database error log information, including error log information that was not deleted due to previous database issues. If `*` is specified, database owner privilege is required. If `*.*` is specified, operating system super-user privilege is required. Non-persistent and persistent error log data must be deleted with their respective `gp_truncate_*` functions.

When multiple WarehousePG external tables are defined with the `gpfdist`, `gpfdists`, or `file` protocol and access the same named pipe a Linux system, WarehousePG restricts access to the named pipe to a single reader. An error is returned if a second reader attempts to access the named pipe.

Compatibility

`CREATE EXTERNAL TABLE` is a WarehousePG extension. The SQL standard makes no provisions for external tables.

7.1.59 CREATE FOREIGN DATA WRAPPER

Defines a new foreign-data wrapper.

Synopsis

```
CREATE FOREIGN DATA WRAPPER <name>
    [ HANDLER <handler_function> | NO HANDLER ]
    [ VALIDATOR <validator_function> | NO VALIDATOR ]
    [ OPTIONS ( [ mpp_execute { 'coordinator' | 'any' | 'all segments' } [, ] ] <option> '<value>' [, ... ] ) ]
```

Description

`CREATE FOREIGN DATA WRAPPER` creates a new foreign-data wrapper in the current database. The user who defines the foreign-data wrapper becomes its owner.

The foreign-data wrapper name must be unique within the database.

Only superusers can create foreign-data wrappers.

Parameters

name The name of the foreign-data wrapper to create. The name must be unique within the database.

HANDLER handler_function The name of a previously registered function that WarehousePG calls to retrieve the execution functions for foreign tables. hander_function must take no arguments, and its return type must be `fdw_handler`. It is possible to create a foreign-data wrapper with no handler function, but you can only declare, not access, foreign tables using such a wrapper.

VALIDATOR validator_function The name of a previously registered function that WarehousePG calls to check the generic options provided to the foreign-data wrapper. This function also checks the options for foreign servers, user mappings, and foreign tables that use the foreign-data wrapper. If no validator function or `NO VALIDATOR` is specified, WarehousePG does not check options at creation time. (Depending upon the implementation, foreign-data wrappers may ignore or reject invalid options at runtime.) validator_function must take two arguments: one of type `text[]`, which contains the array of options as stored in the system catalogs, and one of type `oid`, which identifies the OID of the system catalog containing the options. The return type is ignored; validator_function should report invalid options using the `ereport(ERROR)` function.

OPTIONS (option 'value' [, ...]) The options for the new foreign-data wrapper. Option names must be unique. The option names and values are foreign-data wrapper-specific and are validated using the foreign-data wrappers' validator_function.

mpp_execute { 'coordinator' | 'any' | 'all segments' } A WarehousePG-specific option that identifies the host from which the foreign-data wrapper reads or writes data:

```
-   `coordinator` \(the default\)—Read or write data from the coordinator host.
-   `any`—Read data from either the coordinator host or any one segment, depending on which path costs less.
-   `all segments`—Read or write data from all segments. To support this option value, the foreign-data wrapper must have a policy that matches the segments to
data.

> **Note** WarehousePG supports parallel writes to foreign tables only when you set `mpp_execute 'all segments'`.

Support for the foreign-data wrapper `mpp_execute` option, and the specific modes, is foreign-data wrapper-specific.

The `mpp_execute` option can be specified in multiple commands: `CREATE FOREIGN TABLE`, `CREATE SERVER`, and `CREATE FOREIGN DATA WRAPPER`. The foreign table
setting takes precedence over the foreign server setting, followed by the foreign-data wrapper setting.
```

Notes

The foreign-data wrapper functionality is still under development. Optimization of queries is primitive (and mostly left to the wrapper).

Examples

Create a useless foreign-data wrapper named `dummy`:

```
CREATE FOREIGN DATA WRAPPER dummy;
```

Create a foreign-data wrapper named `file` with a handler function named `file_fdw_handler`:

```
CREATE FOREIGN DATA WRAPPER file HANDLER file_fdw_handler;
```

Create a foreign-data wrapper named `mywrapper` that includes an option:

```
CREATE FOREIGN DATA WRAPPER mywrapper OPTIONS (debug 'true');
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Compatibility

`CREATE FOREIGN DATA WRAPPER` conforms to ISO/IEC 9075-9 (SQL/MED), with the exception that the `HANDLER` and `VALIDATOR` clauses are extensions, and the standard clauses `LIBRARY` and `LANGUAGE` are not implemented in WarehousePG.

Note, however, that the SQL/MED functionality as a whole is not yet conforming.

7.1.60 CREATE FOREIGN TABLE

Defines a new foreign table.

Synopsis

```
CREATE FOREIGN TABLE [ IF NOT EXISTS ] <table_name> ( [
  { <column_name> <data_type> [ OPTIONS ( <option> '<value>' [, ... ] ) ] [ COLLATE <collation> ] [ <column_constraint> [ ... ] ]
    | <table_constraint> }
    [, ... ]
] )
[ INHERITS ( <parent_table> [, ... ] ) ]
  SERVER <server_name>
  [ OPTIONS ( [ mpp_execute { 'coordinator' | 'any' | 'all segments' } [, ] ] <option> '<value>' [, ... ] ) ]

CREATE FOREIGN TABLE [ IF NOT EXISTS ] <table_name>
  PARTITION OF <parent_table> [ (
  { <column_name> [ WITH OPTIONS ] [ <column_constraint> [ ... ] ]
    | <table_constraint> }
    [, ... ]
) ]
{ FOR VALUES <partition_bound_spec> | DEFAULT }
  SERVER <server_name>
  [ OPTIONS ( [ mpp_execute { 'coordinator' | 'any' | 'all segments' } [, ] ] <option> '<value>' [, ... ] ) ]

where <column_constraint> is:

[ CONSTRAINT <constraint_name> ]
{ NOT NULL |
  NULL |
  DEFAULT <default_expr> |
  GENERATED ALWAYS AS ( <generation_expr> ) STORED}

and <table_constraint> is:

[ CONSTRAINT <constraint_name> ]
CHECK ( <expression> ) [ NO INHERIT ]

and <partition_bound_spec> is:

IN ( <partition_bound_expr> [, ...] ) |
FROM ( { <partition_bound_expr> | MINVALUE | MAXVALUE } [, ...] )
  TO ( { <partition_bound_expr> | MINVALUE | MAXVALUE } [, ...] ) |
WITH ( MODULUS <numeric_literal>, REMAINDER <numeric_literal> )
```

Description

`CREATE FOREIGN TABLE` creates a new foreign table in the current database. The user who creates the foreign table becomes its owner.

If you schema-qualify the table name (for example, `CREATE FOREIGN TABLE myschema.mytable ...`), WarehousePG creates the table in the specified schema. Otherwise, the foreign table is created in the current schema. The name of the foreign table must be distinct from the name of any other foreign table, table, sequence, index, view, or materialized view in the same schema.

Because `CREATE FOREIGN TABLE` automatically creates a data type that represents the composite type corresponding to one row of the foreign table, foreign tables cannot have the same name as any existing data type in the same schema.

If the `PARTITION OF` clause is specified, then the table is created as a partition of parent_table with specified bounds.

To create a foreign table, you must have `USAGE` privilege on the foreign server, as well as `USAGE` privilege on all column types used in the table.

Parameters

IF NOT EXISTS Do not throw an error if a relation with the same name already exists. WarehousePG issues a notice in this case. Note that there is no guarantee that the existing relation is anything like the one that would have been created.

table_name The name (optionally schema-qualified) of the foreign table to create.

column_name The name of a column to create in the new foreign table.

data_type The data type of the column, including array specifiers.

COLLATE collation The `COLLATE` clause assigns a collation to the column (which must be of a collatable data type). If not specified, the column data type's default collation is used.

INHERITS (parent_table [, ...]) The optional `INHERITS` clause specifies a list of tables from which the new foreign table automatically inherits all columns. Parent tables can be plain tables or foreign tables. See the similar form of CREATE TABLE for more details.

PARTITION OF parent_table { FOR VALUES partition_bound_spec | DEFAULT } This form can be used to create the foreign table as partition of the given parent table with specified partition bound values. See the similar form of CREATE TABLE for more details. Note that it is currently not allowed to create the foreign table as a partition of the parent table if there are `UNIQUE` indexes on the parent table. (See also ALTER TABLE ATTACH PARTITION.)

CONSTRAINT constraint_name An optional name for a column or table constraint. If the constraint is violated, the constraint name is present in error messages, so constraint names like `col must be positive` can be used to communicate helpful constraint information to client applications. (Double-quotes are needed to specify constraint names that contain spaces.) If a constraint name is not specified, the system generates a name.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

NOT NULL The column is not allowed to contain null values.

NULL The column is allowed to contain null values. This is the default.

```
This clause is provided only for compatibility with non-standard SQL databases. Its use is discouraged in new applications.
```

CHECK (expression) [NO INHERIT] The `CHECK` clause specifies an expression producing a Boolean result which each row in the foreign table is expected to satisfy; that is, the expression should produce TRUE or UNKNOWN, never FALSE, for all rows in the foreign table. A check constraint specified as a column constraint should reference that column's value only, while an expression appearing in a table constraint can reference multiple columns. Currently, `CHECK` expressions cannot contain subqueries nor refer to variables other than columns of the current row. The system column `tableoid` may be referenced, but not any other system column. A constraint marked with `NO INHERIT` will not propagate to child tables.

DEFAULT default_expr The `DEFAULT` clause assigns a default value for the column whose definition it appears within. The value is any variable-free expression; WarehousePG does not allow subqueries and cross-references to other columns in the current table. The data type of the default expression must match the data type of the column. WarehousePG uses the default expression in any insert operation that does not specify a value for the column. If there is no default for a column, then the default is null.

GENERATED ALWAYS AS (generation_expr) STORED This clause creates the column as a generated column. The column cannot be written to, and when read the result of the specified expression will be returned. The keyword `STORED` is required to signify that the column will be computed on write. (The computed value will be presented to the foreign-data wrapper for storage and must be returned on reading.) The generation expression can refer to other columns in the table, but not other generated columns. Any functions and operators used must be immutable. References to other tables are not allowed.

server_name The name of an existing server to use for the foreign table. For details on defining a server, see CREATE SERVER.

OPTIONS (option 'value' [, ...]) The options for the new foreign table or one of its columns. While option names must be unique, a table option and a column option may have the same name. The option names and values are foreign-data wrapper-specific. WarehousePG validates the options and values using the foreign-data wrapper's validator_function.

mpp_execute { 'coordinator' | 'any' | 'all segments' } A WarehousePG-specific option that identifies the host from which the foreign-data wrapper reads or writes data:

```
-   `coordinator` \(the default\)—Read or write data from the coordinator host.
-   `any`—Read data from either the coordinator host or any one segment, depending on which path costs less.
-   `all segments`—Read or write data from all segments. To support this option value, the foreign-data wrapper must have a policy that matches the segments to
data.

> **Note** WarehousePG supports parallel writes to foreign tables only when you set `mpp_execute 'all segments'`.

Support for the foreign table `mpp_execute` option, and the specific modes, is foreign-data wrapper-specific.

The `mpp_execute` option can be specified in multiple commands: `CREATE FOREIGN TABLE`, `CREATE SERVER`, and `CREATE FOREIGN DATA WRAPPER`. The foreign table
setting takes precedence over the foreign server setting, followed by the foreign-data wrapper setting.
```

Notes

Constraints on foreign tables (such as `CHECK` or `NOT NULL` clauses) are not enforced by WarehousePG, and most foreign-data wrappers do not attempt to enforce them either; that is, the constraint is simply assumed to hold true. There would be little point in such enforcement since it would only apply to rows inserted or updated via the foreign table, and not to rows modified by other means, such as directly on the remote server. Instead, a constraint attached to a foreign table should represent a constraint that is being enforced by the remote server.

Some special-purpose foreign-data wrappers might be the only access mechanism for the data they access, and in that case it might be appropriate for the foreign-data wrapper itself to perform constraint enforcement. But you should not assume that a wrapper does that unless its documentation says so.

Although WarehousePG does not attempt to enforce constraints on foreign tables, it does assume that they are correct for purposes of query optimization. If there are rows visible in the foreign table that do not satisfy a declared constraint, queries on the table might produce errors or incorrect answers. It is the user's responsibility to ensure that the constraint definition matches reality.

> **Note:** When a foreign table is used as a partition of a partitioned table, there is an implicit constraint that its contents must satisfy the partitioning rule. Again, it is the user's responsibility to ensure that that is true, which is best done by installing a matching constraint on the remote server.

Within a partitioned table containing foreign-table partitions, an `UPDATE` that changes the partition key value can cause a row to be moved from a local partition to a foreign-table partition, provided the foreign-data wrapper supports tuple routing. However it is not currently possible to move a row from a foreign-table partition to another partition. An `UPDATE` that would require doing that will fail due to the partitioning constraint, assuming that that is properly enforced by the remote server.

Similar considerations apply to generated columns. Stored generated columns are computed on insert or update on the local WarehousePG server and handed to the foreign-data wrapper for writing out to the foreign data store, but it is not enforced that a query of the foreign table returns values for stored generated columns that are consistent with the generation expression. Again, this might result in incorrect query results.

Examples

Create a foreign table named `films` with the server named `film_server`:

```
CREATE FOREIGN TABLE films (
    code        char(5) NOT NULL,
    title       varchar(40) NOT NULL,
    did         integer NOT NULL,
    date_prod   date,
    kind        varchar(10),
    len         interval hour to minute
)
SERVER film_server;
```

Create foreign table `measurement_y2016m07`, which will be accessed through the server `server_07`, as a partition of the range partitioned table measurement:

```
CREATE FOREIGN TABLE measurement_y2016m07
    PARTITION OF measurement FOR VALUES FROM ('2016-07-01') TO ('2016-08-01')
    SERVER server_07;
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Compatibility

`CREATE FOREIGN TABLE` largely conforms to the SQL standard; however, much as with CREATE TABLE, WarehousePG permits `NULL` constraints and zero-column foreign tables. The ability to specify column default values is a WarehousePG extension, as is the `mpp_execute` option. Table inheritance, in the form defined by WarehousePG, is nonstandard.

7.1.61 CREATE FUNCTION

Defines a new function.

Synopsis

```
CREATE [OR REPLACE] FUNCTION <name>
    ( [ [<argmode>] [<argname>] <argtype> [ { DEFAULT | = } <default_expr> ] [, ...] ] )
      [ RETURNS <rettype>
        | RETURNS TABLE ( <column_name> <column_type> [, ...] ) ]
  { LANGUAGE <lang_name>
    | TRANSFORM { FOR TYPE <type_name> } [, ... ]
    | WINDOW
    | { IMMUTABLE | STABLE | VOLATILE }
    | [ NOT ] LEAKPROOF
    | { CALLED ON NULL INPUT | RETURNS NULL ON NULL INPUT | STRICT }
    | { [ EXTERNAL ] SECURITY INVOKER | [ EXTERNAL ] SECURITY DEFINER }
    | EXECUTE ON { ANY | COORDINATOR | ALL SEGMENTS | INITPLAN }
    | PARALLEL { UNSAFE | RESTRICTED | SAFE }
    | COST <execution_cost>
    | ROWS <result_rows>
    | SUPPORT <support_function>
    | SET <configuration_parameter> { TO <value> | = <value> | FROM CURRENT }
    | AS '<definition>'
    | AS '<obj_file>', '<link_symbol>'
    [ WITH ({ DESCRIBE = <describe_function> } [, ...] ) ]
  } ...
```

Description

`CREATE FUNCTION` defines a new function. `CREATE OR REPLACE FUNCTION` either creates a new function, or replaces an existing definition. To define a function, the user must have the `USAGE` privilege on the language.

If a schema name is included, then the function is created in the specified schema. Otherwise it is created in the current schema. The name of the new function must not match any existing function with the same input argument types in the same schema. However, functions of different argument types may share a name (overloading).

To update the current definition of an existing function, use `CREATE OR REPLACE FUNCTION`. It is not possible to change the name or argument types of a function this way (this would actually create a new, distinct function). Also, `CREATE OR REPLACE FUNCTION` will not let you change the return type of an existing function. To do that, you must drop and recreate the function. (When using `OUT` parameters, that means you cannot change the types of any `OUT` parameters except by dropping the function.)

When `CREATE OR REPLACE FUNCTION` is used to replace an existing function, the ownership and permissions of the function do not change. All other function properties are assigned the values specified or implied in the command. You must own the function to replace it (this includes being a member of the owning role).

If you drop and then recreate a function, the new function is not the same entity as the old; you will have to drop existing objects (rules, views, triggers, and so on) that refer to the old function. Use `CREATE OR REPLACE FUNCTION` to change a function definition without breaking objects that refer to the function. Also, ALTER FUNCTION can be used to change most of the auxiliary properties of an existing function.

The user that creates the function becomes the owner of the function.

To be able to create a function, you must have `USAGE` privilege on the argument types and the return type.

For more information about creating functions, refer to the User Defined Functions section of the PostgreSQL documentation.

Limited Use of VOLATILE and STABLE Functions

To prevent data from becoming out-of-sync across the segments in WarehousePG, any function classified as `STABLE` or `VOLATILE` cannot be run at the segment level if it contains SQL or modifies the database in any way. For example, functions such as `random()` or `timeofday()` are not allowed to run on distributed data in WarehousePG because they could potentially cause inconsistent data between the segment instances.

To ensure data consistency, `VOLATILE` and `STABLE` functions can safely be used in statements that are evaluated on and run from the coordinator. For example, the following statements are always run on the coordinator (statements without a `FROM` clause):

```
SELECT setval('myseq', 201);
SELECT foo();
```

In cases where a statement has a `FROM` clause containing a distributed table and the function used in the `FROM` clause simply returns a set of rows, execution may be allowed on the segments:

```
SELECT * FROM foo();
```

One exception to this rule are functions that return a table reference (`rangeFuncs`) or functions that use the `refCursor` data type. Note that you cannot return a `refcursor` from any kind of function in WarehousePG.

Function Volatility and EXECUTE ON Attributes

Volatility attributes (`IMMUTABLE`, `STABLE`, `VOLATILE`) and `EXECUTE ON` attributes specify two different aspects of function execution. In general, volatility indicates when the function is run, and `EXECUTE ON` indicates where it is run.

For example, a function defined with the `IMMUTABLE` attribute can be run at query planning time, while a function with the `VOLATILE` attribute must be run for every row in the query. A function with the `EXECUTE ON COORDINATOR` attribute is run only on the coordinator segment and a function with the `EXECUTE ON ALL SEGMENTS` attribute is run on all primary segment instances (not the coordinator).

See Using Functions and Operators in the *WarehousePG Administrator Guide*.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Functions And Replicated Tables

A user-defined function that runs only `SELECT` commands on replicated tables can run on segments. Replicated tables, created with the `DISTRIBUTED REPLICATED` clause, store all of their rows on every segment. It is safe for a function to read them on the segments, but updates to replicated tables must run on the coordinator instance.

Parameters

name The name (optionally schema-qualified) of the function to create.

argmode The mode of an argument: either `IN`, `OUT`, `INOUT`, or `VARIADIC`. If omitted, the default is `IN`. Only `OUT` arguments can follow an argument declared as `VARIADIC`. Also, `OUT` and `INOUT` arguments cannot be used together with the `RETURNS TABLE` notation.

argname The name of an argument. Some languages (currently only SQL and PL/pgSQL) let you use the name in the function body. For other languages the name of an input argument is just extra documentation, so far as the function itself is concerned; but you can use input argument names when calling a function to improve readability. In any case, the name of an output argument is significant, since it defines the column name in the result row type. (If you omit the name for an output argument, the system will choose a default column name.)

argtype The data type(s) of the function's arguments (optionally schema-qualified), if any. The argument types may be base, composite, or domain types, or may reference the type of a table column.

Depending on the implementation language it may also be allowed to specify pseudotypes such as `cstring`. Pseudotypes indicate that the actual argument type is either incompletely specified, or outside the set of ordinary SQL data types.

The type of a column is referenced by writing `table_name.column_name%TYPE`. Using this feature can sometimes help make a function independent of changes to the definition of a table.

default_expr An expression to be used as the default value if the parameter is not specified. The expression must be coercible to the argument type of the parameter. Only input (including `INOUT`) parameters can have a default value. Each input parameter in the argument list that follows a parameter with a default value must have a default value as well.

rettype The return data type (optionally schema-qualified). The return type can be a base, composite, or domain type, or may reference the type of a table column. Depending on the implementation language it may also be allowed to specify pseudotypes such as `cstring`. If the function is not supposed to return a value, specify `void` as the return type.

When there are `OUT` or `INOUT` parameters, the `RETURNS` clause may be omitted. If present, it must agree with the result type implied by the output parameters `RECORD` if there are multiple output parameters, or the same type as the single output parameter.

The `SETOF` modifier indicates that the function will return a set of items, rather than a single item.

The type of a column is referenced by writing `table_name.column_name%TYPE`.

column_name The name of an output column in the `RETURNS TABLE` syntax. This is effectively another way of declaring a named `OUT` parameter, except that `RETURNS TABLE` also implies `RETURNS SETOF`.

column_type The data type of an output column in the `RETURNS TABLE` syntax.

lang_name The name of the language that the function is implemented in. May be `SQL`, `C`, `internal`, or the name of a user-defined procedural language, e.g. `plpgsql`. Enclosing the name in single quotes is deprecated and requires matching case.

TRANSFORM { FOR TYPE type_name } [, ...] } Lists which transforms a call to the function should apply. Transforms convert between SQL types and language-specific data types. Procedural language implementations usually have hardcoded knowledge of the built-in types, so those don't need to be listed here. If a procedural language implementation does not know how to handle a type and no transform is supplied, it will fall back to a default behavior for converting data types, but this depends on the implementation.

WINDOW `WINDOW` indicates that the function is a window function rather than a plain function. This is currently only useful for functions written in C. The `WINDOW` attribute cannot be changed when replacing an existing function definition.

IMMUTABLE STABLE VOLATILE These attributes inform the query optimizer about the behavior of the function. At most one choice may be specified. If none of these appear, `VOLATILE` is the default assumption. Since WarehousePG currently has limited use of `VOLATILE` functions, if a function is truly `IMMUTABLE`, you must declare it as so to be able to use it without restrictions.

`IMMUTABLE` indicates that the function cannot modify the database and always returns the same result when given the same argument values. It does not do database lookups or otherwise use information not directly present in its argument list. If this option is given, any call of the function with all-constant arguments can be immediately replaced with the function value.

`STABLE` indicates that the function cannot modify the database, and that within a single table scan it will consistently return the same result for the same argument values, but that its result could change across SQL statements. This is the appropriate selection for functions whose results depend on database lookups, parameter variables (such as the current time zone), and so on. Also note that the `current_timestamp()` family of functions qualify as stable, since their values do not change within a transaction.

`VOLATILE` indicates that the function value can change even within a single table scan, so no optimizations can be made. Relatively few database functions are volatile in this sense; some examples are `random()`, `timeofday()`. But note that any function that has side-effects must be classified volatile, even if its result is quite predictable, to prevent calls from being optimized away; an example is `setval()`.

LEAKPROOF `LEAKPROOF` indicates that the function has no side effects. It reveals no information about its arguments other than by its return value. For example, a function that throws an error message for some argument values but not others, or that includes the argument values in any error message, is not leakproof. This affects how the system executes queries against views created with the `security_barrier` option or tables with row level security enabled. The system will enforce conditions from security policies and security barrier views before any user-supplied conditions from the query itself that contain non-leakproof functions, in order to prevent the inadvertent exposure of data. Functions and operators marked as leakproof are assumed to be trustworthy, and may be executed before conditions from security policies and security barrier views. In addition, functions which do not take arguments or which are not passed any arguments from the security barrier view or table do not have to be marked as leakproof to be executed before security conditions. See CREATE VIEW. This option can only be set by the superuser.

CALLED ON NULL INPUT RETURNS NULL ON NULL INPUT STRICT `CALLED ON NULL INPUT` (the default) indicates that the function will be called normally when some of its arguments are null. It is then the function author's responsibility to check for null values if necessary and respond appropriately. `RETURNS NULL ON NULL INPUT` or `STRICT` indicates that the function always returns null whenever any of its arguments are null. If this parameter is specified, the function is not run when there are null arguments; instead a null result is assumed automatically.

[EXTERNAL] SECURITY INVOKER [EXTERNAL] SECURITY DEFINER `SECURITY INVOKER` (the default) indicates that the function is to be run with the privileges of the user that calls it. `SECURITY DEFINER` specifies that the function is to be run with the privileges of the user that created it. The key word `EXTERNAL` is allowed for SQL conformance, but it is optional since, unlike in SQL, this feature applies to all functions not just external ones.

EXECUTE ON ANY EXECUTE ON COORDINATOR EXECUTE ON ALL SEGMENTS EXECUTE ON INITPLAN The `EXECUTE ON` attributes specify where (coordinator or segment instance) a function runs when it is invoked during the query execution process.

`EXECUTE ON ANY` (the default) indicates that the function can be run on the coordinator, or any segment instance, and it returns the same result regardless of where it is run. WarehousePG determines where the function runs.

`EXECUTE ON COORDINATOR` indicates that the function must run only on the coordinator instance.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

`EXECUTE ON ALL SEGMENTS` indicates that the function must run on all primary segment instances, but not the coordinator, for each invocation. The overall result of the function is the `UNION ALL` of the results from all segment instances.

`EXECUTE ON INITPLAN` indicates that the function contains an SQL command that dispatches queries to the segment instances and requires special processing on the coordinator instance by WarehousePG when possible.

```
> **Note** `EXECUTE ON INITPLAN` is only supported in functions that are used in the `FROM` clause of a `CREATE TABLE AS` or `INSERT` command such as the
`get_data()` function in these commands.

```
CREATE TABLE t AS SELECT * FROM get_data();

INSERT INTO t1 SELECT * FROM get_data();
```

WarehousePG does not support the `EXECUTE ON INITPLAN` attribute in a function that is used in the `WITH` clause of a query, a CTE \(common table expression\).
For example, specifying `EXECUTE ON INITPLAN` in function `get_data()` in this CTE is not supported.

```
WITH tbl_a AS (SELECT * FROM get_data() )
   SELECT * from tbl_a
   UNION
   SELECT * FROM tbl_b;
```
```

For information about using `EXECUTE ON` attributes, see Notes.

PARALLEL `PARALLEL UNSAFE` indicates that the function can't be executed in parallel mode and the presence of such a function in an SQL statement forces a serial execution plan. This is the default. `PARALLEL RESTRICTED` indicates that the function can be executed in parallel mode, but the execution is restricted to parallel group leader. `PARALLEL SAFE` indicates that the function is safe to run in parallel mode without restriction. Functions should be labeled parallel unsafe if they modify any database state, or if they make changes to the transaction such as using sub-transactions, or if they access sequences or attempt to make persistent changes to settings (e.g., `setval()`). They should be labeled as parallel restricted if they access temporary tables, client connection state, cursors, prepared statements, or miscellaneous backend-local state which the system cannot synchronize in parallel mode (e.g., `setseed()` cannot be executed other than by the group leader because a change made by another process would not be reflected in the leader). In general, if a function is labeled as being safe when it is restricted or unsafe, or if it is labeled as being restricted when it is in fact unsafe, it may throw errors or produce wrong answers when used in a parallel query. C-language functions could in theory exhibit totally undefined behavior if mislabeled, since there is no way for the system to protect itself against arbitrary C code, but in most likely cases the result will be no worse than for any other function. If in doubt, functions should be labeled as `UNSAFE`, which is the default.

COST execution_cost A positive number identifying the estimated execution cost for the function, in units of cpu_operator_cost. If the function returns a set, execution_cost identifies the cost per returned row. If the cost is not specified, C-language and internal functions default to 1 unit, while functions in other languages default to 100 units. Larger values cause the planner to try to avoid evaluating the function more often than necessary.

ROWS result_rows A positive number giving the estimated number of rows that the planner should expect the function to return. This is only allowed when the function is declared to return a set. The default assumption is 1000 rows.

SUPPORT support_function The name (optionally schema-qualified) of a planner support function to use for this function. You must be superuser to use this option.

configuration_parameter value The `SET` clause applies a value to a session configuration parameter when the function is entered. The configuration parameter is restored to its prior value when the function exits. `SET FROM CURRENT` saves the value of the parameter that is current when `CREATE FUNCTION` is run as the value to be applied when the function is entered. If a `SET` clause is attached to a function, then the effects of a `SET LOCAL` command executed inside the function for the same variable are restricted to the function: the configuration parameter's prior value is still restored at function exit. However, an ordinary `SET` command (without `LOCAL`) overrides the `SET` clause, much as it would do for a previous `SET LOCAL` command: the effects of such a command will persist after function exit, unless the current transaction is rolled back. SeeSET for more information about allowed parameter names and values.

definition A string constant defining the function; the meaning depends on the language. It may be an internal function name, the path to an object file, an SQL command, or text in a procedural language.

It is often helpful to use dollar quoting (refer to Dollar-Quoted String Constants in the PostgreSQL documentation) to write the function definition string, rather than the normal single quote syntax. Without dollar quoting, any single quotes or backslashes in the function definition must be escaped by doubling them.

obj_file, link_symbol This form of the `AS` clause is used for dynamically loadable C language functions when the function name in the C language source code is not the same as the name of the SQL function. The string obj_file is the name of the file containing the dynamically loadable object, and is interpreted as for the LOAD command. The string link_symbol is the name of the function in the C language source code. If the link symbol is omitted, it is assumed to be the same as the name of the SQL function being defined. The C names of all functions must be different, so you must give overloaded SQL functions different C names (for example, use the argument types as part of the C names). When repeated `CREATE FUNCTION` calls refer to the same object file, the file is only loaded once per session. To unload and reload the file (perhaps during development), start a new session. Locating shared libraries either relative to `$libdir` (which is located at `$GPHOME/lib`) or through the dynamic library path (set by the `dynamic_library_path` server configuration parameter) will simplify version upgrades if the new installation is at a different location.

describe_function The name of a callback function to run when a query that calls this function is parsed. The callback function returns a tuple descriptor that indicates the result type.

Overloading

WarehousePG allows function overloading; that is, the same name can be used for several different functions so long as they have distinct input argument types. Whether or not you use it, this capability entails security precautions when calling functions in databases where some users mistrust other users; refer to Functions in the PostgreSQL documentation for more information.

Two functions are considered the same if they have the same names and input argument types, ignoring any `OUT` parameters. Thus for example these declarations conflict:

```
CREATE FUNCTION foo(int) ...
CREATE FUNCTION foo(int, out text) ...
```

Functions that have different argument type lists will not be considered to conflict at creation time, but if defaults are provided they might conflict in use. For example, consider:

```
CREATE FUNCTION foo(int) ...
CREATE FUNCTION foo(int, int default 42) ...
```

A call `foo(10)` will fail due to the ambiguity about which function should be called.

Notes

Any compiled code (shared library files) for custom functions must be placed in the same location on every host in your WarehousePG cluster (coordinator and all segments). This location must also be in the `LD_LIBRARY_PATH` so that the server can locate the files. It is recommended that you locate shared libraries either relative to `$libdir` (which is located at `$GPHOME/lib`) or through the dynamic library path (set by the `dynamic_library_path` server configuration parameter) on all coordinator segment instances in the WarehousePG cluster.

The full SQL type syntax is allowed for input arguments and return value. However, parenthesized type modifiers (e.g., the precision field for type `numeric`) are discarded by `CREATE FUNCTION`. Thus for example `CREATE FUNCTION foo (varchar(10)) ...` is exactly the same as `CREATE FUNCTION foo (varchar) ...`.

When replacing an existing function with `CREATE OR REPLACE FUNCTION`, there are restrictions on changing parameter names. You cannot change the name already assigned to any input parameter (although you can add names to parameters that had none before). If there is more than one output parameter, you cannot change the names of the output parameters, because that would change the column names of the anonymous composite type that describes the function's result. These restrictions are made to ensure that existing calls of the function do not stop working when it is replaced.

If a function is declared `STRICT` with a `VARIADIC` argument, the strictness check tests that the variadic array as a whole is non-null. The function will still be called if the array has null elements.

Using Functions with Queries on Distributed Data

In some cases, WarehousePG does not support using functions in a query where the data in a table specified in the `FROM` clause is distributed over WarehousePG segments. As an example, this SQL query contains the function `func()`:

```
SELECT func(a) FROM table1;
```

The function is not supported for use in the query if all of the following conditions are met:

- The data of table `table1` is distributed over WarehousePG segments.
- The function `func()` reads or modifies data from distributed tables.
- The function `func()` returns more than one row or takes an argument (`a`) that comes from `table1`.

If any of the conditions are not met, the function is supported. Specifically, the function is supported if any of the following conditions apply:

- The function `func()` does not access data from distributed tables, or accesses data that is only on the WarehousePG coordinator.
- The table `table1` is a coordinator only table.
- The function `func()` returns only one row and only takes input arguments that are constant values. The function is supported if it can be changed to require no input arguments.

Using EXECUTE ON attributes

Most functions that run queries to access tables can only run on the coordinator. However, functions that run only `SELECT` queries on replicated tables can run on segments. If the function accesses a hash-distributed table or a randomly distributed table, the function should be defined with the `EXECUTE ON COORDINATOR` attribute. Otherwise, the function might return incorrect results when the function is used in a complicated query. Without the attribute, planner optimization might determine it would be beneficial to push the function invocation to segment instances.

These are limitations for functions defined with the `EXECUTE ON COORDINATOR` or `EXECUTE ON ALL SEGMENTS` attribute:

- The function must be a set-returning function.
- The function cannot be in the `FROM` clause of a query.
- The function cannot be in the `SELECT` list of a query with a `FROM` clause.
- A query that includes the function falls back from GPORCA to the Postgres-based planner.

The attribute `EXECUTE ON INITPLAN` indicates that the function contains an SQL command that dispatches queries to the segment instances and requires special processing on the coordinator instance by WarehousePG. When possible, WarehousePG handles the function on the coordinator instance in the following manner.

1. First, WarehousePG runs the function as part of an InitPlan node on the coordinator instance and holds the function output temporarily.
2. Then, in the MainPlan of the query plan, the function is called in an EntryDB (a special query executor (QE) that runs on the coordinator instance) and WarehousePG returns the data that was captured when the function was run as part of the InitPlan node. The function is not run in the MainPlan.

This simple example uses the function `get_data()` in a CTAS command to create a table using data from the table `country`. The function contains a `SELECT` command that retrieves data from the table `country` and uses the `EXECUTE ON INITPLAN` attribute.

```
CREATE TABLE country(
  c_id integer, c_name text, region int)
  DISTRIBUTED RANDOMLY;

INSERT INTO country VALUES (11,'INDIA', 1 ), (22,'CANADA', 2), (33,'USA', 3);

CREATE OR REPLACE FUNCTION get_data()
  RETURNS TABLE (
   c_id integer, c_name text
   )
AS $$
  SELECT
    c.c_id, c.c_name
  FROM
    country c;
$$
LANGUAGE SQL EXECUTE ON INITPLAN;

CREATE TABLE t AS SELECT * FROM get_data() DISTRIBUTED RANDOMLY;
```

If you view the query plan of the CTAS command with `EXPLAIN ANALYZE VERBOSE`, the plan shows that the function is run as part of an InitPlan node, and one of the listed slices is labeled as `entry db`. The query plan of a simple CTAS command without the function does not have an InitPlan node or an `entry db` slice.

If the function did not contain the `EXECUTE ON INITPLAN` attribute, the CTAS command returns the error `function cannot execute on a QE slice`.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

When a function uses the `EXECUTE ON INITPLAN` attribute, a command that uses the function such as `CREATE TABLE t AS SELECT * FROM get_data()` gathers the results of the function onto the coordinator segment and then redistributes the results to segment instances when inserting the data. If the function returns a large amount of data, the coordinator might become a bottleneck when gathering and redistributing data. Performance might improve if you rewrite the function to run the CTAS command in the user defined function and use the table name as an input parameter. In this example, the function runs a CTAS command and does not require the `EXECUTE ON INITPLAN` attribute. Running the `SELECT` command creates the table `t1` using the function that runs the CTAS command.

```
CREATE OR REPLACE FUNCTION my_ctas(_tbl text) RETURNS VOID AS
$$
BEGIN
  EXECUTE format('CREATE TABLE %s AS SELECT c.c_id, c.c_name FROM country c DISTRIBUTED RANDOMLY', _tbl);
END
$$
LANGUAGE plpgsql;

SELECT my_ctas('t1');
```

Examples

Add two integers using a SQL function:

```
CREATE FUNCTION add(integer, integer) RETURNS integer
    AS 'select $1 + $2;'
    LANGUAGE SQL
    IMMUTABLE
    RETURNS NULL ON NULL INPUT;
```

Increment an integer, making use of an argument name, in PL/pgSQL:

```
CREATE OR REPLACE FUNCTION increment(i integer) RETURNS
integer AS $$
        BEGIN
                RETURN i + 1;
        END;
$$ LANGUAGE plpgsql;
```

Return a record containing multiple output parameters:

```
CREATE FUNCTION dup(in int, out f1 int, out f2 text)
    AS $$ SELECT $1, CAST($1 AS text) || ' is text' $$
    LANGUAGE SQL;

SELECT * FROM dup(42);
```

You can do the same thing more verbosely with an explicitly named composite type:

```
CREATE TYPE dup_result AS (f1 int, f2 text);

CREATE FUNCTION dup(int) RETURNS dup_result
    AS $$ SELECT $1, CAST($1 AS text) || ' is text' $$
    LANGUAGE SQL;

SELECT * FROM dup(42);
```

Another way to return multiple columns is to use a `TABLE` function:

```
CREATE FUNCTION dup(int) RETURNS TABLE(f1 int, f2 text)
    AS $$ SELECT $1, CAST($1 AS text) || ' is text' $$
    LANGUAGE SQL;

SELECT * FROM dup(42);
```

However, a `TABLE` function is different from the preceding examples, because it actually returns a set of records, not just one record.

Increase the default segment host memory per query for a PL/pgSQL function:

```
CREATE OR REPLACE FUNCTION function_with_query() RETURNS
SETOF text AS $$
        BEGIN
                RETURN QUERY
                EXPLAIN ANALYZE SELECT * FROM large_table;
        END;
$$ LANGUAGE plpgsql
SET statement_mem='256MB';
```

Use polymorphic types to return an `ENUM` array:

```
CREATE TYPE rainbow AS ENUM('red','orange','yellow','green','blue','indigo','violet');
CREATE FUNCTION return_enum_as_array( anyenum, anyelement, anyelement )
    RETURNS TABLE (ae anyenum, aa anyarray) AS $$
    SELECT $1, array[$2, $3]
$$ LANGUAGE SQL STABLE;

SELECT * FROM return_enum_as_array('red'::rainbow, 'green'::rainbow, 'blue'::rainbow);
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

This function is defined with the `EXECUTE ON ALL SEGMENTS` to run on all primary segment instances. The `SELECT` command runs the function that returns the time it was run on each segment instance.

```
CREATE FUNCTION run_on_segs (text) returns setof text as $$
  begin
    return next ($1 || ' - ' || now()::text );
  end;
 $$ language plpgsql VOLATILE EXECUTE ON ALL SEGMENTS;

SELECT run_on_segs('my test');
```

This function looks up a part name in the parts table. The parts table is replicated, so the function can run on the coordinator or on the primary segments.

```
CREATE OR REPLACE FUNCTION get_part_name(partno int) RETURNS text AS
$$
DECLARE
   result text := ' ';
BEGIN
    SELECT part_name INTO result FROM parts WHERE part_id = partno;
    RETURN result;
END;
$$ LANGUAGE plpgsql;
```

If you run `SELECT get_part_name(100);` at the coordinator the function runs on the coordinator. (The coordinator instance directs the query to a single primary segment.) If orders is a distributed table and you run the following query, the `get_part_name()` function runs on the primary segments.

```
`SELECT order_id, get_part_name(orders.part_no) FROM orders;`
```

Writing SECURITY DEFINER Functions Safely

Because a `SECURITY DEFINER` function is executed with the privileges of the user that created it, care is needed to ensure that the function cannot be misused. For security, `search_path` should be set to exclude any schemas writable by untrusted users. This prevents malicious users from creating objects that mask objects used by the function. Particularly important in this regard is the temporary-table schema, which is searched first by default, and is normally writable by anyone. A secure arrangement can be had by forcing the temporary schema to be searched last. To do this, write `pg_temp` as the last entry in `search_path`. This function illustrates safe usage:

```
CREATE FUNCTION check_password(uname TEXT, pass TEXT)
RETURNS BOOLEAN AS $$
DECLARE passed BOOLEAN;
BEGIN
        SELECT  (pwd = $2) INTO passed
        FROM    pwds
        WHERE   username = $1;

        RETURN passed;
END;
$$  LANGUAGE plpgsql
    SECURITY DEFINER
    -- Set a secure search_path: trusted schema(s), then 'pg_temp'.
    SET search_path = admin, pg_temp;
```

The `SET` option was not available in earlier versions of WarehousePG, and so older functions may contain rather complicated logic to save, set, and restore `search_path`. The `SET` option is far easier to use for this purpose.

Another point to keep in mind is that by default, execute privilege is granted to `PUBLIC` for newly created functions (see GRANT for more information). Frequently you will wish to restrict use of a security definer function to only some users. To do that, you must revoke the default `PUBLIC` privileges and then grant `EXECUTE` privilege selectively. To avoid having a window where the new function is accessible to all, create it and set the privileges within a single transaction. For example:

```
BEGIN;
CREATE FUNCTION check_password(uname TEXT, pass TEXT) ... SECURITY DEFINER;
REVOKE ALL ON FUNCTION check_password(uname TEXT, pass TEXT) FROM PUBLIC;
GRANT EXECUTE ON FUNCTION check_password(uname TEXT, pass TEXT) TO admins;
COMMIT;
```

Compatibility

`CREATE FUNCTION` is defined in SQL:1999 and later. The WarehousePG version is similar but not fully compatible. The attributes are not portable, neither are the different available languages.

For compatibility with some other database systems, argmode can be written either before or after argname. But only the first way is standard-compliant.

For parameter defaults, the SQL standard specifies only the syntax with the `DEFAULT` key word. The syntax with `=` is used in T-SQL and Firebird.

7.1.62 CREATE GROUP

Defines a new database role.

Synopsis

```
CREATE GROUP <name> [[WITH] <option> [ ... ]]
```

where option can be:

```
      SUPERUSER | NOSUPERUSER
    | CREATEDB | NOCREATEDB
    | CREATEROLE | NOCREATEROLE
    | CREATEEXTTABLE | NOCREATEEXTTABLE
      [ ( <attribute>='<value>'[, ...] ) ]
           where <attributes> and <value> are:
           type='readable'|'writable'
           protocol='gpfdist'|'http'
    | INHERIT | NOINHERIT
    | LOGIN | NOLOGIN
    | REPLICATION | NOREPLICATION
    | BYPASSRLS | NOBYPASSRLS
    | CONNECTION LIMIT <connlimit>
    | [ ENCRYPTED | UNENCRYPTED ] PASSWORD '<password>' | PASSWORD NULL
    | VALID UNTIL '<timestamp>'
    | IN ROLE <role_name> [, ...]
    | IN GROUP <role_name> [, ...]
    | ROLE <role_name> [, ...]
    | ADMIN <role_name> [, ...]
    | USER <role_name> [, ...]
    | SYSID <uid> [, ...]
    | RESOURCE QUEUE <queue_name>
    | RESOURCE GROUP <group_name>
    | [ DENY <deny_point> ]
    | [ DENY BETWEEN <deny_point> AND <deny_point>]
```

Description

`CREATE GROUP` is an alias for CREATE ROLE.

Compatibility

There is no `CREATE GROUP` statement in the SQL standard.

7.1.63 CREATE INDEX

Defines a new index.

Synopsis

```
CREATE [UNIQUE] INDEX [[IF NOT EXISTS] <name>] ON [ONLY] <table_name> [USING <method>]
       ( {<column_name> | (<expression>)} [COLLATE <collation>] [<opclass>] [ ASC | DESC ] [ NULLS { FIRST | LAST } ] [, ...] )
       [ INCLUDE ( column_name [, ...] ) ]
       [ WITH ( <storage_parameter> [= <value>] [, ... ] ) ]
       [ TABLESPACE <tablespace_name> ]
       [ WHERE <predicate> ]
```

Description

`CREATE INDEX` constructs an index on the specified column(s) of the specified table or materialized view. Indexes are primarily used to enhance database performance (though inappropriate use can result in slower performance).

The key field(s) for the index are specified as column names, or alternatively as expressions written in parentheses. Multiple fields can be specified if the index method supports multicolumn indexes.

An index field can be an expression computed from the values of one or more columns of the table row. This feature can be used to obtain fast access to data based on some transformation of the basic data. For example, an index computed on `upper(col)` would allow the clause `WHERE upper(col) = 'JIM'` to use an index.

WarehousePG provides the index methods B-tree, hash, bitmap, GiST, SP-GiST, GIN, and BRIN. Users can also define their own index methods, but that is fairly complicated.

When the `WHERE` clause is present, a partial index is created. A partial index is an index that contains entries for only a portion of a table, usually a portion that is more useful for indexing than the rest of the table. For example, if you have a table that contains both billed and unbilled orders where the unbilled orders take up a small fraction of the total table and yet is most often selected, you can improve performance by creating an index on just that portion. Another possible application is to use `WHERE` with `UNIQUE` to enforce uniqueness over a subset of a table. See Partial Indexes in the PostgreSQL documentation for more information.

The expression used in the `WHERE` clause may refer only to columns of the underlying table, but it can use all columns, not just the ones being indexed. Subqueries and aggregate expressions are also forbidden in `WHERE`. The same restrictions apply to index fields that are expressions.

All functions and operators used in an index definition must be immutable. Their results must depend only on their arguments and never on any outside influence (such as the contents of another table or the current time). This restriction ensures that the behavior of the index is well-defined. To use a user-defined function in an index expression or `WHERE` clause, remember to mark the function `IMMUTABLE` when you create it.

Parameters

UNIQUE Checks for duplicate values in the table when the index is created (if data already exist) and each time data is added. Duplicate entries will generate an error. Unique indexes only apply to B-tree indexes. Additional restrictions apply when unique indexes are applied to partitioned tables; see CREATE TABLE.

IF NOT EXISTS Do not throw an error if a relation with the same name already exists. A notice is issued in this case. Note that there is no guarantee that the existing index is anything like the one that would have been created. Index name is required when `IF NOT EXISTS` is specified.

INCLUDE The optional `INCLUDE` clause specifies a list of columns which will be included in the index as non-key columns. A non-key column cannot be used in an index scan search qualification, and it is disregarded for purposes of any uniqueness or exclusion constraint enforced by the index. However, an index-only scan can return the contents of non-key columns without having to visit the index's table, since they are available directly from the index entry. Thus, addition of non-key columns allows index-only scans to be used for queries that otherwise could not use them.

Be conservative about adding non-key columns to an index, especially wide columns. If an index tuple exceeds the maximum size allowed for the index type, data insertion fails. In any case, non-key columns duplicate data from the index's table and bloat the size of the index, thus potentially slowing searches.

Columns listed in the `INCLUDE` clause don't need appropriate operator classes; the clause can include columns whose data types don't have operator classes defined for a given access method.

Expressions are not supported as included columns since they cannot be used in index-only scans.

Currently, the B-tree and the GiST index access methods support `INCLUDE`. In B-tree and the GiST indexes, the values of columns listed in the `INCLUDE` clause are included in leaf tuples which correspond to heap tuples, but are not included in upper-level index entries used for tree navigation.

name The name of the index to be created. The index is always created in the same schema as its parent table. If the name is omitted, WarehousePG chooses a suitable name based on the parent table's name and the indexed column name(s).

ONLY Indicates not to recurse creating indexes on partitions, if the table is partitioned. The default is to recurse.

table_name The name (optionally schema-qualified) of the table to be indexed.

method The name of the index method to be used. Choices are `btree`, `bitmap`, `hash`, `gist`, `spgist`, `gin`, and `brin`. The default method is `btree`.

GPORCA supports only B-tree, bitmap, GiST, GIN, and BRIN indexes. GPORCA ignores indexes created with unsupported indexing methods.

column_name The name of a column of the table on which to create the index.

expression An expression based on one or more columns of the table. The expression usually must be written with surrounding parentheses, as shown in the syntax. However, the parentheses may be omitted if the expression has the form of a function call.

collation The name of the collation to use for the index. By default, the index uses the collation declared for the column to be indexed or the result collation of the expression to be indexed. Indexes with non-default collations can be useful for queries that involve expressions using non-default collations.

opclass The name of an operator class.

ASC Specifies ascending sort order (which is the default).

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

DESC Specifies descending sort order.

NULLS FIRST Specifies that nulls sort before non-nulls. This is the default when `DESC` is specified.

NULLS LAST Specifies that nulls sort after non-nulls. This is the default when `DESC` is not specified.

storage_parameter The name of an index-method-specific storage parameter. Each index method has its own set of allowed storage parameters. See Index Storage Parameters for details.

tablespace_name The tablespace in which to create the index. If not specified,default_tablespace is consulted, or temp_tablespaces for indexes on temporary tables.

predicate The constraint expression for a partial index.

Index Storage Parameters

The optional `WITH` clause specifies *storage parameters* for the index. Each index method has its own set of allowed storage parameters. The B-tree, bitmap, hash, GiST, and SP-GiST index methods all accept this parameter:

`fillfactor` The `fillfactor` for an index is a percentage that determines how full the index method will try to pack index pages. For B-trees, leaf pages are filled to this percentage during initial index build, and also when extending the index at the right (adding new largest key values). If pages subsequently become completely full, they will be split, leading to gradual degradation in the index's efficiency. B-trees use a default fillfactor of 90, but any integer value from 10 to 100 can be selected. If the table is static then fillfactor 100 is best to minimize the index's physical size, but for heavily updated tables a smaller fillfactor is better to minimize the need for page splits. The other index methods use fillfactor in different but roughly analogous ways; the default fillfactor varies between methods.

B-tree indexes additionally accept this parameter:

vacuum_cleanup_index_scale_factor Per-index value for `vacuum_cleanup_index_scale_factor`.

GiST indexes additionally accept this parameter:

`buffering` Determines whether WarehousePG builds the index using the buffering build technique described in GiST buffering build in the PostgreSQL documentation. With `OFF` it is deactivated, with `ON` it is activated, and with `AUTO` it is initially deactivated, but turned on on-the-fly once the index size reaches effective_cache_size. The default is `AUTO`.

GIN indexes accept different parameters:

`fastupdate` This setting controls usage of the fast update technique described in GIN Fast Update Technique in the PostgreSQL documentation. It is a Boolean parameter that deactivates or activates the GIN index fast update technique. A value of `ON` activates fast update (the default), and `OFF` deactivates it.

Note: Turning `fastupdate` off via `ALTER INDEX` prevents future insertions from going into the list of pending index entries, but does not in itself flush previous entries. You might want to `VACUUM` the table or call `gin_clean_pending_list()` function afterward to ensure the pending list is emptied.

gin_pending_list_limit Custom `gin_pending_list_limit` parameter. This value is specified in kilobytes.

BRIN indexes accept different parameters:

pages_per_range Defines the number of table blocks that make up one block range for each entry of a BRIN index (see the BRIN Index Introduction in the PostgreSQL documentation for details). The default is 128.

autosummarize Defines whether a summarization run is queued for the previous page range whenever an insertion is detected on the next one. See [BRIN Index Maintenance] (https://www.postgresql.org/docs/12/brin-intro.html#BRIN-OPERATION) in the PostgreSQL documentation for more information. The default is `off`.

Notes

Refer to the Indexes topics in the PostgreSQL documentation for information about when indexes can be used, when they are not used, and in which particular situations they can be useful.

Currently, only the B-tree, bitmap, GiST, GIN, and BRIN index methods support multicolumn indexes. You can specify up to 32 fields by default. Only B-tree currently supports unique indexes.

An operator class can be specified for each column of an index. The operator class identifies the operators to be used by the index for that column. For example, a B-tree index on four-byte integers would use the `int4_ops` class; this operator class includes comparison functions for four-byte integers. In practice the default operator class for the column's data type is usually sufficient. The main point of having operator classes is that for some data types, there could be more than one meaningful ordering. For example, we might want to sort a complex-number data type either by absolute value or by real part. We could do this by defining two operator classes for the data type and then selecting the proper class when creating an index. Refer to Operator Classes and Operator Families and Interfacing Extensions to Indexes in the PostgreSQL documentation for more information about operator classes.

When `CREATE INDEX` is invoked on a partitioned table, the default behavior is to recurse to all partitions to ensure they all have matching indexes. Each partition is first checked to determine whether an equivalent index already exists, and if so, that index will become attached as a partition index to the index being created, which will become its parent index. If no matching index exists, a new index will be created and automatically attached; the name of the new index in each partition will be determined as if no index name had been specified in the command. If the `ONLY` option is specified, no recursion is done, and the index is marked invalid. (`ALTER INDEX ... ATTACH PARTITION` marks the index valid, once all partitions acquire matching indexes.) Note, however, that any partition that is created in the future using `CREATE TABLE ... PARTITION OF` or `ALTER TABLE ... ADD PARTITION` will automatically have a matching index, regardless of whether `ONLY` is specified

For index methods that support ordered scans (currently, only B-tree), you can specify the optional clauses `ASC`, `DESC`, `NULLS FIRST`, and/or `NULLS LAST` to modify the sort ordering of the index. Since an ordered index can be scanned either forward or backward, it is not normally useful to create a single-column `DESC` index — that sort ordering is already available with a regular index. The value of these options is that multicolumn indexes can be created that match the sort ordering requested by a mixed-ordering query, such as `SELECT ... ORDER BY x ASC, y DESC`. The `NULLS` options are useful if you need to support "nulls sort low" behavior, rather than the default "nulls sort high", in queries that depend on indexes to avoid sorting steps.

The system regularly collects statistics on all of a table's columns. Newly-created non-expression indexes can immediately use these statistics to determine an index's usefulness. For new expression indexes, you must run ANALYZE to generate statistics for these indexes.

For most index methods, the speed of creating an index is dependent on the setting of maintenance_work_mem. Larger values will reduce the time needed for index creation, so long as you don't make it larger than the amount of memory really available, which would drive the machine into swapping.

`bitmap` indexes perform best for columns that have between 100 and 100,000 distinct values. For a column with more than 100,000 distinct values, the performance and space efficiency of a bitmap index decline. The size of a bitmap index is proportional to the number of rows in the table times the number of distinct values in the indexed column.

Use DROP INDEX to remove an index.

Like any long-running transaction, `CREATE INDEX` on a table can affect which tuples can be removed by concurrent `VACUUM` on any other table.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Prior releases of WarehousePG also had an R-tree index method. This method has been removed because it had no significant advantages over the GiST method. If `USING rtree` is specified, `CREATE INDEX` will interpret it as `USING gist`, to simplify conversion of old databases to GiST.

Examples

To create a unique B-tree index on the column `title` in the table `films`:

```
CREATE UNIQUE INDEX title_idx ON films (title);
```

To create a B-tree index on the column `title` with included columns `director` and `rating` in the table `films`:

```
CREATE INDEX title_idx ON films (title) INCLUDE (director, rating);
```

To create an index on the expression `lower(title)`, allowing efficient case-insensitive searches:

```
CREATE INDEX ON films ((lower(title)));
```

(In this example we have chosen to omit the index name, so the system will choose a name, typically `films_lower_idx`.)

To create an index with non-default collation:

```
CREATE INDEX title_idx_german ON films (title COLLATE "de_DE");
```

To create an index with non-default sort ordering of nulls:

```
CREATE INDEX title_idx_nulls_low ON films (title NULLS FIRST);
```

To create an index with non-default fill factor:

```
CREATE UNIQUE INDEX title_idx ON films (title) WITH
(fillfactor = 70);
```

To create a GIN index with fast updates deactivated:

```
CREATE INDEX gin_idx ON documents_table USING gin (locations) WITH (fastupdate = off);
```

To create an index on the column `code` in the table `films` and have the index reside in the tablespace `indexspace`:

```
CREATE INDEX code_idx ON films (code) TABLESPACE indexspace;
```

To create a GiST index on a point attribute so that we can efficiently use box operators on the result of the conversion function:

```
CREATE INDEX pointloc ON points USING gist (box(location,location));
SELECT * FROM points WHERE box(location,location) && '(0,0),(1,1)'::box;
```

Compatibility

`CREATE INDEX` is a WarehousePG extension to the SQL standard. There are no provisions for indexes in the SQL standard.

WarehousePG does not support the concurrent creation of indexes (`CONCURRENTLY` keyword is not supported).

7.1.64 CREATE LANGUAGE

Defines a new procedural language.

Synopsis

```
CREATE [ OR REPLACE ] [ PROCEDURAL ] LANGUAGE <name>

CREATE [ OR REPLACE ] [ TRUSTED ] [ PROCEDURAL ] LANGUAGE <name>
    HANDLER <call_handler>
   [ INLINE <inline_handler> ]
   [ VALIDATOR <valfunction> ]
```

Description

`CREATE LANGUAGE` registers a new procedural language with a WarehousePG. Subsequently, functions and procedures can be defined in this new language.

> **Note** Procedural languages for WarehousePG have been made into "extensions," and should therefore be installed with CREATE EXTENSION, not `CREATE LANGUAGE`. Using `CREATE LANGUAGE` directly should be restricted to extension installation scripts. If you have a "bare" language in your database, perhaps as a result of an upgrade, you can convert it to an extension using `CREATE EXTENSION <langname> FROM unpackaged`.

`CREATE LANGUAGE` effectively associates the language name with handler function(s) that are responsible for executing functions written in the language.

There are two forms of the `CREATE LANGUAGE` command. In the first form, the user supplies just the name of the desired language, and the WarehousePG server consults the `pg_pltemplate` system catalog to determine the correct parameters. In the second form, the user supplies the language parameters along with the language name. The second form can be used to create a language that is not defined in `pg_pltemplate`, but this approach is considered obsolete.

When the server finds an entry in the `pg_pltemplate` catalog for the given language name, it will use the catalog data even if the command includes language parameters. This behavior simplifies loading of old dump files, which are likely to contain out-of-date information about language support functions.

Ordinarily, the user must have the WarehousePG superuser privilege to register a new language. However, the owner of a database can register a new language within that database if the language is listed in the `pg_pltemplate` catalog and is marked as allowed to be created by database owners (`tmpldbacreate` is `true`). The default is that trusted languages can be created by database owners, but this can be adjusted by superusers by modifying the contents of `pg_pltemplate`. The creator of a language becomes its owner and can later drop it, rename it, or assign it to a new owner.

`CREATE OR REPLACE LANGUAGE` will either create a new language, or replace an existing definition. If the language already exists, its parameters are updated according to the values specified or taken from `pg_pltemplate`, but the language's ownership and permissions settings do not change, and any existing functions written in the language are assumed to still be valid. In addition to the normal privilege requirements for creating a language, the user must be superuser or owner of the existing language. The `REPLACE` case is mainly meant to be used to ensure that the language exists. If the language has a `pg_pltemplate` entry then `REPLACE` will not actually change anything about an existing definition, except in the unusual case where the `pg_pltemplate` entry has been modified since the language was created.

Parameters

TRUSTED `TRUSTED` specifies that the language does not grant access to data that the user would not otherwise have. If this key word is omitted when registering the language, only users with the WarehousePG superuser privilege can use this language to create new functions.

PROCEDURAL This is a noise word.

name The name of the new procedural language. The name must be unique among the languages in the database. For backward compatibility, the name can be enclosed by single quotes.

HANDLER call_handler The name of a previously registered function that will be called to run the procedural language's functions. The call handler for a procedural language must be written in a compiled language such as C with version 1 call convention and registered with WarehousePG as a function taking no arguments and returning the `language_handler` type, a placeholder type that is simply used to identify the function as a call handler.

INLINE inline_handler The name of a previously registered function that is called to run an anonymous code block in this language that is created with the DO command. If no inline_handler function is specified, the language does not support anonymous code blocks. The handler function must take one argument of type `internal`, which is the DO command internal representation. The function typically returns `void`. The return value of the handler is ignored.

VALIDATOR valfunction The name of a previously registered function that will be called when a new function in the language is created, to validate the new function. If no validator function is specified, then WarehousePG will not check a new function when it is created. The validator function must take one argument of type `oid`, which will be the OID of the to-be-created function, and will typically return `void`. A validator function would typically inspect the function body for syntactical correctness, but it can also look at other properties of the function, for example if the language cannot handle certain argument types. To signal an error, the validator function should use the `ereport()` function. The return value of the function is ignored.

> **Note** The `TRUSTED` option and the support function name(s) are ignored if the server has an entry for the specified language name in `pg_pltemplate`.

Notes

Use DROP LANGUAGE to drop procedural languages.

The system catalog pg_language records information about the currently installed languages. Also, the psql command `\dL` lists the installed languages.

To create functions in a procedural language, a user must have the `USAGE` privilege for the language. By default, `USAGE` is granted to `PUBLIC` (everyone) for trusted languages. This may be revoked if desired.

Procedural languages are local to individual databases. However, a language can be installed into the `template1` database, which will cause it to be available automatically in all subsequently-created databases.

The call handler function, the inline handler function (if any), and the validator function (if any) must already exist if the server does not have an entry for the language in `pg_pltemplate`. But when there is an entry, the functions need not already exist; they will be automatically defined if not present in the database. (This might result in `CREATE LANGUAGE` failing, if the shared library that implements the language is not available in the installation.)

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Examples

The preferred way of creating any of the standard procedural languages is to use `CREATE EXTENSION` instead of `CREATE LANGUAGE`. For example:

```
CREATE EXTENSION plperl;
```

For a language not known in the `pg_pltemplate` catalog, a sequence such as this is needed:

```
CREATE FUNCTION plsample_call_handler() RETURNS
language_handler
    AS '$libdir/plsample'
    LANGUAGE C;
CREATE LANGUAGE plsample
    HANDLER plsample_call_handler;
```

Compatibility

`CREATE LANGUAGE` is a WarehousePG extension.

7.1.65 CREATE MATERIALIZED VIEW

Defines a new materialized view.

Synopsis

```
CREATE MATERIALIZED VIEW [ IF  NOT EXISTS ] <table_name>
    [ (<column_name> [, ...] ) ]
    [ USING <method> ]
    [ WITH ( <storage_parameter> [= <value>] [, ... ] ) ]
    [ TABLESPACE <tablespace_name> ]
    AS <query>
    [ WITH [ NO ] DATA ]
    [DISTRIBUTED {| BY <column> [<opclass>], [ ... ] | RANDOMLY | REPLICATED }]
```

Description

`CREATE MATERIALIZED VIEW` defines a materialized view of a query. The query is run and used to populate the view at the time the command is issued (unless `WITH NO DATA` is used) and can be refreshed later using REFRESH MATERIALIZED VIEW.

`CREATE MATERIALIZED VIEW` is similar to `CREATE TABLE AS`, except that it also remembers the query used to initialize the view, so that it can be refreshed later upon demand. To refresh materialized view data, use the `REFRESH MATERIALIZED VIEW` command. A materialized view has many of the same properties as a table, but there is no support for temporary materialized views.

Parameters

IF NOT EXISTS Do not throw an error if a materialized view with the same name already exists. A notice is issued in this case. Note that there is no guarantee that the existing materialized view is anything like the one that would have been created.

table_name The name (optionally schema-qualified) of the materialized view to be created.

column_name The name of a column in the new materialized view. The column names are assigned based on position. The first column name is assigned to the first column of the query result, and so on. If a column name is not provided, it is taken from the output column names of the query.

USING method This optional clause specifies the table access method to use to store the contents for the new materialized view; the method needs be an access method of type `TABLE`. If this option is not specified, the default table access method is chosen for the new materialized view. See default_table_access_method for more information.

WITH (storage_parameter [= value] [, ...]) This clause specifies optional storage parameters for the materialized view. All parameters supported for `CREATE TABLE` are also supported for `CREATE MATERIALIZED VIEW`. See CREATE TABLE for more information.

TABLESPACE tablespace_name The tablespace_name is the name of the tablespace in which the new materialized view is to be created. If not specified, server configuration parameter default_tablespace is consulted.

query A SELECT, TABLE, or VALUES command. This query will run within a security-restricted operation; in particular, calls to functions that themselves create temporary tables will fail.

WITH [NO] DATA This clause specifies whether or not the materialized view should be populated with data at creation time. `WITH DATA` is the default, populate the materialized view. For `WITH NO DATA`, the materialized view is not populated with data, is flagged as unscannable, and cannot be queried until `REFRESH MATERIALIZED VIEW` is used to populate the materialized view.

DISTRIBUTED BY (column [opclass], [...]) DISTRIBUTED RANDOMLY DISTRIBUTED REPLICATED Used to declare the WarehousePG distribution policy for the materialized view data. For information about a table distribution policy, see CREATE TABLE.

Notes

Materialized views are read only. The system will not allow an `INSERT`, `UPDATE`, or `DELETE` on a materialized view. Use `REFRESH MATERIALIZED VIEW` to update the materialized view data.

If you want the data to be ordered upon generation, you must use an `ORDER BY` clause in the materialized view query. However, if a materialized view query contains an `ORDER BY` or `SORT` clause, the data is not guaranteed to be ordered or sorted if `SELECT` is performed on the materialized view.

Examples

Create a view consisting of all comedy films:

```
CREATE MATERIALIZED VIEW comedies AS SELECT * FROM films
WHERE kind = 'comedy';
```

This will create a view containing the columns that are in the `film` table at the time of view creation. Though `*` was used to create the materialized view, columns added later to the table will not be part of the view.

Create a view that gets the top ten ranked baby names:

```
CREATE MATERIALIZED VIEW topten AS SELECT name, rank, gender, year FROM
names, rank WHERE rank < '11' AND names.id=rank.id;
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Compatibility

`CREATE MATERIALIZED VIEW` is a WarehousePG extension of the SQL standard.

See Also

SELECT, VALUES, CREATE VIEW, ALTER MATERIALIZED VIEW, DROP MATERIALIZED VIEW, REFRESH MATERIALIZED VIEW

7.1.66 CREATE OPERATOR

Defines a new operator.

Synopsis

```
CREATE OPERATOR <name> (
       { FUNCTION | PROCEDURE } = <function\_name>
       [, LEFTARG = <left_type>] [, RIGHTARG = <right_type>]
       [, COMMUTATOR = <com_op>] [, NEGATOR = <neg_op>]
       [, RESTRICT = <res_proc>] [, JOIN = <join_proc>]
       [, HASHES] [, MERGES] )
```

Description

`CREATE OPERATOR` defines a new operator. The user who defines an operator becomes its owner. If a schema name is given, then the operator is created in the specified schema. Otherwise, it is created in the current schema.

The operator name is a sequence of up to `NAMEDATALEN`-1 (63 by default) characters from the following list: `+ - * / < > = ~ ! @ # % ^ & | ` ?` .

There are a few restrictions on your choice of name:

- `--` and `/*` cannot appear anywhere in an operator name, since they will be taken as the start of a comment.
- A multicharacter operator name cannot end in `+` or `-`, unless the name also contains at least one of these characters: `~ ! @ # % ^ & | ` ?`

  For example, `@-` is an allowed operator name, but `*-` is not. This restriction allows WarehousePG to parse SQL-compliant commands without requiring spaces between tokens.
- The use of `=>` as an operator name is deprecated. It may be disallowed altogether in a future release.

The operator `!=` is mapped to `<>` on input, so these two names are always equivalent.

At least one of `LEFTARG` and `RIGHTARG` must be defined. For binary operators, both must be defined. For right unary operators, only `LEFTARG` should be defined, while for left unary operators only `RIGHTARG` should be defined.

Note: Right unary, also called postfix, operators are deprecated and may be removed in a future WarehousePG release.

The function_name function must have been previously defined using `CREATE FUNCTION`, must be `IMMUTABLE`, and must be defined to accept the correct number of arguments (either one or two) of the indicated types.

In the syntax of `CREATE OPERATOR`, the keywords `FUNCTION` and `PROCEDURE` are equivalent, but the referenced function must in any case be a function, not a procedure. The use of the keyword `PROCEDURE` here is historical and deprecated.

The other clauses specify optional operator optimization clauses. Their meaning is detailed in the PostgreSQL Operator Optimization Information documentation.

To be able to create an operator, you must have `USAGE` privilege on the argument types and the return type, as well as `EXECUTE` privilege on the underlying function. If a commutator or negator operator is specified, you must own these operators.

Parameters

name The (optionally schema-qualified) name of the operator to be defined. Refer to the *Description* above for allowable characters. The name can be schema-qualified, for example `CREATE OPERATOR myschema.+ (...)`. If not, then the operator is created in the current schema. Two operators in the same schema can have the same name if they operate on different data types. This is called *overloading*.

function_name The function used to implement this operator (must be an `IMMUTABLE` function).

left_type The data type of the operator's left operand, if any. This option would be omitted for a left-unary operator.

right_type The data type of the operator's right operand, if any. This option would be omitted for a right-unary operator.

com_op The commutator of this operator. The optional `COMMUTATOR` clause names an operator that is the commutator of the operator being defined. We say that operator A is the commutator of operator B if (x A y) equals (y B x) for all possible input values x, y. Notice that B is also the commutator of A. For example, operators `<` and `>` for a particular data type are usually each others commutators, and operator + is usually commutative with itself. But operator `-` is usually not commutative with anything. The left operand type of a commutable operator is the same as the right operand type of its commutator, and vice versa. So the name of the commutator operator is all that needs to be provided in the `COMMUTATOR` clause.

neg_op The negator of this operator. The optional `NEGATOR` clause names an operator that is the negator of the operator being defined. We say that operator A is the negator of operator B if both return Boolean results and (x A y) equals NOT (x B y) for all possible inputs x, y. Notice that B is also the negator of A. For example, `<` and `>=` are a negator pair for most data types. An operator's negator must have the same left and/or right operand types as the operator to be defined, so only the operator name need be given in the `NEGATOR` clause.

res_proc The restriction selectivity estimator function for this operator. The optional `RESTRICT` names a restriction selectivity estimation function for the operator. (Note that this is a function name, not an operator name.) `RESTRICT` clauses only make sense for binary operators that return `boolean`.

join_proc The join selectivity estimator function for this operator. The optional `JOIN` clause names a join selectivity estimation function for the operator. (Note that this is a function name, not an operator name.) `JOIN` clauses only make sense for binary operators that return `boolean`.

HASHES Indicates this operator can support a hash join. The optional `HASHES` clause tells the system that it is permissible to use the hash join method for a join based on this operator. `HASHES` only makes sense for a binary operator that returns `boolean`. The hash join operator can only return true for pairs of left and right values that hash to the same hash code. If two values are put in different hash buckets, the join will never compare them, implicitly assuming that the result of the join operator must be false. Because of this, it never makes sense to specify `HASHES` for operators that do not represent equality.

MERGES Indicates this operator can support a merge join. The `MERGES` clause, if present, tells the system that it is permissible to use the merge-join method for a join based on this operator. `MERGES` only makes sense for a binary operator that returns `boolean`, and in practice the operator must represent equality for some data type or pair of data types.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

To give a schema-qualified operator name in com_op or the other optional arguments, use the `OPERATOR()` syntax, for example:

```
COMMUTATOR = OPERATOR(myschema.===) ,
```

Notes

Refer to User-defined Operators in the PostgreSQL documentation for further information.

Any functions used to implement the operator must be defined as `IMMUTABLE`.

It is not possible to specify an operator's lexical precedence in `CREATE OPERATOR`, because the parser's precedence behavior is hard-wired. See Operator Precedence in the PostgreSQL documentation for precedence details.

Use DROP OPERATOR to delete user-defined operators from a database. Use ALTER OPERATOR to modify operators in a database.

Examples

The following command defines a new operator, area-equality, for the data type `box`:

```
CREATE OPERATOR === (
    LEFTARG = box,
    RIGHTARG = box,
    FUNCTION = area_equal_function,
    COMMUTATOR = ===,
    NEGATOR = !==,
    RESTRICT = area_restriction_function,
    JOIN = area_join_function,
    HASHES, MERGES
);
```

The following example creates an operator for adding two complex numbers. The example assumes that we have already created the definition of type `complex`. First define the function that does the work, then define the operator:

```
CREATE FUNCTION complex_add(complex, complex)
    RETURNS complex
    AS 'filename', 'complex_add'
    LANGUAGE C IMMUTABLE STRICT;
CREATE OPERATOR + (
    leftarg = complex,
    rightarg = complex,
    procedure = complex_add,
    commutator = +
);
```

To use this operator in a query:

```
SELECT (a + b) AS c FROM test_complex;
```

Compatibility

`CREATE OPERATOR` is a WarehousePG extension to the SQL standard. The SQL standard does not provide for user-defined operators.

7.1.67 CREATE OPERATOR CLASS

Defines a new operator class.

Synopsis

```
CREATE OPERATOR CLASS <name> [DEFAULT] FOR TYPE <data_type>
  USING <index_method> [ FAMILY <family_name> ] AS
  { OPERATOR <strategy_number> <operator_name> [ ( <op_type>, <op_type> ) ] [ FOR SEARCH | FOR ORDER BY <sort_family_name> ]
  | FUNCTION <support_number> [ ( <op_type> [ , <op_type> ] ) ] <function_name> (<argument_type> [, ...] )
  | STORAGE <storage_type>
  } [, ... ]
```

Description

`CREATE OPERATOR CLASS` creates a new operator class. An operator class defines how a particular data type can be used with an index. The operator class specifies that certain operators will fill particular roles or strategies for this data type and this index method. The operator class also specifies the support functions to be used by the index method when the operator class is selected for an index column. All of the operators and functions used by an operator class must be defined before the operator class is created. Any functions used to implement the operator class must be defined as `IMMUTABLE`.

If a schema name is given, then the operator class is created in the specified schema. Otherwise, it is created in the current schema. Two operator classes in the same schema can have the same name only if they are for different index methods.

The user who defines an operator class becomes its owner. Presently, the creating user must be a superuser. (This restriction is made because an erroneous operator class definition could confuse or even crash the server.)

`CREATE OPERATOR CLASS` does not presently check whether the operator class definition includes all the operators and functions required by the index method, nor whether the operators and functions form a self-consistent set. It is the user's responsibility to define a valid operator class.

Related operator classes can be grouped into operator families. To add a new operator class to an existing family, specify the `FAMILY` option in `CREATE OPERATOR CLASS`. Without this option, the new class is placed into a family named the same as the new class (WarehousePG creates that family if it doesn't already exist).

Refer to Interfacing Extensions to Indexes in the PostgreSQL documentation for more information.

Parameters

name The (optionally schema-qualified) name of the operator class to be defined. Two operator classes in the same schema can have the same name only if they are for different index methods.

DEFAULT If present, makes the operator class the default operator class for its data type. At most one operator class can be the default for a specific data type and index method.

data_type The column data type that this operator class is for.

index_method The name of the index method that this operator class is for.

family_name The name of the existing operator family to add this operator class to. If not specified, a family named the same as the operator class is used (creating it, if it doesn't already exist).

strategy_number The index method's strategy number for an operator associated with the operator class. The operators associated with an operator class are identified by *strategy numbers*, which serve to identify the semantics of each operator within the context of its operator class.

operator_name The name (optionally schema-qualified) of an operator associated with the operator class.

op_type In an `OPERATOR` clause, the operand data type(s) of the operator, or `NONE` to signify a left-unary or right-unary operator. The operand data types can be omitted in the normal case where they are the same as the operator class's data type.

In a `FUNCTION` clause, the operand data type(s) the function is intended to support, if different from the input data type(s) of the function (for B-tree comparison functions and hash functions) or the class's data type (for B-tree sort support functions and all functions in GiST, SP-GiST, GIN, and BRIN operator classes). These defaults are correct, and so op_type need not be specified in `FUNCTION` clauses, except for the case of a B-tree sort support function that is meant to support cross-data-type comparisons.

sort_family_name The name (optionally schema-qualified) of an existing `btree` operator family that describes the sort ordering associated with an ordering operator.

If neither `FOR SEARCH` nor `FOR ORDER BY` is specified, `FOR SEARCH` is the default.

support_number The index method's support function number for a function associated with the operator class.

function_name The name (optionally schema-qualified) of a function that is an index method support function for the operator class.

argument_type The parameter data type(s) of the function.

storage_type The data type actually stored in the index. Normally this is the same as the column data type, but some index methods (currently GiST, GIN, and BRIN) allow it to be different. The `STORAGE` clause must be omitted unless the index method allows a different type to be used. If the column data_type is specified as `anyarray`, the storage_type can be declared as `anyelement` to indicate that the index entries are members of the element type belonging to the actual array type that each particular index is created for.

The `OPERATOR`, `FUNCTION`, and `STORAGE` clauses can appear in any order.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Notes

Because the index machinery does not check access permissions on functions before using them, including a function or operator in an operator class is the same as granting public execute permission on it. This is usually not an issue for the sorts of functions that are useful in an operator class.

The operators should not be defined by SQL functions. A SQL function is likely to be inlined into the calling query, which will prevent the optimizer from recognizing that the query matches an index.

Any functions used to implement the operator class must be defined as `IMMUTABLE`.

Before WarehousePG 6.0, the `OPERATOR` clause could include a `RECHECK` option. This option is no longer supported. WarehousePG now determines whether an index operator is "lossy" on-the-fly at run time. This allows more efficient handling of cases where an operator might or might not be lossy.

Examples

The following example command defines a GiST index operator class for the data type `_int4` (array of int4). See the `intarray` contrib module for the complete example.

```
CREATE OPERATOR CLASS gist__int_ops
    DEFAULT FOR TYPE _int4 USING gist AS
        OPERATOR 3 &&,
        OPERATOR 6 = (anyarray, anyarray),
        OPERATOR 7 @>,
        OPERATOR 8 <@,
        OPERATOR 20 @@ (_int4, query_int),
        FUNCTION 1 g_int_consistent (internal, _int4, smallint, oid, internal),
        FUNCTION 2 g_int_union (internal, internal),
        FUNCTION 3 g_int_compress (internal),
        FUNCTION 4 g_int_decompress (internal),
        FUNCTION 5 g_int_penalty (internal, internal, internal),
        FUNCTION 6 g_int_picksplit (internal, internal),
        FUNCTION 7 g_int_same (_int4, _int4, internal);
```

Compatibility

`CREATE OPERATOR CLASS` is a WarehousePG extension. There is no `CREATE OPERATOR CLASS` statement in the SQL standard.

7.1.68 CREATE OPERATOR FAMILY

Defines a new operator family.

Synopsis

```
CREATE OPERATOR FAMILY <name>  USING <index_method>
```

Description

`CREATE OPERATOR FAMILY` creates a new operator family. An operator family defines a collection of related operator classes, and perhaps some additional operators and support functions that are compatible with these operator classes but not essential for the functioning of any individual index. (Operators and functions that are essential to indexes should be grouped within the relevant operator class, rather than being "loose" in the operator family. Typically, single-data-type operators are bound to operator classes, while cross-data-type operators can be loose in an operator family containing operator classes for both data types.)

The new operator family is initially empty. It should be populated by issuing subsequent `CREATE OPERATOR CLASS` commands to add contained operator classes, and optionally `ALTER OPERATOR FAMILY` commands to add "loose" operators and their corresponding support functions.

If a schema name is given then the operator family is created in the specified schema. Otherwise it is created in the current schema. Two operator families in the same schema can have the same name only if they are for different index methods.

The user who defines an operator family becomes its owner. Presently, the creating user must be a superuser. (This restriction is made because an erroneous operator family definition could confuse or even crash the server.)

Refer to Interfacing Extensions to Indexes in the PostgreSQL documentation for more information.

Parameters

name The (optionally schema-qualified) name of the operator family to be created.

index_method The name of the index method this operator family is for.

Compatibility

`CREATE OPERATOR FAMILY` is a WarehousePG extension. There is no `CREATE OPERATOR FAMILY` statement in the SQL standard.

7.1.69 CREATE POLICY

Defines a new row-level security policy for a table.

Synopsis

```
CREATE POLICY <name> ON <table_name>
    [ AS { PERMISSIVE | RESTRICTIVE } ]
    [ FOR { ALL | SELECT | INSERT | UPDATE | DELETE } ]
    [ TO { <role_name> | PUBLIC | CURRENT_USER | SESSION_USER } [, ...] ]
    [ USING ( <using_expression> ) ]
    [ WITH CHECK ( <check_expression> ) ]
```

Description

The `CREATE POLICY` command defines a new row-level security policy for a table. Note that row-level security must be enabled on the table (using `ALTER TABLE ... ENABLE ROW LEVEL SECURITY`) in order for WarehousePG to apply created policies.

A policy grants the permission to select, insert, update, or delete rows that match the relevant policy expression. Existing table rows are checked against the expression specified in `USING`, while new rows that would be created via `INSERT` or `UPDATE` are checked against the expression specified in `WITH CHECK`. When a `USING` expression returns true for a given row, then that row is visible to the user, while if false or null is returned then the row is not visible. When a `WITH CHECK` expression returns true for a row, then that row is inserted or updated, while if false or null is returned then an error occurs.

For `INSERT` and `UPDATE` statements, `WITH CHECK` expressions are enforced before any actual data modifications are made, and before any other constraints.

Policy names are per-table. Therefore, one policy name can be used for many different tables and have a definition for each table which is appropriate to that table.

Policies can be applied for specific commands or for specific roles. The default for newly-created policies is that they apply for all commands and roles, unless otherwise specified. Multiple policies may apply to a single command; see below for more details. The table in Per-Command Policies summarizes how the different types of policies apply to specific commands.

For policies that can have both `USING` and `WITH CHECK` expressions (`ALL` and `UPDATE`), if no `WITH CHECK` expression is defined, then the `USING` expression will be used both to determine which rows are visible (normal `USING` case) and which new rows will be allowed to be added (`WITH CHECK` case).

If row-level security is enabled for a table, but no applicable policies exist, a "default deny" policy is assumed, so that no rows will be visible or updatable.

Parameters

name The name of the policy to be created. This must be distinct from the name of any other policy defined for the table.

table_name The name (optionally schema-qualified) of the table to which the policy applies.

PERMISSIVE Specify that the policy is to be created as a permissive policy. All permissive policies which are applicable to a given query will be combined together using the Boolean `OR` operator. By creating permissive policies, administrators can add to the set of records which can be accessed. Policies are permissive by default.

RESTRICTIVE Specify that the policy is to be created as a restrictive policy. All restrictive policies which are applicable to a given query will be combined together using the Boolean `AND` operator. By creating restrictive policies, administrators can reduce the set of records which can be accessed as all restrictive policies must be passed for each record.

You must define at least one permissive policy to grant access to records before restrictive policies can be usefully used to reduce that access. If only restrictive policies exist, then no records will be accessible. When a mix of permissive and restrictive policies are present, a record is only accessible if at least one of the permissive policies passes, in addition to all the restrictive policies.

command The command to which the policy applies. Valid options are `ALL`, `SELECT`, `INSERT`, `UPDATE`, and `DELETE`. `ALL` is the default. See below for specifics regarding how these are applied.

role_name The role(s) to which the policy is to be applied. The default is `PUBLIC`, which will apply the policy to all roles.

using_expression Any SQL conditional expression (returning `boolean`). The conditional expression cannot contain any aggregate or window functions. This expression will be added to queries that refer to the table if row-level security is enabled. Rows for which the expression returns true will be visible. Any rows for which the expression returns false or null will not be visible to the user (in a `SELECT`), and will not be available for modification (in an `UPDATE` or `DELETE`). Such rows are silently suppressed; no error is reported.

check_expression Any SQL conditional expression (returning `boolean`). The conditional expression cannot contain any aggregate or window functions. This expression will be used in `INSERT` and `UPDATE` queries against the table if row-level security is enabled. Only rows for which the expression evaluates to true will be allowed. An error will be thrown if the expression evaluates to false or null for any of the records inserted or any of the records that result from the update. Note that the check_expression is evaluated against the proposed new contents of the row, not the original contents.

Per-Command Policies

ALL Using `ALL` for a policy means that it will apply to all commands, regardless of the type of command. If an `ALL` policy exists and more specific policies exist, then both the `ALL` policy and the more specific policy (or policies) will be applied. Additionally, `ALL` policies will be applied to both the selection side of a query and the modification side, using the `USING` expression for both cases if only a `USING` expression has been defined.

As an example, if an `UPDATE` is issued, then the `ALL` policy will be applicable both to what the `UPDATE` will be able to select as rows to be updated (applying the `USING` expression), and to the resulting updated rows, to check if they are permitted to be added to the table (applying the `WITH CHECK` expression, if defined, and the `USING` expression otherwise). If an `INSERT` or `UPDATE` command attempts to add rows to the table that do not pass the `ALL` policy's `WITH CHECK` expression, the entire command will be aborted.

SELECT Using `SELECT` for a policy means that it will apply to `SELECT` queries and whenever `SELECT` permissions are required on the relation that the policy is defined for. The result is that only those records from the relation that pass the `SELECT` policy will be returned during a `SELECT` query, and that queries that require `SELECT` permissions, such as `UPDATE`, will also only see those records that are allowed by the `SELECT` policy. A `SELECT` policy cannot have a `WITH CHECK` expression, as it only applies in cases where records are being retrieved from the relation.

INSERT Using `INSERT` for a policy means that it will apply to `INSERT` commands. Rows being inserted that do not pass this policy will result in a policy violation error, and the entire `INSERT` command will be aborted. An `INSERT` policy cannot have a `USING` expression, as it only applies in cases where records are being added to the relation.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Note that `INSERT` with `ON CONFLICT DO UPDATE` checks `INSERT` policies' `WITH CHECK` expressions only for rows appended to the relation by the `INSERT` path.

UPDATE Using `UPDATE` for a policy means that it will apply to `UPDATE`, `SELECT FOR UPDATE`, and `SELECT FOR SHARE` commands, as well as auxiliary `ON CONFLICT DO UPDATE` clauses of `INSERT` commands. Since `UPDATE` involves pulling an existing record and replacing it with a new modified record, `UPDATE` policies accept both a `USING` expression and a `WITH CHECK` expression. The `USING` expression determines which records the `UPDATE` command will see to operate against, while the `WITH CHECK` expression defines which modified rows are allowed to be stored back into the relation.

Any rows whose updated values do not pass the `WITH CHECK` expression will cause an error, and the entire command will be aborted. If only a `USING` clause is specified, then that clause will be used for both `USING` and `WITH CHECK` cases.

Typically an `UPDATE` command also needs to read data from columns in the relation being updated (e.g., in a `WHERE` clause or a `RETURNING` clause, or in an expression on the right hand side of the `SET` clause). In this case, `SELECT` rights are also required on the relation being updated, and the appropriate `SELECT` or `ALL` policies will be applied in addition to the `UPDATE` policies. Thus the user must have access to the row(s) being updated through a `SELECT` or `ALL` policy in addition to being granted permission to update the row(s) via an `UPDATE` or `ALL` policy.

When an `INSERT` command has an auxiliary `ON CONFLICT DO UPDATE` clause, if the `UPDATE` path is taken, the row to be updated is first checked against the `USING` expressions of any `UPDATE` policies, and then the new updated row is checked against the `WITH CHECK` expressions. Note, however, that unlike a standalone `UPDATE` command, if the existing row does not pass the `USING` expressions, an error will be thrown (the `UPDATE` path will never be silently avoided).

DELETE Using `DELETE` for a policy means that it will apply to `DELETE` commands. Only rows that pass this policy will be seen by a `DELETE` command. There can be rows that are visible through a `SELECT` that are not available for deletion, if they do not pass the `USING` expression for the `DELETE` policy.

In most cases a `DELETE` command also needs to read data from columns in the relation that it is deleting from (e.g., in a `WHERE` clause or a `RETURNING` clause). In this case, `SELECT` rights are also required on the relation, and the appropriate `SELECT` or `ALL` policies will be applied in addition to the `DELETE` policies. Thus the user must have access to the row(s) being deleted through a `SELECT` or `ALL` policy in addition to being granted permission to delete the row(s) via a `DELETE` or `ALL` policy.

A `DELETE` policy cannot have a `WITH CHECK` expression, as it only applies in cases where records are being deleted from the relation, so that there is no new row to check.

Command	SELECT/ALL policy USING expresson	INSERT/ALL policy WITH CHECK expression	UPDATE/ALL policy USING expression	UPDATE/ALL policy WITH CHECK expression	DELETE/ALL policy USING expression
SELECT	Existing row	--	--	--	--
SELECT FOR UPDATE/SHARE	Existing row	--	Existing row	--	--
INSERT	--	New row	--	--	--
INSERT ... RETURNING	New row[a]	New row	--	--	--
UPDATE	Existing and new rows[a]	--	Existing row	New row	--
DELETE	Existing row[a]	--	--	--	Existing row
ON CONFLICT DO UPDATE	Existing and new rows	--	Existing row	New row	--

[a]If read access is required to the existing or new row (for example, a `WHERE` or `RETURNING` clause that refers to columns from the relation).

Application of Multiple Policies

When multiple policies of different command types apply to the same command (for example, `SELECT` and `UPDATE` policies applied to an `UPDATE` command), then the user must have both types of permissions (for example, permission to select rows from the relation as well as permission to update them). Thus the expressions for one type of policy are combined with the expressions for the other type of policy using the `AND` operator.

When multiple policies of the same command type apply to the same command, then there must be at least one `PERMISSIVE` policy granting access to the relation, and all of the `RESTRICTIVE` policies must pass. Thus all the `PERMISSIVE` policy expressions are combined using `OR`, all the `RESTRICTIVE` policy expressions are combined using `AND`, and the results are combined using `AND`. If there are no `PERMISSIVE` policies, then access is denied.

Note that, for the purposes of combining multiple policies, `ALL` policies are treated as having the same type as whichever other type of policy is being applied.

For example, in an `UPDATE` command requiring both `SELECT` and `UPDATE` permissions, if there are multiple applicable policies of each type, they will be combined as follows:

```
expression from RESTRICTIVE SELECT/ALL policy 1
AND
expression from RESTRICTIVE SELECT/ALL policy 2
AND
...
AND
(
  expression from PERMISSIVE SELECT/ALL policy 1
  OR
  expression from PERMISSIVE SELECT/ALL policy 2
  OR
  ...
)
AND
expression from RESTRICTIVE UPDATE/ALL policy 1
AND
expression from RESTRICTIVE UPDATE/ALL policy 2
AND
...
AND
(
  expression from PERMISSIVE UPDATE/ALL policy 1
  OR
  expression from PERMISSIVE UPDATE/ALL policy 2
  OR
  ...
)
```

Notes

You must be the owner of a table to create or change policies for it.

While policies will be applied for explicit queries against tables in the database, they are not applied when the system is performing internal referential integrity checks or validating constraints. This means there are indirect ways to determine that a given value exists. An example of this is attempting to insert a duplicate value into a column that is a primary key or has a unique constraint. If the insert fails then the user can infer that the value already exists. (This example assumes that the user is permitted by policy to insert records which they are not allowed to see.) Another example is where a user is allowed to insert into a table which references another, otherwise hidden table. Existence can be determined by the user inserting values into the referencing table, where success would indicate that the value exists in the referenced table. These issues can be addressed by carefully crafting policies to prevent users from being able to insert, delete, or update records at all which might possibly indicate a value they are not otherwise able to see, or by using generated values (e.g., surrogate keys) instead of keys with external meanings.

Generally, the system will enforce filter conditions imposed using security policies prior to qualifications that appear in user queries, in order to prevent inadvertent exposure of the protected data to user-defined functions which might not be trustworthy. However, functions and operators marked by the system (or the system administrator) as `LEAKPROOF` may be evaluated before policy expressions, as they are assumed to be trustworthy.

Since policy expressions are added to the user's query directly, they will be run with the rights of the user running the overall query. Therefore, users who are using a given policy must be able to access any tables or functions referenced in the expression or they will simply receive a permission denied error when attempting to query the table that has row-level security enabled. This does not change how views work, however. As with normal queries and views, permission checks and policies for the tables which are referenced by a view will use the view owner's rights and any policies which apply to the view owner.

Refer to About Configuring Row-Level Security Policies for more information and practical examples.

Compatibility

`CREATE POLICY` is a WarehousePG extension to the SQL standard.

7.1.70 CREATE PROCEDURE

Defines a new procedure.

Synopsis

```
CREATE [OR REPLACE] PROCEDURE <name>
    ( [ [<argmode>] [<argname>] <argtype> [ { DEFAULT | = } <default_expr> ] [, ...] ] )
  { LANGUAGE <lang_name>
    | TRANSFORM { FOR TYPE <type_name> } [, ... ]
    | { [ EXTERNAL ] SECURITY INVOKER | [ EXTERNAL ] SECURITY DEFINER }
    | SET <configuration_parameter> { TO <value> | = <value> | FROM CURRENT }
    | AS '<definition>'
    | AS '<obj_file>', '<link_symbol>'
  } ...
```

Description

`CREATE PROCEDURE` defines a new procedure. `CREATE OR REPLACE PROCEDURE` either creates a new procedure, or replaces an existing definition. To define a procedure, the user must have the `USAGE` privilege on the language.

If a schema name is included, then the procedure is created in the specified schema. Otherwise it is created in the current schema. The name of the new procedure must not match any existing procedure with the same input argument types in the same schema. However, procedures and functions of different argument types may share a name (overloading).

To update the current definition of an existing procedure, use `CREATE OR REPLACE PROCEDURE`. It is not possible to change the name or argument types of a procedure this way (this would actually create a new, distinct procedure).

When `CREATE OR REPLACE PROCEDURE` is used to replace an existing procedure, the ownership and permissions of the procedure do not change. All other procedure properties are assigned the values specified or implied in the command. You must own the procedure to replace it (this includes being a member of the owning role).

The user that creates the procedure becomes the owner of the procedure.

To be able to create a procedure, you must have `USAGE` privilege on the argument types.

For more information about creating procedures, refer to the User Defined Procedures section of the PostgreSQL documentation.

Parameters

name The name (optionally schema-qualified) of the procedure to create.

argmode The mode of an argument: either `IN`, `INOUT`, or `VARIADIC`. If omitted, the default is `IN`. (`OUT` arguments are currently not supported for procedures. Use `INOUT` instead.)

argname The name of an argument.

argtype The data type(s) of the procedure's arguments (optionally schema-qualified), if any. The argument types may be base, composite, or domain types, or may reference the type of a table column.

Depending on the implementation language it may also be allowed to specify pseudotypes such as `cstring`. Pseudotypes indicate that the actual argument type is either incompletely specified, or outside the set of ordinary SQL data types.

The type of a column is referenced by writing `table_name.column_name%TYPE`. Using this feature can sometimes help make a procedure independent of changes to the definition of a table.

default_expr An expression to be used as the default value if the parameter is not specified. The expression must be coercible to the argument type of the parameter. Each input parameter in the argument list that follows a parameter with a default value must have a default value as well.

lang_name The name of the language that the procedure is implemented in. May be `SQL`, `C`, `internal`, or the name of a user-defined procedural language, e.g. `plpgsql`. Enclosing the name in single quotes is deprecated and requires matching case.

TRANSFORM { FOR TYPE type_name } [, ...] } Lists which transforms a call to the procedure should apply. Transforms convert between SQL types and language-specific data types. Procedural language implementations usually have hardcoded knowledge of the built-in types, so those don't need to be listed here. If a procedural language implementation does not know how to handle a type and no transform is supplied, it will fall back to a default behavior for converting data types, but this depends on the implementation.

[EXTERNAL] SECURITY INVOKER [EXTERNAL] SECURITY DEFINER `SECURITY INVOKER` (the default) indicates that the procedure is to be run with the privileges of the user that calls it. `SECURITY DEFINER` specifies that the procedure is to be run with the privileges of the user that created it. The key word `EXTERNAL` is allowed for SQL conformance, but it is optional since, unlike in SQL, this feature applies to all procedures not just external ones. A `SECURITY DEFINER` procedure cannot execute transaction control statements (for example, `COMMIT` and `ROLLBACK`, depending on the language).

configuration_parameter value The `SET` clause applies a value to a session configuration parameter when the procedure is entered. The configuration parameter is restored to its prior value when the procedure exits. `SET FROM CURRENT` saves the value of the parameter that is current when `CREATE PROCEDURE` is run as the value to be applied when the procedure is entered. If a `SET` clause is attached to a procedure, then the effects of a `SET LOCAL` command executed inside the procedure for the same variable are restricted to the procedure: the configuration parameter's prior value is still restored at procedure exit. However, an ordinary `SET` command (without `LOCAL`) overrides the `SET` clause, much as it would do for a previous `SET LOCAL` command: the effects of such a command will persist after procedure exit, unless the current transaction is rolled back. If a `SET` clause is attached to a procedure, then that procedure cannot execute transaction control statements (for example, `COMMIT` and `ROLLBACK`, depending on the language). See SET for more information about allowed parameter names and values.

definition A string constant defining the procedure; the meaning depends on the language. It may be an internal procedure name, the path to an object file, an SQL command, or text in a procedural language.

It is often helpful to use dollar quoting (refer to Dollar-Quoted String Constants in the PostgreSQL documentation) to write the procedure definition string, rather than the normal single quote syntax. Without dollar quoting, any single quotes or backslashes in the procedure definition must be escaped by doubling them.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

obj_file, link_symbol This form of the `AS` clause is used for dynamically loadable C language procedures when the procedure name in the C language source code is not the same as the name of the SQL procedure. The string obj_file is the name of the file containing the dynamically loadable object, and is interpreted as for the LOAD command. The string link_symbol is the name of the procedure in the C language source code. If the link symbol is omitted, it is assumed to be the same as the name of the SQL procedure being defined. When repeated `CREATE PROCEDURE` calls refer to the same object file, the file is only loaded once per session. To unload and reload the file (perhaps during development), start a new session.

Notes

See CREATE FUNCTION for more details on function creation that also apply to procedures.

Use CALL to execute a procedure.

Examples

```
CREATE PROCEDURE insert_data(a integer, b integer)
LANGUAGE SQL
AS $$
INSERT INTO tbl VALUES (a);
INSERT INTO tbl VALUES (b);
$$;

CALL insert_data(1, 2);
```

Compatibility

A `CREATE PROCEDURE` command is defined in the SQL standard. The WarehousePG version is similar but not fully compatible. For details see also CREATE FUNCTION.

See Also

ALTER PROCEDURE, DROP PROCEDURE, CREATE FUNCTION, CALL

Parent topic: SQL Commands

7.1.71 CREATE PROTOCOL

Registers a custom data access protocol that can be specified when defining a WarehousePG external table.

Synopsis

```
CREATE [TRUSTED] PROTOCOL <name> (
   [readfunc='<read_call_handler>'] [, writefunc='<write_call_handler>']
   [, validatorfunc='<validate_handler>' ])
```

Description

`CREATE PROTOCOL` associates a data access protocol name with call handlers that are responsible for reading from and writing data to an external data source. You must be a superuser to create a protocol.

The `CREATE PROTOCOL` command must specify either a read call handler or a write call handler. The call handlers specified in the `CREATE PROTOCOL` command must be defined in the database.

The protocol name can be specified in a `CREATE EXTERNAL TABLE` command.

For information about creating and enabling a custom data access protocol, refer to theExample Custom Data Access Protocol documentation.

Parameters

TRUSTED If not specified, only superusers and the protocol owner can create external tables using the protocol. If specified, superusers and the protocol owner can `GRANT` permissions on the protocol to other database roles.

name The name of the data access protocol. The protocol name is case sensitive. The name must be unique among the protocols in the database.

readfunc= 'read_call_handler' The name of a previously registered function that WarehousePG calls to read data from an external data source. The command must specify either a read call handler or a write call handler.

writefunc= 'write_call_handler' The name of a previously registered function that WarehousePG calls to write data to an external data source. The command must specify either a read call handler or a write call handler.

validatorfunc='validate_handler' An optional validator function that validates the URL specified in the `CREATE EXTERNAL TABLE` command.

Notes

WarehousePG handles external tables of type `file`, `gpfdist`, and `gpfdists` internally. See s3:// Protocol for information about enabling the `S3` protocol. Refer to pxf:// Protocol for information about using the `pxf` protocol.

Any shared library that implements a data access protocol must be located in the same location on all WarehousePG segment hosts. For example, the shared library can be in a location specified by the operating system environment variable `LD_LIBRARY_PATH` on all hosts. You can also specify the location when you define the handler function. For example, when you define the `s3` protocol in the `CREATE PROTOCOL` command, you specify `$libdir/gps3ext.so` as the location of the shared object, where `$libdir` is located at `$GPHOME/lib`.

Compatibility

`CREATE PROTOCOL` is a WarehousePG extension.

7.1.72 CREATE RESOURCE GROUP

Defines a new resource group.

Synopsis

```
CREATE RESOURCE GROUP <name> WITH (<group_attribute>=<value> [, ... ])
```

where group_attribute is one of:

```
[ CONCURRENCY=<integer> ]
CPU_MAX_PERCENT=<integer> | CPUSET=<coordinator_cores>;<segment_cores>
[ CPU_WEIGHT=<integer> ]
[ MEMORY_QUOTA=<integer> ]
[ MIN_COST=<integer> ]
[ IO_LIMIT=' <tablespace_io_limit_spec> [; ...] ' ]
```

Where `<tablespace_io_limit_spec>` is:

```
<tablespace_name> | <oid> : <io_limit_option_spec> [, ...]
```

Where `<io_limit_option_spec>` is:

```
wbps=<io_limit_option_value>
| rbps=<io_limit_option_value>
| wiops=<io_limit_option_value>
| riops=<io_limit_option_value>
```

Where `<io_limit_option_vlaue>` is:

```
<integer> | max
```

Description

Creates a new resource group for WarehousePG resource management. You can create resource groups to manage resources for roles or to manage the resources of a WarehousePG external component such as PL/Container.

A resource group that you create to manage a user role identifies concurrent transaction, memory, CPU, and disk I/O limits for the role when resource groups are enabled. You may assign such resource groups to one or more roles.

A resource group that you create to manage the resources of a WarehousePG external component such as PL/Container identifies the CPU limits for the component when resource groups are enabled. These resource groups use cgroups for both CPU management. Assignment of resource groups to external components is component-specific. For example, you assign a PL/Container resource group when you configure a PL/Container runtime. You cannot assign a resource group that you create for external components to a role, nor can you assign a resource group that you create for roles to an external component.

You must have `SUPERUSER` privileges to create a resource group. The maximum number of resource groups allowed in your WarehousePG cluster is 100.

WarehousePG pre-defines three default resource groups: `admin_group`, `default_group`, and `system_group`. These group names, as well as the group name `none`, are reserved.

To set appropriate limits for resource groups, the WarehousePG administrator must be familiar with the queries typically run on the system, as well as the users/roles running those queries and the external components they may be using, such as PL/Containers

After creating a resource group for a role, assign the group to one or more roles using the ALTER ROLE or CREATE ROLE commands.

After you create a resource group to manage the CPU resources of an external component, configure the external component to use the resource group. For example, configure the PL/Container runtime `resource_group_id`.

Parameters

name The name of the resource group.

CONCURRENCY integer Optional. The maximum number of concurrent transactions, including active and idle transactions, that are permitted for this resource group. The `CONCURRENCY` value must be an integer in the range [0 .. `max_connections`]. The default `CONCURRENCY` value for resource groups defined for roles is 20.

You must set `CONCURRENCY` to `0` for resource groups that you create for external components.

> **Note** You cannot set the `CONCURRENCY` value for the `admin_group` to `0`.

CPU_MAX_PERCENT integer Optional. The percentage of the maximum available CPU resources that the resource group can use. The value range is `1-100`.

CPU_WEIGHT integer Optional. The scheduling priority of the current group. The value range is `1-500`, the default is `100.

CPUSET <coordinator_cores>;<segment_cores>

`CPUSET` identifies the CPU cores to reserve for this resource group on the coordinator host and on segment hosts. The CPU cores that you specify must be available in the system and cannot overlap with any CPU cores that you specify for other resource groups.

> **Note** You must specify either `CPU_MAX_PERCENT` or `CPUSET` when you create a resource group, but not both.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Specify cores as a comma-separated list of single core numbers or core number intervals. Define the coordinator host cores first, followed by segment host cores, and separate the two with a semicolon. You must enclose the full core configuration in single quotes. For example, '1;1,3-4' configures core 1 for the coordinator host, and cores 1, 3, and 4 for the segment hosts.

> **Note** You can configure `CPUSET` for a resource group only after you have enabled resource group-based resource management for your WarehousePG cluster.

IO_LIMIT='<tablespace_io_limit_spec> [; ...]' Optional. The maximum read/write sequential disk I/O throughput, and the maximum read/write I/O operations per second for the queries assigned to a specific resource group.

Where `<tablespace_io_limit_spec>` is:

```
<tablespace_name> | <oid> : <io_limit_option_spec> [, ...]
```

Where `<io_limit_option_spec>` is:

```
wbps=<io_limit_option_value>
| rbps=<io_limit_option_value>
| wiops=<io_limit_option_value>
| riops=<io_limit_option_value>
```

Where `<io_limit_option_vlaue>` is:

```
<integer> | max
```

When you use this parameter, you may speficy:

- The tablespace name or the tablespace object ID (OID) you set the limits for. Use `*` to set limits for all tablespaces.
- The values for `rbps` and `wbps` to limit the maximum read and write sequential disk I/O throughput in the resource group, in MB/S. The default value is `max`, which means there is no limit.
- The values for `riops` and `wiops` to limit the maximum read and write I/O operations per second in the resource group. The default value is `max`, which means there is no limit.

If the parameter `IO_LIMIT` is not set, the default value for `rbps`, `wpbs`, `riops`, and `wiops` s is set to `max`, which means that there are no disk I/O limits. In this scenario, the `gp_toolkit.gp_resgroup_config` system view displays its value as `-1`.

> **Note** The parameter `IO_LIMIT` is only available when you use Linux Control Groups v2. See Configuring and Using Resource Groups for more information.

MEMORY_QUOTA integer Optional. The maximum available memory, in MB, to reserve for this resource group. This value determines the total amount of memory that all worker processes within a resource group can consume on a segment host during query execution.

The minimum memory quantity you can specify for a resource group is `0`. The default value is `-1`.

When you specify a `MEMORY_QUOTA` of `-1`, `MEMORY_QUOTA` takes the value of the `statement_mem` server configuration parameter.

> **Note** If the server configuration parameter `gp_resgroup_memory_query_fixed_mem` is set, its value overrides at the session level the value of `MEMORY_QUOTA`.

MIN_COST integer Optional. The limit on the cost of the query plan generated by a query in this resource group. When the query plan cost of the query is less than this value, the query will be unassigned from the resource group to which it belongs.

This means that low-cost queries will execute more quickly, as they are not subject to resource constraints.

The value range is `0-500`. The default value is `0`, which means that the cost is not used to bypass the query.

Notes

You cannot submit a `CREATE RESOURCE GROUP` command in an explicit transaction or sub-transaction.

Use the `gp_toolkit.gp_resgroup_config` system view to display the limit settings of all resource groups:

```
SELECT * FROM gp_toolkit.gp_resgroup_config;
```

Examples

Create a resource group with CPU and memory quota of 350 MB:

```
CREATE RESOURCE GROUP rgroup1 WITH (CPU_MAX_PERCENT=35, MEMORY_QUOTA=350);
```

Create a resource group with a concurrent transaction limit of 20, a memory quota of 1500 MB, a CPU limit of 25, and disk I/O limits for the `pg_default` tablespace:

```
CREATE RESOURCE GROUP rgroup2 WITH (CONCURRENCY=20,
  MEMORY_QUOTA=1500, CPU_MAX_PERCENT=25,
  IO_LIMIT='pg_default: wbps=1000, rbps=1000, wiops=100, riops=100');
```

Create a resource group with a concurrent transaction limit of 20, a memory quota of 1500 MB, a CPU limit of 25, and disk I/O limits for a tablespace with oid 1663:

```
CREATE RESOURCE GROUP rgroup2 WITH (CONCURRENCY=20,
  MEMORY_QUOTA=1500, CPU_MAX_PERCENT=25,
  IO_LIMIT='1663: wbps=1000, rbps=1000, wiops=100, riops=100');
```

Create a resource group with a memory quota of 110 MB to which you assign CPU core 1 on the coordinator host, and cores 1 to 3 on segment hosts:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
CREATE RESOURCE GROUP rgroup3 WITH (CPUSET='1;1-3', MEMORY_QUOTA=110);
```

Compatibility

`CREATE RESOURCE GROUP` is a WarehousePG extension. There is no provision for resource groups or resource management in the SQL standard.

7.1.73 CREATE RESOURCE QUEUE

Defines a new resource queue.

Synopsis

```
CREATE RESOURCE QUEUE <name> WITH (<queue_attribute>=<value> [, ... ])
```

where queue_attribute is:

```
    ACTIVE_STATEMENTS=<integer>
        [ MAX_COST=<float >[COST_OVERCOMMIT={TRUE|FALSE}] ]
        [ MIN_COST=<float >]
        [ PRIORITY={MIN|LOW|MEDIUM|HIGH|MAX} ]
        [ MEMORY_LIMIT='<memory_units>' ]

 | MAX_COST=float [ COST_OVERCOMMIT={TRUE|FALSE} ]
        [ ACTIVE_STATEMENTS=<integer >]
        [ MIN_COST=<float >]
        [ PRIORITY={MIN|LOW|MEDIUM|HIGH|MAX} ]
        [ MEMORY_LIMIT='<memory_units>' ]
```

Description

Creates a new resource queue for WarehousePG resource management. A resource queue must have either an `ACTIVE_STATEMENTS` or a `MAX_COST` value (or it can have both). Only a superuser can create a resource queue.

Resource queues with an `ACTIVE_STATEMENTS` threshold set a maximum limit on the number of queries that can be run by roles assigned to that queue. It controls the number of active queries that are allowed to run at the same time. The value for `ACTIVE_STATEMENTS` should be an integer greater than 0.

Resource queues with a `MAX_COST` threshold set a maximum limit on the total cost of queries that can be run by roles assigned to that queue. Cost is measured in the *estimated total cost* for the query as determined by the query planner (as shown in the `EXPLAIN` output for a query). Therefore, an administrator must be familiar with the queries typically run on the system in order to set an appropriate cost threshold for a queue. Cost is measured in units of disk page fetches; 1.0 equals one sequential disk page read. The value for `MAX_COST` is specified as a floating point number (for example 100.0) or can also be specified as an exponent (for example 1e+2). If a resource queue is limited based on a cost threshold, then the administrator can allow `COST_OVERCOMMIT=TRUE` (the default). This means that a query that exceeds the allowed cost threshold will be allowed to run but only when the system is idle. If `COST_OVERCOMMIT=FALSE` is specified, queries that exceed the cost limit will always be rejected and never allowed to run. Specifying a value for `MIN_COST` allows the administrator to define a cost for small queries that will be exempt from resource queueing.

> **Note** GPORCA and the Postgres-based planner utilize different query costing models and may compute different costs for the same query. The WarehousePG resource queue resource management scheme neither differentiates nor aligns costs between GPORCA and the Postgres-based planner; it uses the literal cost value returned from the optimizer to throttle queries.

When resource queue-based resource management is active, use the `MEMORY_LIMIT` and `ACTIVE_STATEMENTS` limits for resource queues rather than configuring cost-based limits. Even when using GPORCA, WarehousePG may fall back to using the Postgres-based planner for certain queries, so using cost-based limits can lead to unexpected results.

If a value is not defined for `ACTIVE_STATEMENTS` or `MAX_COST`, it is set to `-1` by default (meaning no limit). After defining a resource queue, you must assign roles to the queue using theALTER ROLE or CREATE ROLE command.

You can optionally assign a `PRIORITY` to a resource queue to control the relative share of available CPU resources used by queries associated with the queue in relation to other resource queues. If a value is not defined for `PRIORITY`, queries associated with the queue have a default priority of `MEDIUM`.

Resource queues with an optional `MEMORY_LIMIT` threshold set a maximum limit on the amount of memory that all queries submitted through a resource queue can consume on a segment host. This determines the total amount of memory that all worker processes of a query can consume on a segment host during query execution. WarehousePG recommends that `MEMORY_LIMIT` be used in conjunction with `ACTIVE_STATEMENTS` rather than with `MAX_COST`. The default amount of memory allotted per query on statement-based queues is: `MEMORY_LIMIT / ACTIVE_STATEMENTS`. The default amount of memory allotted per query on cost-based queues is: `MEMORY_LIMIT * (query_cost / MAX_COST)`.

The default memory allotment can be overridden on a per-query basis using the `statement_mem` server configuration parameter, provided that `MEMORY_LIMIT` or `max_statement_mem` is not exceeded. For example, to allocate more memory to a particular query:

```
=> SET statement_mem='2GB';
=> SELECT * FROM my_big_table WHERE column='value' ORDER BY id;
=> RESET statement_mem;
```

The `MEMORY_LIMIT` value for all of your resource queues should not exceed the amount of physical memory of a segment host. If workloads are staggered over multiple queues, memory allocations can be oversubscribed. However, queries can be cancelled during execution if the segment host memory limit specified in `gp_vmem_protect_limit` is exceeded.

For information about `statement_mem`, `max_statement`, and `gp_vmem_protect_limit`, see Server Configuration Parameters.

Parameters

name The name of the resource queue.

ACTIVE_STATEMENTS integer Resource queues with an `ACTIVE_STATEMENTS` threshold limit the number of queries that can be run by roles assigned to that queue. It controls the number of active queries that are allowed to run at the same time. The value for `ACTIVE_STATEMENTS` should be an integer greater than 0.

MEMORY_LIMIT 'memory_units' Sets the total memory quota for all statements submitted from users in this resource queue. Memory units can be specified in kB, MB or GB. The minimum memory quota for a resource queue is 10MB. There is no maximum, however the upper boundary at query execution time is limited by the physical memory of a segment host. The default is no limit (`-1`).

MAX_COST float Resource queues with a `MAX_COST` threshold set a maximum limit on the total cost of queries that can be run by roles assigned to that queue. Cost is measured in the *estimated total cost* for the query as determined by the WarehousePG query optimizer (as shown in the `EXPLAIN` output for a query). Therefore, an administrator must be familiar with the queries typically run on the system in order to set an appropriate cost threshold for a queue. Cost is measured in units of disk page fetches; 1.0 equals one sequential disk page read. The value for `MAX_COST` is specified as a floating point number (for example 100.0) or can also be specified as an exponent (for example 1e+2).

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

COST_OVERCOMMIT boolean If a resource queue is limited based on `MAX_COST`, then the administrator can allow `COST_OVERCOMMIT` (the default). This means that a query that exceeds the allowed cost threshold will be allowed to run but only when the system is idle. If `COST_OVERCOMMIT=FALSE` is specified, queries that exceed the cost limit will always be rejected and never allowed to run.

MIN_COST float The minimum query cost limit of what is considered a small query. Queries with a cost under this limit will not be queued and run immediately. Cost is measured in the *estimated total cost* for the query as determined by the query planner (as shown in the `EXPLAIN` output for a query). Therefore, an administrator must be familiar with the queries typically run on the system in order to set an appropriate cost for what is considered a small query. Cost is measured in units of disk page fetches; 1.0 equals one sequential disk page read. The value for `MIN_COST` is specified as a floating point number (for example 100.0) or can also be specified as an exponent (for example 1e+2).

PRIORITY={MIN|LOW|MEDIUM|HIGH|MAX} Sets the priority of queries associated with a resource queue. Queries or statements in queues with higher priority levels will receive a larger share of available CPU resources in case of contention. Queries in low-priority queues may be delayed while higher priority queries are run. If no priority is specified, queries associated with the queue have a priority of `MEDIUM`.

Notes

Use the `gp_toolkit.gp_resqueue_status` system view to see the limit settings and current status of a resource queue:

```
SELECT * from gp_toolkit.gp_resqueue_status WHERE
  rsqname='queue_name';
```

There is also another system view named `pg_stat_resqueue` which shows statistical metrics for a resource queue over time. To use this view, however, you must enable the `stats_queue_level` server configuration parameter. See "Managing Workload and Resources" in the *WarehousePG Administrator Guide* for more information about using resource queues.

`CREATE RESOURCE QUEUE` cannot be run within a transaction.

Also, an SQL statement that is run during the execution time of an `EXPLAIN ANALYZE` command is excluded from resource queues.

Examples

Create a resource queue with an active query limit of 20:

```
CREATE RESOURCE QUEUE myqueue WITH (ACTIVE_STATEMENTS=20);
```

Create a resource queue with an active query limit of 20 and a total memory limit of 2000MB (each query will be allocated 100MB of segment host memory at execution time):

```
CREATE RESOURCE QUEUE myqueue WITH (ACTIVE_STATEMENTS=20,
  MEMORY_LIMIT='2000MB');
```

Create a resource queue with a query cost limit of 3000.0:

```
CREATE RESOURCE QUEUE myqueue WITH (MAX_COST=3000.0);
```

Create a resource queue with a query cost limit of 310 (or 30000000000.0) and do not allow overcommit. Allow small queries with a cost under 500 to run immediately:

```
CREATE RESOURCE QUEUE myqueue WITH (MAX_COST=3e+10,
  COST_OVERCOMMIT=FALSE, MIN_COST=500.0);
```

Create a resource queue with both an active query limit and a query cost limit:

```
CREATE RESOURCE QUEUE myqueue WITH (ACTIVE_STATEMENTS=30,
  MAX_COST=5000.00);
```

Create a resource queue with an active query limit of 5 and a maximum priority setting:

```
CREATE RESOURCE QUEUE myqueue WITH (ACTIVE_STATEMENTS=5,
  PRIORITY=MAX);
```

Compatibility

`CREATE RESOURCE QUEUE` is a WarehousePG extension. There is no provision for resource queues or resource management in the SQL standard.

See Also

ALTER ROLE, CREATE ROLE, ALTER RESOURCE QUEUE, DROP RESOURCE QUEUE

Parent topic: SQL Commands

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.1.74 CREATE ROLE

Defines a new database role (user or group).

Synopsis

```
CREATE ROLE <name> [[WITH] <option> [ ... ]]
```

where option can be:

```
      SUPERUSER | NOSUPERUSER
    | CREATEDB | NOCREATEDB
    | CREATEROLE | NOCREATEROLE
    | CREATEEXTTABLE | NOCREATEEXTTABLE
      [ ( <attribute>='<value>'[, ...] ) ]
           where <attributes> and <value> are:
           type='readable'|'writable'
           protocol='gpfdist'|'http'
    | INHERIT | NOINHERIT
    | LOGIN | NOLOGIN
    | REPLICATION | NOREPLICATION
    | BYPASSRLS | NOBYPASSRLS
    | CONNECTION LIMIT <connlimit>
    | [ ENCRYPTED ] PASSWORD '<password>' | PASSWORD NULL
    | VALID UNTIL '<timestamp>'
    | IN ROLE <role_name> [, ...]
    | IN GROUP <role_name> [, ...]
    | ROLE <role_name> [, ...]
    | ADMIN <role_name> [, ...]
    | USER <role_name> [, ...]
    | SYSID <uid> [, ...]
    | RESOURCE QUEUE <queue_name>
    | RESOURCE GROUP <group_name>
    | [ DENY <deny_point> ]
    | [ DENY BETWEEN <deny_point> AND <deny_point>]
```

Description

`CREATE ROLE` adds a new role to a WarehousePG cluster. A role is an entity that can own database objects and have database privileges. A role can be considered a user, a group, or both depending on how it is used. You must have `CREATEROLE` privilege or be a database superuser to use this command.

Note that roles are defined at the system-level and are valid for all databases in your WarehousePG cluster.

Parameters

name

The name of the new role.

SUPERUSER

NOSUPERUSER

These clauses determine whether the new role is a "superuser". If `SUPERUSER` is specified, the role being defined will be a superuser, who can override all access restrictions within the database. Superuser status is dangerous and should be used only when really needed. You must yourself be a superuser to create a new superuser. `NOSUPERUSER` is the default.

CREATEDB

NOCREATEDB

These clauses define a role's ability to create databases. If `CREATEDB` is specified, the role being defined will be allowed to create new databases. Specifying `NOCREATEDB` (the default) will deny a role the ability to create databases.

CREATEROLE

NOCREATEROLE

These clauses determine whether a role will be permitted to create new roles (that is, execute `CREATE ROLE`). If `CREATEROLE` is specified, the role being defined will be allowed to create new roles, alter other roles, and drop other roles. `NOCREATEROLE` (the default) will deny a role the ability to create roles or modify roles other than their own.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

CREATEEXTTABLE

NOCREATEEXTTABLE

If `CREATEEXTTABLE` is specified, the role being defined is allowed to create external tables. The default `type` is `readable` and the default `protocol` is `gpfdist`, if not specified. Valid types are `gpfdist`, `gpfdists`, `http`, and `https`. `NOCREATEEXTTABLE` (the default type) denies the role the ability to create external tables. Note that external tables that use the `file` or `execute` protocols can only be created by superusers.

Use the `GRANT...ON PROTOCOL` command to allow users to create and use external tables with a custom protocol type, including the `s3` and `pxf` protocols included with WarehousePG.

INHERIT

NOINHERIT

These clauses determine whether a role "inherits" the privileges of roles it is a member of. If specified, `INHERIT` (the default) allows the role to use whatever database privileges have been granted to all roles it is directly or indirectly a member of. With `NOINHERIT`, membership in another role only grants the ability to `SET ROLE` to that other role; the privileges of the other role are only available after having done so.

LOGIN

NOLOGIN

These clauses determine whether a role is allowed to log in; that is, whether the role can be given as the initial session authorization name during client connection. If specified, `LOGIN` allows a role to log in to a database. A role having the `LOGIN` attribute can be thought of as a user. Roles with `NOLOGIN` are useful for managing database privileges, but are not users in the usual sense of the word. If not specified, `NOLOGIN` is the default, except when `CREATE ROLE` is invoked through its alternative spelling CREATE USER.

REPLICATION

NOREPLICATION

These clauses determine whether a role is a replication role. A role must have this attribute (or be a superuser) in order to be able to connect to the server in replication mode (physical or logical replication) and in order to be able to create or drop replication slots. A role having the `REPLICATION` attribute is a very highly privileged role, and should only be used on roles actually used for replication. If not specified, `NOREPLICATION` is the default. You must be a superuser to create a new role having the `REPLICATION` attribute.

BYPASSRLS

NOBYPASSRLS

These clauses determine whether a role bypasses every row-level security (RLS) policy. `NOBYPASSRLS` is the default. You must be a superuser to create a new role having the `BYPASSRLS` attribute.

Note that `pg_dump` will set row_security to `OFF` by default, to ensure all contents of a table are dumped out. If the user running `pg_dump` does not have appropriate permissions, an error will be returned. However, superusers and the owner of the table being dumped always bypass RLS.

CONNECTION LIMIT connlimit

If role can log in, this specifies how many concurrent connections the role can make. The default of `-1` means there is no limit. Note that only normal connections are counted towards this limit. Neither prepared transactions nor background worker connections are counted towards this limit.

[ENCRYPTED] PASSWORD 'password'

PASSWORD NULL

Sets the role's password. (A password is only of use for roles having the `LOGIN` attribute, but you can nonetheless define one for roles without it.) If you do not plan to use password authentication you can omit this option. If no password is specified, the password will be set to null and password authentication will always fail for that user. A null password can optionally be written explicitly as `PASSWORD NULL`.

```
<div class="note"><b>Note:</b>  Specifying an empty string will also set the password to null, but that was not the case before WarehousePG version 7. In earlier versions, an empty string could be used, or not, depending on the authentication method and the exact version, and `libpq` would refuse to use it in any case. To avoid the ambiguity, specifying an empty string should be avoided.</div>
```

The password is always stored encrypted in the system catalogs. The `ENCRYPTED` keyword has no effect, but is accepted for backwards compatibility. The method of encryption is determined by the configuration parameter `password_encryption`. If the presented password string is already in MD5-encrypted or SCRAM-encrypted format, then it is stored as-is regardless of `password_encryption` (since the system cannot decrypt the specified encrypted password string, to encrypt it in a different format). This allows reloading of encrypted passwords during dump/restore.

VALID UNTIL 'timestamp'

The VALID UNTIL clause sets a date and time after which the role's password is no longer valid. If this clause is omitted the password will never expire.

IN ROLE role_name

Adds the new role as a member of the named roles. (Note that there is no option to add the new role as an administrator; use a separate `GRANT` command to do that.)

IN GROUP role_name

`IN GROUP` is an obsolete spelling of `IN ROLE`.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

ROLE role_name

Adds the named roles as members of this role. (This in effect makes the new role a "group".)

ADMIN rolename

The `ADMIN` clause is like `ROLE`, but the named roles are added to the new role `WITH ADMIN OPTION`, giving them the right to grant membership in this role to others.

USER role_name

The `USER` clause is an obsolete spelling of the `ROLE` clause.

SYSID uid

The `SYSID` clause is ignored, but is accepted for backwards compatibility.

RESOURCE GROUP group_name

The name of the resource group to assign to the new role. The role will be subject to the concurrent transaction, memory, and CPU limits configured for the resource group. You can assign a single resource group to one or more roles.

If you do not specify a resource group for a new role, the role is automatically assigned the default resource group for the role's capability, `admin_group` for `SUPERUSER` roles, `default_group` for non-admin roles.

You can assign the `admin_group` resource group to any role having the `SUPERUSER` attribute.

You can assign the `default_group` resource group to any role.

You cannot assign a resource group that you create for an external component to a role.

RESOURCE QUEUE queue_name

The name of the resource queue to which the new user-level role is to be assigned. Only roles with `LOGIN` privilege can be assigned to a resource queue. The special keyword `NONE` means that the role is assigned to the default resource queue. A role can only belong to one resource queue.

Roles with the `SUPERUSER` attribute are exempt from resource queue limits. For a superuser role, queries always run immediately regardless of limits imposed by an assigned resource queue.

DENY deny_point

DENY BETWEEN deny_point AND deny_point

The `DENY` and `DENY BETWEEN` keywords set time-based constraints that are enforced at login. `DENY` sets a day or a day and time to deny access. `DENY BETWEEN` sets an interval during which access is denied. Both use the parameter deny_point that has the following format:

```
DAY day [ TIME 'time' ]
```

The two parts of the `deny_point` parameter use the following formats:

For `day`:

```
{'Sunday' | 'Monday' | 'Tuesday' |'Wednesday' | 'Thursday' | 'Friday' |
'Saturday' | 0-6 }
```

For `time`:

```
{ 00-23 : 00-59 | 01-12 : 00-59 { AM | PM }}
```

The `DENY BETWEEN` clause uses two deny_point parameters:

```
DENY BETWEEN <deny_point> AND <deny_point>
```

Notes

Use ALTER ROLE to change the attributes of a role, and DROP ROLE to remove a role. All the attributes specified by `CREATE ROLE` can be modified by later `ALTER ROLE` commands.

The preferred way to add and remove role members of roles is to use GRANT and REVOKE.

The `VALID UNTIL` clause defines an expiration time for a password only, not for the role *per se*. The expiration time is not enforced when logging in using a non-password-based authentication method.

The `INHERIT` attribute governs inheritance of grantable privileges (access privileges for database objects and role memberships). It does not apply to the special role attributes set by `CREATE ROLE` and `ALTER ROLE`. For example, being a member of a role with `CREATEDB` privilege does not immediately grant the ability to create databases, even if `INHERIT` is set; it would be necessary to become that role via SET ROLE before creating a database.

The `INHERIT` attribute is the default for reasons of backwards compatibility. In prior releases of WarehousePG, users always had access to all privileges of groups they were members of. However, `NOINHERIT` provides a closer match to the semantics specified in the SQL standard.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Be careful with the `CREATEROLE` privilege. There is no concept of inheritance for the privileges of a `CREATEROLE` -role. That means that even if a role does not have a certain privilege but is allowed to create other roles, it can easily create another role with different privileges than its own (except for creating roles with superuser privileges). For example, if a role has the `CREATEROLE` privilege but not the `CREATEDB` privilege, it can create a new role with the `CREATEDB` privilege. Therefore, regard roles that have the `CREATEROLE` privilege as almost-superuser-roles.

WarehousePG includes a program createuser that has the same functionality as `CREATE ROLE` (in fact, it calls this command) but can be run from the command shell.

The `CONNECTION LIMIT` option is only enforced approximately; if two new sessions start at about the same time when just one connection "slot" remains for the role, it is possible that both will fail. Also, the limit is never enforced for superusers.

You must exercise caution when specifying an unencrypted password with this command. The password will be transmitted to the server in clear-text, and it might also be logged in the client's command history or the server log. The client program createuser, however, transmits the password encrypted. Also, psql contains a command `\password` that can be used to safely change the password later.

Examples

Create a role that can log in, but don't give it a password:

```
CREATE ROLE jonathan LOGIN;
```

Create a role with a password:

```
CREATE USER davide WITH PASSWORD 'jw8s0F4';
```

(`CREATE USER` is the same as `CREATE ROLE` except that it implies `LOGIN` .)

Create a role with a password that is valid until the end of 2022:

```
CREATE USER joelle WITH LOGIN PASSWORD 'jw8s0F4' VALID UNTIL '2023-01-01';
```

Create a role that can create databases and manage other roles:

```
CREATE ROLE admin WITH CREATEDB CREATEROLE;
```

Create a role that does not allow login access on Sundays:

```
CREATE ROLE user3 DENY DAY 'Sunday';
```

Create a role that can create readable and writable external tables of type 'gpfdist':

```
CREATE ROLE jan WITH CREATEEXTTABLE(type='readable', protocol='gpfdist')
   CREATEEXTTABLE(type='writable', protocol='gpfdist');
```

Create a role, assigning a resource group:

```
CREATE ROLE bill RESOURCE GROUP rg_light;
```

Create a role that belongs to a resource queue:

```
CREATE ROLE jonathan LOGIN RESOURCE QUEUE poweruser;
```

Compatibility

`CREATE ROLE` is in the SQL standard, but the standard only requires the syntax:

```
CREATE ROLE <name> [WITH ADMIN <rolename>]
```

Allowing multiple initial administrators, and all the other options of `CREATE ROLE` , are WarehousePG extensions.

The SQL standard defines the concepts of users and roles, but it regards them as distinct concepts and leaves all commands defining users to be specified by the database implementation. In WarehousePG users and roles are unified into a single type of object. Roles therefore have many more optional attributes than they do in the standard.

The behavior specified by the SQL standard is most closely approximated by giving users the `NOINHERIT` attribute, while roles are given the `INHERIT` attribute.

7.1.75 CREATE RULE

Defines a new rewrite rule.

Synopsis

```
CREATE [OR REPLACE] RULE <name> AS ON <event>
  TO <table_name> [WHERE <condition>]
  DO [ALSO | INSTEAD] { NOTHING | <command> | (<command>; <command>
  ...) }

where <event> can be one of:

  SELECT | INSERT | UPDATE | DELETE
```

Description

`CREATE RULE` defines a new rule applying to a specified table or view. `CREATE OR REPLACE RULE` will either create a new rule, or replace an existing rule of the same name for the same table.

The WarehousePG rule system allows one to define an alternate action to be performed on insertions, updates, or deletions in database tables. A rule causes additional or alternate commands to be run when a given command on a given table is run. An `INSTEAD` rule can replace a given command by another, or cause a command to not be run at all. Rules can be used to implement SQL views as well. It is important to realize that a rule is really a command transformation mechanism, or command macro. The transformation happens before the execution of the command starts. It does not operate independently for each physical row as does a trigger.

`ON SELECT` rules must be unconditional `INSTEAD` rules and must have actions that consist of a single `SELECT` command. Thus, an `ON SELECT` rule effectively turns the table into a view, whose visible contents are the rows returned by the rule's `SELECT` command rather than whatever had been stored in the table (if anything). It is considered better style to write a `CREATE VIEW` command than to create a real table and define an `ON SELECT` rule for it.

You can create the illusion of an updatable view by defining `ON INSERT`, `ON UPDATE`, and `ON DELETE` rules (or any subset of those that is sufficient for your purposes) to replace update actions on the view with appropriate updates on other tables. If you want to support `INSERT RETURNING` and so on, be sure to put a suitable `RETURNING` clause into each of these rules.

There is a catch if you try to use conditional rules for complex view updates: there *must* be an unconditional `INSTEAD` rule for each action you wish to allow on the view. If the rule is conditional, or is not `INSTEAD`, then the system will still reject attempts to perform the update action, because it thinks it might end up trying to perform the action on the dummy table of the view in some cases. If you want to handle all of the useful cases in conditional rules, add an unconditional `DO INSTEAD NOTHING` rule to ensure that the system understands it will never be called on to update the dummy table. Then make the conditional rules non `INSTEAD`; in the cases where they are applied, they add to the default `INSTEAD NOTHING` action. (This method does not currently work to support `RETURNING` queries, however.)

> **Note** A view that is simple enough to be automatically updatable (see CREATE VIEW) does not require a user-created rule in order to be updatable. While you can create an explicit rule anyway, the automatic update transformation will generally outperform an explicit rule.

Parameters

name The name of a rule to create. This must be distinct from the name of any other rule for the same table. Multiple rules on the same table and same event type are applied in alphabetical name order.

event The event is one of `SELECT`, `INSERT`, `UPDATE`, or `DELETE`. Note that an `INSERT` containing an `ON CONFLICT` clause cannot be used on tables that have either `INSERT` or `UPDATE` rules. Consider using an updatable view instead.

table_name The name (optionally schema-qualified) of the table or view the rule applies to.

condition Any SQL conditional expression (returning `boolean`). The condition expression can not refer to any tables except `NEW` and `OLD`, and can not contain aggregate functions.

INSTEAD `INSTEAD` indicates that the commands should be run *instead of* the original command.

ALSO `ALSO` indicates that the commands should be run *in addition* to the original command. If neither `ALSO` nor `INSTEAD` is specified, `ALSO` is the default.

command The command or commands that make up the rule action. Valid commands are `SELECT`, `INSERT`, `UPDATE`, `DELETE`, or `NOTIFY`.

Within condition and command, the special table names `NEW` and `OLD` can be used to refer to values in the referenced table. `NEW` is valid in `ON INSERT` and `ON UPDATE` rules to refer to the new row being inserted or updated. `OLD` is valid in `ON UPDATE` and `ON DELETE` rules to refer to the existing row being updated or deleted.

Notes

You must be the owner of a table to create or change rules for it.

In a rule for `INSERT`, `UPDATE`, or `DELETE` on a view, you can add a `RETURNING` clause that emits the view's columns. This clause will be used to compute the outputs if the rule is triggered by an `INSERT RETURNING`, `UPDATE RETURNING`, or `DELETE RETURNING` command respectively. When the rule is triggered by a command without `RETURNING`, the rule's `RETURNING` clause will be ignored. The current implementation allows only unconditional `INSTEAD` rules to contain `RETURNING`; furthermore there can be at most one `RETURNING` clause among all the rules for the same event. (This ensures that there is only one candidate `RETURNING` clause to be used to compute the results.) `RETURNING` queries on the view will be rejected if there is no `RETURNING` clause in any available rule.

It is very important to take care to avoid circular rules. For example, though each of the following two rule definitions are accepted by WarehousePG, the `SELECT` command would cause WarehousePG to report an error because of recursive expansion of a rule:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
CREATE RULE "_RETURN" AS
    ON SELECT TO t1
    DO INSTEAD
        SELECT * FROM t2;

CREATE RULE "_RETURN" AS
    ON SELECT TO t2
    DO INSTEAD
        SELECT * FROM t1;

SELECT * FROM t1;
```

If a rule action contains a `NOTIFY` command, the `NOTIFY` command will be executed unconditionally, that is, the `NOTIFY` will be issued even if there are not any rows that the rule should apply to. For example, in:

```
CREATE RULE notify_me AS ON UPDATE TO mytable DO ALSO NOTIFY mytable;

UPDATE mytable SET name = 'foo' WHERE id = 42;
```

one `NOTIFY` event will be sent during the `UPDATE`, whether or not there are any rows that match the condition id = 42.

Compatibility

`CREATE RULE` is a WarehousePG extension, as is the entire query rewrite system.

7.1.76 CREATE SCHEMA

Defines a new schema.

Synopsis

```
CREATE SCHEMA <schema_name> [AUTHORIZATION <role_specification>]
   [<schema_element> [ ... ]]

CREATE SCHEMA AUTHORIZATION <role_specification> [<schema_element> [ ... ]]

CREATE SCHEMA IF NOT EXISTS <schema_name> [ AUTHORIZATION <role_specification> ]

CREATE SCHEMA IF NOT EXISTS AUTHORIZATION <role_specification>

where <role_specification> can be:

    <user_name>
  | CURRENT_USER
  | SESSION_USER
```

Description

`CREATE SCHEMA` enters a new schema into the current database. The schema name must be distinct from the name of any existing schema in the current database.

A schema is essentially a namespace: it contains named objects (tables, data types, functions, and operators) whose names may duplicate those of other objects existing in other schemas. Named objects are accessed either by qualifying their names with the schema name as a prefix, or by setting a search path that includes the desired schema(s). A `CREATE` command specifying an unqualified object name creates the object in the current schema (the one at the front of the search path, which can be determined with the function `current_schema()`).

Optionally, `CREATE SCHEMA` can include subcommands to create objects within the new schema. The subcommands are treated essentially the same as separate commands issued after creating the schema, except that if the `AUTHORIZATION` clause is used, all the created objects will be owned by that role.

Parameters

schema*name The name of a schema to be created. If this is omitted, the user_name is used as the schema name. The name cannot begin with `pg`*, as such names are reserved for system catalog schemas.

user_name The role name of the user who will own the new schema. If omitted, defaults to the user running the command. To create a schema owned by another role, you must be a direct or indirect member of that role, or be a superuser.

schema_element An SQL statement defining an object to be created within the schema. Currently, only `CREATE TABLE`, `CREATE VIEW`, `CREATE INDEX`, `CREATE SEQUENCE`, `CREATE TRIGGER`, and `GRANT` are accepted as clauses within `CREATE SCHEMA`. Other kinds of objects may be created in separate commands after the schema is created.

```
> **Note** WarehousePG does not support triggers.
```

`IF NOT EXISTS` Do nothing (except issuing a notice) if a schema with the same name already exists. schema_element subcommands cannot be included when this option is used.

Notes

To create a schema, the invoking user must have the `CREATE` privilege for the current database or be a superuser.

Examples

Create a schema:

```
CREATE SCHEMA myschema;
```

Create a schema for role `joe`; the schema will also be named `joe`:

```
CREATE SCHEMA AUTHORIZATION joe;
```

Create a schema named `test` that will be owned by user `joe`, unless there already is a schema named `test`. (It does not matter whether `joe` owns the pre-existing schema.)

```
CREATE SCHEMA IF NOT EXISTS test AUTHORIZATION joe;
```

Create a schema and create a table and view within it:

```
CREATE SCHEMA hollywood
    CREATE TABLE films (title text, release date, awards text[])
    CREATE VIEW winners AS
        SELECT title, release FROM films WHERE awards IS NOT NULL;
```

Notice that the individual subcommands do not end with semicolons.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

The following is an equivalent way of accomplishing the same result:

```
CREATE SCHEMA hollywood;
CREATE TABLE hollywood.films (title text, release date, awards text[]);
CREATE VIEW hollywood.winners AS
    SELECT title, release FROM hollywood.films WHERE awards IS NOT NULL;
```

Compatibility

The SQL standard allows a `DEFAULT CHARACTER SET` clause in `CREATE SCHEMA`, as well as more subcommand types than are presently accepted by WarehousePG.

The SQL standard specifies that the subcommands in `CREATE SCHEMA` may appear in any order. The present WarehousePG implementation does not handle all cases of forward references in subcommands; it may sometimes be necessary to reorder the subcommands in order to avoid forward references.

According to the SQL standard, the owner of a schema always owns all objects within it. WarehousePG allows schemas to contain objects owned by users other than the schema owner. This can happen only if the schema owner grants the `CREATE` privilege on the schema to someone else, or a superuser chooses to create objects in it.

The `IF NOT EXISTS` option is a WarehousePG extension.

ALTER SCHEMA, DROP SCHEMA

Parent topic: SQL Commands

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.1.77 CREATE SEQUENCE

Defines a new sequence generator.

Synopsis

```
CREATE [TEMPORARY | TEMP] SEQUENCE [IF NOT EXISTS] <name>
       [ AS data_type ]
       [INCREMENT [BY] <increment>]
       [MINVALUE <minvalue> | NO MINVALUE]
       [MAXVALUE <maxvalue> | NO MAXVALUE]
       [START [ WITH ] <start>]
       [CACHE <cache>]
       [[NO] CYCLE]
       [OWNED BY { <table_name>.<column_name> | NONE }]
```

Description

`CREATE SEQUENCE` creates a new sequence number generator. This involves creating and initializing a new special single-row table with the same name. The generator will be owned by the user issuing the command.

If a schema name is given, then the sequence is created in the specified schema. Otherwise it is created in the current schema. Temporary sequences exist in a special schema, so you may not provide a schema name when creating a temporary sequence. The sequence name must be distinct from the name of any other sequence, table, index, view, or foreign table in the same schema.

After a sequence is created, you use the `nextval()` function to operate on the sequence. For example, to insert a row into a table that gets the next value of a sequence:

```
INSERT INTO distributors VALUES (nextval('myserial'), 'acme');
```

You can also use the function `setval()` to operate on a sequence, but only for queries that do not operate on distributed data. For example, the following query is allowed because it resets the sequence counter value for the sequence generator process on the coordinator:

```
SELECT setval('myserial', 201);
```

But the following query will be rejected in WarehousePG because it operates on distributed data:

```
INSERT INTO product VALUES (setval('myserial', 201), 'gizmo');
```

In a regular (non-distributed) database, functions that operate on the sequence go to the local sequence table to get values as they are needed. In WarehousePG, however, keep in mind that each segment is its own distinct database process. Therefore the segments need a single point of truth to go for sequence values so that all segments get incremented correctly and the sequence moves forward in the right order. A sequence server process runs on the coordinator and is the point-of-truth for a sequence in a WarehousePG distributed database. Segments get sequence values at runtime from the coordinator.

Because of this distributed sequence design, there are some limitations on the functions that operate on a sequence in WarehousePG:

- `lastval()` and `currval()` functions are not supported.
- `setval()` can only be used to set the value of the sequence generator on the coordinator, it cannot be used in subqueries to update records on distributed table data.
- `nextval()` sometimes grabs a block of values from the coordinator for a segment to use, depending on the query. So values may sometimes be skipped in the sequence if all of the block turns out not to be needed at the segment level. Note that a regular PostgreSQL database does this too, so this is not something unique to WarehousePG.

> **Note** The default sequence cache size in WarehousePG is `20`.

Although you cannot update a sequence directly, you can use a query like:

```
SELECT * FROM <sequence_name>;
```

to examine the parameters and current state of a sequence. In particular, the last_value field of the sequence shows the last value allocated by any session. (Note that this value might be obsolete by the time it's printed, if other sessions are actively doing `nextval()` calls.)

Parameters

TEMPORARY | TEMP If specified, the sequence object is created only for this session, and is automatically dropped on session exit. Existing permanent sequences with the same name are not visible (in this session) while the temporary sequence exists, unless they are referenced with schema-qualified names.

IF NOT EXISTS Do not throw an error if a relation with the same name already exists. WarehousePG issues a notice in this case. Note that there is no guarantee that the existing relation is anything like the sequence that would have been created - it might not even be a sequence.

name The name (optionally schema-qualified) of the sequence to be created.

data_type The optional clause `AS data_type` specifies the data type of the sequence. Valid types are `smallint`, `integer`, and `bigint`. `bigint` is the default. The data type determines the default minimum and maximum values of the sequence.

increment Specifies which value is added to the current sequence value to create a new value. A positive value will make an ascending sequence, a negative one a descending sequence. The default value is `1`.

minvalue NO MINVALUE Determines the minimum value a sequence can generate. If this clause is not supplied or `NO MINVALUE` is specified, then the default values will be used. The default for an ascending sequence is the maximum value of the data type. The default for a descending sequence is `-1`.

maxvalue NO MAXVALUE Determines the maximum value for the sequence. If this clause is not supplied or `NO MAXVALUE` is specified, then default values will be used. The defaults are 263-1 and -1 for ascending and descending sequences, respectively.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

start Allows the sequence to begin anywhere. The default starting value is `minvalue` for ascending sequences and `maxvalue` for descending ones.

cache Specifies how many sequence numbers are to be preallocated and stored in memory for faster access. The default value is 20. The minimum value is 1 (no cache).

> **Note** When operating with a cache of sequence numbers (`cache > 1`), WarehousePG may discard some cached sequence values. If you require consecutive values, you must explicitly set `CACHE 1` when you create or alter the sequence.

CYCLE NO CYCLE Allows the sequence to wrap around when the `maxvalue` (for ascending) or `minvalue` (for descending) has been reached. If the limit is reached, the next number generated will be the `minvalue` (for ascending) or `maxvalue` (for descending). If `NO CYCLE` is specified, any calls to `nextval()` after the sequence has reached its maximum value will return an error. If neither `CYCLE` or `NO CYCLE` are specified, `NO CYCLE` is the default.

OWNED BY table_name.colume_name OWNED BY NONE Causes the sequence to be associated with a specific table column, such that if that column (or its whole table) is dropped, the sequence will be automatically dropped as well. The specified table must have the same owner and be in the same schema as the sequence. `OWNED BY NONE` , the default, specifies that there is no such association.

Notes

Use `DROP SEQUENCE` to remove a sequence.

Sequences are based on bigint arithmetic, so the range cannot exceed the range of an eight-byte integer (-9223372036854775808 to 9223372036854775807).

Because `nextval()` and `setval()` calls are never rolled back, sequence objects cannot be used if "gapless" assignment of sequence numbers is needed. It is possible to build gapless assignment by using exclusive locking of a table containing a counter; but this solution is much more expensive than sequence objects, especially if many transactions need sequence numbers concurrently.

Although multiple sessions are guaranteed to allocate distinct sequence values, the values may be generated out of sequence when all the sessions are considered. For example, with a `cache` setting of `10` , session A might reserve values 1..10 and return `nextval=1` , then session B might reserve values 11..20 and return `nextval=11` before session A has generated nextval=2. Thus, with a `cache` setting of one it is safe to assume that `nextval()` values are generated sequentially; with a `cache` setting greater than one you should only assume that the `nextval()` values are all distinct, not that they are generated purely sequentially.

Another consideration is that a `setval()` executed on such a sequence will not be noticed by other sessions until they have used up any preallocated values they have cached.

Examples

Create an ascending sequence named `myseq` , starting at 101:

```
CREATE SEQUENCE myseq START 101;
```

Insert a row into a table that gets the next value of the sequence named `myseq` :

```
INSERT INTO distributors VALUES (nextval('myseq'), 'acme');
```

Reset the sequence counter value on the WarehousePG coordinator:

```
SELECT setval('myseq', 201);
```

Illegal use of `setval()` in WarehousePG (setting sequence values on distributed data):

```
INSERT INTO product VALUES (setval('myseq', 201), 'gizmo');
```

Compatibility

`CREATE SEQUENCE` conforms to the SQL standard, with the following exceptions:

- You obtain the next value using the `nextval()` function instead of the `NEXT VALUE FOR` expression specified in the SQL standard.
- The `OWNED BY` clause is a WarehousePG extension.

ALTER SEQUENCE, DROP SEQUENCE

Parent topic: SQL Commands

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.1.78 CREATE SERVER

Defines a new foreign server.

Synopsis

```
CREATE SERVER [ IF NOT EXISTS ] <server_name> [ TYPE '<server_type>' ] [ VERSION '<server_version>' ]
    FOREIGN DATA WRAPPER <fdw_name>
    [ OPTIONS ( [ mpp_execute { 'coordinator' | 'any' | 'all segments' } [, ] ]
                [ num_segments '<num>' [, ] ]
                [ <option> '<value>' [, ... ]] ) ]
```

Description

`CREATE SERVER` defines a new foreign server. The user who defines the server becomes its owner.

A foreign server typically encapsulates connection information that a foreign-data wrapper uses to access an external data source. Additional user-specific connection information may be specified by means of user mappings.

Creating a server requires the `USAGE` privilege on the foreign-data wrapper specified.

Parameters

IF NOT EXISTS

Do not throw an error if a server with the same name already exists. WarehousePG issues a notice in this case. Note that there is no guarantee that the existing server is anything like the one that would have been created.

server_name The name of the foreign server to create. The server name must be unique within the database.

server_type Optional server type, potentially useful to foreign-data wrappers.

server_version Optional server version, potentially useful to foreign-data wrappers.

fdw_name Name of the foreign-data wrapper that manages the server.

OPTIONS (option 'value' [, ...]) The options for the new foreign server. The options typically define the connection details of the server, but the actual names and values are dependent upon the server's foreign-data wrapper.

mpp_execute { 'coordinator' | 'any' | 'all segments' } A WarehousePG-specific option that identifies the host from which the foreign-data wrapper reads or writes data:

```
-   `coordinator` \(the default\)—Read or write data from the coordinator host.
-   `any`—Read data from either the coordinator host or any one segment, depending on which path costs less.
-   `all segments`—Read or write data from all segments. To support this option value, the foreign-data wrapper should have a policy that matches the segments to
data.

> **Note** WarehousePG supports parallel writes to foreign tables only when you set `mpp_execute 'all segments'`.

Support for the foreign server `mpp_execute` option, and the specific modes, is foreign-data wrapper-specific.

The `mpp_execute` option can be specified in multiple commands: `CREATE FOREIGN TABLE`, `CREATE SERVER`, and `CREATE FOREIGN DATA WRAPPER`. The foreign table
setting takes precedence over the foreign server setting, followed by the foreign-data wrapper setting.
```

num_segments 'num' When `mpp_execute` is set to `'all segments'`, the WarehousePG-specific `num_segments` option identifies the number of query executors that WarehousePG spawns on the source WarehousePG cluster. If you do not provide a value, num defaults to the number of segments in the source cluster.

```
Support for the foreign server `num_segments` option is foreign-data wrapper-specific.
```

Notes

When using the dblink module (see dblink), you can use the foreign server name as an argument of the `dblink_connect()` function to provide the connection parameters. You must have the `USAGE` privilege on the foreign server to use it in this manner.

Examples

Create a foreign server named `myserver` that uses a foreign-data wrapper named `gpfdw1` and includes connection options:

```
CREATE SERVER myserver FOREIGN DATA WRAPPER gpfdw1
    OPTIONS (host 'foo', dbname 'foodb', port '5432');
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Compatibility

`CREATE SERVER` conforms to ISO/IEC 9075-9 (SQL/MED).

See Also

ALTER SERVER, DROP SERVER, CREATE FOREIGN DATA WRAPPER, CREATE FOREIGN TABLE, CREATE USER MAPPING

Parent topic: SQL Commands

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.1.79 CREATE STATISTICS

Defines extended statistics.

Synopsis

```
CREATE STATISTICS [ IF NOT EXISTS ] <statistics_name>
    [ ( <statistics_kind> [, ... ] ) ]
    ON <column_name>, <column_name> [, ...]
    FROM <table_name>
```

Description

`CREATE STATISTICS` creates a new extended statistics object tracking data about the specified table, foreign table, or materialized view. The statistics object is created in the current database and will be owned by the user issuing the command.

If a schema name is given (for example, `CREATE STATISTICS myschema.mystat ...`) then the statistics object is created in the specified schema. Otherwise it is created in the current schema. The name of the statistics object must be distinct from the name of any other statistics object in the same schema.

Parameters

IF NOT EXISTS

Do not throw an error if a statistics object with the same name already exists. WarehousePG issues a notice in this case. Note that only the name of the statistics object is considered here, not the details of its definition.

statistics_name The name (optionally schema-qualified) of the statistics object to create.

statistics_kind A statistics kind to be computed in this statistics object. Currently supported kinds are `ndistinct`, which enables n-distinct statistics, `dependencies`, which enables functional dependency statistics, and `mcv` which enables most-common values lists. If this clause is omitted, all supported statistics kinds are included in the statistics object.

column_name The name of a table column to be covered by the computed statistics. You must specify at least two column names; the order of the column names is insignificant.

table_name The name (optionally schema-qualified) of the table containing the column(s) on which the statistics are computed; seeANALYZE for an explanation of inheritance and partition handling.

Notes

You must be the owner of a table to create a statistics object that reads it. Once created, however, the ownership of the statistics object is independent of the underlying table(s).

Examples

Create table `t1` with two functionally-dependent columns, i.e., knowledge of a value in the first column is sufficient for determining the value in the other column. Then build functional dependency statistics on those columns:

```
CREATE TABLE t1 (
    a   int,
    b   int
);

INSERT INTO t1 SELECT i/100, i/500
                FROM generate_series(1,1000000) s(i);

ANALYZE t1;

-- the number of matching rows will be drastically underestimated:
EXPLAIN ANALYZE SELECT * FROM t1 WHERE (a = 1) AND (b = 0);

CREATE STATISTICS s1 (dependencies) ON a, b FROM t1;

ANALYZE t1;

-- now the row count estimate is more accurate:
EXPLAIN ANALYZE SELECT * FROM t1 WHERE (a = 1) AND (b = 0);
```

Without functional-dependency statistics, the planner assumes that the two `WHERE` conditions are independent, and would multiply their selectivities together to arrive at a much-too-small row count estimate. With such statistics, the planner recognizes that the `WHERE` conditions are redundant and does not underestimate the row count.

Create table `t2` with two perfectly correlated columns (containing identical data), and a MCV list on those columns:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
CREATE TABLE t2 (
    a   int,
    b   int
);

INSERT INTO t2 SELECT mod(i,100), mod(i,100)
                FROM generate_series(1,1000000) s(i);

CREATE STATISTICS s2 (mcv) ON a, b FROM t2;

ANALYZE t2;

-- valid combination (found in MCV)
EXPLAIN ANALYZE SELECT * FROM t2 WHERE (a = 1) AND (b = 1);

-- invalid combination (not found in MCV)
EXPLAIN ANALYZE SELECT * FROM t2 WHERE (a = 1) AND (b = 2);
```

The MCV list gives the planner more detailed information about the specific values that commonly appear in the table, as well as an upper bound on the selectivities of combinations of values that do not appear in the table, allowing it to generate better estimates in both cases.

Compatibility

There is no `CREATE STATISTICS` statement in the SQL standard.

Description

`CREATE TABLE` creates a new, initially empty table in the current database. The user who issues the command owns the table.

To create a table, you must have `USAGE` privilege on all column types or the type in the `OF` clause, respectively.

If you specify a schema name, WarehousePG creates the table in the specified schema. Otherwise WarehousePG creates the table in the current schema. Temporary tables exist in a special schema, so you cannot specify a schema name when creating a temporary table. The name of the table must be distinct from the name of any other table, external table, sequence, index, view, or foreign table in the same schema.

`CREATE TABLE` also automatically creates a data type that represents the composite type corresponding to one row of the table. Therefore, tables cannot have the same name as any existing data type in the same schema.

The optional constraint clauses specify conditions that new or updated rows must satisfy for an insert or update operation to succeed. A constraint is an SQL object that helps define the set of valid values in the table in various ways.

WarehousePG accepts, but does not enforce, referential integrity (foreign key) constraints. The information is retained in the system catalogs but is otherwise ignored.

You can define two types of constraints: table constraints and column constraints. A column constraint is defined as part of a column definition. A table constraint definition is not tied to a particular column, and it can encompass more than one column. Every column constraint can also be written as a table constraint; a column constraint is only a notational convenience for use when the constraint only affects one column.

When creating a table, you specify an additional clause to declare the WarehousePG distribution policy. If a `DISTRIBUTED BY`, `DISTRIBUTED RANDOMLY`, or `DISTRIBUTED REPLICATED` clause is not supplied, then WarehousePG assigns a hash distribution policy to the table using either the `PRIMARY KEY` (if the table has one) or the first column of the table as the distribution key. Columns of geometric or user-defined data types are not eligible to be a WarehousePG distribution key column. If a table does not have a column of an eligible data type, the rows are distributed based on a random distribution. To ensure an even distribution of data in your WarehousePG cluster, you want to choose a distribution key that is unique for each record, or if that is not possible, then choose `DISTRIBUTED RANDOMLY`.

If you supply the `DISTRIBUTED REPLICATED` clause, WarehousePG distributes all rows of the table to all segments in the WarehousePG cluster. You can use this option in cases where user-defined functions must run on the segments, and the functions require access to all rows of the table. Replicated functions can also be used to improve query performance by preventing broadcast motions for the table. The `DISTRIBUTED REPLICATED` clause cannot be used with the `PARTITION` clauses or the `INHERITS` clause. A replicated table also cannot be inherited by another table. The hidden system columns (`ctid`, `cmin`, `cmax`, `xmin`, `xmax`, and `gp_segment_id`) cannot be referenced in user queries on replicated tables because they have no single, unambiguous value. WarehousePG returns a `column does not exist` error for the query.

`CREATE TABLE` supports coordinator-only distribution via the clause `DISTRIBUTED COORDINATOR ONLY`. However, coordinator-only distribution can't be used with inheritance or partitioning: tables using `INHERITS`, `PARTITION BY`, or `PARTITION OF` can't be defined as coordinator-only.

Coordinator-only distribution is intended for specialized use cases and isn't recommended for general workloads. It exists primarily to support some extensions or system components that need to consult their own metadata tables at a very early stage of query processing, before distributed execution can safely occur.

The `PARTITION BY` and `PARTITION OF` clauses allow you to divide the table into multiple sub-tables (or parts) that, taken together, make up the parent table and share its schema.

> **Note** WarehousePG supports both *classic* and *modern* partitioning syntaxes. Refer to Choosing the Partitioning Syntax for more information, including guidance on selecting the appropriate syntax for a partitioned table.

Parameters

GLOBAL | LOCAL These keywords are present for SQL standard compatibility, but have no effect in WarehousePG and are deprecated.

TEMPORARY | TEMP If specified, the table is created as a temporary table. Temporary tables are automatically dropped at the end of a session, or optionally at the end of the current transaction (see `ON COMMIT`). Existing permanent tables with the same name are not visible to the current session while the temporary table exists, unless they are referenced with schema-qualified names. Any indexes created on a temporary table are automatically temporary as well.

Be sure to perform appropriate vacuum and analyze operations on temporary tables via session SQL commands. For example, if you are going to use a temporary table in complex queries, run `ANALYZE` on the temporary table after it is populated.

UNLOGGED If specified, the table is created as an unlogged table. Data written to unlogged tables is not written to the write-ahead (WAL) log, which makes them considerably faster than ordinary tables. However, the contents of an unlogged table are not replicated to mirror segment instances. Also an unlogged table is not crash-safe: WarehousePG automatically truncates an unlogged table after a crash or unclean shutdown. Any indexes created on an unlogged table are automatically unlogged as well.

IF NOT EXISTS Do not throw an error if a relation with the same name already exists. WarehousePG issues a notice in this case. Note that there is no guarantee that the existing relation is anything like the one that would have been created.

table_name The name (optionally schema-qualified) of the table to be created.

OF type_name Creates a *typed table*, which takes its structure from the specified composite type (name optionally schema-qualified). A typed table is tied to its type; for example, the table will be dropped if the type is dropped with `DROP TYPE ... CASCADE`.

When a typed table is created, the data types of the columns are determined by the underlying composite type and are not specified by the `CREATE TABLE` command. But the `CREATE TABLE` command can add defaults and constraints to the table and can specify storage parameters.

column_name The name of a column to be created in the new table.

data_type The data type of the column. This may include array specifiers. For more information on the data types supported by WarehousePG, refer to theData Types documentation.

For table columns that contain textual data, Specify the data type `VARCHAR` or `TEXT`. Specifying the data type `CHAR` is not recommended. In WarehousePG, the data types `VARCHAR` or `TEXT` handle padding added to the data (space characters added after the last non-space character) as significant characters, the data type `CHAR` does not. See Notes.

COLLATE collation The `COLLATE` clause assigns a collation to the column (which must be of a collatable data type). If not specified, the column data type's default collation is used.

```
> **Note** The WarehousePG query optimizer (GPORCA) supports collation only when all columns in the query use the same collation. If columns in the query use
different collations, then WarehousePG uses the Postgres-based planner.
```

ENCODING (storage_directive [, ...]) For a column, the optional `ENCODING` clause specifies the type of compression and block size for the column data. Valid column storage_directives are `compresstype`, `compresslevel`, and `blocksize`.

This clause is valid only for append-optimized, column-oriented tables.

Column compression settings are inherited from the table level to the partition level to the sub-partition level. The lowest-level settings have priority.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

For more information about using column compression, refer toAdding Column-Level Compression.

blocksize Set to the size, in bytes, for each block in a table. The `blocksize` must be between 8192 and 2097152 bytes, and be a multiple of 8192. The default is 32768.

compresslevel For Zstd compression of append-optimized tables, set to an integer value from 1 (fastest compression) to 19 (highest compression ratio). For zlib compression, the valid range is from 1 to 9. For `RLE_TYPE` , the compression level can be an integer value from 1 (fastest compression) to 4 (highest compression ratio).

compresstype Set to `ZLIB` (the default), `ZSTD` , or `RLE_TYPE` , to specify the type of compression used. The value `NONE` deactivates compression. Zstd provides for both speed or a good compression ratio, tunable with the `compresslevel` option. zlib is provided for backwards-compatibility. Zstd outperforms these compression types on usual workloads. The value `RLE_TYPE` , which is supported only for append-optimized, column-oriented tables, enables the run-length encoding (RLE) compression algorithm. RLE compresses data better than the Zstd or zlib compression algorithms when the same data value occurs in many consecutive rows. For columns of type `BIGINT` , `INTEGER` , `DATE` , `TIME` , or `TIMESTAMP` , delta compression is also applied if the `compresstype` option is set to `RLE_TYPE` compression. The delta compression algorithm is based on the delta between column values in consecutive rows and is designed to improve compression when data is loaded in sorted order or the compression is applied to column data that is in sorted order.

INHERITS (parent_table [, ...]) The optional `INHERITS` clause specifies a list of tables from which the new table automatically inherits all columns. Parent tables can be plain tables or foreign tables.

Use of `INHERITS` creates a persistent relationship between the new child table and its parent table(s). Schema modifications to the parent(s) normally propagate to children as well, and by default the data of the child table is included in scans of the parent(s).

If the same column name exists in more than one parent table, an error is reported unless the data types of the columns match in each of the parent tables. If there is no conflict, then the duplicate columns are merged to form a single column in the new table. If the column name list of the new table contains a column name that is also inherited, the data type must likewise match the inherited column(s), and the column definitions are merged into one. If the new table explicitly specifies a default value for the column, this default overrides any defaults from inherited declarations of the column. Otherwise, any parents that specify default values for the column must all specify the same default, or WarehousePG reports an error.

`CHECK` constraints are merged in essentially the same way as columns: if multiple parent tables or the new table definition contain identically-named `CHECK` constraints, these constraints must all have the same check expression, or an error will be reported. Constraints having the same name and expression will be merged into one copy. A constraint marked `NO INHERIT` in a parent will not be considered. Notice that an unnamed `CHECK` constraint in the new table will never be merged, since a unique name will always be chosen for it.

Column `STORAGE` settings are also copied from parent tables.

If a column in the parent table is an identity column, that property is not inherited. You can declare a column in the child table an identity column if desired.

PARTITION BY { RANGE | LIST | HASH } ({ column_name | (expression) } [opclass][, ...]) The optiona `PARTITION BY` clause of the *modern partitioning syntax* specifies a strategy of partitioning the table. The table thus created is referred to as a partitioned table. The parenthesized list of columns or expressions forms the partition key for the table. When using range or hash partitioning, the partition key can include multiple columns or expressions (up to 32), but for list partitioning, the partition key must consist of a single column or expression.

Range and list partitioning require a btree operator class, while hash partitioning requires a hash operator class. If no operator class is specified explicitly, the default operator class of the appropriate type will be used; if no default operator class exists, WarehousePG raises an error. When hash partitioning is used, the operator class used must implement support function 2 (see Index Method Support Routines in the PostgreSQL documentation for details).

> **Note** Only the modern partitioning syntax supports hash partitions.

A partitioned table is divided into sub-tables (called partitions), which are typically created using separate `CREATE TABLE` commands. The partitioned table is itself empty. A data row inserted into the table is routed to a partition based on the value of columns or expressions in the partition key. If no existing partition matches the values in the new row, WarehousePG reports an error.

Partitioned tables do not support `EXCLUDE` constraints; however, you can define these constraints on individual partitions.

Refer to Partitioning Large Tables for further discussion on table partitioning.

PARTITION OF parent_table { FOR VALUES partition_bound_spec | DEFAULT } The `PARTITION OF` clause of the *modern partitioning syntax* creates the table as a *partition* of the specified parent table. You can create the table either as a partition for specific values using `FOR VALUES` or as a default partition using `DEFAULT` . Any indexes and constraints that exist in the parent table are cloned on the new partition.

The partition_bound_spec must correspond to the partitioning method and partition key of the parent table, and must not overlap with any existing partition of that parent. The form with `IN` is used for list partitioning, the form with `FROM` and `TO` is used for range partitioning, and the form with `WITH` is used for hash partitioning.

partition_bound_expr is any variable-free expression (subqueries, window functions, aggregate functions, and set-returning functions are not allowed). Its data type must match the data type of the corresponding partition key column. The expression is evaluated once at table creation time, so it can even contain volatile expressions such as `CURRENT_TIMESTAMP` .

When creating a list partition, you can specify `NULL` to signify that the partition allows the partition key column to be null. However, there cannot be more than one such list partition for a given parent table. `NULL` cannot be specified for range partitions.

When creating a range partition, the lower bound specified with `FROM` is an inclusive bound, whereas the upper bound specified with `TO` is an exclusive bound. That is, the values specified in the `FROM` list are valid values of the corresponding partition key columns for this partition, whereas those in the `TO` list are not. Note that this statement must be understood according to the rules of row-wise comparison (seeRow Constructor Comparison in the PostgreSQL documentation for more information.). For example, given `PARTITION BY RANGE (x, y)` , a partition bound `FROM (1, 2) TO (3, 4)` allows `x=1` with any `y>=2` , `x=2` with any non-null `y` , and `x=3` with any `y<4` .

The special values `MINVALUE` and `MAXVALUE` may be used when creating a range partition to indicate that there is no lower or upper bound on the column's value. For example, a partition defined using `FROM (MINVALUE) TO (10)` allows any values less than 10, and a partition defined using `FROM (10) TO (MAXVALUE)` allows any values greater than or equal to 10.

When creating a range partition involving more than one column, it can also make sense to use `MAXVALUE` as part of the lower bound, and `MINVALUE` as part of the upper bound. For example, a partition defined using `FROM (0, MAXVALUE) TO (10, MAXVALUE)` allows any rows where the first partition key column is greater than 0 and less than or equal to 10. Similarly, a partition defined using `FROM ('a', MINVALUE) TO ('b', MINVALUE)` allows any rows where the first partition key column starts with "a".

Note that if `MINVALUE` or `MAXVALUE` is used for one column of a partitioning bound, the same value must be used for all subsequent columns. For example, `(10, MINVALUE, 0)` is not a valid bound; you must specify `(10, MINVALUE, MINVALUE)` .

Also note that some element types, such as timestamp, have a notion of "infinity", which is just another value that can be stored. This is different from `MINVALUE` and `MAXVALUE` , which are not real values that can be stored, but rather they are ways of saying that the value is unbounded. `MAXVALUE` can be thought of as being greater than any other value, including "infinity" and `MINVALUE` as being less than any other value, including "minus infinity". Thus the range `FROM ('infinity') TO (MAXVALUE)` is not an empty range; it allows precisely one value to be stored — "infinity".

If `DEFAULT` is specified, the table will be created as the default partition of the parent table. This option is not available for hash-partitioned tables. WarehousePG routes a partition key value not fitting into any other partition of the given parent to the default partition.

When a table has an existing `DEFAULT` partition and a new partition is added to it, the default partition must be scanned to verify that it does not contain any rows which properly belong in the new partition. If the default partition contains a large number of rows, this may be a slow operation. WarehousePG skips the scan if the default partition is a foreign table or if it has a constraint which proves that it cannot contain rows which should be placed in the new partition.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

When creating a hash partition, you must specify a modulus and a remainder. The modulus must be a positive integer, and the remainder must be a non-negative integer less than the modulus. Typically, when initially setting up a hash-partitioned table, you should choose a modulus equal to the number of partitions and assign every table the same modulus and a different remainder (see examples below). However, it is not required that every partition have the same modulus, only that every modulus which occurs among the partitions of a hash-partitioned table is a factor of the next larger modulus. This allows the number of partitions to be increased incrementally without needing to move all the data at once. For example, suppose you have a hash-partitioned table with 8 partitions, each of which has modulus 8, but find it necessary to increase the number of partitions to 16. You can detach one of the modulus-8 partitions, create two new modulus-16 partitions covering the same portion of the key space (one with a remainder equal to the remainder of the detached partition, and the other with a remainder equal to that value plus 8), and repopulate them with data. You can then repeat this -- perhaps at a later time -- for each modulus-8 partition until none remain. While this may still involve a large amount of data movement at each step, it is still preferable to having to create a whole new table and move all the data at once.

A partition must have the same column names and types as the partitioned table to which it belongs. Modifications to the column names or types of a partitioned table automatically propagate to all partitions `CHECK` constraints are inherited automatically by every partition, but an individual partition may specify additional `CHECK` constraints; additional constraints with the same name and condition as in the parent will be merged with the parent constraint. Defaults may be specified separately for each partition. But note that a partition's default value is not applied when inserting a tuple through a partitioned table.

WarehousePG automatically routes rows inserted into a partitioned table to the correct partition. If no suitable partition exists, WarehousePG returns an error.

Operations such as `TRUNCATE` which normally affect a table and all of its inheritance children will cascade to all partitions, but may also be performed on an individual partition. Note that dropping a partition with `DROP TABLE` requires taking an `ACCESS EXCLUSIVE` lock on the parent table.

LIKE source_table [like_option `...`] The `LIKE` clause specifies a table from which the new table automatically copies all column names, their data types, not-null constraints, and distribution policy.

> **Note** Storage properties and the partition structure are *not* copied to the new table.

Unlike `INHERITS`, the new table and original table are completely decoupled after creation is complete. Changes to the original table will not be applied to the new table, and it is not possible to include data of the new table in scans of the original table.

Also unlike `INHERITS`, columns and constraints copied by `LIKE` are not merged with similarly named columns and constraints. If the same name is specified explicitly or in another `LIKE` clause, WarehousePG signals an error.

The optional like_option clauses specify which additional properties of the original table to copy. Specifying `INCLUDING` copies the property, specifying `EXCLUDING` omits the property. `EXCLUDING` is the default. If multiple specifications are made for the same kind of object, the last one is used. The available options are:

INCLUDING AM The access method of the original table will be copied. When you include `AM`, you must not explicitly specify the access method of the new table using the `WITH` or the `USING` clauses.

INCLUDING COMMENTS Comments for the copied columns, constraints, and indexes will be copied. The default behavior is to exclude comments, resulting in the copied columns and constraints in the new table having no comments.

INCLUDING CONSTRAINTS `CHECK` constraints will be copied. No distinction is made between column constraints and table constraints. Not-null constraints are always copied to the new table.

INCLUDING DEFAULTS Default expressions for the copied column definitions will be copied. Otherwise, default expressions are not copied, resulting in the copied columns in the new table having null defaults. Note that copying defaults that call database-modification functions, such as `nextval`, may create a functional linkage between the original and new tables.

INCLUDING ENCODING For an append-optimized, column-oriented original table, copies the per-column encodings.

INCLUDING GENERATED Any generation expressions of copied column definitions will be copied. By default, new columns will be regular base columns.

INCLUDING IDENTITY Any identity specifications of copied column definitions will be copied. A new sequence is created for each identity column of the new table, separate from the sequences associated with the old table.

INCLUDING INDEXES Indexes, `PRIMARY KEY`, `UNIQUE`, and `EXCLUDE` constraints on the original table will be created on the new table. Names for the new indexes and constraints are chosen according to the default rules, regardless of how the originals were named. (This behavior avoids possible duplicate-name failures for the new indexes.)

INCLUDING RELOPT Copies relation storage options from the original table. For append-optimized and append-optimized, column-oriented tables, copies the `blocksize`, `compresslevel`, and `compresstype.` For heap tables, copies the `fillfactor`. You can also specify relation storage parameters. : When you include `RELOPT` options, you must not explicitly specify relation storage options for the new table using the `WITH` clause.

INCLUDING STATISTICS Extended statistics are copied to the new table.

INCLUDING STORAGE `STORAGE` settings for the copied column definitions will be copied. The default behavior is to exclude `STORAGE` settings, resulting in the copied columns in the new table having type-specific default settings.

INCLUDING ALL `INCLUDING ALL` is an abbreviated form of all available options (It may be useful to specify individual `EXCLUDING` clauses after `INCLUDING ALL` to select all but some specific options.)

You can also use the `LIKE` clause to copy column definitions from views, foreign tables, or composite types. WarehousePG ignores inapplicable options (for example, `INCLUDING INDEXES` from a view).

CONSTRAINT constraint_name An optional name for a column or table constraint. If the constraint is violated, the constraint name is present in error messages, so constraint names like `column must be positive` can be used to communicate helpful constraint information to client applications. (Use double-quotes to specify constraint names that contain spaces.) If a constraint name is not specified, the system generates a name.

> **Note** The specified constraint_name is used for the constraint, but a system-generated unique name is used for the index name. In some prior releases, the provided name was used for both the constraint name and the index name.

NOT NULL The column is not allowed to contain null values.

NULL The column is allowed to contain null values. This is the default.

This clause is only provided for compatibility with non-standard SQL databases. Its use is discouraged in new applications.

CHECK (expression) [NO INHERIT] The `CHECK` clause specifies an expression producing a Boolean result which new or updated rows must satisfy for an insert or update operation to succeed. Expressions evaluating to `TRUE` or `UNKNOWN` succeed. Should any row of an insert or update operation produce a `FALSE` result, WarehousePG raises an error exception, and the insert or update does not alter the database. A check constraint specified as a column constraint should reference that column's value only, while an expression appearing in a table constraint can reference multiple columns.

Currently, `CHECK` expressions cannot contain subqueries nor refer to variables other than columns of the current row. You can reference the system column `tableoid`, but not any other system column.

A constraint marked with `NO INHERIT` will not propagate to child tables.

When a table has multiple `CHECK` constraints, they will be tested for each row in alphabetical order by name, after checking `NOT NULL` constraints. (Previous WarehousePG versions did not honor any particular firing order for `CHECK` constraints.)

DEFAULT default_expr The `DEFAULT` clause assigns a default data value for the column whose column definition it appears within. The value is any variable-free expression (in particular, cross-references to other columns in the current table are not allowed). Subqueries are not allowed either. The data type of the default expression must match the data type of the column. The default expression will be used in any insert operation that does not specify a value for the column. If there is no default for a column, then the default is null.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

GENERATED ALWAYS AS (generation_expr) STORED This clause creates the column as a *generated column*. The column cannot be written to, and when read the result of the specified expression will be returned. The keyword `STORED` is required to signify that the column will be computed on write and will be stored on disk. The generation expression can refer to other columns in the table, but not other generated columns. Any functions and operators used must be immutable. References to other tables are not allowed.

GENERATED { ALWAYS | BY DEFAULT } AS IDENTITY [(sequence_options)] This clause creates the column as an identity column. WarehousePG attaches an implicit sequence to it, and automatically assigns a value from the sequence to the column in new rows. Such a column is implicitly `NOT NULL`. The clauses `ALWAYS` and `BY DEFAULT` determine how the sequence value is given precedence over a user-specified value in an `INSERT` statement. If `ALWAYS` is specified, a user-specified value is only accepted if the `INSERT` statement specifies `OVERRIDING SYSTEM VALUE`. If `BY DEFAULT` is specified, then the user-specified value takes precedence. See INSERT for details. (In the `COPY` command, ueser-specified values are always used regardless of this setting.) You can use the optional sequence_options clause to override the options of the sequence. See CREATE SEQUENCE for details.

UNIQUE (column_constraint) UNIQUE (column_name [, ...]) [INCLUDE (column_name [, ...])] (table_constraint) The `UNIQUE` constraint specifies that a group of one or more columns of a table may contain only unique values. The behavior of a unique table constraint is the same as that of a unique column constraint, with the additional capability to span multiple columns. The constraint therefore enforces that any two rows must differ in at least one of these columns.

For the purpose of a unique constraint, null values are not considered equal. The column(s) that are unique must contain all the columns of the WarehousePG distribution key. In addition, the `<key>` must contain all the columns in the partition key if the table is partitioned. Note that a `<key>` constraint in a partitioned table is not the same as a simple `UNIQUE INDEX`.

Each unique constraint should name a set of columns that is different from the set of columns named by any other unique or primary key constraint defined for the table. (Otherwise, WarehousePG discards redundant unique constraints.)

When establishing a unique constraint for a multi-level partition hierarchy, all of the columns in the partition key of the target partitioned table, as well as those of all its descendant partitioned tables, must be included in the constraint definition.

Adding a unique constraint automatically creates a unique btree index on the column or group of columns used in the constraint.

The optional `INCLUDE` clause adds to that index one or more columns that are simply "payload": uniqueness is not enforced on them, and the index cannot be searched on the basis of those columns. However they can be retrieved by an index-only scan. Note that although the constraint is not enforced on included columns, it still depends on them. Consequently, some operations on such columns (for example, `DROP COLUMN`) can cause cascaded constraint and index deletion.

PRIMARY KEY (column constraint) PRIMARY KEY (column_name [, ...]) [INCLUDE (column_name [, ...])] (table constraint) The `PRIMARY KEY` constraint specifies that a column or columns of a table may contain only unique (non-duplicate), non-null values. You can specify only one primary key for a table, whether as a column constraint or a table constraint.

The primary key constraint should name a set of columns that is different from the set of columns named by any unique constraint defined for the same table. (Otherwise, the unique constraint is redundant and will be discarded.)

`PRIMARY KEY` enforces the same data constraints as a combination of `UNIQUE` and `NOT NULL`, but identifying a set of columns as the primary key also provides metadata about the design of the schema, since a primary key implies that other tables can rely on this set of columns as a unique identifier for rows.

When placed on a partitioned table, `PRIMARY KEY` constraints share the restrictions previously described for `UNIQUE` constraints.

Adding a `PRIMARY KEY` constraint will automatically create a unique btree index on the column or group of columns used in the constraint.

The optional `INCLUDE` clause adds to that index one or more columns that are simply "payload": uniqueness is not enforced on them, and the index cannot be searched on the basis of those columns. However they can be retrieved by an index-only scan. Note that although the constraint is not enforced on included columns, it still depends on them. Consequently, some operations on such columns (for example, `DROP COLUMN`) can cause cascaded constraint and index deletion.

EXCLUDE [USING index_method] (exclude_element WITH operator [, ...]) index_parameters [WHERE (predicate)] The `EXCLUDE` clause defines an exclusion constraint, which guarantees that if any two rows are compared on the specified column(s) or expression(s) using the specified operator(s), not all of these comparisons will return `TRUE`. If all of the specified operators test for equality, this is equivalent to a `UNIQUE` constraint, although an ordinary unique constraint will be faster. However, exclusion constraints can specify constraints that are more general than simple equality. For example, you can specify a constraint that no two rows in the table contain overlapping circles by using the `&&` operator.

WarehousePG does not support specifying an exclusion constraint on a randomly-distributed table.

Exclusion constraints are implemented using an index, so each specified operator must be associated with an appropriate operator class for the index access method index_method. The operators are required to be commutative. Each exclude_element can optionally specify an operator class and/or ordering options; these are described fully under CREATE INDEX.

The access method must support `amgettuple`; at present this means GIN cannot be used. Although it's allowed, there is little point in using B-tree or hash indexes with an exclusion constraint, because this does nothing that an ordinary unique constraint doesn't do better. So in practice the access method will always be GiST or SP-GiST.

The predicate allows you to specify an exclusion constraint on a subset of the table; internally this creates a partial index. Note that parentheses are required around the predicate.

REFERENCES reftable [(refcolumn)] [MATCH matchtype] [ON DELETE key_action] [ON UPDATE key_action] (column constraint) FOREIGN KEY (column_name [, ...]) REFERENCES reftable [(refcolumn [, ...])] [MATCH matchtype] [ON DELETE referential_action] [ON UPDATE referential_action] (table constraint) The `REFERENCES` and `FOREIGN KEY` clauses specify referential integrity constraints (foreign key constraints). WarehousePG accepts referential integrity constraints but does not enforce them.

DEFERRABLE NOT DEFERRABLE The `[NOT] DEFERRABLE` clause controls whether the constraint can be deferred. A constraint that is not deferrable will be checked immediately after every command. Checking of constraints that are deferrable can be postponed until the end of the transaction (using the `SET CONSTRAINTS` command). `NOT DEFERRABLE` is the default. Currently, only `UNIQUE`, `PRIMARY KEY`, and `EXCLUDE` constraints accept this clause. `NOT NULL` and `CHECK` constraints are not deferrable. `REFERENCES` (foreign key) constraints accept this clause but are not enforced. Note that deferrable constraints cannot be used as conflict arbitrators in an `INSERT` statement that includes an `ON CONFLICT DO UPDATE` clause.

Note that deferrable constraints cannot be used as conflict arbitrators in an `INSERT` statement that includes an `ON CONFLICT DO UPDATE` clause.

INITIALLY IMMEDIATE INITIALLY DEFERRED If a constraint is deferrable, this clause specifies the default time to check the constraint. If the constraint is `INITIALLY IMMEDIATE`, it is checked after each statement. This is the default. If the constraint is `INITIALLY DEFERRED`, it is checked only at the end of the transaction. You can alter the constraint check time with the SET CONSTRAINTS command.

USING access_method The optional `USING` clause specifies the table access method to use to store the contents for the new table you are creating; the method must be an access method of type `TABLE`. Set to `heap` to access the table as a heap-storage table, `ao_row` to access the table as an append-optimized table with row-oriented storage (AO), or `ao_column` to access the table as an append-optimized table with column-oriented storage (AO/CO). The default access method is determined by the value of the default_table_access_method server configuration parameter.

> **Note**
>
> Although you can specify the table's access method using `WITH (appendoptimized=true|false, orientation=row|column)` it is recomended to use `USING <access_method>` instead.

WITH (storage_parameter=value) The `WITH` clause specifies optional storage parameters for a table or index; see Storage Parameters below for details. For backward-compatibility the `WITH` clause for a table can also include `OIDS=FALSE` to specify that rows of the new table should not contain OIDs (object identifiers), `OIDS=TRUE` is no longer supported.

ON COMMIT You can control the behavior of temporary tables at the end of a transaction block using `ON COMMIT`. The three options are:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

PRESERVE ROWS - No special action is taken at the ends of transactions for temporary tables. This is the default behavior.

DELETE ROWS - All rows in the temporary table will be deleted at the end of each transaction block. Essentially, WarehousePG performs an automaticTRUNCATE at each commit. When used on a partitioned table, this operation is not cascaded to its partitions.

DROP - The temporary table will be dropped at the end of the current transaction block. When used on a partitioned table, this action drops its partitions and when used on tables with inheritance children, it drops the dependent children.

TABLESPACE tablespace The name of the tablespace in which the new table is to be created. If not specified, the database'sdefault_tablespace is consulted, or temp_tablespaces if the table is temporary. For partitioned tables, since no storage is required for the table itself, the tablespace specified overrides `default_tablespace` as the default tablespace to use for any newly created partitions when no other tablespace is explicitly specified.

USING INDEX TABLESPACE tablespace This clause allows selection of the tablespace in which the index associated with a `UNIQUE`, `PRIMARY KEY`, or `EXCLUDE` constraint will be created. If not specified, the database's default_tablespace is used, or temp_tablespaces if the table is temporary.

DISTRIBUTED BY (column [opclass] [, ...]) DISTRIBUTED RANDOMLY DISTRIBUTED REPLICATED DISTRIBUTED COORDINATOR ONLY

Used to declare the WarehousePG distribution policy for the table. `DISTRIBUTED BY` uses hash distribution with one or more columns declared as the distribution key. For the most even data distribution, the distribution key should be the primary key of the table or a unique column (or set of columns). If that is not possible, then you may choose `DISTRIBUTED RANDOMLY`, which will send the data randomly to the segment instances. Additionally, an operator class, `opclass`, can be specified, to use a non-default hash function.

The `DISTRIBUTED COORDINATOR ONLY` clause specifies that the data is located only on the coordinator node. This policy is primarily used for small lookup tables or system components that need early access to metadata during query planning.

The WarehousePG server configuration parameter gp_create_table_random_default_distribution controls the default table distribution policy if the DISTRIBUTED BY clause is not specified when you create a table. WarehousePG follows these rules to create a table if a distribution policy is not specified.

If the value of the parameter is `off` (the default), WarehousePG chooses the table distribution key based on the command:

- If a `LIKE` or `INHERITS` clause is specified, then WarehousePG copies the distribution key from the source or parent table.
- If `PRIMARY KEY`, `UNIQUE`, or `EXCLUDE` constraints are specified, then WarehousePG chooses the largest subset of all the key columns as the distribution key.
- If no constraints nor a `LIKE` or `INHERITS` clause is specified, then WarehousePG chooses the first suitable column as the distribution key. (Columns with geometric or user-defined data types are not eligible as WarehousePG distribution key columns.)

If the value of the parameter is set to `on`, WarehousePG follows these rules:

- If `PRIMARY KEY`, `UNIQUE`, or `EXCLUDE` columns are not specified, the distribution of the table is random (`DISTRIBUTED RANDOMLY`). Table distribution is random even if the table creation command contains the `LIKE` or `INHERITS` clause.
- If `PRIMARY KEY`, `UNIQUE`, or `EXCLUDE` columns are specified, you must also specify a `DISTRIBUTED BY` clause If a `DISTRIBUTED BY` clause is not specified as part of the table creation command, the command fails.

The `DISTRIBUTED REPLICATED` clause replicates the entire table to all WarehousePG segment instances. It can be used when it is necessary to run user-defined functions on segments when the functions require access to all rows in the table, or to improve query performance by preventing broadcast motions.

Classic Partitioning Syntax Parameters

Descriptions of additional parameters that are specific to the *classic partitioning syntax* follow.

> **Note** modern partitioning syntax is the preferred recomendation

CREATE TABLE table_name ... PARTITION BY

When creating a partitioned table using the *classic syntax*, WarehousePG creates the root partitioned table with the specified table name. WarehousePG also creates a hierarchy of tables, child tables, that are the sub-partitions based on the partitioning options that you specify. The pg_partitioned_table system catalog contains information about the sub-partition tables.

classic_partition_spec Declares the individual partitions to create. Each partition can be defined individually or, for range partitions, you can use the `EVERY` clause (with a `START` and optional `END` clause) to define an increment pattern to use to create the individual partitions.

DEFAULT PARTITION name Declares a default partition. When data does not match the bouds of an existing partition, WarehousePG inserts it into the default partition. Partition designs that do not identify a default partition will reject incoming rows that do not match an existing partition.

PARTITION name Declares a name to use for the partition. Partitions are created using the following naming convention: `<table_name>_<level#>_prt_<given_name>`.

VALUES For list partitions, defines the value(s) that the partition will contain.

START For range partitions, defines the starting range value for the partition. By default, start values are `INCLUSIVE`. For example, if you declared a start date of `2016-01-01`', then the partition would contain all dates greater than or equal to '`2016-01-01`'. The data type of the `START` expression must support a suitable `+` operator, for example `timestamp` or `integer` (not `float` or `text`) if it is defined with the `EXCLUSIVE` keyword. Typically the data type of the `START` expression is the same type as the partition key column. If that is not the case, then you must explicitly cast to the intended data type.

END For range partitions, defines the ending range value for the partition. By default, end values are `EXCLUSIVE`. For example, if you declared an end date of `2016-02-01`', then the partition would contain all dates less than but not equal to '`2016-02-01`'. The data type of the `END` expression must support a suitable `+` operator, for example `timestamp` or `integer` (not `float` or `text`) if it is defined with the `INCLUSIVE` keyword. The data type of the `END` expression is typically the same type as the partition key column. If that is not the case, then you must explicitly cast to the intended data type.

EVERY For range partitions, defines how to increment the values from `START` to `END` to create individual partitions. The data type of the `EVERY` expression is typically the same type as the partition key column. If that is not the case, then you must explicitly cast to the intended data type.

WITH Sets the table storage options for a partition. For example, you may want older partitions to be append-optimized tables and newer partitions to be regular heap tables. SeeStorage Parameters, below.

TABLESPACE The name of the tablespace in which the partition is to be created.

SUBPARTITION BY Declares one or more columns by which to sub-partition the first-level partitions of the table. For `LIST` partitioning, the partition key must consist of a single column or expression. The format of the sub-partition specification is similar to that of a partition specification described above.

SUBPARTITION TEMPLATE Instead of declaring each sub-partition definition individually for each partition, you can optionally declare a sub-partition template to be used to create the sub-partitions (lower level child tables). This sub-partition specification would then apply to all parent partitions.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Storage Parameters

The `WITH` clause can specify storage parameters for tables, and for indexes associated with a `UNIQUE`, `PRIMARY KEY`, or `EXCLUDE` constraint. Storage parameters for indexes are documented on the CREATE INDEX reference page. The storage parameters currently available for tables are listed below. For many of these parameters, as shown, there is an additional parameter with the same name prefixed with `toast.`, which controls the behavior of the table's secondary TOAST table, if any. If a table parameter value is set and the equivalent `toast.` parameter is not, the TOAST table will use the table's parameter value. Specifying these parameters for partitioned tables is not supported, but you may specify them for individual leaf partitions.

Note that you can also set storage parameters for a particular partition or sub-partition by declaring the `WITH` clause in the *classic syntax* partition specification. The lowest-level partition's settings have priority.

You can specify the defaults for some of the table storage options with the server configuration parametergp_default_storage_options. For information about setting default storage options, seeNotes.

> **Note** Because WarehousePG does not permit autovacuuming user tables, it accepts, but does not apply, certain per-table parameter settings as noted below.

The following table storage parameters are available:

analyze_hll_non_part_table Set this storage parameter to `true` to force collection of HLL statistics even if the table is not part of a partitioned table. This is useful if the table will be exchanged or added to a partitioned table, so that the table does not need to be re-analyzed. The default is `false`.

appendoptimized Set to `TRUE` to create the table as an append-optimized table. If `FALSE` or not declared, the table will be created as a regular heap-storage table.

blocksize Set to the size, in bytes, for each block in a table. The `blocksize` must be between 8192 and 2097152 bytes, and be a multiple of 8192. The default is 32768. The `blocksize` option is valid only if the table is append-optimized.

checksum This option is valid only for append-optimized tables. The value `TRUE` is the default and enables CRC checksum validation for append-optimized tables. The checksum is calculated during block creation and is stored on disk. Checksum validation is performed during block reads. If the checksum calculated during the read does not match the stored checksum, the transaction is cancelled. If you set the value to `FALSE` to deactivate checksum validation, checking the table data for on-disk corruption will not be performed.

compresslevel For Zstd compression of append-optimized tables, set to an integer value from 1 (fastest compression) to 19 (highest compression ratio). For zlib compression, the valid range is from 1 to 9. If not declared, the default is 1. For `RLE_TYPE`, the compression level can be an integer value from 1 (fastest compression) to 4 (highest compression ratio).

The `compresslevel` option is valid only if the table is append-optimized.

compresstype Set to `ZLIB` (the default), `ZSTD`, or `RLE_TYPE` to specify the type of compression used. The value `NONE` deactivates compression. Zstd provides for both speed and a good compression ratio, tunable with the `compresslevel` option. zlib is provided for backward compatibility. Zstd outperforms these compression types on usual workloads. The `compresstype` option is only valid if the table is append-optimized.

The value `RLE_TYPE`, which is supported only for append-optimized, column-oriented tables, enables the run-length encoding (RLE) compression algorithm. RLE compresses data better than the Zstd or zlib compression algorithms when the same data value occurs in many consecutive rows.

For columns of type `BIGINT`, `INTEGER`, `DATE`, `TIME`, or `TIMESTAMP`, delta compression is also applied if the `compresstype` option is set to `RLE_TYPE` compression. The delta compression algorithm is based on the delta between column values in consecutive rows and is designed to improve compression when data is loaded in sorted order or the compression is applied to column data that is in sorted order.

For information about using table compression, see Choosing the Table Storage Model in the *WarehousePG Administrator Guide*.

fillfactor The fillfactor for a table is a percentage between 10 and 100. 100 (complete packing) is the default. When a smaller fillfactor is specified, `INSERT` operations pack table pages only to the indicated percentage; the remaining space on each page is reserved for updating rows on that page. This gives `UPDATE` a chance to place the updated copy of a row on the same page as the original, which is more efficient than placing it on a different page. For a table whose entries are never updated, complete packing is the best choice, but in heavily updated tables smaller fillfactors are appropriate. This parameter cannot be set for TOAST tables.

The fillfactor option is valid only for heap tables (tables that specify the `heap` access method or the `appendoptimized=FALSE` storage parameter).

orientation Set to `column` for column-oriented storage, or `row` (the default) for row-oriented storage. This option is only valid if the table is append-optimized. Heap-storage tables can only be row-oriented.

The following parameters are supported for heap tables only:

toast_tuple_target (integer) The `toast_tuple_target` specifies the minimum tuple length required before WarehousePG attempts to compress and/or move long column values into TOAST tables, and is also the target length WarehousePG tries to reduce the length below once toasting begins. This affects columns marked as External (for move), Main (for compression), or Extended (for both) and applies only to new tuples. There is no effect on existing rows. By default this parameter is set to allow at least 4 tuples per block, which with the default blocksize will be 8184 bytes. Valid values are between 128 bytes and the (blocksize - header), by default 8160 bytes. Changing this value may not be useful for very short or very long rows. Note that the default setting is often close to optimal, and it is possible that setting this parameter could have negative effects in some cases. You can not set this parameter for TOAST tables.

parallel_workers (integer) Sets the number of workers that should be used to assist a parallel scan of this table. If not set, WarehousePG determines a value based on the relation size. The actual number of workers chosen by the planner or by utility statements that use parallel scans may be less, for example due to the setting of `max_worker_processes`.

autovacuum_enabled, toast.autovacuum_enabled (boolean) Enables or disables the autovacuum daemon for a particular table. If `true`, the autovacuum daemon will perform automatic `VACUUM` and/or `ANALYZE` operations on this table following the rules discussed in The Autovacuum Daemon in the PostgreSQL documentation. If `false`, WarehousePG does not autovacuum the table, except to prevent transaction ID wraparound. Note that the autovacuum daemon does not run at all (except to prevent transaction ID wraparound) if the autovacuum parameter is `false`; setting individual tables' storage parameters does not override that. So there is seldom much point in explicitly setting this storage parameter to `true`, only to `false`.

vacuum_index_cleanup, toast.vacuum_index_cleanup (boolean) Enables or disables index cleanup when `VACUUM` is run on this table. The default value is `true`. Disabling index cleanup can speed up `VACUUM` very significantly, but may also lead to severely bloated indexes if table modifications are frequent. The `INDEX_CLEANUP` parameter of `VACUUM`, if specified, overrides the value of this option. Setting this to `false` may be useful when you need to run `VACUUM` as quickly as possible, for example to prevent imminent transaction ID wraparound. However, if you do not perform index cleanup regularly, performance may suffer, because as the table is modified, indexes accumulate dead tuples and the table itself accumulates dead line pointers that cannot be removed until index cleanup completes.

vacuum_truncate, toast.vacuum_truncate (boolean) Enables or disables vacuum to attempt to truncate any empty pages at the end of this table. The default value is `true`. If `true`, `VACUUM` and autovacuum truncate the empty pages, and the disk space for the truncated pages is returned to the operating system. Note that the truncation requires an `ACCESS EXCLUSIVE` lock on the table. The `TRUNCATE` parameter of `VACUUM`, if specified, overrides the value of this option.

autovacuum_vacuum_threshold, toast.autovacuum_vacuum_threshold (integer) Per-table value for the autovacuum_vacuum_threshold server configuration parameter.

> **Note** WarehousePG accepts, but does not apply, values for these storage parameters.

autovacuum_vacuum_scale_factor, toast.autovacuum_vacuum_scale_factor (floating point) Per-table value for the autovacuum_vacuum_scale_factor server configuration parameter.

> **Note** WarehousePG accepts, but does not apply, values for these storage parameters.

autovacuum_analyze_threshold (integer) Per-table value for the `autovacuum_analyze_threshold` server configuration parameter.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

autovacuum_analyze_scale_factor (floating point) Per-table value for the `autovacuum_analyze_scale_factor` server configuration parameter.

autovacuum_vacuum_cost_delay, toast.autovacuum_vacuum_cost_delay (floating point) Per-table value for the `autovacuum_vacuum_cost_delay` server configuration parameter.

> **Note** WarehousePG accepts, but does not apply, values for these storage parameters.

autovacuum_vacuum_cost_limit, toast.autovacuum_vacuum_cost_limit (integer) Per-table value for the `autovacuum_vacuum_cost_limit` server configuration parameter.

> **Note** WarehousePG accepts, but does not apply, values for these storage parameters.

autovacuum_freeze_min_age, toast.autovacuum_freeze_min_age (integer) Per-table value for the vacuum_freeze_min_age parameter. Note that autovacuum will ignore per-table `autovacuum_freeze_min_age` parameters that are larger than half of the system-wide `autovacuum_freeze_max_age` setting.

> **Note** WarehousePG accepts, but does not apply, values for these storage parameters.

autovacuum_freeze_max_age, toast.autovacuum_freeze_max_age (integer) Per-table value for the autovacuum_freeze_max_age server configuration parameter. Note that autovacuum will ignore per-table `autovacuum_freeze_max_age` parameters that are larger than the system-wide setting (it can only be set smaller).

> **Note** WarehousePG accepts, but does not apply, values for these storage parameters.

autovacuum_freeze_table_age, toast.autovacuum_freeze_table_age (integer) Per-table value for the `vacuum_freeze_table_age` server configuration parameter.

> **Note** WarehousePG accepts, but does not apply, values for these storage parameters.

autovacuum_multixact_freeze_min_age, toast.autovacuum_multixact_freeze_min_age (integer) Per-table value for the `vacuum_multixact_freeze_min_age` server configuration parameter. Note that autovacuum will ignore per-table `autovacuum_multixact_freeze_min_age` parameters that are larger than half of the system-wide `autovacuum_multixact_freeze_max_age` setting.

> **Note** WarehousePG accepts, but does not apply, values for these storage parameters.

autovacuum_multixact_freeze_max_age, toast.autovacuum_multixact_freeze_max_age (integer) Per-table value for the `autovacuum_multixact_freeze_max_age` server configuration parameter. Note that autovacuum will ignore per-table `autovacuum_multixact_freeze_max_age` parameters that are larger than the system-wide setting (it can only be set smaller).

> **Note** WarehousePG accepts, but does not apply, values for these storage parameters.

autovacuum_multixact_freeze_table_age, toast.autovacuum_multixact_freeze_table_age (integer) Per-table value for the `vacuum_multixact_freeze_table_age` server configuration parameter.

> **Note** WarehousePG accepts, but does not apply, values for these storage parameters.

log_autovacuum_min_duration, toast.log_autovacuum_min_duration (integer) Per-table value for the `log_autovacuum_min_duration` server configuration parameter.

> **Note** WarehousePG accepts, but does not apply, values for these storage parameters.

Notes

WarehousePG automatically creates an index for each unique constraint and primary key constraint to enforce uniqueness, so it is not necessary to create an index explicitly for primary key columns. (See CREATE INDEX for more information.)

Unique constraints and primary keys are not inherited.

You cannot define a table with more than 1600 columns. (In practice, the effective limit is usually lower because of tuple-length constraints.)

The WarehousePG data types `VARCHAR` or `TEXT` handle padding added to the textual data (space characters added after the last non-space character) as significant characters; the data type `CHAR` does not.

In WarehousePG, values of type `CHAR(<n>)` are padded with trailing spaces to the specified width `<n>`. The values are stored and displayed with the spaces. However, the padding spaces are treated as semantically insignificant. When the values are distributed, the trailing spaces are disregarded. The trailing spaces are also treated as semantically insignificant when comparing two values of data type `CHAR`, and the trailing spaces are removed when converting a character value to one of the other string types.

WarehousePG requires certain special conditions for primary key and unique constraints with regards to columns that are the *distribution key* in a WarehousePG table. For a unique constraint to be enforced in WarehousePG, the table must be hash-distributed (not `DISTRIBUTED RANDOMLY`), and the constraint columns must be the same as, or a superset of, the table's distribution key columns.

Replicated tables (`DISTRIBUTED REPLICATED`) can have both `PRIMARY KEY` and `UNIQUE` column constraints.

A primary key constraint is simply a combination of a unique constraint and a not-null constraint.

Foreign key constraints are not supported in WarehousePG.

For inherited tables, unique constraints, primary key constraints, indexes and table privileges are *not* inherited in the current implementation.

For append-optimized tables, `UPDATE` and `DELETE` are not allowed in a repeatable read or serializable transaction and will cause the transaction to end prematurely.

`DECLARE...FOR UPDATE`, and triggers are not supported with append-optimized tables.

`CLUSTER` on append-optimized tables is only supported over B-tree indexes.

GPORCA does not support list partitions with multi-column (composite) partition keys.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Examples

Create a table named `rank` in the schema named `baby` and distribute the data using the columns `rank` and `year`:

```
CREATE TABLE baby.rank (id int, rank int, year smallint, count int )
DISTRIBUTED BY (rank, year);
```

Create tables named `films` and `distributors` (the primary key will be used as the WarehousePG distribution key by default):

```
CREATE TABLE films (
    code        char(5) CONSTRAINT firstkey PRIMARY KEY,
    title       varchar(40) NOT NULL,
    did         integer NOT NULL,
    date_prod   date,
    kind        varchar(10),
    len         interval hour to minute
);

CREATE TABLE distributors (
    did    integer PRIMARY KEY GENERATED BY DEFAULT AS IDENTITY,
    name   varchar(40) NOT NULL CHECK (name <> '')
);
```

Create a gzip-compressed, append-optimized table:

```
CREATE TABLE sales (txn_id int, qty int, date date)
WITH (appendoptimized=true, compresslevel=5)
DISTRIBUTED BY (txn_id);
```

Create a table with a 2-dimensional array:

```
CREATE TABLE array_int (
    vector  int[][]
);
```

Define a unique table constraint for the table `films`. Unique table constraints can be defined on one or more columns of the table:

```
CREATE TABLE films (
    code        char(5),
    title       varchar(40),
    did         integer,
    date_prod   date,
    kind        varchar(10),
    len         interval hour to minute,
    CONSTRAINT production UNIQUE(date_prod)
);
```

Define a check column constraint:

```
CREATE TABLE distributors (
    did     integer CHECK (did > 100),
    name    varchar(40)
);
```

Define a check table constraint:

```
CREATE TABLE distributors (
    did     integer,
    name    varchar(40),
    CONSTRAINT con1 CHECK (did > 100 AND name <> '')
);
```

Define a primary key table constraint for the table `films`:

```
CREATE TABLE films (
    code        char(5),
    title       varchar(40),
    did         integer,
    date_prod   date,
    kind        varchar(10),
    len         interval hour to minute,
    CONSTRAINT code_title PRIMARY KEY(code,title)
);
```

Define a primary key constraint for table `distributors`. The following two examples are equivalent, the first using the table constraint syntax, the second the column constraint syntax:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
CREATE TABLE distributors (
    did     integer,
    name    varchar(40),
    PRIMARY KEY(did)
);

CREATE TABLE distributors (
    did     integer PRIMARY KEY,
    name    varchar(40)
);
```

Assign a literal constant default value for the column name, arrange for the default value of column `did` to be generated by selecting the next value of a sequence object, and make the default value of `modtime` be the time at which the row is inserted:

```
CREATE TABLE distributors (
    name      varchar(40) DEFAULT 'Luso Films',
    did       integer DEFAULT nextval('distributors_serial'),
    modtime   timestamp DEFAULT current_timestamp
);
```

Define two `NOT NULL` column constraints on the table `distributors`, one of which is explicitly given a name:

```
CREATE TABLE distributors (
    did     integer CONSTRAINT no_null NOT NULL,
    name    varchar(40) NOT NULL
);
```

Define a unique constraint for the `name` column:

```
CREATE TABLE distributors (
    did     integer,
    name    varchar(40) UNIQUE
);
```

The same, specified as a table constraint:

```
CREATE TABLE distributors (
    did     integer,
    name    varchar(40),
    UNIQUE(name)
);
```

Create the same table, specifying 70% fill factor for both the table and its unique index:

```
CREATE TABLE distributors (
    did     integer,
    name    varchar(40),
    UNIQUE(name) WITH (fillfactor=70)
)
WITH (fillfactor=70);
```

Create table `cinemas in tablespace` diskvol1`:

```
CREATE TABLE cinemas (
        id serial,
        name text,
        location text
) TABLESPACE diskvol1;
```

Create a composite type and a typed table:

```
CREATE TYPE employee_type AS (name text, salary numeric);

CREATE TABLE employees OF employee_type (
    PRIMARY KEY (name),
    salary WITH OPTIONS DEFAULT 1000
);
```

Modern Partitioning Syntax Examples

Create a range partitioned table:

```
CREATE TABLE measurement (
    logdate         date not null,
    peaktemp        int,
    unitsales       int
) PARTITION BY RANGE (logdate);
```

Create a range partitioned table with multiple columns in the partition key:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
CREATE TABLE measurement_year_month (
    logdate         date not null,
    peaktemp        int,
    unitsales       int
) PARTITION BY RANGE (EXTRACT(YEAR FROM logdate), EXTRACT(MONTH FROM logdate));
```

Create a list partitioned table:

```
CREATE TABLE cities (
    city_id      bigserial not null,
    name         text not null,
    population   bigint
) PARTITION BY LIST (left(lower(name), 1));
```

Create a hash partitioned table:

```
CREATE TABLE orders (
    order_id     bigint not null,
    cust_id      bigint not null,
    status       text
) PARTITION BY HASH (order_id);
```

Create partition of a range partitioned table:

```
CREATE TABLE measurement_y2016m07
    PARTITION OF measurement (
    unitsales DEFAULT 0
) FOR VALUES FROM ('2016-07-01') TO ('2016-08-01');
```

Create a few partitions of a range partitioned table with multiple columns in the partition key:

```
CREATE TABLE measurement_ym_older
    PARTITION OF measurement_year_month
    FOR VALUES FROM (MINVALUE, MINVALUE) TO (2016, 11);

CREATE TABLE measurement_ym_y2016m11
    PARTITION OF measurement_year_month
    FOR VALUES FROM (2016, 11) TO (2016, 12);

CREATE TABLE measurement_ym_y2016m12
    PARTITION OF measurement_year_month
    FOR VALUES FROM (2016, 12) TO (2017, 01);

CREATE TABLE measurement_ym_y2017m01
    PARTITION OF measurement_year_month
    FOR VALUES FROM (2017, 01) TO (2017, 02);
```

Create partition of a list partitioned table:

```
CREATE TABLE cities_ab
    PARTITION OF cities (
    CONSTRAINT city_id_nonzero CHECK (city_id != 0)
) FOR VALUES IN ('a', 'b');
```

Create partition of a list partitioned table that is itself further partitioned and then add a partition to it:

```
CREATE TABLE cities_ab
    PARTITION OF cities (
    CONSTRAINT city_id_nonzero CHECK (city_id != 0)
) FOR VALUES IN ('a', 'b') PARTITION BY RANGE (population);

CREATE TABLE cities_ab_10000_to_100000
    PARTITION OF cities_ab FOR VALUES FROM (10000) TO (100000);
```

Create partitions of a hash partitioned table:

```
CREATE TABLE orders_p1 PARTITION OF orders
    FOR VALUES WITH (MODULUS 4, REMAINDER 0);
CREATE TABLE orders_p2 PARTITION OF orders
    FOR VALUES WITH (MODULUS 4, REMAINDER 1);
CREATE TABLE orders_p3 PARTITION OF orders
    FOR VALUES WITH (MODULUS 4, REMAINDER 2);
CREATE TABLE orders_p4 PARTITION OF orders
    FOR VALUES WITH (MODULUS 4, REMAINDER 3);
```

Create a default partition:

```
CREATE TABLE cities_partdef
    PARTITION OF cities DEFAULT;
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Classic Partitioning Syntax Examples

Create a simple, single level partitioned table:

```
CREATE TABLE sales (id int, year int, qtr int, c_rank int, code char(1), region text)
DISTRIBUTED BY (id)
PARTITION BY LIST (code)
( PARTITION sales VALUES ('S'),
  PARTITION returns VALUES ('R')
);
```

Create a three level partitioned table that defines sub-partitions without the `SUBPARTITION TEMPLATE` clause:

```
CREATE TABLE sales (id int, year int, qtr int, c_rank int, code char(1), region text)
DISTRIBUTED BY (id)
PARTITION BY LIST (code)
  SUBPARTITION BY RANGE (c_rank)
    SUBPARTITION by LIST (region)

( PARTITION sales VALUES ('S')
   ( SUBPARTITION cr1 START (1) END (2)
      ( SUBPARTITION ca VALUES ('CA') ),
      SUBPARTITION cr2 START (3) END (4)
        ( SUBPARTITION ca VALUES ('CA') ) ),

 PARTITION returns VALUES ('R')
   ( SUBPARTITION cr1 START (1) END (2)
      ( SUBPARTITION ca VALUES ('CA') ),
     SUBPARTITION cr2 START (3) END (4)
        ( SUBPARTITION ca VALUES ('CA') ) )
);
```

Create the same partitioned table as the previous table using the `SUBPARTITION TEMPLATE` clause:

```
CREATE TABLE sales1 (id int, year int, qtr int, c_rank int, code char(1), region text)
DISTRIBUTED BY (id)
PARTITION BY LIST (code)

   SUBPARTITION BY RANGE (c_rank)
     SUBPARTITION TEMPLATE (
     SUBPARTITION cr1 START (1) END (2),
     SUBPARTITION cr2 START (3) END (4) )

     SUBPARTITION BY LIST (region)
       SUBPARTITION TEMPLATE (
       SUBPARTITION ca VALUES ('CA') )

( PARTITION sales VALUES ('S'),
  PARTITION  returns VALUES ('R')
);
```

Create a three level partitioned table using sub-partition templates and default partitions at each level:

```
CREATE TABLE sales (id int, year int, qtr int, c_rank int, code char(1), region text)
DISTRIBUTED BY (id)
PARTITION BY RANGE (year)

  SUBPARTITION BY RANGE (qtr)
    SUBPARTITION TEMPLATE (
    START (1) END (5) EVERY (1),
    DEFAULT SUBPARTITION bad_qtr )

    SUBPARTITION BY LIST (region)
      SUBPARTITION TEMPLATE (
      SUBPARTITION usa VALUES ('usa'),
      SUBPARTITION europe VALUES ('europe'),
      SUBPARTITION asia VALUES ('asia'),
      DEFAULT SUBPARTITION other_regions)

( START (2009) END (2011) EVERY (1),
  DEFAULT PARTITION outlying_years);
```

Compatibility

`CREATE TABLE` command conforms to the SQL standard, with the following exceptions:

Temporary Tables

In the SQL standard, temporary tables are defined just once and automatically exist (starting with empty contents) in every session that needs them. WarehousePG instead requires each session to issue its own `CREATE TEMPORARY TABLE` command for each temporary table to be used. This allows different sessions to use the same temporary table name for different purposes, whereas the standard's approach constrains all instances of a given temporary table name to have the same table structure.

The standard's distinction between global and local temporary tables is not in WarehousePG. WarehousePG will accept the `GLOBAL` and `LOCAL` keywords in a temporary table declaration, but they have no effect and are deprecated.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

If the `ON COMMIT` clause is omitted, the SQL standard specifies that the default behavior as `ON COMMIT DELETE ROWS`. However, the default behavior in WarehousePG is `ON COMMIT PRESERVE ROWS`. The `ON COMMIT DROP` option does not exist in the SQL standard.

Non-Deferred Uniqueness Constraints

When a `UNIQUE` or `PRIMARY KEY` constraint is not deferrable, Greeplum Database checks for uniqueness immediately whenever a row is inserted or modified. The SQL standard states that uniqueness should be enforced only at the end of the statement; this makes a difference when, for example, a single command updates multiple key values. To obtain standard-compliant behavior, declare the constraint as `DEFERRABLE` but not deferred (for example, `INITIALLY IMMEDIATE`). Note that this can be significantly slower than immediate uniqueness checking.

Column Check Constraints

Column Check Constraints — The SQL standard states that `CHECK` column constraints may only refer to the column they apply to; only `CHECK` table constraints may refer to multiple columns. WarehousePG does not enforce this restriction; it treats column and table check constraints alike.

Exclude Constraint — The `EXCLUDE` constraint type is a WarehousePG extension.

NULL Constraint — The `NULL` constraint is a WarehousePG extension to the SQL standard that is included for compatibility with some other database systems (and for symmetry with the `NOT NULL` constraint). Since it is the default for any column, its presence is not required.

Constraint Naming

The SQL standard states that table and domain constraints must have names that are unique across the schema containing the table or domain. WarehousePG is laxer: it only requires constraint names to be unique across the constraints attached to a particular table or domain. However, this extra freedom does not exist for index-based constraints (`UNIQUE`, `PRIMARY KEY`, and `EXCLUDE` constraints), because the associated index is named the same as the constraint, and index names must be unique across all relations within the same schema.

WarehousePG does not currently record names for `NOT NULL` constraints at all, so they are not subject to the uniqueness restriction.

Inheritance

Multiple inheritance via the `INHERITS` clause is a WarehousePG language extension. SQL:1999 and later define single inheritance using a different syntax and different semantics. SQL:1999-style inheritance is not yet supported by WarehousePG.

Zero-Column Tables

WarehousePG allows a table of no columns to be created (for example, `CREATE TABLE foo();`). This is an extension from the SQL standard, which does not allow zero-column tables. Because zero-column tables are not in themselves very useful, disallowing them creates odd special cases for `ALTER TABLE DROP COLUMN`, so WarehousePG ignores this spec restriction.

Multiple Identity Columns

WarehousePG allows a table to have more than one identity column. The standard specifies that a table can have at most one identity column. WarehousePG relaxes this restriction to provide more flexibility for schema changes or migrations. Note that the `INSERT` command supports only one override clause that applies to the entire statement, so having multiple identity columns with different behaviors is not well supported.

Generated Columns

The option `STORED` is not standard but is also used by other SQL implementations. The SQL standard does not specify the storage of generated columns.

LIKE Clause

While a `LIKE` clause exists in the SQL standard, many of the options that WarehousePG accepts for it are not in the standard, and some of the standard's options are not implemented by WarehousePG.

WITH Clause

The `WITH` clause is a WarehousePG extension; storage parameters are in the standard.

Tablespaces

The WarehousePG concept of tablespaces is not part of the SQL standard. The clauses `TABLESPACE` and `USING INDEX TABLESPACE` are extensions.

Typed Tables

Typed tables implement a subset of the SQL standard. According to the standard, a typed table has columns corresponding to the underlying composite type as well as one other column that is the "self-referencing column". WarehousePG does not support self-referencing columns explicitly.

PARTITION BY Clause

Table partitioning via the `PARTITION BY` clause is a WarehousePG extension.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

PARTITION OF Clause

Table partitioning via the `PARTITION OF` clause is a WarehousePG extension.

Data Distribution

The WarehousePG concept of a parallel or distributed database is not part of the SQL standard. The `DISTRIBUTED` clauses are extensions.

ALTER TABLE, DROP TABLE, CREATE EXTERNAL TABLE, CREATE TABLE AS, CREATE TABLESPACE, CREATE TYPE

Parent topic: SQL Commands

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.1.81 CREATE TABLE AS

Defines a new table from the results of a query.

Synopsis

```
CREATE [ [ GLOBAL | LOCAL ] { TEMPORARY | TEMP } | UNLOGGED ] TABLE [ IF NOT EXISTS ] <table_name>
        [ (<column_name> [, ...] ) ]
        [ USING <access_method> ]
        [ WITH ( <storage_parameter> [= <value>] [, ... ] ) | WITHOUT OIDS ]
        [ ON COMMIT { PRESERVE ROWS | DELETE ROWS | DROP } ]
        [ TABLESPACE <tablespace_name> ]
        AS <query>
        [ WITH [ NO ] DATA ]
        [ DISTRIBUTED BY ( <column> [<opclass>] [, ... ] )
           | DISTRIBUTED RANDOMLY
           | DISTRIBUTED REPLICATED ]
```

Description

`CREATE TABLE AS` creates a table and fills it with data computed by a SELECT command. The table columns have the names and data types associated with the output columns of the `SELECT`, however you can override the column names by giving an explicit list of new column names.

`CREATE TABLE AS` creates a new table and evaluates the query just once to fill the new table initially. The new table will not track subsequent changes to the source tables of the query.

Parameters

GLOBAL | LOCAL Ignored for compatibility. These keywords are deprecated; refer to CREATE TABLE for details.

TEMPORARY | TEMP If specified, the new table is created as a temporary table. Refer to CREATE TABLE for details.

UNLOGGED If specified, the table is created as an unlogged table. Refer to CREATE TABLE for details.

IF NOT EXISTS Do not throw an error if a relation with the same name already exists; simply issue a notice and leave the table unmodified.

table_name The name (optionally schema-qualified) of the new table to be created.

column_name The name of a column in the new table. If column names are not provided, they are taken from the output column names of the query.

USING access_method The optional `USING` clause specifies the table access method to use to store the contents for the new table you are creating; the method must be an access method of typeTABLE. Set to `heap` to access the table as a heap-storage table, `ao_row` to access the table as an append-optimized table with row-oriented storage (AO), or `ao_column` to access the table as an append-optimized table with column-oriented storage (AO/CO). The default access method is determined by the value of the default_table_access_method server configuration parameter.

> **Note**
>
> Although you can specify the table's access method using `<code>WITH (appendoptimized=true|false, orientation=row|column)</code>` the recomendation is to use `<code>USING <access_method></code>` instead.

WITH (storage_parameter=value) The `WITH` clause specifies optional storage parameters for the new table. Refer to the Storage Parameters section on the `CREATE TABLE` reference page for more information.

ON COMMIT The behavior of temporary tables at the end of a transaction block can be controlled using `ON COMMIT`. The three options are:

PRESERVE ROWS — WarehousePG takes no special action at the ends of transactions for temporary tables. This is the default behavior.

DELETE ROWS — WarehousePG deletes all rows in the temporary table at the end of each transaction block. Essentially, an automatic TRUNCATE is done at each commit.

DROP — WarehousePG drops the temporary table at the end of the current transaction block.

TABLESPACE tablespace_name The tablespace_name parameter is the name of the tablespace in which the new table is to be created. If not specified, the database'sdefault_tablespace is used, or temp_tablespaces if the table is temporary.

AS query A SELECT, TABLE, or VALUES command, or an EXECUTE command that runs a prepared `SELECT`, `TABLE`, or `VALUES` query.

DISTRIBUTED BY (column [opclass] [, ...]) DISTRIBUTED RANDOMLY DISTRIBUTED REPLICATED Used to declare the WarehousePG distribution policy for the table. Refer toCREATE TABLE for details.

Notes

This command is functionally similar to SELECT INTO, but it is preferred since it is less likely to be confused with other uses of the `SELECT INTO` syntax. Furthermore, `CREATE TABLE AS` offers a superset of the functionality offered by `SELECT INTO`.

`CREATE TABLE AS` can be used for fast data loading from external table data sources. See CREATE EXTERNAL TABLE.

`CREATE TABLE AS` does not support setting distribution to `COORDINATOR ONLY`.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Examples

Create a new table `films_recent` consisting of only recent entries from the table `films`:

```
CREATE TABLE films_recent AS
  SELECT * FROM films WHERE date_prod >= '2020-01-01';
```

To copy a table completely, you can also use the short form by specifying the `TABLE` command:

```
CREATE TABLE films2 AS
  TABLE films;
```

Create a new temporary table `films_recent`, consisting only of recent entries from the table `films`, using a prepared statement. The new table will be dropped at commit:

```
PREPARE recentfilms(date) AS
  SELECT * FROM films WHERE date_prod > $1;
CREATE TEMP TABLE films_recent ON COMMIT DROP AS
  EXECUTE recentfilms('2020-01-01');
```

Compatibility

`CREATE TABLE AS` conforms to the SQL standard, with the following exceptions:

- The standard requires parentheses around the subquery clause; in WarehousePG, these parentheses are optional.
- In the standard, the `WITH [NO] DATA` clause is required, in WarehousePG it is optional.
- WarehousePG handles temporary tables differently from the standard; see CREATE TABLE for details.
- The `WITH` clause is a WarehousePG extension; storage parameters are not part of the standard.
- The WarehousePG concept of tablespaces is not part of the standard. The `TABLESPACE` clause is an extension.

CREATE EXTERNAL TABLE, CREATE MATERIALIZED VIEW, CREATE TABLE, EXECUTE, SELECT, SELECT INTO, VALUES

Parent topic: SQL Commands

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.1.82 CREATE TABLESPACE

Defines a new tablespace.

Synopsis

```
CREATE TABLESPACE <tablespace_name>
   [ OWNER { <owner_name> | CURRENT_USER | SESSION_USER } ]
   LOCATION '<directory>'
   [ WITH (content<ID_1>='<directory>'[, content<ID_2>='<directory>' ... ] [, <tablespace_option = value [, ... ] ] ) ]
```

Description

`CREATE TABLESPACE` registers and configures a new tablespace for your WarehousePG cluster. The tablespace name must be distinct from the name of any existing tablespace in the system. A tablespace is a WarehousePG cluster object (a global object), you can use a tablespace from any database if you have appropriate privileges.

A tablespace allows superusers to define an alternative host file system location where the data files containing database objects (such as tables and indexes) reside.

A user with appropriate privileges can pass tablespace_name to CREATE DATABASE, CREATE TABLE, or CREATE INDEX to direct WarehousePG to store the data files for these objects within the specified tablespace.

In WarehousePG, the file system location must exist on all hosts including the hosts running the coordinator, standby mirror, each primary segment, and each mirror segment.

Parameters

tablespace*name The name of a tablespace to be created. The name cannot begin with `pg*`or`gp_`, as such names are reserved for system tablespaces.

owner_name The name of the user who will own the tablespace. If omitted, defaults to the user running the command. Only superusers can create tablespaces, but they can assign ownership of tablespaces to non-superusers.

LOCATION 'directory' The directory that will be used for the tablespace. The directory should be empty and must be owned by the WarehousePG cluster user. You must specify the absolute path of the directory, and the path name must not be greater than 100 characters in length. (The location is used to create a symlink target in the pg_tblspc directory, and symlink targets are truncated to 100 characters when sending to `tar` from utilities such as `pg_basebackup`.)

You can specify a different tablespace directory for any WarehousePG segment instance in the `WITH` clause.

contentID_i='directory_i' The value ID_i is the content ID for the segment instance. directory_i is the absolute path to the host system file location that the segment instance uses as the root directory for the tablespace. You cannot specify the content ID of the coordinator instance (`-1`). You can specify the same directory for multiple segments.

If a segment instance is not listed in the `WITH` clause, WarehousePG uses the tablespace directory specified in the `LOCATION` clause.

The restrictions identified for the `LOCATION` directory also hold for directory_i.

tablespace_option A tablespace parameter to set or reset. Currently, the only available parameters are `seq_page_cost` and `random_page_cost`. Setting either value for a particular tablespace will override the planner's usual estimate of the cost of reading pages from tables in that tablespace, as established by the configuration parameters of the same name (see seq_page_cost, random_page_cost). This may be useful if one tablespace is located on a disk which is faster or slower than the remainder of the I/O subsystem.

Notes

Because `CREATE TABLESPACE` creates symbolic links from the `pg_tblspc` directory in the coordinator and segment instance data directory to the directories specified in the command, WarehousePG supports tablespaces only on systems that support symbolic links.

You cannot run `CREATE TABLESPACE` inside a transaction block.

When creating tablespaces, ensure that file system locations have sufficient I/O speed and available disk space.

> **Note** WarehousePG does not support different tablespace locations for a primary-mirror pair with the same content ID. It is only possible to configure different locations for different content IDs. Do not modify symbolic links under the `pg_tblspc` directory so that primary-mirror pairs point to different file locations; this will lead to erroneous behavior.

Examples

Create a new tablespace and specify the file system location for the coordinator and all segment instances:

```
CREATE TABLESPACE mytblspace LOCATION '/gpdbtspc/mytestspace';
```

Create a tablespace `indexspace` at `/data/indexes` owned by user `genevieve`:

```
CREATE TABLESPACE indexspace OWNER genevieve LOCATION '/data/indexes';
```

Create a new tablespace and specify a location for segment instances with content ID 0 and 1. For the coordinator and segment instances not listed in the `WITH` clause, the file system location for the tablespace is the directory specified in the `LOCATION` clause.

```
CREATE TABLESPACE mytblspace LOCATION '/gpdbtspc/mytestspace' WITH (content0='/temp/mytest', content1='/temp/mytest');
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

The example specifies the same location for the two segment instances. You can a specify different location for each segment.

Compatibility

`CREATE TABLESPACE` is a WarehousePG extension.

7.1.83 CREATE TEXT SEARCH CONFIGURATION

Defines a new text search configuration.

Synopsis

```
CREATE TEXT SEARCH CONFIGURATION <name> (
    PARSER = <parser_name> |
    COPY = <source_config>
)
```

Description

`CREATE TEXT SEARCH CONFIGURATION` creates a new text search configuration. A text search configuration specifies a text search parser that can divide a string into tokens, plus dictionaries that can be used to determine which tokens are of interest for searching.

If only the parser is specified, then the new text search configuration initially has no mappings from token types to dictionaries, and therefore will ignore all words. SubsequentALTER TEXT SEARCH CONFIGURATION commands must be used to create mappings to make the configuration useful. Alternatively, an existing text search configuration can be copied.

If a schema name is provided then the text search configuration is created in the specified schema. Otherwise it is created in the current schema.

The user who defines a text search configuration becomes its owner.

Refer to Using Full Text Search for further information.

Parameters

name The name of the text search configuration to be created. The name can be schema-qualified.

parser_name The name of the text search parser to use for this configuration.

source_config The name of an existing text search configuration to copy.

Notes

The `PARSER` and `COPY` options are mutually exclusive, because when an existing configuration is copied, its parser selection is copied too.

Compatibility

There is no `CREATE TEXT SEARCH CONFIGURATION` statement in the SQL standard.

7.1.84 CREATE TEXT SEARCH DICTIONARY

Defines a new text search dictionary.

Synopsis

```
CREATE TEXT SEARCH DICTIONARY <name> (
    TEMPLATE = <template>
    [, <option> = <value> [, ... ]]
)
```

Description

CREATE TEXT SEARCH DICTIONARY creates a new text search dictionary. A text search dictionary specifies a way of recognizing interesting or uninteresting words for searching. A dictionary depends on a text search template, which specifies the functions that actually perform the work. Typically the dictionary provides some options that control the detailed behavior of the template's functions.

If a schema name is given then the text search dictionary is created in the specified schema. Otherwise it is created in the current schema.

The user who defines a text search dictionary becomes its owner.

Refer to Using Full Text Search for further information.

Parameters

name The name of the text search dictionary to be created. The name can be schema-qualified.

template The name of the text search template that will define the basic behavior of this dictionary.

option The name of a template-specific option to be set for this dictionary.

value The value to use for a template-specific option. If the value is not a simple identifier or number, it must be quoted (but you can always quote it, if you wish).

The options can appear in any order.

Examples

The following example command creates a Snowball-based dictionary with a nonstandard list of stop words.

```
CREATE TEXT SEARCH DICTIONARY my_russian (
    template = snowball,
    language = russian,
    stopwords = myrussian
);
```

Compatibility

There is no `CREATE TEXT SEARCH DICTIONARY` statement in the SQL standard.

See Also

ALTER TEXT SEARCH DICTIONARY, DROP TEXT SEARCH DICTIONARY

7.1.85 CREATE TEXT SEARCH PARSER

Defines a new text search parser.

Synopsis

```
CREATE TEXT SEARCH PARSER <name> (
    START = <start_function> ,
    GETTOKEN = <gettoken_function> ,
    END = <end_function> ,
    LEXTYPES = <lextypes_function>
    [, HEADLINE = <headline_function> ]
)
```

Description

`CREATE TEXT SEARCH PARSER` creates a new text search parser. A text search parser defines a method for splitting a text string into tokens and assigning types (categories) to the tokens. A parser is not particularly useful by itself, but must be bound into a text search configuration along with some text search dictionaries to be used for searching.

If a schema name is given then the text search parser is created in the specified schema. Otherwise it is created in the current schema.

You must be a superuser to use `CREATE TEXT SEARCH PARSER`. (This restriction is made because an erroneous text search parser definition could confuse or even crash the server.)

Refer to Using Full Text Search for further information.

Parameters

name The name of the text search parser to be created. The name can be schema-qualified.

start_function The name of the start function for the parser.

gettoken_function The name of the get-next-token function for the parser.

end_function The name of the end function for the parser.

lextypes_function The name of the lextypes function for the parser (a function that returns information about the set of token types it produces).

headline_function The name of the headline function for the parser (a function that summarizes a set of tokens).

The function names can be schema-qualified if necessary. Argument types are not given, since the argument list for each type of function is predetermined. All except the headline function are required.

The arguments can appear in any order, not only the one shown above.

Compatibility

There is no `CREATE TEXT SEARCH PARSER` statement in the SQL standard.

See Also

ALTER TEXT SEARCH PARSER, DROP TEXT SEARCH PARSER

7.1.86 CREATE TEXT SEARCH TEMPLATE

Defines a new text search template.

Synopsis

```
CREATE TEXT SEARCH TEMPLATE <name> (
    [ INIT = <init_function> , ]
    LEXIZE = <lexize_function>
)
```

Description

`CREATE TEXT SEARCH TEMPLATE` creates a new text search template. Text search templates define the functions that implement text search dictionaries. A template is not useful by itself, but must be instantiated as a dictionary to be used. The dictionary typically specifies parameters to be given to the template functions.

If a schema name is given then the text search template is created in the specified schema. Otherwise it is created in the current schema.

You must be a superuser to use `CREATE TEXT SEARCH TEMPLATE`. This restriction is made because an erroneous text search template definition could confuse or even crash the server. The reason for separating templates from dictionaries is that a template encapsulates the "unsafe" aspects of defining a dictionary. The parameters that can be set when defining a dictionary are safe for unprivileged users to set, and so creating a dictionary need not be a privileged operation.

Refer to Using Full Text Search for further information.

Parameters

name The name of the text search template to be created. The name can be schema-qualified.

init_function The name of the init function for the template.

lexize_function The name of the lexize function for the template.

The function names can be schema-qualified if necessary. Argument types are not given, since the argument list for each type of function is predetermined. The lexize function is required, but the init function is optional.

The arguments can appear in any order, not only the order shown above.

Compatibility

There is no `CREATE TEXT SEARCH TEMPLATE` statement in the SQL standard.

7.1.87 CREATE TRANSFORM

Defines a new transform

Synopsis

```
CREATE [ OR REPLACE ] TRANSFORM FOR <type_name> LANGUAGE <lang_name> (
  FROM SQL WITH FUNCTION <from_sql_function_name> [ (<argument_type> [, ...]) ],
  TO SQL WITH FUNCTION <to_sql_function_name> [ (<argument_type> [, ...]) ]
);
```

Description

`CREATE TRANSFORM` defines a new transform. `CREATE OR REPLACE TRANSFORM` will either create a new transform, or replace an existing definition.

A transform specifies how to adapt a data type to a procedural language. For example, when writing a function in PL/Python using the `hstore` type, PL/Python has no prior knowledge how to present `hstore` values in the Python environment. Language implementations usually default to using the text representation, but that is inconvenient when, for example, an associative array or a list would be more appropriate.

A transform specifies two functions:

- A "from SQL" function that converts the type from the SQL environment to the language. This function will be invoked on the arguments of a function written in the language.
- A "to SQL" function that converts the type from the language to the SQL environment. This function will be invoked on the return value of a function written in the language.

It is not necessary to provide both of these functions. If one is not specified, the language-specific default behavior will be used if necessary. (To prevent a transformation in a certain direction from happening at all, you could also write a transform function that always errors out.)

To create a transform, you must own and have `USAGE` privilege on the type, have `USAGE` privilege on the language, and own and have `EXECUTE` privilege on the from-SQL and to-SQL functions, if specified.

Parameters

type_name The name of the data type of the transform.

lang_name The name of the language of the transform.

from_sql_function_name[(argument_type [, ...])] The name of the function for converting the type from the SQL environment to the language. It must take a single argument of type `internal` and return type `internal`. The actual argument will be of the type for the transform, and the function should be coded as if it were. (An SQL-level function returning `internal` must declare at least one argument of type `internal`.) The actual return value will be something specific to the language implementation. If no argument list is specified, the function name must be unique in its schema.

to_sql_function_name[(argument_type [, ...])] The name of the function for converting the type from the language to the SQL environment. It must take a single argument of type `internal` and return the type that is the type for the transform. The actual argument value will be something specific to the language implementation. If no argument list is specified, the function name must be unique in its schema.

Notes

Use DROP TRANSFORM to remove transforms.

Examples

To create a transform for type `hstore` and language `plpython3u`, first set up the type and the language:

```
CREATE EXTENSION IF NOT EXISTS hstore;

CREATE EXTENSION
plpython3u;
```

Then create the necessary functions:

```
CREATE FUNCTION hstore_to_plpython(val internal) RETURNS
internal
LANGUAGE C STRICT
IMMUTABLE
AS ...;

CREATE FUNCTION plpython_to_hstore(val internal) RETURNS
hstore
LANGUAGE C STRICT
IMMUTABLE
AS ...;
```

And finally create the transform to connect them all together:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
CREATE TRANSFORM FOR hstore LANGUAGE plpython3u
(
    FROM SQL WITH FUNCTION
hstore_to_plpython(internal),
    TO SQL WITH FUNCTION
plpython_to_hstore(internal)
);
```

In practice, these commands would be wrapped up in an extension.

Compatibility

This form of `CREATE TRANSFORM` is a WarehousePG extension. There is a `CREATE TRANSFORM` command in the SQL standard, but it is for adapting data types to client languages. That usage is not supported by WarehousePG.

7.1.88 CREATE TYPE

Defines a new data type.

Synopsis

```
CREATE TYPE <name> AS
    ( [ <attribute_name> <data_type> [ COLLATE <collation> ] [, ... ] ] )

CREATE TYPE <name> AS ENUM
    ( [ '<label>' [, ... ] ] )

CREATE TYPE <name> AS RANGE (
    SUBTYPE = <subtype>
    [ , SUBTYPE_OPCLASS = <subtype_operator_class> ]
    [ , COLLATION = <collation> ]
    [ , CANONICAL = <canonical_function> ]
    [ , SUBTYPE_DIFF = <subtype_diff_function> ]
)

CREATE TYPE <name> (
    INPUT = <input_function>,
    OUTPUT = <output_function>
    [, RECEIVE = <receive_function>]
    [, SEND = <send_function>]
    [, TYPMOD_IN = <type_modifier_input_function> ]
    [, TYPMOD_OUT = <type_modifier_output_function> ]
    [, ANALYZE = <analyze_function>]
    [, INTERNALLENGTH = {<internallength> | VARIABLE}]
    [, PASSEDBYVALUE]
    [, ALIGNMENT = <alignment>]
    [, STORAGE = <storage>]
    [, LIKE = <like_type>
    [, CATEGORY = <category>]
    [, PREFERRED = <preferred>]
    [, DEFAULT = <default>]
    [, ELEMENT = <element>]
    [, DELIMITER = <delimiter>]
    [, COLLATABLE = <collatable>]
    [, COMPRESSTYPE = <compression_type>]
    [, COMPRESSLEVEL = <compression_level>]
    [, BLOCKSIZE = <blocksize>] )

CREATE TYPE <name>
```

Description

`CREATE TYPE` registers a new data type for use in the current database. The user who defines a type becomes its owner.

If a schema name is given then the type is created in the specified schema. Otherwise it is created in the current schema. The type name must be distinct from the name of any existing type or domain in the same schema. The type name must also be distinct from the name of any existing table in the same schema.

There are five forms of `CREATE TYPE`, as shown in the syntax synopsis above. They respectively create a *composite type*, an *enum type*, a *range type*, a *base type*, or a *shell type*. The first four of these are discussed in turn below. A shell type is simply a placeholder for a type to be defined later; it is created by issuing `CREATE TYPE` with no parameters except for the type name. Shell types are needed as forward references when creating range types and base types, as discussed in those sections.

Composite Types

The first form of `CREATE TYPE` creates a composite type. The composite type is specified by a list of attribute names and data types. An attribute's collation can be specified too, if its data type is collatable. A composite type is essentially the same as the row type of a table, but using `CREATE TYPE` avoids the need to create an actual table when all that is wanted is to define a type. A stand-alone composite type is useful, for example, as the argument or return type of a function.

To create a composite type, you must have `USAGE` privilege on all attribute types.

Enumerated Types

The second form of `CREATE TYPE` creates an enumerated (`ENUM`) type, as described in Enumerated Types in the PostgreSQL documentation. `ENUM` types take a list of quoted labels, each of which must be less than `NAMEDATALEN` bytes long (64).

It is possible to create an enumerated type with zero labels, but such a type cannot be used to hold values before at least one label is added using ALTER TYPE.

Range Types

The third form of `CREATE TYPE` creates a new range type, as described in Range Types.

The range type's subtype can be any type with an associated b-tree operator class (to determine the ordering of values for the range type). Normally the subtype's default b-tree operator class is used to determine ordering; to use a non-default operator class, specify its name with subtype_opclass. If the subtype is collatable, and you want to use a non-default collation in the range's ordering, specify the desired collation with the collation option.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

The optional canonical function must take one argument of the range type being defined, and return a value of the same type. This is used to convert range values to a canonical form, when applicable. SeeDefining New Range Types for more information. Creating a canonical function is a bit tricky, since it must be defined before the range type can be declared. To do this, you must first create a shell type, which is a placeholder type that has no properties except a name and an owner. This is done by issuing the command `CREATE TYPE name`, with no additional parameters. Then the function can be declared using the shell type as argument and result, and finally the range type can be declared using the same name. This automatically replaces the shell type entry with a valid range type.

The optional subtype_diff_function must take two values of the subtype type as argument, and return a double precision value representing the difference between the two given values. While this is optional, providing it allows much greater efficiency of GiST indexes on columns of the range type. See Defining New Range Types for more information.

Base Types

The fourth form of `CREATE TYPE` creates a new base type (scalar type). You must be a superuser to create a new base type. (This restriction is in place because an erroneous type definition could confuse or even crash the server.)

The parameters may appear in any order, not only that shown in the syntax, and most are optional. You must register two or more functions (using `CREATE FUNCTION`) before defining the type. The support functions input_function and output_function are required, while the functions receive_function, send_function, type_modifier_input_function, type_modifier_output_function, and analyze_function are optional. Generally these functions have to be coded in C or another low-level language. In WarehousePG, any function used to implement a data type must be defined as `IMMUTABLE`.

The input_function converts the type's external textual representation to the internal representation used by the operators and functions defined for the type. output_function performs the reverse transformation. The input function may be declared as taking one argument of type `cstring`, or as taking three arguments of types `cstring`, `oid`, `integer`. The first argument is the input text as a C string, the second argument is the type's own OID (except for array types, which instead receive their element type's OID), and the third is the `typmod` of the destination column, if known (`-1` will be passed if not). The input function must return a value of the data type itself. Usually, an input function should be declared `STRICT`; if it is not, it will be called with a `NULL` first parameter when reading a `NULL` input value. The function must still return `NULL` in this case, unless it raises an error. (This case is mainly meant to support domain input functions, which may need to reject `NULL` inputs.) The output function must be declared as taking one argument of the new data type. The output function must return type `cstring`. Output functions are not invoked for `NULL` values.

The optional receive_function converts the type's external binary representation to the internal representation. If this function is not supplied, the type cannot participate in binary input. The binary representation should be chosen to be cheap to convert to internal form, while being reasonably portable. (For example, the standard integer data types use network byte order as the external binary representation, while the internal representation is in the machine's native byte order.) The receive function should perform adequate checking to ensure that the value is valid. The receive function may be declared as taking one argument of type `internal`, or as taking three arguments of types `internal`, `oid`, `integer`. The first argument is a pointer to a `StringInfo` buffer holding the received byte string; the optional arguments are the same as for the text input function. The receive function must return a value of the data type itself. Usually, a receive function should be declared `STRICT`; if it is not, it will be called with a `NULL` first parameter when reading a NULL input value. The function must still return `NULL` in this case, unless it raises an error. (This case is mainly meant to support domain receive functions, which may need to reject `NULL` inputs.) Similarly, the optional send_function converts from the internal representation to the external binary representation. If this function is not supplied, the type cannot participate in binary output. The send function must be declared as taking one argument of the new data type. The send function must return type `bytea`. Send functions are not invoked for `NULL` values.

How can the input and output functions be declared to have results or arguments of the new type, when they have to be created before the new type can be created? The type should first be defined as a shell type, which is a placeholder type that has no properties except a name and an owner. This is done by issuing the command `CREATE TYPE name`, with no additional parameters. Then the I/O functions can be defined referencing the shell type. Finally, `CREATE TYPE` with a full definition replaces the shell entry with a complete, valid type definition, after which the new type can be used normally.

The optional type_modifier_input_function and type_modifier_output_function are required if the type supports modifiers. Modifiers are optional constraints attached to a type declaration, such as `char(5)` or `numeric(30,2)`. While WarehousePG allows user-defined types to take one or more simple constants or identifiers as modifiers, this information must fit into a single non-negative integer value for storage in the system catalogs. WarehousePG passes the declared modifier(s) to the type_modifier_input_function in the form of a `cstring` array. The modifier input function must check the values for validity, throwing an error if they are incorrect. If the values are correct, the modifier input function returns a single non-negative integer value that WarehousePG stores as the column `typmod`. Type modifiers are rejected if the type was not defined with a type_modifier_input_function. The type_modifier_output_function converts the internal integer `typmod` value back to the correct form for user display. The modifier output function must return a `cstring` value that is the exact string to append to the type name. For example, `numeric`'s function might return `(30,2)`. The type_modifier_output_function is optional. When not specified, the default display format is the stored `typmod` integer value enclosed in parentheses.

The optional analyze_function performs type-specific statistics collection for columns of the data type. By default, `ANALYZE` attempts to gather statistics using the type's "equals" and "less-than" operators, if there is a default b-tree operator class for the type. For non-scalar types this behavior is likely to be unsuitable, so it can be overridden by specifying a custom analysis function. The analysis function must be declared to take a single argument of type `internal`, and return a `boolean` result.

While the details of the new type's internal representation are only known to the I/O functions and other functions you create to work with the type, there are several properties of the internal representation that must be declared to WarehousePG. Foremost of these is internallength. Base data types can be fixed-length, in which case internallength is a positive integer, or variable length, indicated by setting internallength to `VARIABLE`. (Internally, this is represented by setting `typlen` to `-1`.) The internal representation of all variable-length types must start with a 4-byte integer giving the total length of this value of the type.

The optional flag `PASSEDBYVALUE` indicates that values of this data type are passed by value, rather than by reference. You may not pass by value types whose internal representation is larger than the size of the `Datum` type (4 bytes on most machines, 8 bytes on a few).

The alignment parameter specifies the storage alignment required for the data type. The allowed values equate to alignment on 1, 2, 4, or 8 byte boundaries. Note that variable-length types must have an alignment of at least 4, since they necessarily contain an `int4` as their first component.

The storage parameter allows selection of storage strategies for variable-length data types. (Only `plain` is allowed for fixed-length types.) `plain` specifies that data of the type will always be stored in-line and not compressed. `extended` specifies that the system will first try to compress a long data value, and will move the value out of the main table row if it's still too long. `external` allows the value to be moved out of the main table, but the system will not try to compress it. `main` allows compression, but discourages moving the value out of the main table. (Data items with this storage strategy may still be moved out of the main table if there is no other way to make a row fit, but they will be kept in the main table preferentially over `extended` and `external` items.)

All storage values other than `plain` imply that the functions of the data type can handle values that have been toasted as described inTOAST and TOAST CONSIDERATIONS in the PostgreSQL documentation. The specific other value given merely determines the default TOAST storage strategy for columns of a toastable data type; users can pick other strategies for individual columns using `ALTER TABLE SET STORAGE`.

The like_type parameter provides an alternative method for specifying the basic representation properties of a data type: copy them from some existing type. The values `internallength`, `passedbyvalue`, `alignment`, and `storage` are copied from the named type. (It is possible, though usually undesirable, to override some of these values by specifying them along with the `LIKE` clause.) Specifying representation this way is especially useful when the low-level implementation of the new type "piggybacks" on an existing type in some fashion.

The *category* and *preferred* parameters can be used to help control which implicit cast WarehousePG applies in ambiguous situations. Each data type belongs to a category named by a single ASCII character, and each type is either "preferred" or not within its category. The parser will prefer casting to preferred types (but only from other types within the same category) when this rule helps resolve overloaded functions or operators. For types that have no implicit casts to or from any other types, it is sufficient to retain the default settings. However, for a group of related types that have implicit casts, it is often helpful to mark them all as belonging to a category and select one or two of the "most general" types as being preferred within the category. The *category* parameter is especially useful when you add a user-defined type to an existing built-in category, such as the numeric or string types. It is also possible to create new entirely-user-defined type categories. Select any ASCII character other than an upper-case letter to name such a category.

A default value may be specified, in case a user wants columns of the data type to default to something other than the null value. Specify the default with the `DEFAULT` key word. (Such a default may be overridden by an explicit `DEFAULT` clause attached to a particular column.)

To indicate that a type is an array, specify the type of the array elements using the `ELEMENT` key word. For example, to define an array of 4-byte integers (int4), specify `ELEMENT = int4`. More details about array types appear below.

To indicate the delimiter to be used between values in the external representation of arrays of this type, `delimiter` can be set to a specific character. The default delimiter is the comma (,). Note that the delimiter is associated with the array element type, not the array type itself.

If the optional Boolean parameter collatable is true, column definitions and expressions of the type may carry collation information through use of the `COLLATE` clause. It is up to the implementations of the functions operating on the type to actually make use of the collation information; this does not happen automatically merely by marking the type collatable.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Array Types

Whenever a user-defined type is created, WarehousePG automatically creates an associated array type, whose name consists of the element type's name prepended with an underscore, and truncated if necessary to keep it less than `NAMEDATALEN` bytes long. (If the name so generated collides with an existing type name, the process is repeated until a non-colliding name is found.) This implicitly-created array type is variable length and uses the built-in input and output functions `array_in` and `array_out`. The array type tracks any changes in its element type's owner or schema, and is dropped if the element type is.

Why is there is an `ELEMENT` option, when the system makes the correct array type automatically? The only case where it's useful to use `ELEMENT` is when you are making a fixed-length type that happens to be internally an array of a number of identical things, and you want to allow these things to be accessed directly by subscripting, in addition to whatever operations you plan to provide for the type as a whole. For example, type `point` is represented as just two floating-point numbers, each can be accessed using `point[0]` and `point[1]`. Note that this facility only works for fixed-length types whose internal form is exactly a sequence of identical fixed-length fields. A subscriptable variable-length type must have the generalized internal representation used by `array_in` and `array_out`. For historical reasons, subscripting of fixed-length array types starts from zero, rather than from one as for variable-length arrays.

Parameters

name The name (optionally schema-qualified) of a type to be created.

attribute_name The name of an attribute (column) for the composite type.

data_type The name of an existing data type to become a column of the composite type.

collation The name of an existing collation to be associated with a column of a composite type, or with a range type.

label A string literal representing the textual label associated with one value of an enum type.

subtype The name of the element type that the range type will represent ranges of.

subtype_operator_class The name of a b-tree operator class for the subtype.

canonical_function The name of the canonicalization function for the range type.

subtype_diff_function The name of a difference function for the subtype.

input_function The name of a function that converts data from the type's external textual form to its internal form.

output_function The name of a function that converts data from the type's internal form to its external textual form.

receive_function The name of a function that converts data from the type's external binary form to its internal form.

send_function The name of a function that converts data from the type's internal form to its external binary form.

type_modifier_input_function The name of a function that converts an array of modifier(s) for the type to internal form.

type_modifier_output_function The name of a function that converts the internal form of the type's modifier(s) to external textual form.

analyze_function The name of a function that performs statistical analysis for the data type.

internallength A numeric constant that specifies the length in bytes of the new type's internal representation. The default assumption is that it is variable-length.

alignment The storage alignment requirement of the data type. Must be one of `char`, `int2`, `int4`, or `double`. The default is `int4`.

storage The storage strategy for the data type. Must be one of `plain`, `external`, `extended`, or `main`. The default is `plain`.

like_type The name of an existing data type that the new type will have the same representation as. The values internallength, passedbyvalue, alignment, and storage, are copied from that type, unless overridden by explicit specification elsewhere in this `CREATE TYPE` command.

category The category code (a single ASCII character) for this type. The default is '`U`', signifying a user-defined type. You can find the other standard category codes in `pg_type` Category Codes. You may also assign unused ASCII characters to custom categories that you create.

preferred `true` if this type is a preferred type within its type category, else `false`. The default value is `false`. Be careful when you create a new preferred type within an existing type category; this could cause surprising behaviour changes.

default The default value for the data type. If this is omitted, the default is null.

element The type being created is an array; this specifies the type of the array elements.

delimiter The delimiter character to be used between values in arrays made of this type.

collatable True if this type's operations can use collation information. The default is false.

compression_type Set to `ZLIB` (the default), `ZSTD`, or `RLE_TYPE` to specify the type of compression used in columns of this type.

compression_level For Zstd compression, set to an integer value from 1 (fastest compression) to 19 (highest compression ratio). For zlib compression, the valid range is from 1 to 9. For `RLE_TYPE`, the compression level can be set to an integer value from 1 (fastest compression) to 6 (highest compression ratio). The default compression level is 1.

blocksize Set to the size, in bytes, for each block in the column. The `BLOCKSIZE` must be between 8192 and 2097152 bytes, and be a multiple of 8192. The default block size is 32768.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Notes

User-defined type names cannot begin with the underscore character (_) and can only be 62 characters long (or in general `NAMEDATALEN - 2`, rather than the `NAMEDATALEN - 1` characters allowed for other names). Type names beginning with underscore are reserved for internally-created array type names.

WarehousePG does not support adding storage options for row or composite types.

Storage options defined at the table- and column- level override the default storage options defined for a scalar type.

Because there are no restrictions on use of a data type once it's been created, creating a base type or range type is tantamount to granting public execute permission on the functions mentioned in the type definition. (The creator of the type is therefore required to own these functions.) This is usually not an issue for the sorts of functions that are useful in a type definition. But you might want to think twice before designing a type in a way that would require 'secret' information to be used while converting it to or from external form.

Use `pg_type.typarray` to locate the array type associated with a given type.

Examples

This example creates a composite type and uses it in a function definition:

```
CREATE TYPE compfoo AS (f1 int, f2 text);

CREATE FUNCTION getfoo() RETURNS SETOF compfoo AS $$
    SELECT fooid, fooname FROM foo
$$ LANGUAGE SQL;
```

This example creates the enumerated type `mood` and uses it in a table definition.

```
CREATE TYPE mood AS ENUM ('sad', 'ok', 'happy');
CREATE TABLE person (
    name text,
    current_mood mood
);
INSERT INTO person VALUES ('Moe', 'happy');
SELECT * FROM person WHERE current_mood = 'happy';
 name | current_mood
------+--------------
 Moe  | happy
(1 row)
```

This example creates a range type:

```
CREATE TYPE float8_range AS RANGE (subtype = float8, subtype_diff = float8mi);
```

This example creates the base data type `box` and then uses the type in a table definition:

```
CREATE TYPE box;

CREATE FUNCTION my_box_in_function(cstring) RETURNS box AS
... ;

CREATE FUNCTION my_box_out_function(box) RETURNS cstring AS
... ;

CREATE TYPE box (
    INTERNALLENGTH = 16,
    INPUT = my_box_in_function,
    OUTPUT = my_box_out_function
);

CREATE TABLE myboxes (
    id integer,
    description box
);
```

If the internal structure of `box` were an array of four `float4` elements, we might instead use:

```
CREATE TYPE box (
    INTERNALLENGTH = 16,
    INPUT = my_box_in_function,
    OUTPUT = my_box_out_function,
    ELEMENT = float4
);
```

which would allow a box value's component numbers to be accessed by subscripting. Otherwise the type behaves the same as before.

This example creates a large object type and uses it in a table definition:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
CREATE TYPE bigobj (
    INPUT = lo_filein, OUTPUT = lo_fileout,
    INTERNALLENGTH = VARIABLE
);

CREATE TABLE big_objs (
    id integer,
    obj bigobj
    );
```

Compatibility

The first form of the `CREATE TYPE` command, which creates a composite type, conforms to the SQL standard. The other forms are WarehousePG extensions. The `CREATE TYPE` statement in the SQL standard also defines other forms that are not implemented in WarehousePG.

The ability to create a composite type with zero attributes is a WarehousePG-specific deviation from the standard (analogous to the same case in `CREATE TABLE`).

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.1.89 CREATE USER

Defines a new database role.

Synopsis

```
CREATE USER <name> [[WITH] <option> [ ... ]]

where option can be:
      SUPERUSER | NOSUPERUSER
    | CREATEDB | NOCREATEDB
    | CREATEROLE | NOCREATEROLE
    | CREATEEXTTABLE | NOCREATEEXTTABLE
      [ ( <attribute>='<value>'[, ...] ) ]
           where <attributes> and <value> are:
           type='readable'|'writable'
           protocol='gpfdist'|'http'
    | INHERIT | NOINHERIT
    | LOGIN | NOLOGIN
    | REPLICATION | NOREPLICATION
    | BYPASSRLS | NOBYPASSRLS
    | CONNECTION LIMIT <connlimit>
    | [ ENCRYPTED ] PASSWORD '<password>' | PASSWORD NULL
    | VALID UNTIL '<timestamp>'
    | IN ROLE <role_name> [, ...]
    | IN GROUP <role_name>
    | ROLE <role_name> [, ...]
    | ADMIN <role_name> [, ...]
    | USER <role_name> [, ...]
    | SYSID <uid>
    | RESOURCE QUEUE <queue_name>
    | RESOURCE GROUP <group_name>
    | [ DENY <deny_point> ]
    | [ DENY BETWEEN <deny_point> AND <deny_point>]
```

Description

`CREATE USER` is an alias for CREATE ROLE. The only difference is that when the command `CREATE USER` is invoked, `LOGIN` is assumed by default, whereas `NOLOGIN` is assumed when the command invoked is `CREATE ROLE`.

Compatibility

The `CREATE USER` statement is a WarehousePG extension. The SQL standard leaves the definition of users to the implementation.

CREATE ROLE

Parent topic: SQL Commands

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.1.90 CREATE USER MAPPING

Defines a new mapping of a user to a foreign server.

Synopsis

```
CREATE USER MAPPING [ IF NOT EXISTS ] FOR { <user_name> | USER | CURRENT_USER | PUBLIC }
    SERVER <server_name>
    [ OPTIONS ( <option> '<value>' [, ... ] ) ]
```

Description

`CREATE USER MAPPING` defines a mapping of a user to a foreign server. A user mapping typically encapsulates connection information that a foreign-data wrapper uses together with the information encapsulated by a foreign server to access an external data resource.

The owner of a foreign server can create user mappings for that server for any user. Also, a user can create a user mapping for their own user name if they have been granted `USAGE` privilege on the server.

Parameters

IF NOT EXISTS Do not throw an error if a mapping of the given user to the given foreign server already exists. WarehousePG issues a notice in this case. Note that there is no guarantee that the existing user mapping is anything like the one that would have been created.

user_name The name of an existing user that is mapped to the foreign server. `CURRENT_USER` and `USER` match the name of the current user. When `PUBLIC` is specified, WarehousePG creates a so-called public mapping that is used when no user-specific mapping is applicable.

server_name The name of an existing server for which WarehousePG is to create the user mapping.

OPTIONS (option 'value' [, ...]) The options for the new user mapping. The options typically define the actual user name and password of the mapping. Option names must be unique. The option names and values are specific to the server's foreign-data wrapper.

Examples

Create a user mapping for user `bob`, server `foo`:

```
CREATE USER MAPPING FOR bob SERVER foo OPTIONS (user 'bob', password 'secret');
```

Compatibility

`CREATE USER MAPPING` conforms to ISO/IEC 9075-9 (SQL/MED).

See Also

ALTER USER MAPPING, DROP USER MAPPING, CREATE FOREIGN DATA WRAPPER, CREATE SERVER

Parent topic: SQL Commands

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.1.91 CREATE VIEW

Defines a new view.

Synopsis

```
CREATE [OR REPLACE] [TEMP | TEMPORARY] [RECURSIVE] VIEW <name> [ ( <column_name> [, ...] ) ]
    [ WITH ( view_option_name [= view_option_value] [, ... ] ) ]
    AS <query>
    [ WITH [ CASCADED | LOCAL ] CHECK OPTION ]
```

Description

`CREATE VIEW` defines a view of a query. The view is not physically materialized. Instead, WarehousePG runs the query every time the view is referenced in a query.

`CREATE OR REPLACE VIEW` is similar, but if a view of the same name already exists, it is replaced. The new query must generate the same columns that were generated by the existing view query (that is, the same column names in the same order, and with the same data types), but it may add additional columns to the end of the list. The calculations giving rise to the output columns may be completely different.

If a schema name is given (for example, `CREATE VIEW myschema.myview ...`) then the view is created in the specified schema. Otherwise it is created in the current schema. Temporary views exist in a special schema, so you may not provide a schema name when creating a temporary view. The name of the view must be distinct from the name of any other view, table, sequence, index, or foreign table in the same schema.

Parameters

TEMPORARY | TEMP If specified, the view is created as a temporary view. Temporary views are automatically dropped at the end of the current session. Existing permanent relations with the same name are not visible to the current session while the temporary view exists, unless they are referenced with schema-qualified names. If any of the tables referenced by the view are temporary, the view is created as a temporary view (whether `TEMPORARY` is specified or not).

RECURSIVE Creates a recursive view. The syntax

```
```
CREATE RECURSIVE VIEW [<schema> .] <view_name> (<column_names>) AS SELECT <...>;
```

is equivalent to

```
```
CREATE VIEW [ <schema> . ] <view_name> AS WITH RECURSIVE <view_name> (<column_names>) AS (SELECT <...>) SELECT <column_names> FROM <view_name>;
```

A view column name list must be specified for a recursive view.
```

name The name (optionally schema-qualified) of a view to be created.

column_name An optional list of names to be used for columns of the view. If not given, the column names are deduced from the query.

WITH ( view_option_name [= view_option_value] [, ... ] ) This clause specifies optional parameters for a view; the following parameters are supported:

```
check_option \(string\)
This parameter may be either `local` or `cascaded`, and is equivalent to specifying `WITH [ CASCADED | LOCAL ] CHECK OPTION` \(see below\). This option can be
changed on existing views using [ALTER VIEW](ALTER_VIEW.html).

security_barrier \(boolean\)
This should be used if the view is intended to provide row-level security. Refer to [Rules and Privileges](https://www.postgresql.org/docs/12/rules-
privileges.html) in the PostgreSQL documentation for more information.
```

query A SELECT or VALUES command which will provide the columns and rows of the view.

WITH [CASCADED | LOCAL] CHECK OPTION This option controls the behavior of automatically updatable views. When this option is specified, `INSERT` and `UPDATE` commands on the view will be checked to ensure that new rows satisfy the view-defining condition (that is, the new rows are checked to ensure that they are visible through the view). If they are not, WarehousePG Databvase rejects the update. If the `CHECK OPTION` is not specified, `INSERT` and `UPDATE` commands on the view are allowed to create rows that are not visible through the view. The following check options are supported:

```
LOCAL
New rows are only checked against the conditions defined directly in the view itself. Any conditions defined on underlying base views are not checked \(unless
they also specify the `CHECK OPTION`\).

CASCADED
New rows are checked against the conditions of the view and all underlying base views. If the `CHECK OPTION` is specified, and neither `LOCAL` nor `CASCADED` is
specified, then `CASCADED` is assumed.
```

The `CHECK OPTION` may not be used with `RECURSIVE` views.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.
```

Notes

Use the DROP VIEW statement to drop views.

Ensure that the names and data types of the view's columns are assigned the way you want. For example:

```
CREATE VIEW vista AS SELECT 'Hello World';
```

is bad form in two ways: the column name defaults to `?column?`, and the column data type defaults to `text`, which might not be what you wanted. If you want a string literal in a view's result, use something like:

```
CREATE VIEW vista AS SELECT text 'Hello World' AS hello;
```

Access to tables referenced in the view is determined by permissions of the view owner not the current user (even if the current user is a superuser). This can be confusing in the case of superusers, since superusers typically have access to all objects. In the case of a view, even superusers must be explicitly granted access to tables referenced in the view if they are not the owner of the view. In some cases, a view can be used to provide secure but restricted access to the underlying tables. However, not all views are secure against tampering, see Rules and Privileges in the PostgreSQL documentation for details.

Functions called in the view are treated the same as if they had been called directly from the query using the view. Therefore the user of a view must have permissions to call any functions used by the view.

When both `CREATE VIEW <view> ...` and `SELECT ... FROM <view>` specify an `ORDER BY` clause, WarehousePG ignores the `ORDER BY` clause in the `CREATE VIEW` statement.

When `CREATE OR REPLACE VIEW` is used on an existing view, only the view's defining `SELECT` rule is changed. Other view properties, including ownership, permissions, and non-`SELECT` rules, remain unchanged. You must own the view to replace it (this includes being a member of the owning role).

Updatable Views

Simple views are automatically updatable: WarehousePG allows you to invoke `INSERT`, `UPDATE`, and `DELETE` statements on the view in the same way as on a regular table. A view is automatically updatable if it satisfies all of the following conditions:

- The view must have exactly one entry in its `FROM` list, which must be a table or another updatable view.
- The view definition must not contain `WITH`, `DISTINCT`, `GROUP BY`, `HAVING`, `LIMIT`, or `OFFSET` clauses at the top level.
- The view definition must not contain set operations (`UNION`, `INTERSECT`, or `EXCEPT`) at the top level.
- The view's select list must not contain any aggregates, window functions, or set-returning functions.

An automatically updatable view may contain a mix of updatable and non-updatable columns. A column is updatable if it is a simple reference to an updatable column of the underlying base relation; otherwise the column is read-only, and WarehousePG raises an error if an `INSERT` or `UPDATE` statement attempts to assign a value to it.

If the view is automatically updatable the system will convert any `INSERT`, `UPDATE`, or `DELETE` statement on the view into the corresponding statement on the underlying base relation. `INSERT` statements that have an `ON CONFLICT UPDATE` clause are fully supported.

If an automatically updatable view contains a `WHERE` condition, the condition restricts which rows of the base relation are available to be modified by `UPDATE` and `DELETE` statements on the view. However, an `UPDATE` is permitted to change a row so that it no longer satisfies the `WHERE` condition, and thus is no longer visible through the view. Similarly, an `INSERT` command can potentially insert base-relation rows that do not satisfy the `WHERE` condition and thus are not visible through the view (`ON CONFLICT UPDATE` may similarly affect an existing row not visible through the view). The `CHECK OPTION` may be used to prevent `INSERT` and `UPDATE` commands from creating such rows that are not visible through the view.

If an automatically updatable view is marked with the `security_barrier` property, then all of the view's `WHERE` conditions (and any conditions using operators which are marked as `LEAKPROOF`) will always be evaluated before any conditions that a user of the view has added. Refer to Rules and Privileges in the PostgreSQL documenatation for full details. Note that, due to this, rows which are not ultimately returned (because they do not pass the user's `WHERE` conditions) may still end up being locked. You can use the `EXPLAIN` command to see which conditions are applied at the relation level (and therefore do not lock rows) and which are not.

A more complex view that does not satisfy all of these conditions is read-only by default: the system will not allow an insert, update, or delete on the view. You can get the effect of an updatable view by creating rules (see CREATE RULE).

Note that the user performing the insert, update or delete on the view must have the corresponding insert, update or delete privilege on the view. In addition the view's owner must have the relevant privileges on the underlying base relations, but the user performing the update does not need any permissions on the underlying base relations (again, refer to Rules and Privileges in the PostgreSQL documentation).

Examples

Create a view consisting of all comedy films:

```
CREATE VIEW comedies AS
    SELECT * FROM films
    WHERE kind = 'comedy';
```

This creates a view containing the columns that are in the `film` table at the time of view creation. Though `*` was used to create the view, columns added later to the table will not be part of the view.

Create a view with `LOCAL CHECK OPTION`:

```
CREATE VIEW universal_comedies AS
    SELECT *
    FROM comedies
    WHERE classification = 'U'
    WITH LOCAL CHECK OPTION;
```

This creates a view based on the comedies `view`, showing only films with `kind = 'Comedy'` and `classification = 'U'`. Any attempt to `INSERT` or `UPDATE` a row in the view is rejected if the new row doesn't have `classification = 'U'`, but the film `kind` will not be checked.

Create a view with `CASCADED CHECK OPTION`:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
CREATE VIEW pg_comedies AS
    SELECT *
    FROM comedies
    WHERE classification = 'PG'
    WITH CASCADED CHECK OPTION;
```

This creates a view that checks both the `kind` and `classification` of new rows.

Create a view with a mix of updatable and non-updatable columns:

```
CREATE VIEW comedies AS
    SELECT f.*,
           country_code_to_name(f.country_code) AS country,
           (SELECT avg(r.rating)
            FROM user_ratings r
            WHERE r.film_id = f.id) AS avg_rating
    FROM films f
    WHERE f.kind = 'Comedy';
```

This view supports `INSERT`, `UPDATE`, and `DELETE`. All the columns from the `films` table will be updatable, whereas the computed columns `country` and `avg_rating` will be read-only.

Create a view that gets the top ten ranked baby names:

```
CREATE VIEW topten AS
    SELECT name, rank, gender, year
    FROM names, rank
    WHERE rank < '11' AND names.id=rank.id;
```

Create a recursive view consisting of the numbers from 1 to 100:

```
CREATE RECURSIVE VIEW public.nums_1_100 (n) AS
    VALUES (1)
UNION ALL
    SELECT n+1 FROM nums_1_100 WHERE n < 100;
```

Notice that although the recursive view's name is schema-qualified in this `CREATE VIEW` command, its internal self-reference is not schema-qualified. This is because the implicitly-created CTE's name cannot be schema-qualified.

Compatibility

`CREATE OR REPLACE VIEW` is a WarehousePG extension. So is the concept of a temporary view. The `WITH ( ... )` clause is an extension as well.

7.1.92 DEALLOCATE

Deallocates a prepared statement.

Synopsis

```
DEALLOCATE [PREPARE] { <name> | ALL }
```

Description

`DEALLOCATE` is used to deallocate a previously prepared SQL statement. If you do not explicitly deallocate a prepared statement, it is deallocated when the session ends.

For more information on prepared statements, see PREPARE.

Parameters

PREPARE Optional key word which is ignored.

name The name of the prepared statement to deallocate.

ALL Deallocate all prepared statements

Examples

Deallocate the previously prepared statement named `insert_names`:

```
DEALLOCATE insert_names;
```

Compatibility

The SQL standard includes a `DEALLOCATE` statement, but it is only for use in embedded SQL.

See Also

EXECUTE, PREPARE

Parent topic: SQL Commands

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.1.93 DECLARE

Defines a cursor.

Synopsis

```
DECLARE <name> [BINARY] [INSENSITIVE] [NO SCROLL] [PARALLEL RETRIEVE] CURSOR
     [{WITH | WITHOUT} HOLD]
     FOR <query>
```

Description

`DECLARE` allows a user to create a cursor, which can be used to retrieve a small number of rows at a time out of a larger query. Cursors can return data using`FETCH`.

> **Note** This page describes usage of cursors at the SQL command level. If you are trying to use cursors inside a PL/pgSQL function, the rules are different, see`PL/pgSQL`.

Normal cursors return data in text format, the same as a `SELECT` would produce. Since data is stored natively in binary format, the system must do a conversion to produce the text format. Once the information comes back in text form, the client application may need to convert it to a binary format to manipulate it. In addition, data in the text format is often larger in size than in the binary format. Binary cursors return the data in a binary representation that may be more easily manipulated. Nevertheless, if you intend to display the data as text anyway, retrieving it in text form will save you some effort on the client side.

As an example, if a query returns a value of one from an integer column, you would get a string of 1 with a default cursor whereas with a binary cursor you would get a 4-byte field containing the internal representation of the value (in big-endian byte order).

Binary cursors should be used carefully. Many applications, including `psql`, are not prepared to handle binary cursors and expect data to come back in the text format.

> **Note** When the client application uses the 'extended query' protocol to issue a `FETCH` command, the Bind protocol message specifies whether data is to be retrieved in text or binary format. This choice overrides the way that the cursor is defined. The concept of a binary cursor as such is thus obsolete when using extended query protocol — any cursor can be treated as either text or binary.

A cursor can be specified in the `WHERE CURRENT OF` clause of the`UPDATE` or`DELETE` statement to update or delete table data. The `UPDATE` or `DELETE` statement can only be run on the server, for example in an interactive `psql` session or a script.

Parallel Retrieve Cursors

WarehousePG supports a special type of cursor, a *parallel retrieve cursor*. You can use a parallel retrieve cursor to retrieve query results, in parallel, directly from the WarehousePG segments, bypassing the WarehousePG coordinator.

Parallel retrieve cursors do not support the `WITH HOLD` clause. WarehousePG ignores the `BINARY` clause when you declare a parallel retrieve cursor.

You open a special retrieve session to each parallel retrieve cursor endpoint, and use the`RETRIEVE` command to retrieve the query results from a parallel retrieve cursor.

Parameters

name The name of the cursor to be created.

BINARY Causes the cursor to return data in binary rather than in text format.

```
> **Note** WarehousePG ignores the `BINARY` clause when you declare a `PARALLEL RETRIEVE` cursor.
```

INSENSITIVE Indicates that data retrieved from the cursor should be unaffected by updates to the table(s) underlying the cursor that occur after the cursor is created. In WarehousePG, all cursors are insensitive. This key word currently has no effect and is present only for compatibility with the SQL standard.

NO SCROLL The cursor cannot be used to retrieve rows in a nonsequential fashion. This is the default behavior in WarehousePG; scrollable cursors `SCROLL`) are not supported.

PARALLEL RETRIEVE Declare a parallel retrieve cursor. A parallel retrieve cursor is a special type of cursor that you can use to retrieve results directly from WarehousePG segments, in parallel.

WITH HOLD WITHOUT HOLD `WITH HOLD` specifies that the cursor may continue to be used after the transaction that created it successfully commits. `WITHOUT HOLD` specifies that the cursor cannot be used outside of the transaction that created it. `WITHOUT HOLD` is the default.

```
> **Note** WarehousePG does not support declaring a `PARALLEL RETRIEVE` cursor with the `WITH HOLD` clause. `WITH HOLD` also cannot not be specified when the
`query` includes a `FOR UPDATE` or `FOR SHARE` clause.
```

query A`SELECT` or`VALUES` command which will provide the rows to be returned by the cursor.

If the cursor is used in the `WHERE CURRENT OF` clause of the`UPDATE` or`DELETE` command, the `SELECT` command must satisfy the following conditions:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
-   Cannot reference a view or external table.
-   References only one table.
    <br/><br/>The table must be a heap table, and it must not be replicated-distributed (must not be a view, external table, or append-optimized column-oriented
table).

-   Cannot contain any of the following:
    -   A grouping clause
    -   A set operation such as `UNION ALL` or `UNION DISTINCT`
    -   A sorting clause
    -   A windowing clause
    -   A join or a self-join
    <br/><br/>Specifying the `FOR UPDATE` clause in the `SELECT` command prevents other sessions from changing the rows between the time they are fetched and the
time they are updated. Without the `FOR UPDATE` clause, a subsequent use of the `UPDATE` or `DELETE` command with the `WHERE CURRENT OF` clause has no effect if
the row was changed since the cursor was created.
    <br/><br/>> **Note** Specifying the `FOR UPDATE` clause in the `SELECT` command locks the entire table, not just the selected rows.
```

The key words `BINARY`, `INSENSITIVE`, and `NO SCROLL` can appear in any order.

Notes

Unless `WITH HOLD` is specified, the cursor created by this command can only be used within the current transaction. Thus, `DECLARE` without `WITH HOLD` is useless outside a transaction block: the cursor would survive only to the completion of the statement. Therefore WarehousePG reports an error if this command is used outside a transaction block. Use `BEGIN` and `COMMIT` (or `ROLLBACK`) to define a transaction block.

If `WITH HOLD` is specified and the transaction that created the cursor successfully commits, the cursor can continue to be accessed by subsequent transactions in the same session. (But if the creating transaction ends prematurely, the cursor is removed.) A cursor created with `WITH HOLD` is closed when an explicit `CLOSE` command is issued on it, or the session ends. In the current implementation, the rows represented by a held cursor are copied into a temporary file or memory area so that they remain available for subsequent transactions.

If you create a cursor with the `DECLARE` command in a transaction, you cannot use the `SET` command in the transaction until you close the cursor with the `CLOSE` command.

Scrollable cursors are not currently supported in WarehousePG. You can only use `FETCH` or `RETRIEVE` to move the cursor position forward, not backwards.

`DECLARE...FOR UPDATE` is not supported with append-optimized tables.

You can see all available cursors by querying the pg_cursors system view.

Examples

Declare a cursor:

```
DECLARE mycursor CURSOR FOR SELECT * FROM mytable;
```

Declare a parallel retrieve cursor for the same query:

```
DECLARE myprcursor PARALLEL RETRIEVE CURSOR FOR SELECT * FROM mytable;
```

Compatibility

SQL standard allows cursors only in embedded SQL and in modules. WarehousePG permits cursors to be used interactively.

WarehousePG does not implement an `OPEN` statement for cursors. A cursor is considered to be open when it is declared.

The SQL standard allows cursors to move both forward and backward. All WarehousePG cursors are forward moving only (not scrollable).

Binary cursors are a WarehousePG extension.

The SQL standard makes no provisions for parallel retrieve cursors.

CLOSE, DELETE, FETCH, MOVE, RETRIEVE, SELECT, UPDATE

Parent topic: SQL Commands

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.1.94 DELETE

Deletes rows from a table.

Synopsis

```
[ WITH [ RECURSIVE ] <with_query> [, ...] ]
DELETE FROM [ONLY] <table_name> [[AS] <alias>]
      [USING <from_item> [, ...] ]
      [WHERE <condition> | WHERE CURRENT OF <cursor_name>]
      [RETURNING * | <output_expression> [[AS] <output_name>] [, …]]
```

Description

`DELETE` deletes rows that satisfy the `WHERE` clause from the specified table. If the `WHERE` clause is absent, the effect is to delete all rows in the table. The result is a valid, but empty table.

Tip: TRUNCATE provides a faster mechanism to remove all rows from a table.

There are two ways to delete rows in a table using information contained in other tables in the database: using sub-selects, or specifying additional tables in the `USING` clause. Which technique is more appropriate depends on the specific circumstances.

The optional `RETURNING` clause causes `DELETE` to compute and return value(s) based on each row actually deleted. Any expression using the table's columns, and/or columns of other tables mentioned in `USING`, can be computed. The syntax of the `RETURNING` list is identical to that of the output list of `SELECT`.

You must have the `DELETE` privilege on the table to delete from it, as well as the `SELECT` privilege for any table in the `USING` clause or whose values are read in the condition.

> **Note** The `RETURNING` clause is not supported when deleting from append-optimized tables.

> **Note** As the default, WarehousePG acquires an `EXCLUSIVE` lock on tables for `DELETE` operations on heap tables. When the Global Deadlock Detector is enabled, the lock mode for `DELETE` operations on heap tables is `ROW EXCLUSIVE`. See Global Deadlock Detector.

Parameters

with_query The `WITH` clause allows you to specify one or more subqueries that can be referenced by name in the `DELETE` query.

For a `DELETE` command that includes a `WITH` clause, the clause can only contain `SELECT` statements, the `WITH` clause cannot contain a data-modifying command (`INSERT`, `UPDATE`, or `DELETE`).

See WITH Queries (Common Table Expressions) and SELECT for details.

table_name The name (optionally schema-qualified) of the table to delete rows from. If you specify `ONLY` before the table name, WarehousePG deletes matching rows from the named table only. If `ONLY` is not specified, matching rows are also deleted from any tables inheriting from the named table. Optionally, you can specify `*` after the table name to explicitly indicate that descendant tables are included.

alias A substitute name for the target table. When an alias is provided, it completely hides the actual name of the table. For example, given `DELETE FROM foo AS f`, the remainder of the `DELETE` statement must refer to this table as `f` not `foo`.

from_item A table expression allowing columns from other tables to appear in the `WHERE` condition. This uses the same syntax as the `FROM` clause of a SELECT statement; for example, you can specify an alias for the table name. Do not repeat the target table in the from_item, unless you wish to set up a self-join (in which case it must appear with an alias in the from_item).

condition An expression that returns a value of type `boolean`. WarehousePG deletes only those rows for which this expression returns `true`.

cursor_name The name of the cursor to use in a `WHERE CURRENT OF` condition. The row to be deleted is the one most recently fetched from this cursor. The cursor must be a non-grouping query on the `DELETE`'s target table. Note that `WHERE CURRENT OF` cannot be specified together with a Boolean condition. See DECLARE for more information about using cursors with `WHERE CURRENT OF`.

The `DELETE...WHERE CURRENT OF` cursor statement can only be run on the server, for example in an interactive psql session or a script. Language extensions such as PL/pgSQL do not have support for updatable cursors.

output_expression An expression to be computed and returned by the `DELETE` command after each row is deleted. The expression can use any column names of the table named by table_name or table(s) listed in `USING`. Write `*` to return all columns.

output_name A name to use for a returned column.

Outputs

On successful completion, a `DELETE` command returns a command tag of the form

```
DELETE <count>
```

The count is the number of rows deleted. If count is 0, no rows were deleted by the query (this is not considered an error).

If the `DELETE` command contains a `RETURNING` clause, the result will be similar to that of a `SELECT` statement containing the columns and values defined in the `RETURNING` list, computed over the row(s) deleted by the command.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Notes

The `RETURNING` clause is not supported when deleting from append-optimized tables.

The `WHERE CURRENT OF` clause is not supported with replicated tables.

WarehousePG lets you reference columns of other tables in the `WHERE` condition by specifying the other tables in the `USING` clause. For example, to delete all films produced by a given producer, one can run:

```
DELETE FROM films USING producers
  WHERE producer_id = producers.id AND producers.name = 'foo';
```

What is essentially happening here is a join between `films` and `producers`, with all successfully joined `films` rows being marked for deletion. This syntax is not standard. A more standard way to accomplish this is:

```
DELETE FROM films
  WHERE producer_id IN (SELECT id FROM producers WHERE name = 'foo');
```

For a partitioned table, all of the child tables are locked during the `DELETE` operation when the Global Deadlock Detector is not enabled (the default). Only some of the leaf child tables are locked when the Global Deadlock Detector is enabled. For information about the Global Deadlock Detector, see Global Deadlock Detector.

Examples

Delete all films but musicals:

```
DELETE FROM films WHERE kind <> 'Musical';
```

Clear the table films:

```
DELETE FROM films;
```

Delete completed tasks, returning full details of the deleted rows:

```
DELETE FROM tasks WHERE status = 'DONE' RETURNING *;
```

Delete the row of tasks on which the cursor `c_tasks` is currently positioned:

```
DELETE FROM tasks WHERE CURRENT OF c_tasks;
```

Delete using a join:

```
DELETE FROM rank USING names WHERE names.id = rank.id AND
name = 'Hannah';
```

Compatibility

This command conforms to the SQL standard, except that the `USING` and `RETURNING` clauses are WarehousePG extensions, as is the ability to use `WITH` with `DELETE`.

7.1.95 DISCARD

Discards the session state.

Synopsis

```
DISCARD { ALL | PLANS | SEQUENCES | TEMPORARY | TEMP }
```

Description

`DISCARD` releases internal resources associated with a database session. This command is useful for partially or fully resetting the session's state. There are several subcommands to release different types of resources; the `DISCARD ALL` variant subsumes all the others, and also resets additional state.

WarehousePG does not support invoking `DISCARD ALL` in a transaction.

Parameters

PLANS Releases all cached query plans, forcing re-planning to occur the next time the associated prepared statement is used.

SEQUENCES Discards all cached sequence-related state, including any preallocated sequence values that have not yet been returned by `nextval()`. (See CREATE SEQUENCE for a description of preallocated sequence values.)

TEMPORARY/TEMP Drops all temporary tables created in the current session.

ALL Releases all temporary resources associated with the current session and resets the session to its initial state. Currently, this has the same effect as executing the following sequence of statements:

```
```
CLOSE ALL;
SET SESSION AUTHORIZATION DEFAULT;
RESET ALL;
DEALLOCATE ALL;
UNLISTEN *;
SELECT pg_advisory_unlock_all();
DISCARD PLANS;
DISCARD SEQUENCES;
DISCARD TEMP;
```
```

Notes

`DISCARD ALL` cannot be run inside a transaction block.

Compatibility

`DISCARD` is a WarehousePG extension.

Parent topic: SQL Commands

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.1.96 DO

Runs anonymous code block as a transient anonymous function.

Synopsis

```
DO [ LANGUAGE <lang_name> ] <code>
```

Description

`DO` runs an anonymous code block, or in other words a transient anonymous function in a procedural language.

The code block is treated as though it were the body of a function with no parameters, returning `void`. It is parsed and run a single time.

The optional `LANGUAGE` clause can appear either before or after the code block.

Anonymous blocks are procedural language structures that provide the capability to create and run procedural code on the fly without persistently storing the code as database objects in the system catalogs. The concept of anonymous blocks is similar to UNIX shell scripts, which enable several manually entered commands to be grouped and run as one step. As the name implies, anonymous blocks do not have a name, and for this reason they cannot be referenced from other objects. Although built dynamically, anonymous blocks can be easily stored as scripts in the operating system files for repetitive execution.

Anonymous blocks are standard procedural language blocks. They carry the syntax and obey the rules that apply to the procedural language, including declaration and scope of variables, execution, exception handling, and language usage.

The compilation and execution of anonymous blocks are combined in one step, while a user-defined function needs to be re-defined before use each time its definition changes.

Parameters

code The procedural language code to be run. This must be specified as a string literal, just as with the `CREATE FUNCTION` command. Use of a dollar-quoted literal is recommended.

lang_name The name of the procedural language in which the code is written. The default is `plpgsql`.

Notes

The procedural language to be used must already have been installed into the current database by means of `CREATE EXTENSION`. The PL/pgSQL language is installed wih WarehousePG and is registered by default every user-created database. The PL/Python and PL/Perl languages are installed by default, but not registered. Other languages are neither installed nor registered. The pg_language system catalog contains information about the registered languages in a database.

The user must have `USAGE` privilege for the procedural language, or must be a superuser if the language is untrusted. This is the same privilege requirement as for creating a function in the language.

If `DO` is run in a transaction block, then the procedure code cannot execute transaction control statements. Transaction control statements are allowed only if `DO` is run in its own transaction.

Anonymous blocks do not support function volatility or `EXECUTE ON` attributes.

Examples

This PL/pgSQL example grants all privileges on all views in schema `public` to role `webuser`:

```
DO $$DECLARE r record;
BEGIN
    FOR r IN SELECT table_schema, table_name FROM information_schema.tables
             WHERE table_type = 'VIEW' AND table_schema = 'public'
    LOOP
        EXECUTE 'GRANT ALL ON ' || quote_ident(r.table_schema) || '.' || quote_ident(r.table_name) || ' TO webuser';
    END LOOP;
END$$;
```

Compatibility

There is no `DO` statement in the SQL standard.

7.1.97 DROP ACCESS METHOD

Removes an access method

Synopsis

```
DROP ACCESS METHOD [IF EXISTS] <name> [CASCADE | RESTRICT]
```

Description

`DROP ACCESS METHOD` removes an existing access method. Only superusers can drop access methods.

Parameters

IF EXISTS Do not throw an error if the access method does not exist. WarehousePG issues a notice in this case.

name The name of an existing access method.

CASCADE Automatically drop objects that depend on the access method (such as operator classes, operator families, and indexes), and in turn all objects that depend on those objects.

RESTRICT Refuse to drop the access method if any objects depend on it. This is the default.

Examples

Drop the access method `heptree`;

```
DROP ACCESS METHOD
heptree;
```

Compatibility

`DROP ACCESS METHOD` is a WarehousePG extension.

See Also

CREATE ACCESS METHOD

Parent topic: SQL Commands

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.1.98 DROP AGGREGATE

Removes an aggregate function.

Synopsis

```
DROP AGGREGATE [IF EXISTS] <name> ( <aggregate_signature> ) [, ...] [CASCADE | RESTRICT]

where <aggregate_signature> is:

* |
[ <argmode> ] [ <argname> ] <argtype> [ , ... ] |
[ [ <argmode> ] [ <argname> ] <argtype> [ , ... ] ] ORDER BY [ <argmode> ] [ <argname> ] <argtype> [ , ... ]
```

Description

`DROP AGGREGATE` removes an existing aggregate function. To run this command the current user must be the owner of the aggregate function.

Parameters

IF EXISTS Do not throw an error if the aggregate does not exist. A notice is issued in this case.

name The name (optionally schema-qualified) of an existing aggregate function.

argmode The mode of an argument: `IN` or `VARIADIC`. If omitted, the default is `IN`.

argname The name of an argument. Note that `DROP AGGREGATE` does not actually pay any attention to argument names, since only the argument data types are needed to determine the aggregate function's identity.

argtype An input data type on which the aggregate function operates. To reference a zero-argument aggregate function, write `*` in place of the list of argument specifications. To reference an ordered-set aggregate function, write `ORDER BY` between the direct and aggregated argument specifications.

CASCADE Automatically drop objects that depend on the aggregate function (such as views using it) and in turn all objects that depend on those objects.

RESTRICT Refuse to drop the aggregate function if any objects depend on it. This is the default.

Notes

Alternative syntaxes for referencing ordered-set aggregates are described under ALTER AGGREGATE.

Examples

To remove the aggregate function `myavg` for type `integer`:

```
DROP AGGREGATE myavg(integer);
```

To remove the hypothetical-set aggregate function `myrank`, which takes an arbitrary list of ordering columns and a matching list of direct arguments:

```
DROP AGGREGATE myrank(VARIADIC "any" ORDER BY VARIADIC "any");
```

To remove multiple aggregate functions in one command:

```
DROP AGGREGATE myavg(integer), myavg(bigint);
```

Compatibility

There is no `DROP AGGREGATE` statement in the SQL standard.

See Also

ALTER AGGREGATE, CREATE AGGREGATE

Parent topic: SQL Commands

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.1.99 DROP CAST

Removes a cast.

Synopsis

```
DROP CAST [IF EXISTS] (<sourcetype> AS <targettype>) [CASCADE | RESTRICT]
```

Description

`DROP CAST` will delete a previously defined cast. To be able to drop a cast, you must own the source or the target data type. These are the same privileges that are required to create a cast.

Parameters

IF EXISTS Do not throw an error if the cast does not exist. A notice is issued in this case.

sourcetype The name of the source data type of the cast.

targettype The name of the target data type of the cast.

CASCADE RESTRICT These keywords have no effect since there are no dependencies on casts.

Examples

To drop the cast from type `text` to type `int`:

```
DROP CAST (text AS int);
```

Compatibility

There `DROP CAST` command conforms to the SQL standard.

See Also

CREATE CAST

Parent topic: SQL Commands

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.1.100 DROP COLLATION

Removes a previously defined collation.

Synopsis

```
DROP COLLATION [ IF EXISTS ] <name> [ CASCADE | RESTRICT ]
```

Description

`DROP COLLATION` removes a previously defined collation. To be able to drop a collation, you must own the collation.

Parameters

`IF EXISTS` Do not throw an error if the collation does not exist. A notice is issued in this case.

name The name of the collation. The collation name can be schema-qualified.

`CASCADE` Automatically drop objects that depend on the collation, and in turn all objects that depend on those objects.

`RESTRICT` Refuse to drop the collation if any objects depend on it. This is the default.

Examples

To drop the collation named `german`:

```
DROP COLLATION german;
```

Compatibility

The `DROP COLLATION` command conforms to the SQL standard, apart from the `IF EXISTS` option, which is a WarehousePG extension.

See Also

ALTER COLLATION, CREATE COLLATION

Parent topic: SQL Commands

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.1.101 DROP CONVERSION

Removes a conversion.

Synopsis

```
DROP CONVERSION [IF EXISTS] <name> [CASCADE | RESTRICT]
```

Description

`DROP CONVERSION` removes a previously defined conversion. To be able to drop a conversion, you must own the conversion.

Parameters

IF EXISTS Do not throw an error if the conversion does not exist. A notice is issued in this case.

name The name of the conversion. The conversion name may be schema-qualified.

CASCADE RESTRICT These keywords have no effect since there are no dependencies on conversions.

Examples

Drop the conversion named `myname`:

```
DROP CONVERSION myname;
```

Compatibility

There is no `DROP CONVERSION` statement in the SQL standard. The standard has `CREATE TRANSLATION` and `DROP TRANSLATION` statements that are similar to the WarehousePG `CREATE CONVERSION` and `DROP CONVERSION` statements.

See Also

ALTER CONVERSION, CREATE CONVERSION

Parent topic: SQL Commands

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.1.102 DROP DATABASE

Removes a database.

Synopsis

```
DROP DATABASE [IF EXISTS] <name>
```

Description

`DROP DATABASE` drops a database. It removes the catalog entries for the database and deletes the directory containing the data. It can only be run by the database owner. Also, it cannot be run while you or anyone else are connected to the target database. (Connect to `postgres` or any other database to issue this command.)

> **Caution** `DROP DATABASE` cannot be undone. Use it with care!

Parameters

IF EXISTS Do not throw an error if the database does not exist. A notice is issued in this case.

name The name of the database to remove.

Notes

`DROP DATABASE` cannot be run inside a transaction block.

This command cannot be run while connected to the target database. Thus, it might be more convenient to use the programdropdb instead, which is a wrapper around this command.

Examples

Drop the database named `testdb`:

```
DROP DATABASE testdb;
```

Compatibility

There is no `DROP DATABASE` statement in the SQL standard.

See Also

ALTER DATABASE, CREATE DATABASE

Parent topic: SQL Commands

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.1.103 DROP DOMAIN

Removes a domain.

Synopsis

```
DROP DOMAIN [IF EXISTS] <name> [, ...]  [CASCADE | RESTRICT]
```

Description

`DROP DOMAIN` removes a previously defined domain. Only the owner of a domain can remove it.

Parameters

IF EXISTS Do not throw an error if the domain does not exist. A notice is issued in this case.

name The name (optionally schema-qualified) of an existing domain.

CASCADE Automatically drop objects that depend on the domain (such as table columns), and in turn all objects that depend on those objects.

RESTRICT Refuse to drop the domain if any objects depend on it. This is the default.

Examples

Remove the domain named `us_postal_code`:

```
DROP DOMAIN us_postal_code;
```

Compatibility

This command conforms to the SQL standard, except for the `IF EXISTS` option, which is a WarehousePG extension.

See Also

ALTER DOMAIN, CREATE DOMAIN

Parent topic: SQL Commands

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.1.104 DROP EXTENSION

Removes an extension from a WarehousePG.

Synopsis

```
DROP EXTENSION [ IF EXISTS ] <name> [, ...] [ CASCADE | RESTRICT ]
```

Description

`DROP EXTENSION` removes extensions from the database. Dropping an extension causes its component objects to be dropped as well.

> **Note** The supporting extension files that were installed to create the extension (for example, the library and `.control` files) are not deleted. The files must be manually removed from the WarehousePG hosts.

You must own the extension to use `DROP EXTENSION`.

Parameters

IF EXISTS Do not throw an error if the extension does not exist. WarehousePG issues a notice in this case.

name The name of an installed extension.

CASCADE Automatically drop objects that depend on the extension, and in turn all objects that depend on those objects. Refer to the PostgreSQL Dependency Tracking documentation for more information.

> **Important** Before issuing a `DROP EXTENSION` with the `CASCADE` keyword, you should be aware of all object that depend on the extension to avoid unintended consequences.

RESTRICT Refuse to drop an extension if any objects depend on it (other than its own member objects and other extensions listed in the same `DROP` command). This is the default.

Examples

To remove the extension `hstore` from the current database:

```
DROP EXTENSION hstore;
```

This command fails if any of the extension objects are in use in the database. For example, if a table is defined with columns of the `hstore` type. Add the `CASCADE` option to forcibly remove those dependent objects.

Compatibility

`DROP EXTENSION` is a WarehousePG extension.

See Also

CREATE EXTENSION, ALTER EXTENSION

Parent topic: SQL Commands

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.1.105 DROP EXTERNAL TABLE

Removes an external table definition.

Synopsis

```
DROP EXTERNAL [WEB] TABLE [IF EXISTS] <name> [CASCADE | RESTRICT]
```

Description

`DROP EXTERNAL TABLE` drops an existing external table definition from the database system. The external data sources or files are not deleted. To run this command you must be the owner of the external table.

Parameters

WEB Optional keyword for dropping external web tables.

IF EXISTS Do not throw an error if the external table does not exist. WarehousePG issues a notice in this case.

name The name (optionally schema-qualified) of an existing external table.

CASCADE Automatically drop objects that depend on the external table (such as views).

RESTRICT Refuse to drop the external table if any objects depend on it. This is the default.

Examples

Remove the external table named `staging` if it exists:

```
DROP EXTERNAL TABLE IF EXISTS staging;
```

Compatibility

There is no `DROP EXTERNAL TABLE` statement in the SQL standard.

See Also

CREATE EXTERNAL TABLE, ALTER EXTERNAL TABLE

Parent topic: SQL Commands

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.1.106 DROP FOREIGN DATA WRAPPER

Removes a foreign-data wrapper.

Synopsis

```
DROP FOREIGN DATA WRAPPER [ IF EXISTS ] <name> [ CASCADE | RESTRICT ]
```

Description

`DROP FOREIGN DATA WRAPPER` removes an existing foreign-data wrapper from the current database. A foreign-data wrapper may be removed only by its owner.

Parameters

IF EXISTS Do not throw an error if the foreign-data wrapper does not exist. WarehousePG issues a notice in this case.

name The name of an existing foreign-data wrapper.

CASCADE Automatically drop objects that depend on the foreign-data wrapper (such as foreign tables and servers), and in turn all objects that depend on those objects.

RESTRICT Refuse to drop the foreign-data wrapper if any object depends on it. This is the default.

Examples

Drop the foreign-data wrapper named `dbi`:

```
DROP FOREIGN DATA WRAPPER dbi;
```

Compatibility

`DROP FOREIGN DATA WRAPPER` conforms to ISO/IEC 9075-9 (SQL/MED). The `IF EXISTS` clause is a WarehousePG extension.

See Also

CREATE FOREIGN DATA WRAPPER, ALTER FOREIGN DATA WRAPPER

Parent topic: SQL Commands

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.1.107 DROP FOREIGN TABLE

Removes a foreign table.

Synopsis

```
DROP FOREIGN TABLE [ IF EXISTS ] <name> [, ...] [ CASCADE | RESTRICT ]
```

Description

`DROP FOREIGN TABLE` removes an existing foreign table. Only the owner of a foreign table can remove it.

Parameters

IF EXISTS Do not throw an error if the foreign table does not exist. WarehousePG issues a notice in this case.

name The name (optionally schema-qualified) of the foreign table to drop.

CASCADE Automatically drop objects that depend on the foreign table (such as views), and in turn all objects that depend on those objects.

RESTRICT Refuse to drop the foreign table if any objects depend on it. This is the default.

Examples

To destroy two foreign tables, `films` and `distributors`:

```
DROP FOREIGN TABLE films, distributors;
```

Compatibility

`DROP FOREIGN TABLE` conforms to ISO/IEC 9075-9 (SQL/MED), except that the standard only allows one foreign table to be dropped per command. The `IF EXISTS` clause is a WarehousePG extension.

See Also

ALTER FOREIGN TABLE, CREATE FOREIGN TABLE

Parent topic: SQL Commands

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.1.108 DROP FUNCTION

Removes a function.

Synopsis

```
DROP FUNCTION [IF EXISTS] name ( [ [argmode] [argname] argtype [, ...] ] )
    [CASCADE | RESTRICT]
```

Description

`DROP FUNCTION` removes the definition of an existing function. To run this command the user must be the owner of the function. The argument types to the function must be specified, since several different functions may exist with the same name and different argument lists.

Parameters

IF EXISTS Do not throw an error if the function does not exist. A notice is issued in this case.

name The name (optionally schema-qualified) of an existing function.

argmode The mode of an argument: either `IN`, `OUT`, `INOUT`, or `VARIADIC`. If omitted, the default is `IN`. Note that `DROP FUNCTION` does not actually pay any attention to `OUT` arguments, since only the input arguments are needed to determine the function's identity. So it is sufficient to list the `IN`, `INOUT`, and `VARIADIC` arguments.

argname The name of an argument. Note that `DROP FUNCTION` does not actually pay any attention to argument names, since only the argument data types are needed to determine the function's identity.

argtype The data type(s) of the function's arguments (optionally schema-qualified), if any.

CASCADE Automatically drop objects that depend on the function (such as operators).

RESTRICT Refuse to drop the function if any objects depend on it. This is the default.

Examples

This command removes the square root function:

```
DROP FUNCTION sqrt(integer);
```

Compatibility

A `DROP FUNCTION` statement is defined in the SQL standard, but it is not compatible with this command.

See Also

CREATE FUNCTION, ALTER FUNCTION

Parent topic: SQL Commands

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.1.109 DROP GROUP

Removes a database role.

Synopsis

```
DROP GROUP [IF EXISTS] <name> [, ...]
```

Description

`DROP GROUP` is an alias for DROP ROLE.

Compatibility

There is no `DROP GROUP` statement in the SQL standard.

See Also

DROP ROLE

Parent topic: SQL Commands

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.1.110 DROP INDEX

Removes an index.

Synopsis

```
DROP INDEX [ CONCURRENTLY ] [ IF EXISTS ] <name> [, ...] [ CASCADE | RESTRICT ]
```

Description

`DROP INDEX` drops an existing index from the database system. To run this command you must be the owner of the index.

Parameters

CONCURRENTLY Drop the index without locking out concurrent selects, inserts, updates, and deletes on the index's table. A normal `DROP INDEX` acquires an `ACCESS EXCLUSIVE` lock on the table, blocking other accesses until the index drop can be completed. With this option, the command instead waits until conflicting transactions have completed.

There are several caveats to be aware of when using this option. Only one index name can be specified, and the `CASCADE` option is not supported. (Thus, an index that supports a `UNIQUE` or `PRIMARY KEY` constraint cannot be dropped this way.) Also, regular `DROP INDEX` commands can be performed within a transaction block, but `DROP INDEX CONCURRENTLY` cannot.

IF EXISTS Do not throw an error if the index does not exist. A notice is issued in this case.

name The name (optionally schema-qualified) of an index to remove.

CASCADE Automatically drop objects that depend on the index, and in turn all objects that depend on those objects.

RESTRICT Refuse to drop the index if any objects depend on it. This is the default.

Examples

Remove the index `title_idx`:

```
DROP INDEX title_idx;
```

Compatibility

`DROP INDEX` is a WarehousePG language extension. There are no provisions for indexes in the SQL standard.

See Also

ALTER INDEX, CREATE INDEX

Parent topic: SQL Commands

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.1.111 DROP LANGUAGE

Removes a procedural language.

Synopsis

```
DROP [PROCEDURAL] LANGUAGE [IF EXISTS] <name> [CASCADE | RESTRICT]
```

Description

`DROP LANGUAGE` removes the definition of the previously registered procedural language. You must be a superuser or owner of the language to drop a language.

Parameters

PROCEDURAL Optional keyword - has no effect.

IF EXISTS Do not throw an error if the language does not exist. A notice is issued in this case.

name The name of an existing procedural language. For backward compatibility, the name may be enclosed by single quotes.

CASCADE Automatically drop objects that depend on the language (such as functions written in that language), and in turn all objects that depend on those objects.

RESTRICT Refuse to drop the language if any objects depend on it. This is the default.

Examples

Remove the procedural language `plsample`:

```
DROP LANGUAGE plsample;
```

Compatibility

There is no `DROP LANGUAGE` statement in the SQL standard.

See Also

ALTER LANGUAGE, CREATE LANGUAGE

Parent topic: SQL Commands

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.1.112 DROP MATERIALIZED VIEW

Removes a materialized view.

Synopsis

```
DROP MATERIALIZED VIEW [ IF EXISTS ] <name> [, ...] [ CASCADE | RESTRICT ]
```

Description

`DROP MATERIALIZED VIEW` drops an existing materialized view. To run this command, you must be the owner of the materialized view.

Parameters

IF EXISTS Do not throw an error if the materialized view does not exist. A notice is issued in this case.

name The name (optionally schema-qualified) of a materialized view to be dropped.

CASCADE Automatically drop objects that depend on the materialized view (such as other materialized views, or regular views), and in turn all objects that depend on those objects.

RESTRICT Refuse to drop the materialized view if any objects depend on it. This is the default.

Examples

This command removes the materialized view called `order_summary`.

```
DROP MATERIALIZED VIEW order_summary;
```

Compatibility

`DROP MATERIALIZED VIEW` is a WarehousePG extension of the SQL standard.

See Also

ALTER MATERIALIZED VIEW, CREATE MATERIALIZED VIEW, REFRESH MATERIALIZED VIEW

Parent topic: SQL Commands

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.1.113 DROP OPERATOR

Removes an operator.

Synopsis

```
DROP OPERATOR [IF EXISTS] <name> ( {<left_type> | NONE} ,
    {<right_type> | NONE} ) [, ...] [CASCADE | RESTRICT]
```

Description

`DROP OPERATOR` drops an existing operator from the database system. To run this command you must be the owner of the operator.

Parameters

IF EXISTS Do not throw an error if the operator does not exist. A notice is issued in this case.

name The name (optionally schema-qualified) of an existing operator.

left_type The data type of the operator's left operand; write `NONE` if the operator has no left operand.

right_type The data type of the operator's right operand; write `NONE` if the operator has no right operand.

CASCADE Automatically drop objects that depend on the operator (such as views using it), and in turn all objects that depend on those objects.

RESTRICT Refuse to drop the operator if any objects depend on it. This is the default.

Examples

Remove the power operator `a^b` for type `integer`:

```
DROP OPERATOR ^ (integer, integer);
```

Remove the left unary bitwise complement operator `~b` for type `bit`:

```
DROP OPERATOR ~ (none, bit);
```

Remove the right unary factorial operator `x!` for type `bigint`:

```
DROP OPERATOR ! (bigint, none);
```

Remove multiple operators in one command:

```
DROP OPERATOR ~ (none, bit), ! (bigint, none);
```

Compatibility

There is no `DROP OPERATOR` statement in the SQL standard.

See Also

ALTER OPERATOR, CREATE OPERATOR

Parent topic: SQL Commands

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.1.114 DROP OPERATOR CLASS

Removes an operator class.

Synopsis

```
DROP OPERATOR CLASS [IF EXISTS] <name> USING <index_method> [CASCADE | RESTRICT]
```

Description

`DROP OPERATOR` drops an existing operator class. To run this command you must be the owner of the operator class.

`DROP OPERATOR CLASS` does not drop any of the operators or functions referenced by the class. If there are any indexes depending on the operator class, you will need to specify `CASCADE` for the drop to complete.

Parameters

IF EXISTS Do not throw an error if the operator class does not exist. A notice is issued in this case.

name The name (optionally schema-qualified) of an existing operator class.

index_method The name of the index access method the operator class is for.

CASCADE Automatically drop objects that depend on the operator class (such as indexes), and in turn all objects that depend on those objects.

RESTRICT Refuse to drop the operator class if any objects depend on it. This is the default.

Notes

`DROP OPERATOR CLASS` will not drop the operator family containing the class, even if there is nothing else left in the family (in particular, in the case where the family was implicitly created by `CREATE OPERATOR CLASS`). An empty operator family is harmless, but for the sake of tidiness you might wish to remove the family with `DROP OPERATOR FAMILY`; or perhaps better, use `DROP OPERATOR FAMILY` in the first place.

Examples

Remove the B-tree operator class `widget_ops`:

```
DROP OPERATOR CLASS widget_ops USING btree;
```

This command will not succeed if there are any existing indexes that use the operator class. Add `CASCADE` to drop such indexes along with the operator class.

Compatibility

There is no `DROP OPERATOR CLASS` statement in the SQL standard.

See Also

ALTER OPERATOR CLASS, CREATE OPERATOR CLASS, DROP OPERATOR FAMILY

Parent topic: SQL Commands

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.1.115 DROP OPERATOR FAMILY

Removes an operator family.

Synopsis

```
DROP OPERATOR FAMILY [IF EXISTS] <name> USING <index_method> [CASCADE | RESTRICT]
```

Description

`DROP OPERATOR FAMILY` drops an existing operator family. To run this command you must be the owner of the operator family.

`DROP OPERATOR FAMILY` includes dropping any operator classes contained in the family, but it does not drop any of the operators or functions referenced by the family. If there are any indexes depending on operator classes within the family, you will need to specify `CASCADE` for the drop to complete.

Parameters

IF EXISTS Do not throw an error if the operator family does not exist. A notice is issued in this case.

name The name (optionally schema-qualified) of an existing operator family.

index_method The name of the index access method the operator family is for.

CASCADE Automatically drop objects that depend on the operator family, and in turn all objects that depend on those objects.

RESTRICT Refuse to drop the operator family if any objects depend on it. This is the default.

Examples

Remove the B-tree operator family `float_ops`:

```
DROP OPERATOR FAMILY float_ops USING btree;
```

This command will not succeed if there are any existing indexes that use the operator family. Add `CASCADE` to drop such indexes along with the operator family.

Compatibility

There is no `DROP OPERATOR FAMILY` statement in the SQL standard.

See Also

ALTER OPERATOR FAMILY, CREATE OPERATOR FAMILY, ALTER OPERATOR CLASS, CREATE OPERATOR CLASS, DROP OPERATOR CLASS

7.1.116 DROP OWNED

Removes database objects owned by a database role.

Synopsis

```
DROP OWNED BY { <name> | CURRENT_USER | SESSION_USER } [, ...] [CASCADE | RESTRICT]
```

Description

`DROP OWNED` drops all of the objects in the current database that are owned by one of the specified roles. Any privileges granted to the given roles on objects in the current database or on shared objects (databases, tablespaces) will also be revoked.

Parameters

name The name of a role whose objects will be dropped, and whose privileges will be revoked.

CASCADE Automatically drop objects that depend on the affected objects, and in turn all objects that depend on those objects.

RESTRICT Refuse to drop the objects owned by a role if any other database objects depend on one of the affected objects. This is the default.

Notes

`DROP OWNED` is often used to prepare for the removal of one or more roles. Because `DROP OWNED` only affects the objects in the current database, it is usually necessary to run this command in each database that contains objects owned by a role that is to be removed.

Using the `CASCADE` option may make the command recurse to objects owned by other users.

The REASSIGN OWNED command is an alternative that reassigns the ownership of all the database objects owned by one or more roles. However, `REASSIGN OWNED` does not deal with privileges for other objects.

Databases and tablespaces owned by the role(s) will not be removed.

Examples

Remove any database objects owned by the role named `sally`:

```
DROP OWNED BY sally;
```

Compatibility

The `DROP OWNED` command is a WarehousePG extension.

See Also

REASSIGN OWNED, DROP ROLE

Parent topic: SQL Commands

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.1.117 DROP POLICY

Removes a row-level security policy from a table.

Synopsis

```
DROP POLICY [ IF EXISTS ] <name> ON <table_name> [ CASCADE | RESTRICT ]
```

Description

`DROP POLICY` removes the specified policy from the table. Note that if the last policy is removed for a table and the table still has row-level security enabled via `ALTER TABLE`, then the default-deny policy will be used. `ALTER TABLE ... DISABLE ROW LEVEL SECURITY` can be used to disable row-level security for a table, whether policies for the table exist or not.

Parameters

IF EXISTS Do not throw an error if the policy does not exist. A notice is issued in this case.

name The name of the policy to drop.

table_name The name (optionally schema-qualified) of the table that the policy is on.

CASCADE RESTRICT These key words have no effect, since there are no dependencies on policies.

Examples

To drop the policy called `p1` on the table named `my_table`:

```
DROP POLICY p1 ON my_table;
```

Compatibility

`DROP POLICY` is a WarehousePG extension to the SQL standard.

See Also

CREATE POLICY, ALTER POLICY

Parent topic: SQL Commands

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.1.118 DROP PROCEDURE

Removes a procedure.

Synopsis

```
DROP PROCEDURE [IF EXISTS] name ( [ [argmode] [argname] argtype [, ...] ] )
    [CASCADE | RESTRICT]
```

Description

`DROP PROCEDURE` removes the definition of an existing procedure. To run this command the user must be the owner of the procedure. The argument types to the procedure must be specified, since several different procedures may exist with the same name and different argument lists.

Parameters

IF EXISTS Do not throw an error if the procedure does not exist. A notice is issued in this case.

name The name (optionally schema-qualified) of an existing procedure. If no argument list is specified, the name must be unique in its schema.

argmode The mode of an argument: `IN` or `VARIADIC`. If omitted, the default is `IN`.

argname The name of an argument. Note that `DROP PROCEDURE` does not actually pay any attention to argument names, since only the argument data types are needed to determine the procedure's identity.

argtype The data type(s) of the procedure's arguments (optionally schema-qualified), if any.

CASCADE Automatically drop objects that depend on the procedure, and in turn all objects that depend on those objects.

RESTRICT Refuse to drop the procedure if any objects depend on it. This is the default.

Examples

This command removes the procedure named `do_db_maintenance`:

```
DROP PROCEDURE do_db_maintenance();
```

Compatibility

This command conforms to the SQL standard, with these WarehousePG extensions:

- The standard only allows one procedure to be dropped per command.
- The `IF EXISTS` option.
- The ability to specify argument modes and names.

See Also

CREATE PROCEDURE, ALTER PROCEDURE

Parent topic: SQL Commands

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.1.119 DROP PROTOCOL

Removes a data access protocol from a database.

Synopsis

```
DROP PROTOCOL [IF EXISTS] <name>
```

Description

`DROP PROTOCOL` removes the specified protocol from a database. You specify a protocol name in the `CREATE EXTERNAL TABLE` command to read data from or write data to an external data source.

You must be a superuser or the protocol owner to drop a protocol.

> **Caution** If you drop a data access prococol, external tables that have been defined specifying the protocol will no longer be able to access the external data source.

Parameters

IF EXISTS Do not throw an error if the protocol does not exist. WarehousePG issues a notice in this case.

name The name of an existing data access protocol.

Notes

Dropping a data access protocol, does not drop the protocol's call handlers. You must drop these functions manually.

Be sure to remove any shared libraries that were used by the protocol from the WarehousePG hosts.

Compatibility

`DROP PROTOCOL` is a WarehousePG extension.

See Also

CREATE EXTERNAL TABLE, CREATE PROTOCOL

Parent topic: SQL Commands

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.1.120 DROP RESOURCE GROUP

Removes a resource group.

Synopsis

```
DROP RESOURCE GROUP <group_name>
```

Description

This command removes a resource group from WarehousePG. Only a superuser can drop a resource group. When you drop a resource group, the memory and CPU resources reserved by the group are returned to WarehousePG.

To drop a role resource group, the group cannot be assigned to any roles, nor can it have any statements pending or running in the group. If you drop a resource group that you created for an external component, the behavior is determined by the external component. For example, dropping a resource group that you assigned to a PL/Container runtime stops running containers in the group.

You cannot drop the pre-defined `admin_group` and `default_group` resource groups.

Parameters

group_name The name of the resource group to remove.

Notes

You cannot submit a `DROP RESOURCE GROUP` command in an explicit transaction or sub-transaction.

Use ALTER ROLE to remove a resource group assigned to a specific user/role.

Perform the following query to view all of the currently active queries for all resource groups:

```
SELECT usename, query, waiting, pid,
    rsgid, rsgname, rsgqueueduration
  FROM pg_stat_activity;
```

To view the resource group assignments, perform the following query on the `pg_roles` and `pg_resgroup` system catalog tables:

```
SELECT rolname, rsgname
  FROM pg_roles, pg_resgroup
  WHERE pg_roles.rolresgroup=pg_resgroup.oid;
```

Examples

Remove the resource group assigned to a role. This operation then assigns the default resource group `default_group` to the role:

```
ALTER ROLE bob RESOURCE GROUP NONE;
```

Remove the resource group named `adhoc` :

```
DROP RESOURCE GROUP adhoc;
```

Compatibility

The `DROP RESOURCE GROUP` statement is a WarehousePG extension.

See Also

ALTER RESOURCE GROUP, CREATE RESOURCE GROUP, ALTER ROLE

Parent topic: SQL Commands

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.1.121 DROP RESOURCE QUEUE

Removes a resource queue.

Synopsis

```
DROP RESOURCE QUEUE <queue_name>
```

Description

This command removes a resource queue from WarehousePG. To drop a resource queue, the queue cannot have any roles assigned to it, nor can it have any statements waiting in the queue. Only a superuser can drop a resource queue.

Parameters

queue_name The name of a resource queue to remove.

Notes

Use ALTER ROLE to remove a user from a resource queue.

To see all the currently active queries for all resource queues, perform the following query of the `pg_locks` table joined with the `pg_roles` and `pg_resqueue` tables:

```
SELECT rolname, rsqname, locktype, objid, pid,
mode, granted FROM pg_roles, pg_resqueue, pg_locks WHERE
pg_roles.rolresqueue=pg_locks.objid AND
pg_locks.objid=pg_resqueue.oid;
```

To see the roles assigned to a resource queue, perform the following query of the `pg_roles` and `pg_resqueue` system catalog tables:

```
SELECT rolname, rsqname FROM pg_roles, pg_resqueue WHERE
pg_roles.rolresqueue=pg_resqueue.oid;
```

Examples

Remove a role from a resource queue (and move the role to the default resource queue, `pg_default`):

```
ALTER ROLE bob RESOURCE QUEUE NONE;
```

Remove the resource queue named `adhoc`:

```
DROP RESOURCE QUEUE adhoc;
```

Compatibility

The `DROP RESOURCE QUEUE` statement is a WarehousePG extension.

See Also

ALTER RESOURCE QUEUE, CREATE RESOURCE QUEUE, ALTER ROLE

Parent topic: SQL Commands

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.1.122 DROP ROLE

Removes a database role.

Synopsis

```
DROP ROLE [IF EXISTS] <name> [, ...]
```

Description

`DROP ROLE` removes the specified role(s). To drop a superuser role, you must be a superuser yourself. To drop non-superuser roles, you must have `CREATEROLE` privilege.

A role cannot be removed if it is still referenced in any database; an error will be raised if so. Before dropping the role, you must drop all the objects it owns (or reassign their ownership) and revoke any privileges the role has been granted on other objects. The REASSIGN OWNED and DROP OWNED commands can be useful for this purpose.

However, it is not necessary to remove role memberships involving the role; `DROP ROLE` automatically revokes any memberships of the target role in other roles, and of other roles in the target role. The other roles are not dropped nor otherwise affected.

Parameters

IF EXISTS Do not throw an error if the role does not exist. A notice is issued in this case.

name The name of the role to remove.

Examples

Remove the roles named `sally` and `bob`:

```
DROP ROLE sally, bob;
```

Compatibility

The SQL standard defines `DROP ROLE`, but it allows only one role to be dropped at a time, and it specifies different privilege requirements than WarehousePG uses.

See Also

REASSIGN OWNED, DROP OWNED, CREATE ROLE, ALTER ROLE, SET ROLE

Parent topic: SQL Commands

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.1.123 DROP ROUTINE

Removes a routine.

Synopsis

```
DROP ROUTINE [IF EXISTS] name ( [ [argmode] [argname] argtype [, ...] ] )
    [CASCADE | RESTRICT]
```

Description

`DROP ROUTINE` removes the definition of an existing routine, which can be an aggregate function, a normal function, or a procedure. Refer to DROP AGGREGATE, DROP FUNCTION, and DROP PROCEDURE for the description of the parameters, more examples, and further details.

Examples

To drop the routine `foo` for type `integer`:

```
DROP ROUTINE foo(integer);
```

This command will work independent of whether `foo` is an aggregate, function, or procedure.

Compatibility

This command conforms to the SQL standard, with these WarehousePG extensions:

- The standard only allows one routine to be dropped per command.
- The `IF EXISTS` option.
- The ability to specify argument modes and names.
- Aggregate functions are an extension.

See Also

DROP AGGREGATE, DROP FUNCTION, DROP PROCEDURE, ALTER ROUTINE

Parent topic: SQL Commands

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.1.124 DROP RULE

Removes a rewrite rule.

Synopsis

```
DROP RULE [IF EXISTS] <name> ON <table_name> [CASCADE | RESTRICT]
```

Description

`DROP RULE` drops a rewrite rule from a table or view.

Parameters

IF EXISTS Do not throw an error if the rule does not exist. WarehousePG issues a notice in this case.

name The name of the rule to remove.

table_name The name (optionally schema-qualified) of the table or view that the rule applies to.

CASCADE Automatically drop objects that depend on the rule, and in turn all objects that depend on those objects.

RESTRICT Refuse to drop the rule if any objects depend on it. This is the default.

Examples

Remove the rewrite rule `sales_2006` on the table `sales`:

```
DROP RULE sales_2006 ON sales;
```

Compatibility

`DROP RULE` is a WarehousePG extension, as is the entire query rewrite system.

See Also

ALTER RULE, CREATE RULE

Parent topic: SQL Commands

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.1.125 DROP SCHEMA

Removes a schema.

Synopsis

```
DROP SCHEMA [IF EXISTS] <name> [, ...] [CASCADE | RESTRICT]
```

Description

`DROP SCHEMA` removes schemas from the database.

A schema can be dropped only by its owner or a superuser. Note that the owner can drop the schema (and thereby all contained objects) even if they do not own some of the objects within the schema.

Parameters

IF EXISTS Do not throw an error if the schema does not exist. A notice is issued in this case.

name The name of the schema to remove.

CASCADE Automatically drop objects (tables, functions, etc.) that are contained in the schema, and in turn all objects that depend on those objects.

RESTRICT Refuse to drop the schema if it contains any objects. This is the default.

Notes

Using the `CASCADE` option may result in the command removing objects in other schemas besides the one(s) named.

Examples

Remove the schema `mystuff` from the database, along with everything it contains:

```
DROP SCHEMA mystuff CASCADE;
```

Compatibility

`DROP SCHEMA` is fully conforming with the SQL standard, except that the standard only allows one schema to be dropped per command. Also, the `IF EXISTS` option is a WarehousePG extension.

See Also

CREATE SCHEMA, ALTER SCHEMA

Parent topic: SQL Commands

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.1.126 DROP SEQUENCE

Removes a sequence.

Synopsis

```
DROP SEQUENCE [IF EXISTS] <name> [, ...] [CASCADE | RESTRICT]
```

Description

`DROP SEQUENCE` removes sequence number generators. You must own the sequence to drop it (or be a superuser).

Parameters

IF EXISTS Do not throw an error if the sequence does not exist. WarehousePG issues a notice in this case.

name The name (optionally schema-qualified) of the sequence to remove.

CASCADE Automatically drop objects that depend on the sequence, and in turn all objects that depend on those objects.

RESTRICT Refuse to drop the sequence if any objects depend on it. This is the default.

Examples

Remove the sequence `myserial`:

```
DROP SEQUENCE myserial;
```

Compatibility

`DROP SEQUENCE` conforms to the SQL standard, except that the standard allows only one sequence to be dropped per command. Also, the `IF EXISTS` option is a WarehousePG extension.

See Also

ALTER SEQUENCE, CREATE SEQUENCE

Parent topic: SQL Commands

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.1.127 DROP SERVER

Removes a foreign server descriptor.

Synopsis

```
DROP SERVER [ IF EXISTS ] <name> [, ...] [ CASCADE | RESTRICT ]
```

Description

`DROP SERVER` removes an existing foreign server descriptor. The user running this command must be the owner of the server.

Parameters

IF EXISTS Do not throw an error if the server does not exist. WarehousePG issues a notice in this case.

name The name of an existing server.

CASCADE Automatically drop objects that depend on the server (such as user mappings), and in turn all objects that depend on those objects.

RESTRICT Refuse to drop the server if any object depends on it. This is the default.

Examples

Drop the server named `foo` if it exists:

```
DROP SERVER IF EXISTS foo;
```

Compatibility

`DROP SERVER` conforms to ISO/IEC 9075-9 (SQL/MED). The `IF EXISTS` clause is a WarehousePG extension.

See Also

CREATE SERVER, ALTER SERVER

Parent topic: SQL Commands

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.1.128 DROP STATISTICS

Removes extended statistics.

Synopsis

```
DROP STATISTICS [ IF EXISTS ] <name> [, ...] [ CASCADE | RESTRICT ]
```

Description

`DROP STATISTICS` removes statistics object(s) from the database. Only the statistics object's owner, the schema owner, or a superuser can drop a statistics object.

Parameters

`IF EXISTS` Do not throw an error if the statistics object does not exist. WarehousePG issues a notice in this case.

name The name (optionally schema-qualified) of the statistics object to drop.

CASCADE RESTRICT These key words have no effect, since there are no dependencies on statistics.

Examples

Destroy two statistics objects in different schemas, without failing if they do not exist:

```
DROP STATISTICS IF EXISTS
    accounting.users_uid_creation,
    public.grants_user_role;
```

Compatibility

There is no `DROP STATISTICS` command in the SQL standard.

See Also

ALTER STATISTICS, CREATE STATISTICS

Parent topic: SQL Commands

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.1.129 DROP TABLE

Removes a table.

Synopsis

```
DROP TABLE [IF EXISTS] <name> [, ...] [CASCADE | RESTRICT]
```

Description

`DROP TABLE` removes tables from the database. Only the table owner, the schema owner, and superuser can drop a table. To empty a table of rows without removing the table definition, useDELETE or TRUNCATE.

`DROP TABLE` always removes any indexes, rules, triggers, and constraints that exist for the target table. However, to drop a table that is referenced by a view, `CASCADE` must be specified. `CASCADE` removes a dependent view entirely.

Parameters

IF EXISTS Do not throw an error if the table does not exist. WarehousePG issues a notice in this case.

name The name (optionally schema-qualified) of the table to remove.

CASCADE Automatically drop objects that depend on the table (such as views), and in turn all objects that depend on those objects.

RESTRICT Refuse to drop the table if any objects depend on it. This is the default.

Examples

Remove the table `mytable`:

```
DROP TABLE mytable;
```

Remove two tables, `films` and `distributors`:

```
DROP TABLE films, distributors;
```

Compatibility

`DROP TABLE` conforms to the SQL standard, except that the standard allows only one table to be dropped per command. Also, the `IF EXISTS` option is a WarehousePG extension.

See Also

ALTER TABLE, CREATE TABLE

Parent topic: SQL Commands

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.1.130 DROP TABLESPACE

Removes a tablespace.

Synopsis

```
DROP TABLESPACE [IF EXISTS] <name>
```

Description

`DROP TABLESPACE` removes a tablespace from the system.

A tablespace can only be dropped by its owner or a superuser. The tablespace must be empty of all database objects before it can be dropped. It is possible that objects in other databases may still reside in the tablespace even if no objects in the current database are using the tablespace. Also, if the tablespace is listed in the temp_tablespaces setting of any active session, `DROP TABLESPACE` might fail due to temporary files residing in the tablespace.

Parameters

IF EXISTS Do not throw an error if the tablespace does not exist. WarehousePG issues a notice in this case.

name The name of the tablespace to remove.

Notes

You cannot run `DROP TABLESPACE` inside a transaction block.

Run `DROP TABLESPACE` during a period of low activity to avoid issues due to concurrent creation of tables and temporary objects. When a tablespace is dropped, there is a small window in which a table could be created in the tablespace that is currently being dropped. If this occurs, WarehousePG returns a warning. This is an example of the `DROP TABLESPACE` warning.

```
testdb=# DROP TABLESPACE mytest;
WARNING:  tablespace with oid "16415" is not empty  (seg1 192.168.8.145:25433 pid=29023)
WARNING:  tablespace with oid "16415" is not empty  (seg0 192.168.8.145:25432 pid=29022)
WARNING:  tablespace with oid "16415" is not empty
DROP TABLESPACE
```

The table data in the tablespace directory is not dropped. You can use the ALTER TABLE command to change the tablespace defined for the table and move the data to an existing tablespace.

Examples

Remove the tablespace `mystuff`:

```
DROP TABLESPACE mystuff;
```

Compatibility

`DROP TABLESPACE` is a WarehousePG extension.

See Also

CREATE TABLESPACE, ALTER TABLESPACE

Parent topic: SQL Commands

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.1.131 DROP TEXT SEARCH CONFIGURATION

Removes a text search configuration.

Synopsis

```
DROP TEXT SEARCH CONFIGURATION [ IF EXISTS ] <name> [ CASCADE | RESTRICT ]
```

Description

`DROP TEXT SEARCH CONFIGURATION` drops an existing text search configuration. You must be the owner of the configuration to run this command.

Parameters

IF EXISTS Do not throw an error if the text search configuration does not exist. WarehousePG issues a notice in this case.

name The name (optionally schema-qualified) of an existing text search configuration.

CASCADE Automatically drop objects that depend on the text search configuration, and in turn all objects that depend on those objects.

RESTRICT Refuse to drop the text search configuration if any objects depend on it. This is the default.

Examples

Remove the text search configuration `my_english`:

```
DROP TEXT SEARCH CONFIGURATION my_english;
```

This command will not succeed if there are any existing indexes that reference the configuration in `to_tsvector` calls. Add `CASCADE` to drop such indexes along with the text search configuration.

Compatibility

There is no `DROP TEXT SEARCH CONFIGURATION` statement in the SQL standard.

See Also

ALTER TEXT SEARCH CONFIGURATION, CREATE TEXT SEARCH CONFIGURATION

Parent topic: SQL Commands

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.1.132 DROP TEXT SEARCH DICTIONARY

Removes a text search dictionary.

Synopsis

```
DROP TEXT SEARCH DICTIONARY [ IF EXISTS ] <name> [ CASCADE | RESTRICT ]
```

Description

`DROP TEXT SEARCH DICTIONARY` drops an existing text search dictionary. You must be the owner of the dictionary to run this command.

Parameters

IF EXISTS Do not throw an error if the text search dictionary does not exist. WarehousePG issues a notice in this case.

name The name (optionally schema-qualified) of an existing text search dictionary.

CASCADE Automatically drop objects that depend on the text search dictionary, and in turn all objects that depend on those objects.

RESTRICT Refuse to drop the text search dictionary if any objects depend on it. This is the default.

Examples

Remove the text search dictionary `english`:

```
DROP TEXT SEARCH DICTIONARY english;
```

This command will not succeed if there are any existing text search configurations that use the dictionary. Add `CASCADE` to drop such configurations along with the dictionary.

Compatibility

There is no `CREATE TEXT SEARCH DICTIONARY` statement in the SQL standard.

See Also

ALTER TEXT SEARCH DICTIONARY, CREATE TEXT SEARCH DICTIONARY

Parent topic: SQL Commands

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.1.133 DROP TEXT SEARCH PARSER

Removes a text search parser.

Synopsis

```
DROP TEXT SEARCH PARSER [ IF EXISTS ] <name> [ CASCADE | RESTRICT ]
```

Description

`DROP TEXT SEARCH PARSER` drops an existing text search parser. You must be a superuser to use this command.

Parameters

IF EXISTS Do not throw an error if the text search parser does not exist. WarehousePG issues a notice in this case.

name The name (optionally schema-qualified) of an existing text search parser.

CASCADE Automatically drop objects that depend on the text search parser, and in turn all objects that depend on those objects.

RESTRICT Refuse to drop the text search parser if any objects depend on it. This is the default.

Examples

Remove the text search parser `my_parser`:

```
DROP TEXT SEARCH PARSER my_parser;
```

This command will not succeed if there are any existing text search configurations that use the parser. Add `CASCADE` to drop such configurations along with the parser.

Compatibility

There is no `DROP TEXT SEARCH PARSER` statement in the SQL standard.

See Also

ALTER TEXT SEARCH PARSER, CREATE TEXT SEARCH PARSER

Parent topic: SQL Commands

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.1.134 DROP TEXT SEARCH TEMPLATE

Removes a text search template.

Synopsis

```
DROP TEXT SEARCH TEMPLATE [ IF EXISTS ] <name> [ CASCADE | RESTRICT ]
```

Description

`DROP TEXT SEARCH TEMPLATE` drops an existing text search template. You must be a superuser to use this command.

You must be a superuser to use `ALTER TEXT SEARCH TEMPLATE`.

Parameters

IF EXISTS Do not throw an error if the text search template does not exist. WarehousePG issues a notice in this case.

name The name (optionally schema-qualified) of an existing text search template.

CASCADE Automatically drop objects that depend on the text search template, and in turn all objects that depend on those objects.

RESTRICT Refuse to drop the text search template if any objects depend on it. This is the default.

Examples

Remove the text search template `thesaurus`:

```
DROP TEXT SEARCH TEMPLATE thesaurus;
```

This command will not succeed if there are any existing text search dictionaries that use the template. Add `CASCADE` to drop such dictionaries along with the template.

Compatibility

There is no `DROP TEXT SEARCH TEMPLATE` statement in the SQL standard.

See Also

ALTER TEXT SEARCH TEMPLATE, CREATE TEXT SEARCH TEMPLATE

Parent topic: SQL Commands

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.1.135 DROP TRANSFORM

Removes a transform.

Synopsis

```
DROP TRANSFORM [IF EXISTS] FOR <type_name> LANGUAGE <lang_name> [CASCADE | RESTRICT]
```

Description

`DROP TRANSFORM` removes a previously defined transform.

To drop a transform, you must own the type and the language. These are the same privileges that are required to create a transform.

Parameters

IF EXISTS Do not throw an error if the transform does not exist. WarehousePG issues a notice in this case.

type_name The name of the data type of the transform.

lang_name The name of the language of the transform.

CASCADE Automatically drop objects that depend on the transform, and in turn all objects that depend on those objects.

RESTRICT Refuse to drop the transform if any objects depend on it. This is the default.

Examples

To drop the transform for type `hstore` and language `plpython3u`:

```
DROP TRANSFORM FOR hstore LANGUAGE
plpython3u;
```

Compatibility

This form of `DROP TRANSFORM` is a WarehousePG extension. See CREATE TRANSFORM for details.

See Also

CREATE TRANSFORM

Parent topic: SQL Commands

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.1.136 DROP TYPE

Removes a data type.

Synopsis

```
DROP TYPE [IF EXISTS] <name> [, ...] [CASCADE | RESTRICT]
```

Description

`DROP TYPE` will remove a user-defined data type. Only the owner of a type can remove it.

Parameters

IF EXISTS Do not throw an error if the type does not exist. WarehousePG issues a notice in this case.

name The name (optionally schema-qualified) of the data type to remove.

CASCADE Automatically drop objects that depend on the type (such as table columns, functions, operators), and in turn all objects that depend on those objects.

RESTRICT Refuse to drop the type if any objects depend on it. This is the default.

Examples

Remove the data type `box`;

```
DROP TYPE box;
```

Compatibility

This command is similar to the corresponding command in the SQL standard, apart from the `IF EXISTS` option, which is a WarehousePG extension. But note that much of the `CREATE TYPE` command and the data type extension mechanisms in WarehousePG differ from the SQL standard.

See Also

ALTER TYPE, CREATE TYPE

Parent topic: SQL Commands

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.1.137 DROP USER

Removes a database role.

Synopsis

```
DROP USER [IF EXISTS] <name> [, ...]
```

Description

`DROP USER` is an alias for DROP ROLE.

Compatibility

The `DROP USER` statement is a WarehousePG extension. The SQL standard leaves the definition of users to the implementation.

See Also

DROP ROLE

Parent topic: SQL Commands

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.1.138 DROP USER MAPPING

Removes a user mapping for a foreign server.

Synopsis

```
DROP USER MAPPING [ IF EXISTS ] { <user_name> | USER | CURRENT_USER | PUBLIC }
    SERVER <server_name>
```

Description

`DROP USER MAPPING` removes an existing user mapping from a foreign server.

The owner of a foreign server can drop user mappings for that server for any user. Also, a user can drop a user mapping for their own user name if they have been granted the `USAGE` privilege on the server.

Parameters

IF EXISTS Do not throw an error if the user mapping does not exist. WarehousePG issues a notice in this case.

user_name User name of the mapping. `CURRENT_USER` and `USER` match the name of the current user. `PUBLIC` is used to match all present and future user names in the system.

server_name Server name of the user mapping.

Examples

Drop the user mapping named `bob`, server `foo` if it exists:

```
DROP USER MAPPING IF EXISTS FOR bob SERVER foo;
```

Compatibility

`DROP SERVER` conforms to ISO/IEC 9075-9 (SQL/MED). The `IF EXISTS` clause is a WarehousePG extension.

7.1.139 DROP VIEW

Removes a view.

Synopsis

```
DROP VIEW [IF EXISTS] <name> [, ...] [CASCADE | RESTRICT]
```

Description

`DROP VIEW` removes an existing view. Only the owner of a view can remove it.

Parameters

IF EXISTS Do not throw an error if the view does not exist. WarehousePG issues a notice in this case.

name The name (optionally schema-qualified) of the view to remove.

CASCADE Automatically drop objects that depend on the view (such as other views), and in turn all objects that depend on those objects.

RESTRICT Refuse to drop the view if any objects depend on it. This is the default.

Examples

Remove the view `topten`:

```
DROP VIEW topten;
```

Compatibility

`DROP VIEW` fully conforms to the SQL standard, except that the standard only allows one view to be dropped per command. Also, the `IF EXISTS` option is a WarehousePG extension.

7.1.140 END

Commits the current transaction.

Synopsis

```
END [WORK | TRANSACTION] [AND [NO] CHAIN]
```

Description

`END` commits the current transaction. All changes made by the transaction become visible to others and are guaranteed to be durable if a crash occurs. This command is a WarehousePG extension that is equivalent toCOMMIT.

Parameters

WORK TRANSACTION Optional keywords. They have no effect.

AND CHAIN If `AND CHAIN` is specified, a new transaction is immediately started with the same transaction characteristics (see SET TRANSACTION) as the just finished one. Otherwise, no new transaction is started.

Notes

Use ROLLBACK to terminate a transaction.

Issuing `END` when not inside a transaction does no harm, but it will provoke a warning message.

Examples

To commit the current transaction and make all changes permanent:

```
END;
```

Compatibility

`END` is a WarehousePG extension that provides functionality equivalent to COMMIT, which is specified in the SQL standard.

See Also

BEGIN, COMMIT, ROLLBACK

7.1.141 EXECUTE

Runs a prepared SQL statement.

Synopsis

```
EXECUTE <name> [ (<parameter> [, ...] ) ]
```

Description

`EXECUTE` is used to run a previously prepared statement. Since prepared statements only exist for the duration of a session, the prepared statement must have been created by a `PREPARE` statement run earlier in the current session.

If the `PREPARE` statement that created the statement specified some parameters, a compatible set of parameters must be passed to the `EXECUTE` statement, or else WarehousePG raises an error. Because (unlike functions) prepared statements are not overloaded based on the type or number of their parameters, the name of a prepared statement must be unique within a database session.

For more information on the creation and usage of prepared statements, see PREPARE.

Parameters

name The name of the prepared statement to run.

parameter The actual value of a parameter to the prepared statement. This must be an expression yielding a value that is compatible with the data type of this parameter, as was determined when the prepared statement was created.

Outputs

The command tag returned by `EXECUTE` is that of the prepared statement, and not `EXECUTE`.

Examples

Create a prepared statement for an `INSERT` statement, and then run it:

```
PREPARE fooplan (int, text, bool, numeric) AS
    INSERT INTO foo VALUES($1, $2, $3, $4);
EXECUTE fooplan(1, 'Hunter Valley', 't', 200.00);
```

Compatibility

The SQL standard includes an `EXECUTE` statement, but it is only for use in embedded SQL. This version of the `EXECUTE` statement also uses a somewhat different syntax.

7.1.142 EXPLAIN

Shows the query plan of a statement.

Synopsis

```
EXPLAIN [ ( <option> [, ...] ) ] <statement>
EXPLAIN [ANALYZE] [VERBOSE] <statement>
```

where option can be one of:

```
    ANALYZE [ <boolean> ]
    VERBOSE [ <boolean> ]
    COSTS [ <boolean> ]
    BUFFERS [ <boolean> ]
    TIMING [ <boolean> ]
    FORMAT { TEXT | XML | JSON | YAML }
```

Description

`EXPLAIN` displays the query plan that the WarehousePG or Postgres-based planner generates for the supplied statement. Query plans are a tree plan of nodes. Each node in the plan represents a single operation, such as table scan, join, aggregation or a sort.

Plans should be read from the bottom up as each node feeds rows into the node directly above it. The bottom nodes of a plan are usually table scan operations (sequential, index or bitmap index scans). If the query requires joins, aggregations, or sorts (or other operations on the raw rows) then there will be additional nodes above the scan nodes to perform these operations. The topmost plan nodes are usually the WarehousePG motion nodes (redistribute, explicit redistribute, broadcast, or gather motions). These are the operations responsible for moving rows between the segment instances during query processing.

The output of `EXPLAIN` has one line for each node in the plan tree, showing the basic node type plus the following cost estimates that the planner made for the execution of that plan node:

- **cost** — the planner's guess at how long it will take to run the statement (measured in cost units that are arbitrary, but conventionally mean disk page fetches). Two cost numbers are shown: the start-up cost before the first row can be returned, and the total cost to return all the rows. Note that the total cost assumes that all rows will be retrieved, which may not always be the case (if using `LIMIT` for example).
- **rows** — the total number of rows output by this plan node. This is usually less than the actual number of rows processed or scanned by the plan node, reflecting the estimated selectivity of any `WHERE` clause conditions. Ideally the top-level nodes estimate will approximate the number of rows actually returned, updated, or deleted by the query.
- **width** — total bytes of all the rows output by this plan node.

It is important to note that the cost of an upper-level node includes the cost of all its child nodes. The topmost node of the plan has the estimated total execution cost for the plan. This is this number that the planner seeks to minimize. It is also important to realize that the cost only reflects things that the query optimizer cares about. In particular, the cost does not consider the time spent transmitting result rows to the client.

`EXPLAIN ANALYZE` causes the statement to be actually run, not only planned. The `EXPLAIN ANALYZE` plan shows the actual results along with the planner's estimates. This is useful for seeing whether the planner's estimates are close to reality. In addition to the information shown in the `EXPLAIN` plan, `EXPLAIN ANALYZE` will show the following additional information:

- The total elapsed time (in milliseconds) that it took to run the query.
- The number of *workers* (segments) involved in a plan node operation. Only segments that return rows are counted.
- The maximum number of rows returned by the segment that produced the most rows for an operation. If multiple segments produce an equal number of rows, the one with the longest *time to end* is the one chosen.
- The segment id number of the segment that produced the most rows for an operation.
- For relevant operations, the work_mem used by the operation. If `work_mem` was not sufficient to perform the operation in memory, the plan will show how much data was spilled to disk and how many passes over the data were required for the lowest performing segment. For example:

  ```
  Work_mem used: 64K bytes avg, 64K bytes max (seg0).
  Work_mem wanted: 90K bytes avg, 90K bytes max (seg0) to abate workfile
  I/O affecting 2 workers.
  [seg0] pass 0: 488 groups made from 488 rows; 263 rows written to
  workfile
  [seg0] pass 1: 263 groups made from 263 rows
  ```

- The time (in milliseconds) it took to retrieve the first row from the segment that produced the most rows, and the total time taken to retrieve all rows from that segment. The *<time> to first row* may be omitted if it is the same as the *<time> to end*.

> **Important** Keep in mind that the statement is actually run when `ANALYZE` is used. Although `EXPLAIN ANALYZE` will discard any output that a `SELECT` would return, other side effects of the statement will happen as usual. If you wish to use `EXPLAIN ANALYZE` on a DML statement without letting the command affect your data, use this approach:

```
BEGIN;
EXPLAIN ANALYZE ...;
ROLLBACK;
```

Only the `ANALYZE` and `VERBOSE` options can be specified, and only in that order, without surrounding the option list in parentheses.

Parameters

ANALYZE Carry out the command and show the actual run times and other statistics. This parameter defaults to `FALSE` if you omit it; specify `ANALYZE true` to enable it.

VERBOSE Display additional information regarding the plan. Specifically, include the output column list for each node in the plan tree, schema-qualify table and function names, always label variables in expressions with their range table alias, and always print the name of each trigger for which statistics are displayed. This parameter defaults to `FALSE` if you omit it; specify `VERBOSE true` to enable it.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

COSTS Include information on the estimated startup and total cost of each plan node, as well as the estimated number of rows and the estimated width of each row. This parameter defaults to `TRUE` if you omit it; specify `COSTS false` to deactivate it.

BUFFERS Include information on buffer usage. This parameter may be specified only when `ANALYZE` is also specified. If omitted, the default value is `false`, buffer usage information is not included.

> **Note** WarehousePG does not support specifying `BUFFERS [true]` for distributed queries; ignore any displayed buffer usage information.

TIMING Include actual startup time and time spent in each node in the output. The overhead of repeatedly reading the system clock can slow down the query significantly on some systems, so it may be useful to set this parameter to `FALSE` when only actual row counts, and not exact times, are needed. Run time of the entire statement is always measured, even when node-level timing is turned off with this option. This parameter may only be used when `ANALYZE` is also enabled. It defaults to `TRUE`.

FORMAT Specify the output format, which can be `TEXT`, `XML`, `JSON`, or `YAML`. Non-text output contains the same information as the text output format, but is easier for programs to parse. This parameter defaults to `TEXT`.

boolean Specifies whether the selected option should be turned on or off. You can write `TRUE`, `ON`, or `1` to enable the option, and `FALSE`, `OFF`, or `0` to deactivate it. The boolean value can also be omitted, in which case `TRUE` is assumed.

statement Any `SELECT`, `INSERT`, `UPDATE`, `DELETE`, `VALUES`, `EXECUTE`, `DECLARE`, or `CREATE TABLE AS` statement, whose execution plan you wish to see.

Notes

In order to allow the query optimizer to make reasonably informed decisions when optimizing queries, the `ANALYZE` statement should be run to record statistics about the distribution of data within the table. If you have not done this (or if the statistical distribution of the data in the table has changed significantly since the last time `ANALYZE` was run), the estimated costs are unlikely to conform to the real properties of the query, and consequently an inferior query plan may be chosen.

An SQL statement that is run during the execution of an `EXPLAIN ANALYZE` command is excluded from WarehousePG resource queues.

For more information about query profiling, see "Query Profiling" in the *WarehousePG Administrator Guide*. For more information about resource queues, see "Resource Management with Resource Queues" in the *WarehousePG Administrator Guide*.

Examples

To illustrate how to read an `EXPLAIN` query plan, consider the following example for a very simple query:

```
EXPLAIN SELECT * FROM names WHERE name = 'Joelle';
                                QUERY PLAN
-------------------------------------------------------------------------------
 Gather Motion 3:1  (slice1; segments: 3)  (cost=0.00..431.27 rows=1 width=58)
   ->  Seq Scan on names  (cost=0.00..431.27 rows=1 width=58)
         Filter: (name = 'Joelle'::text)
 Optimizer: GPORCA
(4 rows)
```

If we read the plan from the bottom up, the query optimizer starts by doing a sequential scan of the `names` table. Notice that the `WHERE` clause is being applied as a *filter* condition. This means that the scan operation checks the condition for each row it scans, and outputs only the ones that pass the condition.

The results of the scan operation are passed up to a *gather motion* operation. In WarehousePG, a gather motion is when segments send rows up to the coordinator. In this case we have 3 segment instances sending to 1 coordinator instance (3:1). This operation is working on `slice1` of the parallel query execution plan. In WarehousePG a query plan is divided into *slices* so that portions of the query plan can be worked on in parallel by the segments.

The estimated startup cost for this plan is `00.00` (no cost) and a total cost of `431.27`. The planner is estimating that this query will return one row.

Here is the same query, with cost estimates suppressed:

```
EXPLAIN (COSTS FALSE) SELECT * FROM names WHERE name = 'Joelle';
               QUERY PLAN
-----------------------------------------
 Gather Motion 3:1  (slice1; segments: 3)
   ->  Seq Scan on names
         Filter: (name = 'Joelle'::text)
 Optimizer: GPORCA
(4 rows)
```

Here is the same query, with JSON formatting:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
EXPLAIN (FORMAT JSON) SELECT * FROM names WHERE name = 'Joelle';
                  QUERY PLAN
-----------------------------------------------
 [                                           +
   {                                         +
     "Plan": {                               +
       "Node Type": "Gather Motion",         +
       "Senders": 3,                         +
       "Receivers": 1,                       +
       "Slice": 1,                           +
       "Segments": 3,                        +
       "Gang Type": "primary reader",        +
       "Startup Cost": 0.00,                 +
       "Total Cost": 431.27,                 +
       "Plan Rows": 1,                       +
       "Plan Width": 58,                     +
       "Plans": [                            +
         {                                   +
           "Node Type": "Seq Scan",          +
           "Parent Relationship": "Outer",   +
           "Slice": 1,                       +
           "Segments": 3,                    +
           "Gang Type": "primary reader",    +
           "Relation Name": "names",         +
           "Alias": "names",                 +
           "Startup Cost": 0.00,             +
           "Total Cost": 431.27,             +
           "Plan Rows": 1,                   +
           "Plan Width": 58,                 +
           "Filter": "(name = 'Joelle'::text)"+
         }                                   +
       ]                                     +
     },                                      +
     "Settings": {                           +
       "Optimizer": "(GPORCA) version 3.23.0"      +
     }                                       +
   }                                         +
 ]
(1 row)
```

If there is an index and we use a query with an indexable `WHERE` condition, `EXPLAIN` might show a different plan. This query generates a plan with an index scan, with YAML formatting:

```
EXPLAIN (FORMAT YAML) SELECT * FROM NAMES WHERE LOCATION='Sydney, Australia';
                         QUERY PLAN
------------------------------------------------------------
 - Plan                                                   +
     Node Type: "Gather Motion"                               +
     Senders: 3                                               +
     Receivers: 1                                             +
     Slice: 1                                                 +
     Segments: 3                                              +
     Gang Type: "primary reader"                              +
     Startup Cost: 0.00                                       +
     Total Cost: 10.81                                        +
     Plan Rows: 10000                                         +
     Plan Width: 70                                           +
     Plans                                                +
       - Node Type: "Index Scan"                              +
         Parent Relationship: "Outer"                         +
         Slice: 1                                             +
         Segments: 3                                          +
         Gang Type: "primary reader"                          +
         Scan Direction: "Forward"                            +
         Index Name: "names_idx_loc"                          +
         Relation Name: "names"                               +
         Alias: "names"                                       +
         Startup Cost: 0.00                                   +
         Total Cost: 7.77                                     +
         Plan Rows: 10000                                     +
         Plan Width: 70                                       +
         Index Cond: "(location = 'Sydney, Australia'::text)"+
   Settings                                               +
     Optimizer: " (GPORCA) version 3.23.0"
(1 row)
```

Compatibility

There is no `EXPLAIN` statement defined in the SQL standard.

7.1.143 FETCH

Retrieves rows from a query using a cursor.

Synopsis

```
FETCH [ <forward_direction> { FROM | IN } ] <cursor_name>
```

where <forward_direction> can be empty or one of:

```
    NEXT
    FIRST
    ABSOLUTE <count>
    RELATIVE <count>
    <count>
    ALL
    FORWARD
    FORWARD <count>
    FORWARD ALL
```

Description

`FETCH` retrieves rows using a previously-created cursor.

> **Note** You cannot `FETCH` from a `PARALLEL RETRIEVE CURSOR`, you must RETRIEVE the rows from it.

A cursor has an associated position, which is used by `FETCH`. The cursor position can be before the first row of the query result, on any particular row of the result, or after the last row of the result. When created, a cursor is positioned before the first row. After fetching some rows, the cursor is positioned on the row most recently retrieved. If `FETCH` runs off the end of the available rows then the cursor is left positioned after the last row. `FETCH ALL` will always leave the cursor positioned after the last row.

> **Note** Because WarehousePG does not support scrollable cursors, it is not possible to move a cursor position backwards. You can only move a cursor forward in position using `FETCH`.

The forms `NEXT`, `FIRST`, `ABSOLUTE`, `RELATIVE` fetch a single row after moving the cursor appropriately. If there is no such row, an empty result is returned, and the cursor is left positioned before the first row or after the last row as appropriate.

The forms using `FORWARD` retrieve the indicated number of rows moving in the forward direction, leaving the cursor positioned on the last-returned row (or after all rows, if the count exceeds the number of rows available).

`RELATIVE 0` and `FORWARD 0` request fetching the current row without moving the cursor, that is, re-fetching the most recently fetched row. This will succeed unless the cursor is positioned before the first row or after the last row, in which case no row is returned.

> **Note** This page describes usage of cursors at the SQL command level. If you are trying to use cursors inside a PL/pgSQL function, the rules are different. SeePL/pgSQL function.

Parameters

forward_direction Defines the fetch direction and number of rows to fetch. Only forward fetches are allowed in WarehousePG. It can be one of the following:

NEXT Fetch the next row. This is the default if direction is omitted.

FIRST Fetch the first row of the query (same as `ABSOLUTE 1`). Only allowed if it is the first `FETCH` operation using this cursor.

ABSOLUTE count Fetch the specified row of the query. Position after last row if count is out of range. Only allowed if the row specified by count moves the cursor position forward.

RELATIVE count Fetch the specified row of the query count rows ahead of the current cursor position. `RELATIVE 0` re-fetches the current row, if any. Only allowed if count moves the cursor position forward.

count Fetch the next count number of rows (same as `FORWARD count`).

ALL Fetch all remaining rows (same as `FORWARD ALL`).

FORWARD Fetch the next row (same as `NEXT`).

FORWARD count Fetch the next count number of rows. `FORWARD 0` re-fetches the current row.

FORWARD ALL Fetch all remaining rows.

cursor_name The name of an open cursor.

Outputs

On successful completion, a `FETCH` command returns a command tag of the form

```
FETCH <count>
```

The count is the number of rows fetched (possibly zero). Note that in `psql`, the command tag will not actually be displayed, since `psql` displays the fetched rows instead.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Notes

WarehousePG does not support scrollable cursors, so you can only use `FETCH` to move the cursor position forward.

`ABSOLUTE` fetches are not any faster than navigating to the desired row with a relative move: the underlying implementation must traverse all the intermediate rows anyway.

`DECLARE` is used to define a cursor. Use `MOVE` to change cursor position without retrieving data.

Examples

Start the transaction:

```
BEGIN;
```

Set up a cursor:

```
DECLARE mycursor CURSOR FOR SELECT * FROM films;
```

Fetch the first 5 rows in the cursor `mycursor`:

```
FETCH FORWARD 5 FROM mycursor;
 code  |          title          | did | date_prod  |   kind   |  len
-------+-------------------------+-----+------------+----------+-------
 BL101 | The Third Man           | 101 | 1949-12-23 | Drama    | 01:44
 BL102 | The African Queen       | 101 | 1951-08-11 | Romantic | 01:43
 JL201 | Une Femme est une Femme | 102 | 1961-03-12 | Romantic | 01:25
 P_301 | Vertigo                 | 103 | 1958-11-14 | Action   | 02:08
 P_302 | Becket                  | 103 | 1964-02-03 | Drama    | 02:28
```

Close the cursor and end the transaction:

```
CLOSE mycursor;
COMMIT;
```

Change the `kind` column of the table `films` in the row at the `c_films` cursor's current position:

```
UPDATE films SET kind = 'Dramatic' WHERE CURRENT OF c_films;
```

Compatibility

SQL standard allows cursors only in embedded SQL and in modules. WarehousePG permits cursors to be used interactively.

The variant of `FETCH` described here returns the data as if it were a `SELECT` result rather than placing it in host variables. Other than this point, `FETCH` is fully upward-compatible with the SQL standard.

The `FETCH` forms involving `FORWARD`, as well as the forms `FETCH` count and `FETCH ALL`, in which `FORWARD` is implicit, are WarehousePG extensions. `BACKWARD` is not supported.

The SQL standard allows only `FROM` preceding the cursor name; the option to use `IN`, or to leave them out altogether, is an extension.

7.1.144 GRANT

Defines access privileges.

Synopsis

```
GRANT { {SELECT | INSERT | UPDATE | DELETE | REFERENCES |
TRIGGER | TRUNCATE } [, ...] | ALL [PRIVILEGES] }
    ON { [TABLE] [[[ONLY] <table_name> [, ...]] [, ...]]
         | ALL TABLES IN SCHEMA <schema_name> [, ...] }
    TO <role_specification> [, ...] [ WITH GRANT OPTION ]

GRANT { { SELECT | INSERT | UPDATE | REFERENCES } ( <column_name> [, ...] )
    [, ...] | ALL [ PRIVILEGES ] ( <column_name> [, ...] ) }
    ON [TABLE] [[[ONLY] <table_name> [, ...]] [, ...]]
    TO <role_specification> [, ...] [ WITH GRANT OPTION ]

GRANT { {USAGE | SELECT | UPDATE} [, ...] | ALL [PRIVILEGES] }
    ON { SEQUENCE <sequence_name> [, ...]
         | ALL SEQUENCES IN SCHEMA <schema_name> [, ...] }
    TO <role_specification> [, ...] [ WITH GRANT OPTION ]

GRANT { {CREATE | CONNECT | TEMPORARY | TEMP} [, ...] | ALL
[PRIVILEGES] }
    ON DATABASE <database_name> [, ...]
    TO <role_specification> [, ...] [ WITH GRANT OPTION ]

GRANT { USAGE | ALL [ PRIVILEGES ] }
    ON DOMAIN <domain_name> [, ...]
    TO <role_specification> [, ...] [ WITH GRANT OPTION ]

GRANT { USAGE | ALL [ PRIVILEGES ] }
    ON FOREIGN DATA WRAPPER <fdw_name> [, ...]
    TO <role_specification> [, ...] [ WITH GRANT OPTION ]

GRANT { USAGE | ALL [ PRIVILEGES ] }
    ON FOREIGN SERVER <server_name> [, ...]
    TO <role_specification> [, ...] [ WITH GRANT OPTION ]

GRANT { EXECUTE | ALL [PRIVILEGES] }
    ON { { FUNCTION | PROCEDURE | ROUTINE } <routine_name> [ ( [ [ <argmode> ] [ <argname> ] <argtype> [, ...] ] ) ] [, ...]
        | ALL { FUNCTIONS | PROCEDURES | ROUTINES }  IN SCHEMA <schema_name> [, ...] }
    TO <role_specification> [, ...] [ WITH GRANT OPTION ]

GRANT { USAGE | ALL [PRIVILEGES] }
    ON LANGUAGE <lang_name> [, ...]
    TO <role_specification> [, ...] [ WITH GRANT OPTION ]

GRANT { { CREATE | USAGE } [, ...] | ALL [PRIVILEGES] }
    ON SCHEMA <schema_name> [, ...]
    TO <role_specification> [, ...] [ WITH GRANT OPTION ]

GRANT { CREATE | ALL [PRIVILEGES] }
    ON TABLESPACE <tablespace_name> [, ...]
    TO <role_specification> [ WITH GRANT OPTION ]

GRANT { USAGE | ALL [ PRIVILEGES ] }
    ON TYPE <type_name> [, ...]
    TO <role_specification> [, ...] [ WITH GRANT OPTION ]

GRANT <role_name> [, ...] TO <role_specification> [, ...]
    [ WITH ADMIN OPTION ]
    [ GRANTED BY <role_specification> ]

GRANT { SELECT | INSERT | ALL [PRIVILEGES] }
    ON PROTOCOL <protocolname>
    TO <username>

where <role_specification> can be:

    [ GROUP ] <role_name>
  | PUBLIC
  | CURRENT_USER
  | SESSION_USER
```

Description

The `GRANT` command has two basic variants: one that grants privileges on a database object (table, column, view, foreign table, sequence, database, foreign-data wrapper, foreign server, function, procedural language, schema, or tablespace), and one that grants membership in a role. These variants are similar in many ways, but they are different enough to be described separately.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

GRANT on Database Objects

This variant of the `GRANT` command gives specific privileges on a database object to one or more roles. These privileges are added to those already granted, if any.

The keyword `PUBLIC` indicates that the privileges are to be granted to all roles, including those that may be created later. `PUBLIC` may be thought of as an implicitly defined group-level role that always includes all roles. Any particular role will have the sum of privileges granted directly to it, privileges granted to any role it is presently a member of, and privileges granted to `PUBLIC`.

If `WITH GRANT OPTION` is specified, the recipient of the privilege may in turn grant it to others. Without a grant option, the recipient cannot do that. Grant options cannot be granted to `PUBLIC`.

There is no need to grant privileges to the owner of an object (usually the role that created it), as the owner has all privileges by default. (The owner could, however, choose to revoke some of their own privileges for safety.) it The right to drop an object, or to alter its definition in any way is not treated as a grantable privilege; it is inherent in the owner, and cannot be granted or revoked. (However, a similar effect can be obtained by granting or revoking membership in the role that owns the object; see below.) The owner implicitly has all grant options for the object, too.

The possible privileges are:

- `SELECT`
- `INSERT`
- `UPDATE`
- `DELETE`
- `TRUNCATE`
- `REFERENCES`
- `TRIGGER`
- `CREATE`
- `CONNECT`
- `TEMPORARY`, `TEMP`
- `EXECUTE`
- `USAGE`
- `ALL PRIVILEGES`

The `FUNCTION` syntax works for plain functions, aggregate functions, and window functions, but not for procedures; use `PROCEDURE` for those. Alternatively, use `ROUTINE` to refer to a function, aggregate function, window function, or procedure regardless of its precise type.

There is also an option to grant privileges on all objects of the same type within one or more schemas. This functionality is currently supported only for tables, sequences, functions, and procedures. `ALL TABLES` also affects views and foreign tables, just like the specific-object `GRANT` command. `ALL FUNCTIONS` also affects aggregate and window functions, but not procedures, again just like the specific-object `GRANT` command. Use `ALL ROUTINES` to include procedures.

GRANT on Roles

This variant of the `GRANT` command grants membership in a role to one or more other roles. Membership in a role is significant because it conveys the privileges granted to a role to each of its members.

If `WITH ADMIN OPTION` is specified, the member may in turn grant membership in the role to others, and revoke membership in the role as well. Without the admin option, ordinary users cannot do that. A role is not considered to hold `WITH ADMIN OPTION` on itself, but it may grant or revoke membership in itself from a database session where the session user matches the role. Database superusers can grant or revoke membership in any role to anyone. Roles having `CREATEROLE` privilege can grant or revoke membership in any role that is not a superuser.

If `GRANTED BY` is specified, the grant is recorded as having been done by the specified role. Only database superusers may use this option, except when it names the same role executing the command.

Unlike the case with privileges, membership in a role cannot be granted to `PUBLIC`. Note also that this form of the command does not allow the noise word `GROUP` in role_specification.

GRANT on Partitioned Tables

By default, when you grant privileges to a partitioned table, WarehousePG recurses the operation to its child tables. To direct WarehousePG to perform the `GRANT` on the partitioned table only, specify the `ONLY <table_name>` clause.

GRANT on Protocols

You can also use the `GRANT` command to specify which users can access a trusted protocol. (If the protocol is not trusted, you cannot give any other user permission to use it to read or write data.)

- To allow a user to create a readable external table with a trusted protocol:

  ```
  GRANT SELECT ON PROTOCOL <protocolname> TO <username>
  ```

- To allow a user to create a writable external table with a trusted protocol:

  ```
  GRANT INSERT ON PROTOCOL <protocolname> TO <username>
  ```

- To allow a user to create both readable and writable external table with a trusted protocol:

  ```
  GRANT ALL ON PROTOCOL <protocolname> TO <username>
  ```

You can also use this command to grant users permissions to create and use `s3` and `pxf` external tables. However, external tables of type `http`, `https`, `gpfdist`, and `gpfdists`, are implemented internally in WarehousePG instead of as custom protocols. For these types, use the `CREATE ROLE` or `ALTER ROLE` command to set the `CREATEEXTTABLE` or `NOCREATEEXTTABLE` attribute for each user. See CREATE ROLE for syntax and examples.

Parameters

SELECT Allows `SELECT` from any column, or the specific columns listed, of the specified table, view, or sequence. Also allows the use of `COPY TO`. This privilege is also needed to reference existing column values in `UPDATE` or `DELETE`.

INSERT Allows `INSERT` of a new row into the specified table. If specific columns are listed, only those columns may be assigned to in the `INSERT` command (other columns will receive default values). Also allows `COPY FROM`.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

UPDATE Allows `UPDATE` of any column, or the specific columns listed, of the specified table. `SELECT ... FOR UPDATE` and `SELECT ... FOR SHARE` also require this privilege on at least one column, (as well as the `SELECT` privilege). For sequences, this privilege allows the use of the `nextval()` and `setval()` functions.

DELETE Allows `DELETE` of a row from the specified table.

REFERENCES This keyword is accepted, although foreign key constraints are currently not supported in WarehousePG. To create a foreign key constraint, it is necessary to have this privilege on both the referencing and referenced columns. The privilege may be granted for all columns of a table, or just specific columns.

TRIGGER Allows the creation of a trigger on the specified table.

```
> **Note** WarehousePG does not support triggers.
```

TRUNCATE Allows `TRUNCATE` of all rows from the specified table.

CREATE For databases, allows new schemas to be created within the database.

For schemas, allows new objects to be created within the schema. To rename an existing object, you must own the object and have this privilege for the containing schema.

For tablespaces, allows tables and indexes to be created within the tablespace, and allows databases to be created that have the tablespace as their default tablespace. (Note that revoking this privilege will not alter the placement of existing objects.)

CONNECT Allows the user to connect to the specified database. This privilege is checked at connection startup (in addition to checking any restrictions imposed by `pg_hba.conf`).

TEMPORARY TEMP Allows temporary tables to be created while using the database.

EXECUTE Allows the use of the specified function and the use of any operators that are implemented on top of the function. This is the only type of privilege that is applicable to functions. (This syntax works for aggregate functions, as well.)

USAGE For procedural languages, allows the use of the specified language for the creation of functions in that language. This is the only type of privilege that is applicable to procedural languages.

For schemas, allows access to objects contained in the specified schema (assuming that the objects' own privilege requirements are also met). Essentially this allows the grantee to look up objects within the schema.

For sequences, this privilege allows the use of the `currval()` and `nextval()` function.

For types and domains, this privilege allows the use of the type or domain in the creation of tables, functions, and other schema objects. (Note that it does not control general "usage" of the type, such as values of the type appearing in queries. It only prevents objects from being created that depend on the type. The main purpose of the privilege is controlling which users create dependencies on a type, which could prevent the owner from changing the type later.)

For foreign-data wrappers, this privilege enables the grantee to create new servers using that foreign-data wrapper.

For servers, this privilege enables the grantee to create foreign tables using the server, and also to create, alter, or drop their own user's user mappings associated with that server.

ALL PRIVILEGES Grant all of the available privileges at once. The `PRIVILEGES` key word is optional in WarehousePG, though it is required by strict SQL.

PUBLIC A special group-level role that denotes that the privileges are to be granted to all roles, including those that may be created later.

WITH GRANT OPTION The recipient of the privilege may in turn grant it to others.

WITH ADMIN OPTION The member of a role may in turn grant membership in the role to others.

Notes

The REVOKE command is used to revoke access privileges.

WarehousePG unifies the concepts of users and groups into a single kind of entity called a role. It is therefore not necessary to use the keyword `GROUP` to identify whether a grantee is a user or a group. `GROUP` is still allowed in the command, but it is a noise word.

A user may perform `SELECT`, `INSERT`, and so forth, on a column if they hold that privilege for either the specific column or the whole table. Granting the privilege at the table level and then revoking it for one column does not do what you might wish: the table-level grant is unaffected by a column-level operation.

When a non-owner of an object attempts to `GRANT` privileges on the object, the command will fail outright if the user has no privileges whatsoever on the object. As long as some privilege is available, the command will proceed, but it will grant only those privileges for which the user has grant options. The `GRANT ALL PRIVILEGES` forms will issue a warning message if no grant options are held, while the other forms will issue a warning if grant options for any of the privileges specifically named in the command are not held. (In principle these statements apply to the object owner as well, but since the owner is always treated as holding all grant options, the cases can never occur.)

Database superusers can access all objects regardless of object privilege settings. This is comparable to the rights of `root` in a Unix system. As with `root`, it's unwise to operate as a superuser except when absolutely necessary. One exception to this rule is view objects. Access to tables referenced in the view is determined by permissions of the view owner not the current user (even if the current user is a superuser).

If a superuser chooses to issue a `GRANT` or `REVOKE` command, the command is performed as though it were issued by the owner of the affected object. In particular, privileges granted via such a command will appear to have been granted by the object owner. (For role membership, the membership appears to have been granted by the containing role itself.)

`GRANT` and `REVOKE` can also be done by a role that is not the owner of the affected object, but is a member of the role that owns the object, or is a member of a role that holds privileges `WITH GRANT OPTION` on the object. In this case the privileges will be recorded as having been granted by the role that actually owns the object or holds the privileges `WITH GRANT OPTION`. For example, if table `t1` is owned by role `g1`, of which role `u1` is a member, then `u1` can grant privileges on `t1` to `u2`, but those privileges will appear to have been granted directly by `g1`. Any other member of role `g1` could revoke them later.

If the role executing `GRANT` holds the required privileges indirectly via more than one role membership path, it is unspecified which containing role will be recorded as having done the grant. In such cases it is best practice to use `SET ROLE` to become the specific role you want to do the `GRANT` as.

Granting permission on a table does not automatically extend permissions to any sequences used by the table, including sequences tied to `SERIAL` columns. Permissions on a sequence must be set separately.

The `GRANT` command cannot be used to set privileges for the protocols `file`, `gpfdist`, or `gpfdists`. These protocols are implemented internally in WarehousePG. Instead, use the CREATE ROLE or ALTER ROLE command to set the `CREATEEXTTABLE` attribute for the role.

Use `psql`'s `\dp` meta-command to obtain information about existing privileges for tables and columns. There are other `\d` meta-commands that you can use to display the privileges of non-table objects.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Examples

Grant insert privilege to all roles on table `mytable`:

```
GRANT INSERT ON mytable TO PUBLIC;
```

Grant all available privileges to user `manuel` on view `kinds`:

```
GRANT ALL PRIVILEGES ON kinds TO manuel;
```

Note that while the above will indeed grant all privileges if run by a superuser or the owner of `kinds`, when run by someone else it will only grant those permissions for which the granting role has grant options.

Grant membership in role `admins` to user `joe`:

```
GRANT admins TO joe;
```

Compatibility

According to the SQL standard, the `PRIVILEGES` key word in `ALL PRIVILEGES` is required, but it is optional in WarehousePG. The SQL standard does not support setting the privileges on more than one object per command.

WarehousePG allows an object owner to revoke their own ordinary privileges: for example, a table owner can make the table read-only to theirself by revoking their own `INSERT`, `UPDATE`, `DELETE`, and `TRUNCATE` privileges. This is not possible according to the SQL standard. WarehousePG treats the owner's privileges as having been granted by the owner to the owner; therefore they can revoke them too. In the SQL standard, the owner's privileges are granted by an assumed *system* entity. Not being *system*, the owner cannot revoke these rights.

The SQL standard allows the `GRANTED BY` option to be used in all forms of `GRANT`. WarehousePG only supports it when granting role membership, and even then only superusers may use it in nontrivial ways.

The SQL standard provides for a `USAGE` privilege on other kinds of objects: character sets, collations, translations.

In the SQL standard, sequences only have a `USAGE` privilege, which controls the use of the `NEXT VALUE FOR` expression, which is equivalent to the function `nextval()` in WarehousePG. The sequence privileges `SELECT` and `UPDATE` are WarehousePG extensions. The application of the sequence `USAGE` privilege to the `currval()` function is also a WarehousePG extension (as is the function itself).

Privileges on databases, tablespaces, schemas, and languages are WarehousePG extensions.

7.1.145 IMPORT FOREIGN SCHEMA

Imports table definitions from a foreign server.

Synopsis

```
IMPORT FOREIGN SCHEMA <remote_schema>
    [ { LIMIT TO | EXCEPT } ( <table_name> [, ...] ) ]
    FROM SERVER <server_name>
    INTO <local_schema>
    [ OPTIONS ( <option> '<value>' [, ... ] ) ]
```

Description

`IMPORT FOREIGN SCHEMA` creates foreign tables that represent tables existing on a foreign server. The new foreign tables will be owned by the user issuing the command and are created with the correct column definitions and options to match the remote tables.

By default, all tables and views existing in a particular schema on the foreign server are imported. Optionally, the list of tables can be limited to a specified subset, or specific tables can be excluded. The new foreign tables are all created in the target schema, which must already exist.

To use `IMPORT FOREIGN SCHEMA`, the user must have `USAGE` privilege on the foreign server, as well as `CREATE` privilege on the target schema.

Support for importing foreign schemas is foreign-data wrapper-specific.

Parameters

remote_schema The remote schema to import from. The specific meaning of a remote schema depends on the foreign data wrapper in use.

LIMIT TO (table_name [, ...]) Import only foreign tables matching one of the given table names. Other tables existing in the foreign schema will be ignored.

EXCEPT (table_name [, ...]) Exclude specified foreign tables from the import. All tables existing in the foreign schema will be imported except the ones listed here.

server_name The name of the foreign server from which to import the table definitions.

local_schema The schema in which WarehousePG will create the imported foreign tables.

OPTIONS (option 'value' [, ...]) The options to be used during the import. The allowed option names and values are specific to each foreign-data wrapper.

Examples

Import table definitions from a remote schema `foreign_films` on server `film_server`, creating the foreign tables in local schema `films`:

```
IMPORT FOREIGN SCHEMA foreign_films
    FROM SERVER film_server INTO films;
```

As above, but import only the two tables `actors` and `directors` (if they exist):

```
IMPORT FOREIGN SCHEMA foreign_films LIMIT TO (actors, directors)
    FROM SERVER film_server INTO films;
```

Compatibility

The `IMPORT FOREIGN SCHEMA` command conforms to the SQL standard, except that the `OPTIONS` clause is a WarehousePG extension.

7.1.146 INSERT

Creates new rows in a table.

Synopsis

```
[ WITH [ RECURSIVE ] <with_query> [, ...] ]
INSERT INTO <table_name> [ AS <alias> ] [( <column_name> [, ...] )]
   [ OVERRIDING { SYSTEM | USER } VALUE ]
   {DEFAULT VALUES | VALUES ( {<expression> | DEFAULT} [, ...] ) [, ...] | <query>}
   [ ON CONFLICT [ <conflict_target> ] <conflict_action> ]
   [RETURNING * | <output_expression> [ [AS] <output_name> ] [, ...]]

where <conflict_target> can be one of:

    ( { <index_column_name> | ( <index_expression> ) } [ COLLATE <collation> ] [ <opclass> ] [, ...] )
    [ WHERE <index_predicate> ]
    ON CONSTRAINT <constraint_name>

and <conflict_action> is one of:

    DO NOTHING
    DO UPDATE SET { <column_name> = { <expression> | DEFAULT } |
                    ( <column_name> [, ...] ) = [ ROW ] ( { <expression> | DEFAULT } [, ...] ) |
                    ( <column_name> [, ...] ) = ( sub-SELECT )
                  } [, ...]
              [ WHERE <condition> ]
```

Description

`INSERT` inserts new rows into a table. One can insert one or more rows specified by value expressions, or zero or more rows resulting from a query.

The target column names may be listed in any order. If no list of column names is given at all, the default is the columns of the table in their declared order; or the first *N* column names, if there are only *N* columns supplied by the `VALUES` clause or query. The values supplied by the `VALUES` clause or query are associated with the explicit or implicit column list left-to-right.

Each column not present in the explicit or implicit column list will be filled with a default value, either its declared default value or null if there is no default.

If the expression for any column is not of the correct data type, WarehousePG attempts automatic type conversion.

`INSERT` into tables that lack unique indexes will not be blocked by concurrent activity. Tables with unique indexes might block if concurrent sessions perform actions that lock or modify rows matching the unique index values being inserted; the details are covered in Index Uniqueness Checks in the PostgreSQL documentation. `ON CONFLICT` can be used to specify an alternative action to raising a unique constraint or exclusion constraint violation error. (See ON CONFLICT Clause below.)

The optional `RETURNING` clause causes `INSERT` to compute and return value(s) based on each row actually inserted (or updated, if an `ON CONFLICT DO UPDATE` clause was used). This is primarily useful for obtaining values that were supplied by defaults, such as a serial sequence number. However, any expression using the table's columns is allowed. The syntax of the `RETURNING` list is identical to that of the output list of `SELECT`. Only rows that were successfully inserted or updated will be returned. For example, if a row was locked but not updated because an `ON CONFLICT DO UPDATE ... WHERE` clause condition was not satisfied, the row will not be returned.

You must have `INSERT` privilege on a table in order to insert into it. If `ON CONFLICT DO UPDATE` is present, `UPDATE` privilege on the table is also required.

When a column list is specified, you only need `INSERT` privilege on the listed columns. Similarly, when `ON CONFLICT DO UPDATE` is specified, you only need `UPDATE` privilege on the column(s) that are listed to be updated. However, `ON CONFLICT DO UPDATE` also requires `SELECT` privilege on any column whose values are read in the `ON CONFLICT DO UPDATE` expressions or condition.

Use of the `RETURNING` clause requires `SELECT` privilege on all columns mentioned in `RETURNING`. If you use the query clause to insert rows from a query, you must have `SELECT` privilege on any table or column referenced in the query.

Parameters

Inserting

This section covers parameters that may be used when only inserting new rows. Parameters exclusively used with the `ON CONFLICT` clause are described separately.

with_query The `WITH` clause allows you to specify one or more subqueries that can be referenced by name in the `INSERT` query. See WITH Queries (Common Table Expressions) and SELECT for details.

It is possible for the query (`SELECT` statement) to also contain a `WITH` clause. In such a case both sets of with_query can be referenced within the `INSERT` query, but the second one takes precedence since it is more closely nested.

table_name The name (optionally schema-qualified) of an existing table.

alias A substitute name for table_name. When an alias is provided, it completely hides the actual name of the table. This is particularly useful when `ON CONFLICT DO UPDATE` targets a table named `excluded`, since that will otherwise be taken as the name of the special table representing the row proposed for insertion.

column_name The name of a column in the table named by table_name. The column name can be qualified with a subfield name or array subscript, if needed. (Inserting into only some fields of a composite column leaves the other fields null.) When referencing a column with `ON CONFLICT DO UPDATE`, do not include the table's name in the specification of a target column. For example, `INSERT INTO table_name ... ON CONFLICT DO UPDATE SET table_name.col = 1` is invalid (this follows the general behavior for `UPDATE`).

OVERRIDING SYSTEM VALUE Without this clause, it is an error to specify an explicit value (other than `DEFAULT`) for an identity column defined as `GENERATED ALWAYS`. This clause overrides that restriction.

OVERRIDING USER VALUE If this clause is specified, then any values supplied for identity columns defined as `GENERATED BY DEFAULT` are ignored and the default sequence-generated values are applied.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

This clause is useful for example when copying values between tables. Writing `INSERT INTO tbl2 OVERRIDING USER VALUE SELECT * FROM tbl1` will copy from `tbl1` all columns that are not identity columns in `tbl2` while values for the identity columns in `tbl2` will be generated by the sequences associated with `tbl2`.

DEFAULT VALUES All columns will be filled with their default values. (An `OVERRIDING` clause is not permitted in this form.)

expression An expression or value to assign to the corresponding column.

DEFAULT The corresponding column will be filled with its default value.

query A query (`SELECT` statement) that supplies the rows to be inserted. Refer to the SELECT statement for a description of the syntax.

output_expression An expression to be computed and returned by the `INSERT` command after each row is inserted or updated. The expression can use any column names of the table named by table_name. Write `*` to return all columns of the inserted row(s).

output_name A name to use for a returned column.

To insert data into a partitioned table, you specify the root partitioned table, the table created with the `CREATE TABLE` command. You also can specify a leaf partition in an `INSERT` command. An error is returned if the data is not valid for the specified leaf partition.

For a partitioned table, all the child tables are locked during the `INSERT` operation when the Global Deadlock Detector is not enabled (the default). Only some of the leaf partitions are locked when the Global Deadlock Detector is enabled. For information about the Global Deadlock Detector, see Global Deadlock Detector.

ON CONFLICT Clause

The optional `ON CONFLICT` clause specifies an alternative action to raising a unique violation or exclusion constraint violation error. For each individual row proposed for insertion, either the insertion proceeds, or, if an arbiter constraint or index specified by conflict_target is violated, the alternative conflict_action is taken. `ON CONFLICT DO NOTHING` simply avoids inserting a row as its alternative action. `ON CONFLICT DO UPDATE` updates the existing row that conflicts with the row proposed for insertion as its alternative action.

conflict_target can perform unique index inference. When performing inference, it consists of one or more index_column_name columns and/or index_expression expressions, and an optional index_predicate. All table_name unique indexes that, without regard to order, contain exactly the conflict_target-specified columns/expressions are inferred (chosen) as arbiter indexes. If an index_predicate is specified, it must, as a further requirement for inference, satisfy arbiter indexes. Note that this means a non-partial unique index (a unique index without a predicate) will be inferred (and thus used by `ON CONFLICT`) if such an index satisfying every other criteria is available. If an attempt at inference is unsuccessful, WarehousePG raises an error.

`ON CONFLICT DO UPDATE` guarantees an atomic `INSERT` or `UPDATE` outcome; provided there is no independent error, one of those two outcomes is guaranteed, even under high concurrency. This is also known as *UPSERT*—`UPDATE` or `INSERT`.

> **NOTE** `ON CONFLICT DO UPDATE` (or `UPSERT`) is available for heap tables only.

conflict_target Specifies which conflicts `ON CONFLICT` takes the alternative action on by choosing arbiter indexes. Either performs unique index inference, or names a constraint explicitly. For `ON CONFLICT DO NOTHING`, it is optional to specify a conflict_target; when omitted, conflicts with all usable constraints (and unique indexes) are handled. For `ON CONFLICT DO UPDATE`, a conflict_target must be provided.

conflict_action conflict_action specifies an alternative `ON CONFLICT` action. It can be either `DO NOTHING`, or a `DO UPDATE` clause specifying the exact details of the `UPDATE` action to be performed in case of a conflict. The `SET` and `WHERE` clauses in `ON CONFLICT DO UPDATE` have access to the existing row using the table's name (or an alias), and to the row proposed for insertion using the special excluded table. `SELECT` privilege is required on any column in the target table where corresponding excluded columns are read.

Note that the effects of all per-row `BEFORE INSERT` triggers are reflected in excluded values, since those effects may have contributed to the row being excluded from insertion.

index_column_name The name of a table_name column. Used to infer arbiter indexes. Follows `CREATE INDEX` format. `SELECT` privilege on index_column_name is required.

index_expression Similar to index_column_name, but used to infer expressions on table_name columns appearing within index definitions (not simple columns). Follows `CREATE INDEX` format. `SELECT` privilege on any column appearing within index_expression is required.

collation When specified, mandates that corresponding index_column_name or index_expression use a particular collation in order to be matched during inference. Typically this is omitted, as collations usually do not affect whether or not a constraint violation occurs. Follows `CREATE INDEX` format.

opclass When specified, mandates that corresponding index_column_name or index_expression use particular operator class in order to be matched during inference. Typically this is omitted, as the equality semantics are often equivalent across a type's operator classes anyway, or because it's sufficient to trust that the defined unique indexes have the pertinent definition of equality. Follows `CREATE INDEX` format.

index_predicate Used to allow inference of partial unique indexes. Any indexes that satisfy the predicate (which need not actually be partial indexes) can be inferred. Follows `CREATE INDEX` format. `SELECT` privilege on any column appearing within index_predicate is required.

constraint_name Explicitly specifies an arbiter constraint by name, rather than inferring a constraint or index.

condition An expression that returns a value of type `boolean`. Only rows for which this expression returns `true` will be updated, although all rows will be locked when the `ON CONFLICT DO UPDATE` action is taken. Note that condition is evaluated last, after a conflict has been identified as a candidate to update.

Note that exclusion constraints are not supported as arbiters with `ON CONFLICT DO UPDATE`. In all cases, only `NOT DEFERRABLE` constraints and unique indexes are supported as arbiters.

`INSERT` with an `ON CONFLICT DO UPDATE` clause is a "deterministic" statement. This means that the command will not be allowed to affect any single existing row more than once; a cardinality violation error will be raised when this situation arises. Rows proposed for insertion should not duplicate each other in terms of attributes constrained by an arbiter index or constraint.

Note that it is currently not supported for the `ON CONFLICT DO UPDATE` clause of an `INSERT` applied to a partitioned table to update the partition key of a conflicting row such that it requires the row be moved to a new partition.

Tip: It is often preferable to use unique index inference rather than naming a constraint directly using `ON CONFLICT ON CONSTRAINT constraint_name`. Inference will continue to work correctly when the underlying index is replaced by another more or less equivalent index in an overlapping way, for example when using `CREATE UNIQUE INDEX ... CONCURRENTLY` before dropping the index being replaced.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Outputs

On successful completion, an `INSERT` command returns a command tag of the form:

```
INSERT <oid> <count>
```

The count is the number of rows inserted or updated. oid is always `0` (it used to be the OID assigned to the inserted row if count was exactly one and the target table was declared `WITH OIDS` and 0 otherwise, but creating a table `WITH OIDS` is no longer supported).

If the `INSERT` command contains a `RETURNING` clause, the result will be similar to that of a `SELECT` statement containing the columns and values defined in the `RETURNING` list, computed over the row(s) inserted or updated by the command.

Notes

If the specified table is a partitioned table, WarehousePG routes each row to the appropriate partition and inserts into it. If the specified table is a partition, an error will occur if one of the input rows violates the partition constraint.

For a partitioned table, all of the child tables are locked during the `INSERT` operation when the Global Deadlock Detector is not enabled (the default). Only some of the leaf child tables are locked when the Global Deadlock Detector is enabled. For information about the Global Deadlock Detector, see Global Deadlock Detector.

WarehousePG supports a maximum of 127 concurrent `INSERT` transactions into a single append-optimized table.

Examples

Insert a single row into table `films`:

```
INSERT INTO films VALUES
    ('UA502', 'Bananas', 105, '1971-07-13', 'Comedy', '82 minutes');
```

In this example, the `len` column is omitted and therefore it will have the default value:

```
INSERT INTO films (code, title, did, date_prod, kind)
    VALUES ('T_601', 'Yojimbo', 106, '1961-06-16', 'Drama');
```

This example uses the `DEFAULT` clause for the `date_prod` column rather than specifying a value:

```
INSERT INTO films VALUES
    ('UA502', 'Bananas', 105, DEFAULT, 'Comedy', '82 minutes');
INSERT INTO films (code, title, did, date_prod, kind)
    VALUES ('T_601', 'Yojimbo', 106, DEFAULT, 'Drama');
```

To insert a row consisting entirely of default values:

```
INSERT INTO films DEFAULT VALUES;
```

To insert multiple rows using the multirow `VALUES` syntax:

```
INSERT INTO films (code, title, did, date_prod, kind) VALUES
    ('B6717', 'Tampopo', 110, '1985-02-10', 'Comedy'),
    ('HG120', 'The Dinner Game', 140, DEFAULT, 'Comedy');
```

This example inserts some rows into table `films` from a table `tmp_films` with the same column layout as `films`:

```
INSERT INTO films SELECT * FROM tmp_films WHERE date_prod <
'2004-05-07';
```

This example inserts into array columns:

```
-- Create an empty 3x3 gameboard for noughts-and-crosses
INSERT INTO tictactoe (game, board[1:3][1:3])
    VALUES (1, '{{" "," "," "},{" "," "," "},{" "," "," "}}');
-- The subscripts in the above example aren't really needed
INSERT INTO tictactoe (game, board)
    VALUES (2, '{{X," "," "},{" ",O," "},{" ",X," "}}');
```

Insert a single row into table distributors, returning the sequence number generated by the DEFAULT clause:

```
INSERT INTO distributors (did, dname) VALUES (DEFAULT, 'XYZ Widgets')
   RETURNING did;
```

Increment the sales count of the salesperson who manages the account for Acme Corporation, and record the whole updated row along with current time in a log table:

```
WITH upd AS (
  UPDATE employees SET sales_count = sales_count + 1 WHERE id =
    (SELECT sales_person FROM accounts WHERE name = 'Acme Corporation')
    RETURNING *
)
INSERT INTO employees_log SELECT *, current_timestamp FROM upd;
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Insert or update new distributors as appropriate. Assumes a unique index has been defined that constrains values appearing in the `did` column. Note that the special `excluded` table is used to reference values originally proposed for insertion:

```
INSERT INTO distributors (did, dname)
    VALUES (5, 'Gizmo Transglobal'), (6, 'Associated Computing, Inc')
    ON CONFLICT (did) DO UPDATE SET dname = EXCLUDED.dname;
```

Insert a distributor, or do nothing for rows proposed for insertion when an existing, excluded row (a row with a matching constrained column or columns after before row insert triggers fire) exists. Example assumes a unique index has been defined that constrains values appearing in the `did` column:

```
INSERT INTO distributors (did, dname) VALUES (7, 'Redline GmbH')
    ON CONFLICT (did) DO NOTHING;
```

Insert or update new distributors as appropriate. Example assumes a unique index has been defined that constrains values appearing in the `did` column. `WHERE` clause is used to limit the rows actually updated (any existing row not updated will still be locked, though):

```
-- Don't update existing distributors based in a certain ZIP code
INSERT INTO distributors AS d (did, dname) VALUES (8, 'Anvil Distribution')
    ON CONFLICT (did) DO UPDATE
    SET dname = EXCLUDED.dname || ' (formerly ' || d.dname || ')'
    WHERE d.zipcode <> '21201';

-- Name a constraint directly in the statement (uses associated
-- index to arbitrate taking the DO NOTHING action)
INSERT INTO distributors (did, dname) VALUES (9, 'Antwerp Design')
    ON CONFLICT ON CONSTRAINT distributors_pkey DO NOTHING;
```

Insert new distributor if possible; otherwise `DO NOTHING`. Example assumes a unique index has been defined that constrains values appearing in the `did` column on a subset of rows where the `is_active` Boolean column evaluates to `true`:

```
-- This statement could infer a partial unique index on "did"
-- with a predicate of "WHERE is_active", but it could also
-- just use a regular unique constraint on "did"
INSERT INTO distributors (did, dname) VALUES (10, 'Conrad International')
    ON CONFLICT (did) WHERE is_active DO NOTHING;
```

Compatibility

`INSERT` conforms to the SQL standard, except that the `RETURNING` clause is a WarehousePG extension, as is the ability to use `WITH` with `INSERT`, and the ability to specify an alternative action with `ON CONFLICT`. Also, the case in which a column name list is omitted, but not all of the columns are filled from the `VALUES` clause or query, is disallowed by the standard.

The SQL standard specifies that `OVERRIDING SYSTEM VALUE` can only be specified if an identity column that is generated always exists. WarehousePG allows the clause in any case and ignores it if it is not applicable.

Possible limitations of the query clause are documented under SELECT.

7.1.147 LISTEN

Listens for a notification.

Synopsis

```
LISTEN <channel>
```

Description

`LISTEN` registers the current session as a listener on the notification channel named channel. If the current session is already registered as a listener for this notification channel, nothing is done.

Whenever the command `NOTIFY <channel>` is invoked, either by this session or another one connected to the same database, all of the sessions currently listening on that notification channel are notified, and each will in turn notify its connected client application.

A session can be unregistered for a given notification channel with the `UNLISTEN` command. A session's listen registrations are automatically cleared when the session ends.

The method a client application must use to detect notification events depends on which PostgreSQL application programming interface it uses. With the `libpq` library, the application issues `LISTEN` as an ordinary SQL command, and then must periodically call the function `PQnotifies()` to find out whether any notification events have been received. Other interfaces such as `libpgtcl` provide higher-level methods for handling notify events; indeed, with `libpgtcl` the application programmer should not even issue `LISTEN` or `UNLISTEN` directly. Refer to the documentation for the interface that you are using for more details.

NOTIFY contains a more extensive discussion of the use of `LISTEN` and `NOTIFY`.

Parameters

channel The name of a notification channel (any identifier).

Notes

`LISTEN` takes effect at transaction commit. If `LISTEN` or `UNLISTEN` is run within a transaction that later rolls back, the set of notification channels being listened to is unchanged.

A transaction that has executed `LISTEN` cannot be prepared for two-phase commit.

Examples

Configure and execute a listen/notify sequence from `psql`:

```
LISTEN virtual;
NOTIFY virtual;
Asynchronous notification "virtual" received from server process with PID 8448.
```

Compatibility

There is no `LISTEN` statement in the SQL standard.

7.1.148 LOAD

Loads or reloads a shared library file.

Synopsis

```
LOAD '<filename>'
```

Description

This command loads a shared library file into the WarehousePG server address space. If the file had been loaded previously, it is first unloaded. This command is primarily useful to unload and reload a shared library file that has been changed since the server first loaded it. To make use of the shared library, function(s) in it need to be declared using the `CREATE FUNCTION` command.

The library file name is typically given as just a bare file name, which is sought in the server's library search path (set by `dynamic_library_path`). Alternatively it can be given as a full path name. In either case the platform's standard shared library file name extension may be omitted.

Note that in WarehousePG the shared library file (`.so` file) must reside in the same path location on every host in the WarehousePG cluster (coordinators, segments, and mirrors).

Non-superusers can only apply `LOAD` to library files located in `$libdir/plugins/` — the specified `filename` must begin with exactly that string. You must ensure that only "safe" libraries are installed there.

Parameters

filename The path and file name of a shared library file. This file must exist in the same location on all hosts in your WarehousePG cluster.

Examples

Load a shared library file:

```
LOAD '/usr/edb/whpg7/lib/myfuncs.so';
```

Compatibility

`LOAD` is a WarehousePG extension.

7.1.149 LOCK

Locks a table.

Synopsis

```
LOCK [TABLE] [ONLY] name [ * ] [, ...] [IN <lockmode> MODE] [NOWAIT] [COORDINATOR ONLY]
```

where lockmode is one of:

```
    ACCESS SHARE | ROW SHARE | ROW EXCLUSIVE | SHARE UPDATE EXCLUSIVE
  | SHARE | SHARE ROW EXCLUSIVE | EXCLUSIVE | ACCESS EXCLUSIVE
```

Description

`LOCK TABLE` obtains a table-level lock, waiting if necessary for any conflicting locks to be released. If `NOWAIT` is specified, `LOCK TABLE` does not wait to acquire the desired lock: if it cannot be acquired immediately, the command is stopped and an error is emitted. Once obtained, the lock is held for the remainder of the current transaction. There is no `UNLOCK TABLE` command; locks are always released at transaction end.

When acquiring locks automatically for commands that reference tables, WarehousePG always uses the least restrictive lock mode possible. `LOCK TABLE` provides for cases when you might need more restrictive locking. For example, suppose an application runs a transaction at the `READ COMMITTED` isolation level and needs to ensure that data in a table remains stable for the duration of the transaction. To achieve this you could obtain `SHARE` lock mode over the table before querying. This will prevent concurrent data changes and ensure subsequent reads of the table see a stable view of committed data, because `SHARE` lock mode conflicts with the `ROW EXCLUSIVE` lock acquired by writers, and your `LOCK TABLE <name> IN SHARE MODE` statement will wait until any concurrent holders of `ROW EXCLUSIVE` mode locks commit or rolls back. Thus, once you obtain the lock, there are no uncommitted writes outstanding; furthermore none can begin until you release the lock.

To achieve a similar effect when running a transaction at the `REPEATABLE READ` or `SERIALIZABLE` isolation level, you have to run the `LOCK TABLE` statement before running any `SELECT` or data modification statement. A `REPEATABLE READ` or `SERIALIZABLE` transaction's view of data will be frozen when its first `SELECT` or data modification statement begins. A `LOCK TABLE` later in the transaction will still prevent concurrent writes — but it won't ensure that what the transaction reads corresponds to the latest committed values.

If a transaction of this sort is going to change the data in the table, then it should use `SHARE ROW EXCLUSIVE` lock mode instead of `SHARE` mode. This ensures that only one transaction of this type runs at a time. Without this, a deadlock is possible: two transactions might both acquire `SHARE` mode, and then be unable to also acquire `ROW EXCLUSIVE` mode to actually perform their updates. Note that a transaction's own locks never conflict, so a transaction can acquire `ROW EXCLUSIVE` mode when it holds `SHARE` mode — but not if anyone else holds `SHARE` mode. To avoid deadlocks, make sure all transactions acquire locks on the same objects in the same order, and if multiple lock modes are involved for a single object, then transactions should always acquire the most restrictive mode first.

Parameters

name The name (optionally schema-qualified) of an existing table to lock. If `ONLY` is specified, only that table is locked. If `ONLY` is not specified, the table and all its descendant tables (if any) are locked. Optionally, `*` can be specified after the table name to explicitly indicate that descendant tables are included.

If multiple tables are given, tables are locked one-by-one in the order specified in the `LOCK TABLE` command.

lockmode The lock mode specifies which locks this lock conflicts with. If no lock mode is specified, then `ACCESS EXCLUSIVE`, the most restrictive mode, is used. Lock modes are as follows:

```
-   ACCESS SHARE — Conflicts with the `ACCESS EXCLUSIVE` lock mode only. The `SELECT` command acquires a lock of this mode on referenced tables. In general, any
query that only reads a table and does not modify it will acquire this lock mode.
-   ROW SHARE — Conflicts with the `EXCLUSIVE` and `ACCESS EXCLUSIVE` lock modes. The `SELECT FOR SHARE` command automatically acquires a lock of this mode on the
target table\(s\) \(in addition to `ACCESS SHARE` locks on any other tables that are referenced but not selected `FOR SHARE`\).
-   ROW EXCLUSIVE — Conflicts with the `SHARE`, `SHARE ROW EXCLUSIVE`, `EXCLUSIVE`, and `ACCESS EXCLUSIVE` lock modes. The commands `INSERT` and `COPY`
automatically acquire this lock mode on the target table \(in addition to `ACCESS SHARE` locks on any other referenced tables\) See [Note](#lock_note).
-   SHARE UPDATE EXCLUSIVE — Conflicts with the `SHARE UPDATE EXCLUSIVE`, `SHARE`, `SHARE ROW EXCLUSIVE`, `EXCLUSIVE`, and `ACCESS EXCLUSIVE` lock modes. This
mode protects a table against concurrent schema changes and `VACUUM` runs. Acquired by `VACUUM` \(without `FULL`\) on heap tables and `ANALYZE`.
-   SHARE — Conflicts with the `ROW EXCLUSIVE`, `SHARE UPDATE EXCLUSIVE`, `SHARE ROW EXCLUSIVE, EXCLUSIVE`, and `ACCESS EXCLUSIVE` lock modes. This mode protects
a table against concurrent data changes. Acquired automatically by `CREATE INDEX`.
-   SHARE ROW EXCLUSIVE — Conflicts with the `ROW EXCLUSIVE`, `SHARE UPDATE EXCLUSIVE`, `SHARE`, `SHARE ROW EXCLUSIVE`, `EXCLUSIVE`, and `ACCESS EXCLUSIVE` lock
modes. This mode protects a table against concurrent data changes, and is self-exclusive so that only one session can hold it at a time. This lock mode is not
automatically acquired by any WarehousePG command.
-   EXCLUSIVE — Conflicts with the `ROW SHARE`, `ROW EXCLUSIVE`, `SHARE UPDATE EXCLUSIVE`, `SHARE`, `SHARE ROW EXCLUSIVE`, `EXCLUSIVE`, and `ACCESS EXCLUSIVE`
lock modes. This mode allows only concurrent `ACCESS SHARE` locks, i.e., only reads from the table can proceed in parallel with a transaction holding this lock
mode. This lock mode is automatically acquired for `UPDATE`, `SELECT FOR UPDATE`, and `DELETE` in WarehousePG \(which is more restrictive locking than in regular
PostgreSQL\). See [Note](#lock_note).
-   ACCESS EXCLUSIVE — Conflicts with locks of all modes \(`ACCESS SHARE`, `ROW SHARE`, `ROW EXCLUSIVE`, `SHARE UPDATE EXCLUSIVE`, `SHARE`, `SHARE ROW EXCLUSIVE`,
`EXCLUSIVE`, and `ACCESS EXCLUSIVE`\). This mode guarantees that the holder is the only transaction accessing the table in any way. Acquired automatically by the
`ALTER TABLE`, `DROP TABLE`, `TRUNCATE`, `REINDEX`, `CLUSTER`, and `VACUUM FULL` commands. This is the default lock mode for `LOCK TABLE` statements that do not
specify a mode explicitly. This lock is also briefly acquired by `VACUUM` \(without `FULL`\) on append-optimized tables during processing.

> **Note** As the default, WarehousePG acquires an `EXCLUSIVE` lock on tables for `DELETE`, `UPDATE`, and `SELECT FOR UPDATE` operations on heap tables. When the
Global Deadlock Detector is enabled, the lock mode for the operations on heap tables is `ROW EXCLUSIVE`. See [Global Deadlock Detector]
(../../admin_guide/dml.html#topic_gdd).
```

NOWAIT Specifies that `LOCK TABLE` should not wait for any conflicting locks to be released: if the specified lock(s) cannot be acquired immediately without waiting, the transaction is cancelled.

COORDINATOR ONLY Specifies that when a `LOCK TABLE` command is issued, WarehousePG will lock tables on the coordinator only, rather than on the coordinator and all of the segments. This is particularly useful for metadata-only operations.

```
<br/><br/>> **Note** This option is only supported in `ACCESS SHARE MODE`.
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Notes

`LOCK TABLE ... IN ACCESS SHARE MODE` requires `SELECT` privileges on the target table. All other forms of `LOCK` require table-level `UPDATE`, `DELETE`, or `TRUNCATE` privileges.

`LOCK TABLE` is useless outside of a transaction block: the lock would be held only to the completion of the `LOCK` statement. Therefore, WarehousePG reports an error if `LOCK` is used outside of a transaction block. Use `BEGIN` and `END` to define a transaction block.

`LOCK TABLE` only deals with table-level locks, and so the mode names involving `ROW` are all misnomers. These mode names should generally be read as indicating the intention of the user to acquire row-level locks within the locked table. Also, `ROW EXCLUSIVE` mode is a shareable table lock. Keep in mind that all the lock modes have identical semantics so far as `LOCK TABLE` is concerned, differing only in the rules about which modes conflict with which. For information on how to acquire an actual row-level lock, see the `FOR UPDATE/FOR SHARE` clause in the SELECT reference documentation.

Examples

Obtain a `SHARE` lock on the `films` table when going to perform inserts into the `films_user_comments` table:

```
BEGIN WORK;
LOCK TABLE films IN SHARE MODE;
SELECT id FROM films
    WHERE name = 'Star Wars: Episode I - The Phantom Menace';
-- Do ROLLBACK if record was not returned
INSERT INTO films_user_comments VALUES
    (_id_, 'GREAT! I was waiting for it for so long!');
COMMIT WORK;
```

Take a `SHARE ROW EXCLUSIVE` lock on a table when performing a delete operation:

```
BEGIN WORK;
LOCK TABLE films IN SHARE ROW EXCLUSIVE MODE;
DELETE FROM films_user_comments WHERE id IN
    (SELECT id FROM films WHERE rating < 5);
DELETE FROM films WHERE rating < 5;
COMMIT WORK;
```

Compatibility

There is no `LOCK TABLE` in the SQL standard, which instead uses `SET TRANSACTION` to specify concurrency levels on transactions. WarehousePG supports that too; see SET TRANSACTION for details.

Except for `ACCESS SHARE`, `ACCESS EXCLUSIVE`, and `SHARE UPDATE EXCLUSIVE` lock modes, the WarehousePG lock modes and the `LOCK TABLE` syntax are compatible with those present in Oracle.

See Also

BEGIN, SET TRANSACTION, SELECT

Parent topic: SQL Commands

7.1.150 MOVE

Positions a cursor.

Synopsis

```
MOVE [ <forward_direction> [ FROM | IN ] ] <cursor_name>
```

where <forward_direction> can be empty or one of:

```
    NEXT
    FIRST
    LAST
    ABSOLUTE <count>
    RELATIVE <count>
    <count>
    ALL
    FORWARD
    FORWARD <count>
    FORWARD ALL
```

Description

`MOVE` repositions a cursor without retrieving any data. `MOVE` works exactly like the FETCH command, except it only positions the cursor and does not return rows.

> **Note** You cannot `MOVE` a `PARALLEL RETRIEVE CURSOR`.

> **Note** Because WarehousePG does not support scrollable cursors, it is not possible to move a cursor position backwards. You can only move a cursor forward in position using `MOVE`.

The parameters for the `MOVE` command are identical to those of the `FETCH` command; refer to FETCH for details on syntax and usage.

Outputs

On successful completion, a `MOVE` command returns a command tag of the form

```
MOVE <count>
```

The count is the number of rows that a `FETCH` command with the same parameters would have returned (possibly zero).

Examples

Start the transaction:

```
BEGIN;
```

Create a cursor:

```
DECLARE mycursor CURSOR FOR SELECT * FROM films;
```

Skip the first 5 rows in the cursor `mycursor`:

```
MOVE FORWARD 5 IN mycursor;
MOVE 5
```

Fetch the next row after that (row 6):

```
FETCH 1 FROM mycursor;
 code  | title  | did | date_prod  |  kind  |  len
-------+--------+-----+------------+--------+-------
 P_303 | 48 Hrs | 103 | 1982-10-22 | Action | 01:37
(1 row)
```

Close the cursor and end the transaction:

```
CLOSE mycursor;
COMMIT;
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Compatibility

There is no `MOVE` statement in the SQL standard.

See Also

DECLARE, FETCH, CLOSE

7.1.151 NOTIFY

Generates a notification.

Synopsis

```
NOTIFY <channel> [ , <payload> ]
```

Description

The `NOTIFY` command sends a notification event together with an optional "payload" string to each client application that has previously executed `LISTEN <channel>` for the specified channel name in the current database. Notifications are visible to all users.

`NOTIFY` provides a simple interprocess communication mechanism for a collection of processes accessing the same WarehousePG. A payload string can be sent along with the notification, and higher-level mechanisms for passing structured data can be built by using tables in the database to pass additional data from notifier to listener(s).

The information passed to the client for a notification event includes the notification channel name, the notifying session's server process PID, and the payload string, which is an empty string if it has not been specified.

It is up to the database designer to define the channel names that will be used in a given database and what each one means. Commonly, the channel name is the same as the name of some table in the database, and the notify event essentially means, "I changed this table, take a look at it to see what's new". But no such association is enforced by the `NOTIFY` and `LISTEN` commands. For example, a database designer could use several different channel names to signal different sorts of changes to a single table. Alternatively, the payload string could be used to differentiate various cases.

When `NOTIFY` is used to signal the occurrence of changes to a particular table, a useful programming technique is to put the `NOTIFY` in a statement trigger that is triggered by table updates. In this way, notification happens automatically when the table is changed, and the application programmer cannot accidentally forget to do it.

`NOTIFY` interacts with SQL transactions in some important ways. Firstly, if a `NOTIFY` is executed inside a transaction, the notify events are not delivered until and unless the transaction is committed. This is appropriate, since if the transaction is aborted, all the commands within it have had no effect, including `NOTIFY`. But it can be disconcerting if one is expecting the notification events to be delivered immediately. Secondly, if a listening session receives a notification signal while it is within a transaction, the notification event will not be delivered to its connected client until just after the transaction is completed (either committed or aborted). Again, the reasoning is that if a notification were delivered within a transaction that was later aborted, one would want the notification to be undone somehow — but the server cannot "take back" a notification once it has sent it to the client. So notification events are only delivered between transactions. The upshot of this is that applications using `NOTIFY` for real-time signaling should try to keep their transactions short.

If the same channel name is signaled multiple times from the same transaction with identical payload strings, the database server can decide to deliver a single notification only. On the other hand, WarehousePG will always deliver notifications with distinct payload strings as distinct notifications. Similarly, notifications from different transactions will never get folded into one notification. Except for dropping later instances of duplicate notifications, `NOTIFY` guarantees that notifications from the same transaction get delivered in the order they were sent. It is also guaranteed that messages from different transactions are delivered in the order in which the transactions committed.

It is common for a client that executes `NOTIFY` to be listening on the same notification channel itself. In that case it will get back a notification event, just like all the other listening sessions. Depending on the application logic, this could result in useless work, for example, reading a database table to find the same updates that that session just wrote out. It is possible to avoid such extra work by noticing whether the notifying session's server process PID (supplied in the notification event message) is the same as one's own session's PID (available from `libpq`). When they are the same, the notification event is one's own work bouncing back, and can be ignored.

Parameters

channel The name of a notification channel (any identifier).

payload The "payload" string to be communicated along with the notification. This must be specified as a simple string literal. In the default configuration it must be shorter than 8000 bytes. (If binary data or large amounts of information need to be communicated, it's best to put it in a database table and send the key of the record.)

Notes

There is a queue that holds notifications that have been sent but not yet processed by all listening sessions. If this queue becomes full, transactions calling `NOTIFY` will fail at commit. The queue is quite large (8GB in a standard installation) and should be sufficiently sized for almost every use case. However, no cleanup can take place if a session executes `LISTEN` and then enters a transaction for a very long time. Once the queue is half full you will see warnings in the log file pointing you to the session that is preventing cleanup. In this case you should make sure that this session ends its current transaction so that cleanup can proceed.

The function `pg_notification_queue_usage()` returns the fraction of the queue that is currently occupied by pending notifications.

A transaction that has executed `NOTIFY` cannot be prepared for two-phase commit.

pg_notify

To send a notification you can also use the function `pg_notify(text, text)`. The function takes the channel name as the first argument and the payload as the second. The function is much easier to use than the `NOTIFY` command if you need to work with non-constant channel names and payloads.

Examples

Configure and execute a listen/notify sequence from `psql`:

```
LISTEN virtual;
NOTIFY virtual;
Asynchronous notification "virtual" received from server process with PID 8448.
NOTIFY virtual, 'This is the payload';
Asynchronous notification "virtual" with payload "This is the payload" received from server process with PID 8448.

LISTEN foo;
SELECT pg_notify('fo' || 'o', 'pay' || 'load');
Asynchronous notification "foo" with payload "payload" received from server process with PID 14728.
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Compatibility

There is no `NOTIFY` statement in the SQL standard.

See Also

LISTEN, UNLISTEN

Parent topic: SQL Commands

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.1.152 PREPARE

Prepares a statement for execution.

Synopsis

```
PREPARE <name> [ (<data_type> [, ...] ) ] AS <statement>
```

Description

`PREPARE` creates a prepared statement. A prepared statement is a server-side object that can be used to optimize performance. When the `PREPARE` statement is run, the specified statement is parsed, analyzed, and rewritten. When an `EXECUTE` command is subsequently issued, the prepared statement is planned and run. This division of labor avoids repetitive parse analysis work, while allowing the execution plan to depend on the specific parameter values supplied.

Prepared statements can take parameters, values that are substituted into the statement when it is run. When creating the prepared statement, refer to parameters by position, using `$1`, `$2`, etc. You can optionally specify a corresponding list of parameter data types. When a parameter's data type is not specified or is declared as `unknown`, the type is inferred from the context in which the parameter is first referenced (if possible). When running the statement, specify the actual values for these parameters in the EXECUTE statement.

Prepared statements last only for the duration of the current database session. When the session ends, the prepared statement is forgotten, so it must be recreated before being used again. This also means that a single prepared statement cannot be used by multiple simultaneous database clients; however, each client can create their own prepared statement to use. You can manually clean up a prepared statement using the DEALLOCATE command.

Prepared statements have the largest performance advantage when a single session is being used to run a large number of similar statements. The performance difference will be particularly significant if the statements are complex to plan or rewrite, for example, if the query involves a join of many tables or requires the application of several rules. If the statement is relatively simple to plan and rewrite but relatively expensive to run, the performance advantage of prepared statements will be less noticeable.

Parameters

name An arbitrary name given to this particular prepared statement. It must be unique within a single session and is subsequently used to run or deallocate a previously prepared statement.

data_type The data type of a parameter to the prepared statement. If the data type of a particular parameter is unspecified or is specified as `unknown`, it will be inferred from the context in which the parameter is first referenced. To refer to the parameters in the prepared statement itself, use `$1`, `$2`, etc.

statement Any `SELECT`, `INSERT`, `UPDATE`, `DELETE`, or `VALUES` statement.

Notes

A prepared statement can be run with either a *generic plan* or a *custom plan*. A generic plan is the same across all executions, while a custom plan is generated for a specific execution using the parameter values given in that call. Use of a generic plan avoids planning overhead, but in some situations a custom plan will be much more efficient to run because the planner can make use of knowledge of the parameter values. If the prepared statement has no parameters, a generic plan is always used.

By default (with the default value, `auto`, for the server configuration parameter plan_cache_mode), the server automatically chooses whether to use a generic or custom plan for a prepared statement that has parameters. The current rule for this is that the first five executions are done with custom plans and then WarehousePG calculates the average estimated cost of those plans. Then a generic plan is created and its estimated cost is compared to the average custom-plan cost. Subsequent executions use the generic plan if its cost is not so much higher than the average custom-plan cost as to make repeated replanning seem preferable.

You can override this heuristic, forcing the server to use either generic or custom plans, by setting `plan_cache_mode` to `force_generic_plan` or `force_custom_plan` respectively. This setting is primarily useful if the generic plan's cost estimate is badly off for some reason, allowing it to be chosen even though its actual cost is much more than that of a custom plan.

To examine the query plan WarehousePG is using for a prepared statement, use EXPLAIN, for example:

```
EXPLAIN EXECUTE <name>(<parameter_values>);
```

If a generic plan is in use, it will contain parameter symbols `$n`, while a custom plan will have the supplied parameter values substituted into it.

For more information on query planning and the statistics collected by WarehousePG for that purpose, see theANALYZE documentation.

Although the main point of a prepared statement is to avoid repeated parse analysis and planning of the statement, WarehousePG will force re-analysis and re-planning of the statement before using it whenever database objects used in the statement have undergone definitional (DDL) changes since the previous use of the prepared statement. Also, if the value of search_path changes from one use to the next, the statement will be re-parsed using the new `search_path`. These rules make use of a prepared statement semantically almost equivalent to re-submitting the same query text over and over, but with a performance benefit if no object definitions are changed, especially if the best plan remains the same across uses. An example of a case where the semantic equivalence is not perfect is that if the statement refers to a table by an unqualified name, and then a new table of the same name is created in a schema appearing earlier in the `search_path`, no automatic re-parse will occur since no object used in the statement changed. However, if some other change forces a re-parse, the new table will be referenced in subsequent uses.

You can see all prepared statements available in the session by querying the pg_prepared_statements system view.

Examples

Create a prepared statement for an `INSERT` statement, and then run it:

```
PREPARE fooplan (int, text, bool, numeric) AS
    INSERT INTO foo VALUES($1, $2, $3, $4);
EXECUTE fooplan(1, 'Hunter Valley', 't', 200.00);
```

Create a prepared statement for a `SELECT` statement, and then run it. Note that the data type of the second parameter is not specified, so it is inferred from the context in which `$2` is used:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
PREPARE usrrptplan (int) AS
    SELECT * FROM users u, logs l WHERE u.usrid=$1 AND u.usrid=l.usrid
    AND l.date = $2;
EXECUTE usrrptplan(1, current_date);
```

Compatibility

The SQL standard includes a `PREPARE` statement, but it can only be used in embedded SQL, and it uses a different syntax.

7.1.153 REASSIGN OWNED

Changes the ownership of database objects owned by a database role.

Synopsis

```
REASSIGN OWNED BY { <old_role> | CURRENT_USER | SESSION_USER } [, ...]
               TO { <new_role> | CURRENT_USER | SESSION_USER }
```

Description

`REASSIGN OWNED` changes the ownership of database objects owned by any of the old_roles to new_role.

Parameters

old_role The name of a role. The ownership of all the objects in the current database, and of all shared objects (databases, tablespaces), owned by this role will be reassigned to new_role.

new_role The name of the role that will be made the new owner of the affected objects.

Notes

`REASSIGN OWNED` is often used to prepare for the removal of one or more roles. Because `REASSIGN OWNED` does not affect objects in other databases, it is usually necessary to run this command in each database that contains objects owned by a role that is to be removed.

`REASSIGN OWNED` requires privileges on both the source role(s) and the target role.

The DROP OWNED command is an alternative that simply drops all of the database objects owned by one or more roles.

The `REASSIGN OWNED` command does not affect any privileges granted to the old_roles on objects that are not owned by them. Likewise, it does not affect default privileges created with `ALTER DEFAULT PRIVILEGES`. Use `DROP OWNED` to revoke such privileges.

Examples

Reassign any database objects owned by the role named `sally` and `bob` to `admin`:

```
REASSIGN OWNED BY sally, bob TO admin;
```

Compatibility

The `REASSIGN OWNED` command is a WarehousePG extension.

See Also

DROP OWNED, DROP ROLE, ALTER DATABASE

7.1.154 REFRESH MATERIALIZED VIEW

Replaces the contents of a materialized view.

Synopsis

```
REFRESH MATERIALIZED VIEW [ CONCURRENTLY ] <name>
    [ WITH [ NO ] DATA ]
```

Description

`REFRESH MATERIALIZED VIEW` completely replaces the contents of a materialized view. The old contents are discarded. To run this command you must be the owner of the materialized view. If `WITH DATA` is specified (or defaults), the backing query is executed to provide the new data, and the materialized view is left in a scannable state. If `WITH NO DATA` is specified, no new data is generated, and the materialized view is left in an unscannable state.

You may not specify `CONCURRENTLY` and `WITH NO DATA` together.

Parameters

CONCURRENTLY Refresh the materialized view without locking out concurrent selects on the materialized view. Without this option, a refresh that affects a lot of rows tends to use fewer resources and completes more quickly, but could block other connections which are trying to read from the materialized view. This option might be faster in cases where a small number of rows are affected. This option is only allowed if there is at least one `UNIQUE` index on the materialized view which uses only column names and includes all rows; that is, it must not index on any expressions nor include a `WHERE` clause. You can not use this option when the materialized view is not already populated. Even with this option, only one `REFRESH` at a time may run against any one materialized view.

name The name (optionally schema-qualified) of the materialized view to refresh.

WITH [NO] DATA `WITH DATA` is the default and specifies that the materialized view query is run to provide new data, and the materialized view is left in a scannable state. If `WITH NO DATA` is specified, no new data is generated and the materialized view is left in an unscannable state.

Notes

If there is an `ORDER BY` clause in the materialized view's defining query, the original contents of the materialized view will be ordered that way; but `REFRESH MATERIALIZED VIEW` does not guarantee to preserve that ordering.

Examples

This command replaces the contents of the materialized view `order_summary` using the query from the materialized view's definition, and leaves it in a scannable state.

```
REFRESH MATERIALIZED VIEW order_summary;
```

This command frees storage associated with the materialized view `annual_statistics_basis` and leaves it in an unscannable state.

```
REFRESH MATERIALIZED VIEW annual_statistics_basis WITH NO DATA;
```

Compatibility

`REFRESH MATERIALIZED VIEW` is a WarehousePG extension of the SQL standard.

See Also

ALTER MATERIALIZED VIEW, CREATE MATERIALIZED VIEW, DROP MATERIALIZED VIEW

7.1.155 REINDEX

Rebuilds indexes.

Synopsis

```
REINDEX [ (VERBOSE) ] { INDEX | TABLE | SCHEMA | DATABASE | SYSTEM } <name>
```

Description

`REINDEX` rebuilds an index using the data stored in the index's table, replacing the old copy of the index. There are several scenarios in which to use `REINDEX`:

- An index has become corrupted, and no longer contains valid data. Although in theory this should never happen, in practice indexes can become corrupted due to software bugs or hardware failures. `REINDEX` provides a recovery method.
- An index has become bloated, that is, it contains many empty or nearly-empty pages. This can occur with B-tree indexes in WarehousePG under certain uncommon access patterns. `REINDEX` provides a way to reduce the space consumption of the index by writing a new version of the index without the dead pages.
- You have altered a storage parameter (such as `fillfactor`) for an index, and wish to ensure that the change has taken full effect.

Parameters

INDEX Recreate the specified index.

TABLE Recreate all indexes of the specified table. If the table has a secondary "TOAST" table, that is reindexed as well.

SCHEMA Recreate all indexes of the specified schema. If a table of this schema has a secondary "TOAST" table, that is reindexed as well. Indexes on shared system catalogs are also processed. You cannot run this form of `REINDEX` inside a transaction block.

DATABASE Recreate all indexes within the current database. Indexes on shared system catalogs are also processed. This form of `REINDEX` cannot be run inside a transaction block.

SYSTEM Recreate all indexes on system catalogs within the current database. Indexes on shared system catalogs are included. Indexes on user tables are not processed. This form of `REINDEX` cannot be run inside a transaction block.

name The name of the specific index, table, or database to be reindexed. Index and table names may be schema-qualified. Presently, `REINDEX DATABASE` and `REINDEX SYSTEM` can only reindex the current database, so their parameter must match the current database's name.

VERBOSE Prints a progress report as each index is reindexed.

Notes

WarehousePG does not support concurrently recreating indexes (`CONCURRENTLY` keyword is not supported).

`REINDEX` causes locking of system catalog tables, which could affect currently running queries. To avoid disrupting ongoing business operations, schedule the `REINDEX` operation during a period of low activity.

`REINDEX` is similar to a drop and recreate of the index in that the index contents are rebuilt from scratch. However, the locking considerations are rather different. `REINDEX` locks out writes but not reads of the index's parent table. It also takes an `ACCESS EXCLUSIVE` lock on the specific index being processed, which will block reads that attempt to use that index. In contrast, `DROP INDEX` momentarily takes an `ACCESS EXCLUSIVE` lock on the parent table, blocking both writes and reads. The subsequent `CREATE INDEX` locks out writes but not reads; since the index is not there, no read will attempt to use it, meaning that there will be no blocking but reads may be forced into expensive sequential scans.

Reindexing a single index or table requires being the owner of that index or table. Reindexing a schema or database requires being the owner of the schema or database. Note that it is therefore sometimes possible for non-superusers to rebuild indexes of tables owned by other users. However, as a special exception, when a non-superuser issues `REINDEX DATABASE`, `REINDEX SCHEMA` or `REINDEX SYSTEM`, WarehousePG skips indexes on shared catalogs unless the user owns the catalog (which typically won't be the case). Of course, superusers can always reindex anything.

REINDEX`does not update the` reltuples `and` relpages `statistics for the index. To update those statistics, run` ANALYZE` on the table after reindexing.

Examples

Rebuild a single index:

```
REINDEX INDEX my_index;
```

Rebuild all the indexes on the table `my_table`:

```
REINDEX TABLE my_table;
```

Rebuild all indexes in a particular database, without trusting the system indexes to be valid already:

```
$ export PGOPTIONS="-P"
$ psql broken_db
...
broken_db=> REINDEX DATABASE broken_db;
broken_db=> \q
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Compatibility

There is no `REINDEX` command in the SQL standard.

See Also

CREATE INDEX, DROP INDEX, VACUUM, reindexdb

Parent topic: SQL Commands

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.1.156 RELEASE SAVEPOINT

Destroys a previously defined savepoint.

Synopsis

```
RELEASE [SAVEPOINT] <savepoint_name>
```

Description

`RELEASE SAVEPOINT` destroys a savepoint previously defined in the current transaction.

Destroying a savepoint makes it unavailable as a rollback point, but it has no other user visible behavior. It does not undo the effects of commands run after the savepoint was established. (To do that, see ROLLBACK TO SAVEPOINT.) Destroying a savepoint when it is no longer needed may allow the system to reclaim some resources earlier than transaction end.

`RELEASE SAVEPOINT` also destroys all savepoints that were established *after* the named savepoint was established.

Parameters

savepoint_name The name of the savepoint to destroy.

Notes

Specifying a savepoint name that was not previously defined is an error.

It is not possible to release a savepoint when the transaction is in an aborted state.

If multiple savepoints have the same name, WarehousePG releases only the most recently defined unreleased savepoint. Repeated commands release progressively older savepoints.

Examples

To establish and later destroy a savepoint:

```
BEGIN;
    INSERT INTO table1 VALUES (3);
    SAVEPOINT my_savepoint;
    INSERT INTO table1 VALUES (4);
    RELEASE SAVEPOINT my_savepoint;
COMMIT;
```

The above transaction inserts both 3 and 4.

Compatibility

This command conforms to the SQL standard. The standard specifies that the key word `SAVEPOINT` is mandatory, but WarehousePG allows it to be omitted.

7.1.157 RESET

Restores the value of a run-time system configuration parameter to the default value.

Synopsis

```
RESET <configuration_parameter>

RESET ALL
```

Description

`RESET` restores system configuration parameters to their default values. `RESET` is an equivalent command for

```
SET <configuration_parameter> TO DEFAULT
```

Refer to SET for details.

The default value is defined as the value that the parameter would have had, had no `SET` ever been issued for it in the current session. The actual source of this value might be a compiled-in default, the coordinator `postgresql.conf` configuration file, command-line options, or per-database or per-user default settings. This is subtly different from defining it as "the value that the parameter had at session start", because if the value came from the configuration file, it will be reset to whatever is specified by the configuration file now. See Server Configuration Parameters for more information.

The transactional behavior of `RESET` is the same as `SET`: its effects will be undone by transaction rollback.

Parameters

configuration_parameter The name of a settable run-time system configuration parameter. See Server Configuration Parameters for details.

ALL Resets all settable run-time configuration parameters to their default values.

Examples

Set the `statement_mem` configuration parameter to its default value:

```
RESET statement_mem;
```

Compatibility

`RESET` is a WarehousePG extension.

7.1.158 RETRIEVE

Retrieves rows from a query using a parallel retrieve cursor.

Synopsis

```
RETRIEVE { <count> | ALL } FROM ENDPOINT <endpoint_name>
```

Description

`RETRIEVE` retrieves rows using a previously-created parallel retrieve cursor. You retrieve the rows in individual retrieve sessions, separate direct connections to individual segment endpoints that will serve the results for each individual segment. When you initiate a retrieve session, you must specify gp_retrieve_conn=true on the connection request. Because a retrieve session is independent of the parallel retrieve cursors or their corresponding endpoints, you can `RETRIEVE` from multiple endpoints in the same retrieve session.

A parallel retrieve cursor has an associated position, which is used by `RETRIEVE`. The cursor position can be before the first row of the query result, on any particular row of the result, or after the last row of the result.

> **Note** Because WarehousePG does not support scrollable cursors, the `RETRIEVE` command moves a parallel retrieve cursor only forward in position.

When it is created, a parallel retrieve cursor is positioned before the first row. After retrieving some rows, the cursor is positioned on the row most recently retrieved.

If `RETRIEVE` runs off the end of the available rows then the cursor is left positioned after the last row.

`RETRIEVE ALL` always leaves the parallel retrieve cursor positioned after the last row.

Parameters

count Retrieve the next count number of rows. count must be a positive number.

ALL Retrieve all remaining rows.

endpoint_name The name of the endpoint from which to retrieve the rows.

Outputs

On successful completion, a `RETRIEVE` command returns the fetched rows (possibly empty) and a count of the number of rows fetched (possibly zero).

Notes

Use `DECLARE ... PARALLEL RETRIEVE CURSOR` to define a parallel retrieve cursor.

Parallel retrieve cursors do not support `FETCH` or `MOVE` operations.

Examples

Start the transaction:

```
BEGIN;
```

Create a parallel retrieve cursor:

```
DECLARE mycursor PARALLEL RETRIEVE CURSOR FOR SELECT * FROM films;
```

List the cursor endpoints:

```
SELECT * FROM gp_endpoints WHERE cursorname='mycursor';
```

Note the hostname, port, auth_token, and name associated with each endpoint.

In another terminal window, initiate a retrieve session using a hostname, port, and auth_token returned from the previous query. For example:

```
PGPASSWORD=d3825fc07e56bee5fcd2b1d0b600c85e PGOPTIONS='-c gp_retrieve_conn=true' psql -d testdb -h sdw3 -p 6001;
```

Fetch all rows from an endpoint (for example, the endpoint named `prc10000001100000005`):

```
RETRIEVE ALL FROM ENDPOINT prc10000001100000005;
```

Exit the retrieve session.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
\q
```

Back in the original session, close the cursor and end the transaction:

```
CLOSE mycursor;
COMMIT;
```

Compatibility

`RETRIEVE` is a WarehousePG extension. The SQL standard makes no provisions for parallel retrieve cursors.

REVOKE [ADMIN OPTION FOR] <role_name> [, ...]
       FROM [ GROUP ] <role_specification> [, ...]
       [GRANTED BY <role_specification> ]
       [CASCADE | RESTRICT]

where <role_specification> can be:

    [ GROUP ] <role_name>
  | PUBLIC
  | CURRENT_USER
  | SESSION_USER
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Description

`REVOKE` command revokes previously granted privileges from one or more roles. The key word `PUBLIC` refers to the implicitly defined group of all roles.

See the description of the GRANT command for the meaning of the privilege types.

Note that any particular role will have the sum of privileges granted directly to it, privileges granted to any role it is presently a member of, and privileges granted to `PUBLIC`. Thus, for example, revoking `SELECT` privilege from `PUBLIC` does not necessarily mean that all roles have lost `SELECT` privilege on the object: those who have it granted directly or via another role will still have it. Similarly, revoking `SELECT` from a user might not prevent that user from using `SELECT` if `PUBLIC` or another membership role still has `SELECT` rights.

If `GRANT OPTION FOR` is specified, only the grant option for the privilege is revoked, not the privilege itself. Otherwise, both the privilege and the grant option are revoked.

If a role holds a privilege with grant option and has granted it to other roles then the privileges held by those other roles are called dependent privileges. If the privilege or the grant option held by the first role is being revoked and dependent privileges exist, those dependent privileges are also revoked if `CASCADE` is specified, else the revoke action will fail. This recursive revocation only affects privileges that were granted through a chain of roles that is traceable to the role that is the subject of this `REVOKE` command. Thus, the affected roles may effectively keep the privilege if it was also granted through other roles.

When you revoke privileges on a table, WarehousePG revokes the corresponding column privileges (if any) on each column of the table, as well. On the other hand, if a role has been granted privileges on a table, then revoking the same privileges from individual columns will have no effect.

By default, when you revoke privileges on a partitioned table, WarehousePG recurses the operation to its child tables. To direct WarehousePG to perform the `REVOKE` on the partitioned table only, specify the `ONLY <table_name>` clause.

When revoking membership in a role, `GRANT OPTION` is instead called `ADMIN OPTION`, but the behavior is similar. This form of the command also allows a `GRANTED BY` option, but that option is currently ignored (except for checking the existence of the named role). Note also that this form of the command does not allow the noise word `GROUP` in role_specification.

Parameters

See GRANT.

Notes

A user may revoke only those privileges directly granted by that user. If, for example, user A grants a privilege with grant option to user B, and user B has in turn granted it to user C, then user A cannot revoke the privilege directly from C. Instead, user A could revoke the grant option from user B and use the `CASCADE` option so that the privilege is in turn revoked from user C. For another example, if both A and B grant the same privilege to C, A can revoke their own grant but not B's grant, so C effectively still has the privilege.

When a non-owner of an object attempts to `REVOKE` privileges on the object, the command fails outright if the user has no privileges whatsoever on the object. As long as some privilege is available, the command proceeds, but it will revoke only those privileges for which the user has grant options. The `REVOKE ALL PRIVILEGES` forms issue a warning message if no grant options are held, while the other forms issue a warning if grant options for any of the privileges specifically named in the command are not held. (In principle these statements apply to the object owner as well, but since WarehousePG always treats the owner as holding all grant options, the cases can never occur.)

If a superuser chooses to issue a `GRANT` or `REVOKE` command, WarehousePG performs the command as though it were issued by the owner of the affected object. Since all privileges ultimately come from the object owner (possibly indirectly via chains of grant options), it is possible for a superuser to revoke all privileges, but this might require use of `CASCADE` as stated above.

`REVOKE` may also be invoked by a role that is not the owner of the affected object, but is a member of the role that owns the object, or is a member of a role that holds privileges `WITH GRANT OPTION` on the object. In this case, WarehousePG performs the command as though it were issued by the containing role that actually owns the object or holds the privileges `WITH GRANT OPTION`. For example, if table `t1` is owned by role `g1`, of which role `u1` is a member, then `u1` can revoke privileges on `t1` that are recorded as being granted by `g1`. This includes grants made by `u1` as well as by other members of role `g1`.

If the role that runs `REVOKE` holds privileges indirectly via more than one role membership path, it is unspecified which containing role will be used to perform the command. In such cases it is best practice to use `SET ROLE` to become the specific role as which you want to do the `REVOKE`. Failure to do so may lead to revoking privileges other than the ones you intended, or not revoking any privileges at all.

Use `psql`'s `\dp` meta-command to obtain information about existing privileges for tables and columns. There are other `\d` meta-commands that you can use to display the privileges of non-table objects.

Examples

Revoke insert privilege for the public on table `films`:

```
REVOKE INSERT ON films FROM PUBLIC;
```

Revoke all privileges from user `manuel` on view `kinds`. Note that this actually means revoke all privileges that the current role granted (if not a superuser).

```
REVOKE ALL PRIVILEGES ON kinds FROM manuel;
```

Revoke membership in role `admins` from user `joe`:

```
REVOKE admins FROM joe;
```

Compatibility

The compatibility notes of the GRANT command also apply to `REVOKE`.

Either `RESTRICT` or `CASCADE` is required according to the standard, but WarehousePG assumes `RESTRICT` by default.

7.1.160 ROLLBACK

Stops the current transaction.

Synopsis

```
ROLLBACK [WORK | TRANSACTION] [AND [NO] CHAIN]
```

Description

`ROLLBACK` rolls back the current transaction and causes all the updates made by the transaction to be discarded.

Parameters

WORK TRANSACTION Optional key words. They have no effect.

AND CHAIN If `AND CHAIN` is specified, a new transaction is immediately started with the same transaction characteristics (see SET TRANSACTION) as the just finished one. Otherwise, no new transaction is started.

Notes

Use COMMIT to successfully end the current transaction.

Issuing `ROLLBACK` when not inside a transaction block emits a warning and otherwise has no effect. `ROLLBACK AND CHAIN` outside of a transaction block is an error.

Examples

To discard all changes made in the current transaction:

```
ROLLBACK;
```

Compatibility

The command `ROLLBACK` conforms to the SQL standard. The form `ROLLBACK TRANSACTION` is a WarehousePG extension.

See Also

BEGIN, COMMIT, ROLLBACK TO SAVEPOINT, SAVEPOINT

Parent topic: SQL Commands

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.1.161 ROLLBACK TO SAVEPOINT

Rolls back the current transaction to a savepoint.

Synopsis

```
ROLLBACK [ WORK | TRANSACTION ] TO [ SAVEPOINT ] <savepoint_name>
```

Description

This command rolls back all commands that were run after the savepoint was established. The savepoint remains valid and can be rolled back to again later, if needed.

`ROLLBACK TO SAVEPOINT` implicitly destroys all savepoints that were established after the named savepoint.

Parameters

WORK TRANSACTION Optional key words. They have no effect.

savepoint_name The name of the savepoint to roll back to.

Notes

Use RELEASE SAVEPOINT to destroy a savepoint without discarding the effects of commands run after it was established.

Specifying a savepoint name that has not been established is an error.

Cursors have somewhat non-transactional behavior with respect to savepoints. Any cursor that is opened inside a savepoint will be closed when the savepoint is rolled back. If a previously opened cursor is affected by a `FETCH` command inside a savepoint that is later rolled back, the cursor remains at the position that `FETCH` left it pointing to (that is, cursor motion caused by `FETCH` is not rolled back). Closing a cursor is not undone by rolling back, either. However, other side-effects caused by the cursor's query (such as side-effects of volatile functions called by the query) *are* rolled back if they occur during a savepoint that is later rolled back. A cursor whose execution causes a transaction to end prematurely is put in a cannot-execute state, so while the transaction can be restored using `ROLLBACK TO SAVEPOINT`, the cursor can no longer be used.

Examples

To undo the effects of the commands run after `my_savepoint` was established:

```
ROLLBACK TO SAVEPOINT my_savepoint;
```

Cursor positions are not affected by a savepoint rollback:

```
BEGIN;
DECLARE foo CURSOR FOR SELECT 1 UNION SELECT 2;
SAVEPOINT foo;
FETCH 1 FROM foo;
column
----------
        1

ROLLBACK TO SAVEPOINT foo;
FETCH 1 FROM foo;
column
----------
        2

COMMIT;
```

Compatibility

The SQL standard specifies that the key word `SAVEPOINT` is mandatory, but WarehousePG (and Oracle) allow it to be omitted. SQL allows only `WORK`, not `TRANSACTION`, as a noise word after `ROLLBACK`. Also, SQL has an optional clause `AND [NO] CHAIN` which is not currently supported by WarehousePG. Otherwise, this command conforms to the SQL standard.

7.1.162 SAVEPOINT

Defines a new savepoint within the current transaction.

Synopsis

```
SAVEPOINT <savepoint_name>
```

Description

`SAVEPOINT` establishes a new savepoint within the current transaction.

A savepoint is a special mark inside a transaction that allows all commands that are run after it was established to be rolled back, restoring the transaction state to what it was at the time of the savepoint.

Parameters

savepoint_name The name of the new savepoint. If savepoints with the same name already exist, they are inaccessible until newer identically-named savepoints are released.

Notes

Use ROLLBACK TO SAVEPOINT to rollback to a savepoint. Use RELEASE SAVEPOINT to destroy a savepoint, keeping the effects of commands run after it was established.

Savepoints can be established only inside a transaction block. You can define multiple savepoints within a transaction.

Examples

To establish a savepoint and later undo the effects of all commands run after it was established:

```
BEGIN;
    INSERT INTO table1 VALUES (1);
    SAVEPOINT my_savepoint;
    INSERT INTO table1 VALUES (2);
    ROLLBACK TO SAVEPOINT my_savepoint;
    INSERT INTO table1 VALUES (3);
COMMIT;
```

The above transaction inserts the values 1 and 3, but not 2.

To establish and later destroy a savepoint:

```
BEGIN;
    INSERT INTO table1 VALUES (3);
    SAVEPOINT my_savepoint;
    INSERT INTO table1 VALUES (4);
    RELEASE SAVEPOINT my_savepoint;
COMMIT;
```

The above transaction inserts both 3 and 4.

To use a single savepoint name:

```
BEGIN;
    INSERT INTO table1 VALUES
(1);
    SAVEPOINT my_savepoint;
    INSERT INTO table1 VALUES
(2);
    SAVEPOINT my_savepoint;
    INSERT INTO table1 VALUES
(3);

    -- rollback to the second
savepoint
    ROLLBACK TO SAVEPOINT my_savepoint;
    SELECT * FROM table1;               -- shows rows 1 and
2

    -- release the second
savepoint
    RELEASE SAVEPOINT my_savepoint;

    -- rollback to the first
savepoint
    ROLLBACK TO SAVEPOINT my_savepoint;
    SELECT * FROM table1;               -- shows only row
1
COMMIT;
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

The above transaction shows row 3 being rolled back first, then row 2.

Compatibility

SQL requires a savepoint to be destroyed automatically when another savepoint with the same name is established. In WarehousePG, the old savepoint is kept, though only the more recent one is used when rolling back or releasing. (Releasing the newer savepoint will cause the older one to again become accessible to ROLLBACK TO SAVEPOINT and RELEASE SAVEPOINT.) Otherwise, `SAVEPOINT` is fully SQL conforming.

TABLE [ ONLY ] <table_name> [ * ]
```

Description

`SELECT` retrieves rows from zero or more tables. The general processing of `SELECT` is as follows:

1. All queries in the `WITH` clause are computed. These effectively serve as temporary tables that can be referenced in the `FROM` list. A `WITH` query that is referenced more than once in `FROM` is computed only once, unless specified otherwise with `NOT MATERIALIZED`. (See WITH Clause below.)
2. All elements in the `FROM` list are computed. (Each element in the `FROM` list is a real or virtual table.) If more than one element is specified in the `FROM` list, they are cross-joined together. (See FROM Clause below.)
3. If the `WHERE` clause is specified, all rows that do not satisfy the condition are eliminated from the output. (See WHERE Clause below.)
4. If the `GROUP BY` clause is specified, or if there are aggregate function calls, the output is combined into groups of rows that match on one or more values, and the results of aggregate functions are computed. If the `HAVING` clause is present, it eliminates groups that do not satisfy the given condition. (See GROUP BY Clause and HAVING Clause below.)
5. The actual output rows are computed using the `SELECT` output expressions for each selected row or row group. (See SELECT List below.)
6. `SELECT DISTINCT` eliminates duplicate rows from the result. `SELECT DISTINCT ON` eliminates rows that match on all the specified expressions. `SELECT ALL` (the default) will return all candidate rows, including duplicates. (See DISTINCT Clause below.)
7. If a window expression is specified (and optional `WINDOW` clause), the output is organized according to the positional (row) or value-based (range) window frame. (See WINDOW Clause below.)
8. Using the operators `UNION`, `INTERSECT`, and `EXCEPT`, the output of more than one `SELECT` statement can be combined to form a single result set. The `UNION` operator returns all rows that are in one or both of the result sets. The `INTERSECT` operator returns all rows that are strictly in both result sets. The `EXCEPT` operator returns the rows that are in the first result set but not in the second. In all three cases, duplicate rows are eliminated unless `ALL` is specified. The noise word `DISTINCT` can be added to explicitly specify eliminating duplicate rows. Notice that `DISTINCT` is the default behavior here, even though `ALL` is the default for `SELECT` itself. (See UNION Clause, INTERSECT Clause, and EXCEPT Clause below.)
9. If the `ORDER BY` clause is specified, the returned rows are sorted in the specified order. If `ORDER BY` is not given, the rows are returned in whatever order the system finds fastest to produce. (See ORDER BY Clause below.)
10. If the `LIMIT` (or `FETCH FIRST`) or `OFFSET` clause is specified, the `SELECT` command only returns a subset of the result rows. (See LIMIT Clause below.)
11. If `FOR UPDATE`, `FOR NO KEY UPDATE`, `FOR SHARE`, or `FOR KEY SHARE` is specified, the `SELECT` command locks the entire table against concurrent updates when the Global Deadlock Detector is deactivated (the default). When the Global Deadlock Detector is activated, it affects some simple `SELECT` statements that contain a locking clause. (See The Locking Clause below.)

You must have `SELECT` privilege on each column used in a `SELECT` command. The use of `FOR NO KEY UPDATE`, `FOR UPDATE`, `FOR SHARE`, or `FOR KEY SHARE` requires `UPDATE` privilege as well (for at least one column of each table so selected).

Parameters

The WITH Clause

The `WITH` clause allows you to specify one or more subqueries that can be referenced by name in the primary query. The subqueries effectively act as temporary tables or views for the duration of the primary query. Each subquery can be a `SELECT`, `TABLE`, `VALUES`, `INSERT`, `UPDATE`, or `DELETE` statement. When writing a data-modifying statement (`INSERT`, `UPDATE`, or `DELETE`) in `WITH`, it is usual to include a `RETURNING` clause. It is the output of `RETURNING`, *not* the underlying table that the statement modifies, that forms the temporary table that is read by the primary query. If `RETURNING` is omitted, the statement is still run, but it produces no output so it cannot be referenced as a table by the primary query.

For a `SELECT` command that includes a `WITH` clause, the clause can contain at most a single clause that modifies table data (`INSERT`, `UPDATE`, or `DELETE` command).

A name (without schema qualification) must be specified for each `WITH` query. Optionally, you can specify a list of column names; if this is omitted, the names are inferred from the subquery.

If `RECURSIVE` is specified, it allows a `SELECT` subquery to reference itself by name. Such a subquery must have the form:

```
<non_recursive_term> UNION [ALL | DISTINCT] <recursive_term>
```

where the recursive self-reference appears on the right-hand side of the `UNION`. Only one recursive self-reference is permitted per query. Recursive data-modifying statements are not supported, but you can use the results of a recursive `SELECT` query in a data-modifying statement.

If the `RECURSIVE` keyword is specified, the `WITH` queries need not be ordered: a query can reference another query that is later in the list. However, circular references, or mutual recursion, are not supported. Without the `RECURSIVE` keyword, `WITH` queries can reference only sibling `WITH` queries that are earlier in the `WITH` list.

When there are multiple queries in the `WITH` clause, `RECURSIVE` should be written only once, immediately after `WITH`. It applies to all queries in the `WITH` clause, though it has no effect on queries that do not use recursion or forward references.

`WITH RECURSIVE` limitations. These items are not supported:

- A recursive `WITH` clause that contains the following in the `<recursive_term>`.
  - Subqueries with a self-reference
  - `DISTINCT` clause
  - `GROUP BY` clause
  - A window function
- A recursive `WITH` clause where the `<with_query_name>` is a part of a set operation.

Following is an example of the set operation limitation. This query returns an error because the set operation `UNION` contains a reference to the table `foo`.

```
WITH RECURSIVE foo(i) AS (
    SELECT 1
  UNION ALL
    SELECT i+1 FROM (SELECT * FROM foo UNION SELECT 0) bar
)
SELECT * FROM foo LIMIT 5;
```

This recursive CTE is allowed because the set operation `UNION` does not have a reference to the CTE `foo`.

```
WITH RECURSIVE foo(i) AS (
    SELECT 1
  UNION ALL
    SELECT i+1 FROM (SELECT * FROM bar UNION SELECT 0) bar, foo
    WHERE foo.i = bar.a
)
SELECT * FROM foo LIMIT 5;
```

The primary query and the `WITH` queries are all (notionally) run at the same time. This implies that the effects of a data-modifying statement in `WITH` cannot be seen from other parts of the query, other than by reading its `RETURNING` output. If two such data-modifying statements attempt to modify the same row, the results are unspecified.

A key property of `WITH` queries is that they are evaluated only once per execution of the primary query, even if the primary query refers to them more than once. In particular, data-modifying statements are guaranteed to be run once and only once, regardless of whether the primary query reads all or any of their output.

However, a `WITH` query can be marked `NOT MATERIALIZED` to remove this guarantee. In that case, the `WITH` query can be folded into the primary query much as though it were a simple sub `SELECT` in the primary query's `FROM` clause. This results in duplicate computations if the primary query refers to that `WITH` query more than once; but if each such use requires only a few rows of the `WITH` query's total output, `NOT MATERIALIZED` can provide a net savings by allowing the queries to be optimized jointly. `NOT MATERIALIZED` is ignored if it is attached to a `WITH` query that is recursive or is not side-effect-free (for example, is not a plain `SELECT` containing no volatile functions).

By default, a side-effect-free `WITH` query is folded into the primary query if it is used exactly once in the primary query's `FROM` clause. This allows joint optimization of the two query levels in situations where that should be semantically invisible. However, such folding can be prevented by marking the `WITH` query as `MATERIALIZED`. That might be useful, for example, if the `WITH` query is being used as an optimization fence to prevent the planner from choosing a bad plan. WarehousePG versions before 7 never did such folding, so queries written for older versions might rely on `WITH` to act as an optimization fence.

See WITH Queries (Common Table Expressions) in the *WarehousePG Administrator Guide* for additional information.

The FROM Clause

The `FROM` clause specifies one or more source tables for the `SELECT`. If multiple sources are specified, the result is the Cartesian product (cross join) of all the sources. But usually qualification conditions are added (via `WHERE`) to restrict the returned rows to a small subset of the Cartesian product.

The `FROM` clause can contain the following elements:

table_name The name (optionally schema-qualified) of an existing table or view. If `ONLY` is specified before the table name, only that table is scanned. If `ONLY` is not specified, the table and all of its descendant tables (if any) are scanned. Optionally, you can specify `*` after the table name to explicitly indicate that descendant tables are included.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

alias A substitute name for the `FROM` item containing the alias. An alias is used for brevity or to eliminate ambiguity for self-joins (where the same table is scanned multiple times). When you provide an alias, it completely hides the actual name of the table or function; for example given `FROM foo AS f`, the remainder of the `SELECT` must refer to this `FROM` item as `f` not `foo`. If you specify an alias, you can also specify a column alias list to provide substitute names for one or more columns of the table.

TABLESAMPLE sampling_method (argument [, ...]) [REPEATABLE (seed)] A `TABLESAMPLE` clause after a `table_name` indicates that the specified sampling_method should be used to retrieve a subset of the rows in that table. This sampling precedes the application of any other filters such as `WHERE` clauses. The standard WarehousePG distribution includes two sampling methods, `BERNOULLI` and `SYSTEM`. You can install the additional sampling methods `SYSTEM_ROWS` and `SYSTEM_TIME` in the database via extensions.

The `BERNOULLI` and `SYSTEM` sampling methods each accept a single argument which is the fraction of the table to sample, expressed as a percentage between 0 and 100. This argument can be any real-valued expression. (Other sampling methods might accept more or different arguments.) These two methods each return a randomly-chosen sample of the table that will contain approximately the specified percentage of the table's rows. The `BERNOULLI` method scans the whole table and selects or ignores individual rows independently with the specified probability. The `SYSTEM` method does block-level sampling with each block having the specified chance of being selected; all rows in each selected block are returned. The `SYSTEM` method is significantly faster than the `BERNOULLI` method when small sampling percentages are specified, but it may return a less-random sample of the table as a result of clustering effects.

The `SYSTEM ROWS` table sampling method accepts a single integer argument that is the maximum number of rows to read. The resulting sample will always contain exactly that many rows, unless the table does not contain enough rows, in which case the whole table is selected.

The `SYSTEM_TIME` table sampling method takes a single floating-point argument that specifies the maximum number of milliseconds to spend reading the table. This allows you to control how long the query takes; the tradeoff is that the size of the sample becomes hard to predict. The resulting sample will contain as many rows as could be read in the specified time, unless the whole table has been read first.

Like the built-in `SYSTEM` sampling method, `SYSTEM_ROWS` and `SYSTEM_TIME` perform block-level sampling, so that, rather than being completely random, the sample may be subject to clustering effects, particularly when a small number of rows are selected.

> **IMPORTANT** To call the `SYSTEM_ROWS` and `SYSTEM_TIME` sampling methods, you must install the WarehousePG extensions that provide access to them: `tsm_system_rows` and `tsm_system_time`, repectively. See the tsm_system_rows and tsm_system_time topics for details.

Sampling performance on append-optimized tables will improve if the table has a block directory (if the table has any index or had any index in the past) and the improvement is directly proportional to the degree of compression of the table and inversely proportional to the size of the sample requested. To create a block directory for a table that doesn't have an index, issue the following command:

```
CREATE INDEX dummy ON tab(i) WHERE false; DROP INDEX dummy;
```

The optional `REPEATABLE` clause specifies a seed number or expression to use for generating random numbers within the sampling method. The seed value can be any non-null floating-point value. Two queries that specify the same seed and argument values will select the same sample of the table, if the table has not been changed meanwhile. But different seed values usually produce different samples. If `REPEATABLE` is not specified, then WarehousePG selects a new random sample for each query, based upon a system-generated seed. Note that some add-on sampling methods do not accept `REPEATABLE`, and will always produce new samples on each use.

select A sub-`SELECT` can appear in the `FROM` clause. This acts as though its output were created as a temporary table for the duration of this single `SELECT` command. Note that the sub-`SELECT` must be surrounded by parentheses, and an alias *must* be provided for it. A VALUES command can also be used here. See "Non-standard Clauses" in theCompatibility section for limitations of using correlated sub-selects in WarehousePG.

with_query_name A `WITH` query is referenced in the `FROM` clause by specifying its name, just as though the name were a table name. You can provide an alias in the same way as for a table.

The `WITH` query hides a table of the same name for the purposes of the primary query. If necessary, you can refer to a table of the same name by schema-qualifying the table's name.

function_name Function calls can appear in the `FROM` clause. (This is especially useful for functions that return result sets, but any function can be used.) This acts as though the function's output were created as a temporary table for the duration of this single `SELECT` command. When you add the optional `WITH ORDINALITY` clause to the function call, WarehousePG appends a new column after all of the function's output columns with numbering for each row. You can provide an alias in the same way as for a table. If an alias is specified, you can also specify a column alias list to provide substitute names for one or more attributes of the function's composite return type, including the column added by `ORDINALITY` if present. You can combine multiple function calls into a single `FROM`-clause item by surrounding them with `ROWS FROM( ... )`. The output of such an item is the concatenation of the first row from each function, then the second row from each function, etc. If some of the functions produce fewer rows than others, null values are substituted for the missing data, so that the total number of rows returned is always the same as for the function that produced the most rows. If the function has been defined as returning the `record` data type, then an alias or the key word `AS` must be present, followed by a column definition list in the form `( <column_name> <data_type> [, ... ] )`. The column definition list must match the actual number and types of columns returned by the function. When using the `ROWS FROM( ... )` syntax, if one of the functions requires a column definition list, it's preferred to put the column definition list after the function call inside `ROWS FROM( ... )`. A column definition list can be placed after the `ROWS FROM( ... )` construct only if there's just a single function and no `WITH ORDINALITY` clause. To use `ORDINALITY` together with a column definition list, you must use the `ROWS FROM( ... )` syntax and put the column definition list inside `ROWS FROM( ... )`.

join_type One of:

- `[INNER] JOIN`
- `LEFT [OUTER] JOIN`
- `RIGHT [OUTER] JOIN`
- `FULL [OUTER] JOIN`

For the `INNER` and `OUTER` join types, you must specify a join condition, namely exactly one of `NATURAL`, `ON <join_condition>`, or `USING ( <join_column> [, ...])`. Continue reading for the meaning.

A JOIN clause combines two `FROM` items, which for convenience are referred to as "tables", though in reality they can be any type of `FROM` item. Use parentheses if necessary to determine the order of nesting. In the absence of parentheses, `JOIN`s nest left-to-right. `JOIN` binds more tightly than the commas separating `FROM`-list items. All of the `JOIN` options are a notational convenience; they do nothing that cannot be achieved with plain `FROM` and `WHERE`.

`LEFT OUTER JOIN` returns all rows in the qualified Cartesian product (i.e., all combined rows that pass its join condition), plus one copy of each row in the left-hand table for which there was no right-hand row that passed the join condition. This left-hand row is extended to the full width of the joined table by inserting null values for the right-hand columns. Note that only the `JOIN` clause's own condition is considered while deciding which rows have matches. Outer conditions are applied afterwards.

Conversely, `RIGHT OUTER JOIN` returns all the joined rows, plus one row for each unmatched right-hand row (extended with nulls on the left). This is just a notational convenience, since you could convert it to a `LEFT OUTER JOIN` by switching the left and right tables.

`FULL OUTER JOIN` returns all the joined rows, plus one row for each unmatched left-hand row (extended with nulls on the right), plus one row for each unmatched right-hand row (extended with nulls on the left).

ON join_condition join_condition is an expression resulting in a value of type `boolean` (similar to a `WHERE` clause) that specifies which rows in a join are considered to match.

USING (join_column [, ...]) A clause of the form `USING ( a, b, ... )` is shorthand for `ON left_table.a = right_table.a AND left_table.b = right_table.b ...`. Also, `USING` implies that only one of each pair of equivalent columns will be included in the join output, not both.

NATURAL `NATURAL` is shorthand for a `USING` list that mentions all columns in the two tables that have the same names. If there are no common column names, `NATURAL` is equivalent to `ON TRUE`.

CROSS JOIN `CROSS JOIN` is equivalent to `INNER JOIN ON (TRUE)`, that is, no rows are removed by qualification. They produce a simple Cartesian product, the same result as you get from listing the two tables at the top level of `FROM`, but restricted by the join condition (if any).

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

LATERAL The `LATERAL` key word can precede a sub-`SELECT FROM` item. This allows the sub-`SELECT` to refer to columns of `FROM` items that appear before it in the `FROM` list. (Without `LATERAL`, WarehousePG evaluates each sub-`SELECT` independently and so cannot cross-reference any other `FROM` item.)

`LATERAL` can also precede a function-call `FROM` item. In this case it is a noise word, because the function expression can refer to earlier `FROM` items.

A `LATERAL` item can appear at top level in the `FROM` list, or within a `JOIN` tree. In the latter case it can also refer to any items that are on the left-hand side of a `JOIN` that it is on the right-hand side of.

When a `FROM` item contains `LATERAL` cross-references, evaluation proceeds as follows: for each row of the `FROM` item providing the cross-referenced column(s), or set of rows of multiple `FROM` items providing the columns, the `LATERAL` item is evaluated using that row or row set's values of the columns. The resulting row(s) are joined as usual with the rows they were computed from. This is repeated for each row or set of rows from the column source table(s).

The column source table(s) must be `INNER` or `LEFT` joined to the `LATERAL` item, else there would not be a well-defined set of rows from which to compute each set of rows for the `LATERAL` item. Thus, although a construct such as `<X> RIGHT JOIN LATERAL <Y>` is syntactically valid, WarehousePG does not permit `<Y>` to reference `<X>`.

The WHERE Clause

The optional `WHERE` clause has the general form:

```
WHERE <condition>
```

where condition is any expression that evaluates to a result of type `boolean`. Any row that does not satisfy this condition will be eliminated from the output. A row satisfies the condition if it returns true when the actual row values are substituted for any variable references.

The GROUP BY Clause

The optional `GROUP BY` clause has the general form:

```
GROUP BY <grouping_element> [, ...]
```

where `<grouping_element>` can be one of:

```
()
<expression>
ROLLUP (<expression> [,...])
CUBE (<expression> [,...])
GROUPING SETS ((<grouping_element> [, ...]))
```

`GROUP BY` condenses into a single row all selected rows that share the same values for the grouped expressions. An expression used inside a grouping_element can be an input column name, or the name or ordinal number of an output column (`SELECT` list item), or an arbitrary expression formed from input-column values. In case of ambiguity, a `GROUP BY` name will be interpreted as an input-column name rather than an output column name.

If any of `GROUPING SETS`, `ROLLUP`, or `CUBE` are present as grouping elements, then the `GROUP BY` clause as a whole defines some number of independent grouping sets. The effect of this is equivalent to constructing a `UNION ALL` between subqueries with the individual grouping sets as their `GROUP BY` clauses. For further details on the handling of grouping sets, refer to GROUPING SETS, CUBE, and ROLLUP in the PostgreSQL documentation.

Aggregate functions, if any are used, are computed across all rows making up each group, producing a separate value for each group. (If there are aggregate functions but no `GROUP BY` clause, the query is treated as having a single group comprising all of the selected rows.) You can further filter the set of rows fed to each aggregate function by attaching a `FILTER` clause to the aggregate function call. When a `FILTER` clause is present, only those rows matching it are included in the input to that aggregate function. See Aggregate Expressions.

When `GROUP BY` is present, or any aggregate functions are present, it is not valid for the `SELECT` list expressions to refer to ungrouped columns except within aggregate functions or when the ungrouped column is functionally dependent on the grouped columns, since there would otherwise be more than one possible value to return for an ungrouped column. A functional dependency exists if the grouped columns (or a subset thereof) are the primary key of the table containing the ungrouped column.

Keep in mind that all aggregate functions are evaluated before evaluating any "scalar" expressions in the `HAVING` clause or `SELECT` list. This means that, for example, a `CASE` expression cannot be used to skip evaluation of an aggregate function; see Expression Evaluation Rules.

Currently, `FOR NO KEY UPDATE`, `FOR UPDATE`, `FOR SHARE`, and `FOR KEY SHARE` cannot be specified with `GROUP BY`.

WarehousePG has the following additional OLAP grouping extensions (often referred to as *supergroups*):

ROLLUP A `ROLLUP` grouping is an extension to the `GROUP BY` clause that creates aggregate subtotals that roll up from the most detailed level to a grand total, following a list of grouping columns (or expressions). `ROLLUP` takes an ordered list of grouping columns, calculates the standard aggregate values specified in the `GROUP BY` clause, then creates progressively higher-level subtotals, moving from right to left through the list. Finally, it creates a grand total. A `ROLLUP` grouping can be thought of as a series of grouping sets. For example:

```
```
GROUP BY ROLLUP (a,b,c)
```

is equivalent to:

```
GROUP BY GROUPING SETS( (a,b,c), (a,b), (a), () )
```

Notice that the n elements of a `ROLLUP` translate to n+1 grouping sets. Also, the order in which the grouping expressions are specified is significant in a `ROLLUP`.
```

CUBE A `CUBE` grouping is an extension to the `GROUP BY` clause that creates subtotals for all of the possible combinations of the given list of grouping columns (or expressions). In terms of multidimensional analysis, `CUBE` generates all the subtotals that could be calculated for a data cube with the specified dimensions. For example:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
GROUP BY CUBE (a,b,c)
```

is equivalent to:

```
GROUP BY GROUPING SETS( (a,b,c), (a,b), (a,c), (b,c), (a),
(b), (c), () )
```

Notice that n elements of a `CUBE` translate to 2n grouping sets. Consider using `CUBE` in any situation requiring cross-tabular reports. `CUBE` is typically most suitable in queries that use columns from multiple dimensions rather than columns representing different levels of a single dimension. For instance, a commonly requested cross-tabulation might need subtotals for all the combinations of month, state, and product.

GROUPING SETS You can selectively specify the set of groups that you want to create using a `GROUPING SETS` expression within a `GROUP BY` clause. This allows precise specification across multiple dimensions without computing a whole `ROLLUP` or `CUBE`. For example:

```
GROUP BY GROUPING SETS( (a,c), (a,b) )
```

If using the grouping extension clauses `ROLLUP`, `CUBE`, or `GROUPING SETS`, two challenges arise. First, how do you determine which result rows are subtotals, and then the exact level of aggregation for a given subtotal. Or, how do you differentiate between result rows that contain both stored `NULL` values and "NULL" values created by the `ROLLUP` or `CUBE`. Secondly, when duplicate grouping sets are specified in the `GROUP BY` clause, how do you determine which result rows are duplicates? There are two additional grouping functions you can use in the `SELECT` list to help with this:

- **grouping(column [, ...])** — The `grouping` function can be applied to one or more grouping attributes to distinguish super-aggregated rows from regular grouped rows. This can be helpful in distinguishing a "NULL" representing the set of all values in a super-aggregated row from a `NULL` value in a regular row. Each argument in this function produces a bit — either `1` or `0`, where `1` means the result row is super-aggregated, and `0` means the result row is from a regular grouping. The `grouping` function returns an integer by treating these bits as a binary number and then converting it to a base-10 integer.
- **group_id()** — For grouping extension queries that contain duplicate grouping sets, the `group_id` function is used to identify duplicate rows in the output. All *unique* grouping set output rows will have a `<group_id>` value of 0. For each duplicate grouping set detected, the `group_id` function assigns a `<group_id>` number greater than 0. All output rows in a particular duplicate grouping set are identified by the same `<group_id>` number.

The HAVING Clause

The optional `HAVING` clause has the general form:

```
HAVING <condition>
```

where `<condition>` is the same as specified for the `WHERE` clause.

`HAVING` eliminates group rows that do not satisfy the condition. `HAVING` is different from `WHERE`: `WHERE` filters individual rows before the application of `GROUP BY`, while `HAVING` filters group rows created by `GROUP BY`. Each column referenced in `<condition>` must unambiguously reference a grouping column, unless the reference appears within an aggregate function or the ungrouped column is functionally dependent on the grouping columns.

The presence of `HAVING` turns a query into a grouped query even if there is no `GROUP BY` clause. This is the same as what happens when the query contains aggregate functions but no `GROUP BY` clause. All of the selected rows are considered to form a single group, and the `SELECT` list and `HAVING` clause can only reference table columns from within aggregate functions. Such a query will emit a single row if the `HAVING` condition is true, zero rows if it is not true.

Currently, `FOR NO KEY UPDATE`, `FOR UPDATE`, `FOR SHARE`, and `FOR KEY SHARE` cannot be specified with `HAVING`.

The WINDOW Clause

The optional `WINDOW` clause specifies the behavior of window functions appearing in the query's `SELECT` list or `ORDER BY` clause. The `WINDOW` clause has the general form:

```
WINDOW <window_name> AS ( <window_definition> ) [, ...]
```

where `<window_name>` is a name that can be referenced from `OVER` clauses or subsequent window definitions, and `<window_definition>` is:

```
[<existing_window_name>]
[PARTITION BY <expression> [, ...]]
[ORDER BY <expression> [ASC | DESC | USING <operator>] [NULLS {FIRST | LAST}] [, ...] ]
[<frame_clause>]
```

A `WINDOW` clause entry does not have to be referenced anywhere, however; if it is not used in the query it is simply ignored. It is possible to use window functions without any `WINDOW` clause at all, since a window function call can specify its window definition directly in its `OVER` clause. However, the `WINDOW` clause saves typing when the same window definition is needed for more than one window function.

For example:

```
SELECT vendor, rank() OVER (mywindow) FROM sale
GROUP BY vendor
WINDOW mywindow AS (ORDER BY sum(prc*qty));
```

existing_window_name If an existing_window_name is specified, it must refer to an earlier entry in the `WINDOW` list; the new window copies its partitioning clause from that entry, as well as its ordering clause if any. The new window cannot specify its own `PARTITION BY` clause, and it can specify `ORDER BY` only if the copied window does not have one. The new window always uses its own frame clause; the copied window must not specify a frame clause.

PARTITION BY The `PARTITION BY` clause organizes the result set into logical groups based on the unique values of the specified expression. The elements of the `PARTITION BY` clause are interpreted in much the same fashion as elements of a GROUP BY Clause, except that they are always simple expressions and never the name or number of an output column. Another difference is that these expressions can contain aggregate function calls, which are not allowed in a regular `GROUP BY` clause. They are allowed here because windowing occurs after grouping and aggregation. When used with window functions, the functions are applied to each partition independently. For example, if you follow `PARTITION BY` with a column name, the result set is partitioned by the distinct values of that column. If omitted, the entire result set is considered one partition.

ORDER BY Similarly, the elements of the `ORDER BY` list are interpreted in much the same fashion as elements of an ORDER BY Clause, except that the expressions are always taken as simple expressions and never the name or number of an output column.

> **Note** The elements of the `ORDER BY` clause define how to sort the rows in each partition of the result set. If omitted, rows are returned in whatever order is most efficient and may vary.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

frame_clause The optional frame_clause defines the *window frame* for window functions that depend on the frame (not all do). The window frame is a set of related rows for each row of the query (called the *current row*). The frame_clause can be one of

```
{ RANGE | ROWS | GROUPS } <frame_start> [ <frame_exclusion> ]
{ RANGE | ROWS | GROUPS } BETWEEN <frame_start> AND <frame_end> [ <frame_exclusion> ]
```

where `<frame_start>` and `<frame_end>` can be one of

```
UNBOUNDED PRECEDING
<offset> PRECEDING
CURRENT ROW
<offset> FOLLOWING
UNBOUNDED FOLLOWING
```

and `<frame_exclusion>` can be one of

```
EXCLUDE CURRENT ROW
EXCLUDE GROUP
EXCLUDE TIES
EXCLUDE NO OTHERS
```

If `<frame_end>` is omitted it defaults to `CURRENT ROW`. Restrictions are that `<frame_start>` cannot be `UNBOUNDED FOLLOWING`, `<frame_end>` cannot be `UNBOUNDED PRECEDING`, and the `<frame_end>` choice cannot appear earlier in the above list of `<frame_start>` and `<frame_end>` options than the `<frame_start>` choice does — for example `RANGE BETWEEN CURRENT ROW AND <offset> PRECEDING` is not allowed.

The default framing option is `RANGE UNBOUNDED PRECEDING`, which is the same as `RANGE BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW`; it sets the frame to be all rows from the partition start up through the current row's last peer (a row that the window's `ORDER BY` clause considers equivalent to the current row; all rows are peers if there is no `ORDER BY`). In general, `UNBOUNDED PRECEDING` means that the frame starts with the first row of the partition, and similarly `UNBOUNDED FOLLOWING` means that the frame ends with the last row of the partition, regardless of `RANGE`, `ROWS` or `GROUPS` mode. In `ROWS` mode, `CURRENT ROW` means that the frame starts or ends with the current row; but in `RANGE` or `GROUPS` mode it means that the frame starts or ends with the current row's first or last peer in the `ORDER BY` ordering. The `<offset> PRECEDING` and `<offset> FOLLOWING` options vary in meaning depending on the frame mode. In `ROWS` mode, the `<offset>` is an integer indicating that the frame starts or ends that many rows before or after the current row. In `GROUPS` mode, the `<offset>` is an integer indicating that the frame starts or ends that many peer groups before or after the current row's peer group, where a peer group is a group of rows that are equivalent according to the window's `ORDER BY` clause. In `RANGE` mode, use of an `<offset>` option requires that there be exactly one `ORDER BY` column in the window definition. Then the frame contains those rows whose ordering column value is no more than `<offset>` less than (for `PRECEDING`) or more than (for `FOLLOWING`) the current row's ordering column value. In these cases the data type of the `<offset>` expression depends on the data type of the ordering column. For numeric ordering columns it is typically of the same type as the ordering column, but for datetime ordering columns it is an `interval`. In all these cases, the value of the `<offset>` must be non-null and non-negative. Also, while the offset does not have to be a simple constant, it cannot contain variables, aggregate functions, or window functions.

The `<frame_exclusion>` option allows rows around the current row to be excluded from the frame, even if they would be included according to the frame start and frame end options. `EXCLUDE CURRENT ROW` excludes the current row from the frame. `EXCLUDE GROUP` excludes the current row and its ordering peers from the frame. `EXCLUDE TIES` excludes any peers of the current row from the frame, but not the current row itself. `EXCLUDE NO OTHERS` simply specifies explicitly the default behavior of not excluding the current row or its peers.

Beware that the `ROWS` mode can produce unpredictable results if the `ORDER BY` ordering does not order the rows uniquely. The `RANGE` and `GROUPS` modes are designed to ensure that rows that are peers in the `ORDER BY` ordering are treated alike: all rows of a given peer group will be in the frame or excluded from it.

Use either a `ROWS`, `RANGE`, or `GROUPS` clause to express the bounds of the window. The window bound can be one, many, or all rows of a partition. You can express the bound of the window either in terms of a range of data values offset from the value in the current row (`RANGE`), in terms of the number of rows offset from the current row (`ROWS`), or in terms of the number of peer groups (`GROUPS`). When using the `RANGE` or the `GROUPS` clause, you must also use an `ORDER BY` clause. This is because the calculation performed to produce the window requires that the values be sorted. Additionally, the `ORDER BY` clause cannot contain more than one expression, and the expression must result in either a date or a numeric value. When using the `ROWS`, `RANGE` or `GROUPS` clauses, if you specify only a starting row, the current row is used as the last row in the window.

PRECEDING — The `PRECEDING` clause defines the first row of the window using the current row as a reference point. The starting row is expressed in terms of the number of rows preceding the current row. For example, in the case of `ROWS` framing, `5 PRECEDING` sets the window to start with the fifth row preceding the current row. In the case of `RANGE` framing, it sets the window to start with the first row whose ordering column value precedes that of the current row by 5 in the given order. If the specified order is ascending by date, this will be the first row within 5 days before the current row. `UNBOUNDED PRECEDING` sets the first row in the window to be the first row in the partition.

BETWEEN — The `BETWEEN` clause defines the first and last row of the window, using the current row as a reference point. First and last rows are expressed in terms of the number of rows preceding and following the current row, respectively. For example, `BETWEEN 3 PRECEDING AND 5 FOLLOWING` sets the window to start with the third row preceding the current row, and end with the fifth row following the current row. Use `BETWEEN UNBOUNDED PRECEDING AND UNBOUNDED FOLLOWING` to set the first and last rows in the window to be the first and last row in the partition, respectively. This is equivalent to the default behavior if no `ROWs`, `RANGE` or `GROUPS` clause is specified.

FOLLOWING — The `FOLLOWING` clause defines the last row of the window using the current row as a reference point. The last row is expressed in terms of the number of rows following the current row. For example, in the case of `ROWS` framing, `5 FOLLOWING` sets the window to end with the fifth row following the current row. In the case of `RANGE` framing, it sets the window to end with the last row whose ordering column value follows that of the current row by 5 in the given order. If the specified order is ascending by date, this will be the last row within 5 days after the current row. Use `UNBOUNDED FOLLOWING` to set the last row in the window to be the last row in the partition.

If you do not specify a `ROWS`, a `RANGE` or a `GROUPS` clause, the window bound starts with the first row in the partition (`UNBOUNDED PRECEDING`) and ends with the current row (`CURRENT ROW`) if `ORDER BY` is used. If an `ORDER BY` is not specified, the window starts with the first row in the partition (`UNBOUNDED PRECEDING`) and ends with last row in the partition (`UNBOUNDED FOLLOWING`).

The purpose of a `WINDOW` clause is to specify the behavior of window functions appearing in the query's SELECT List or ORDER BY Clause. These functions can reference the `WINDOW` clause entries by name in their `OVER` clauses. A `WINDOW` clause entry does not have to be referenced anywhere, however; if it is not used in the query it is simply ignored. It is possible to use window functions without any `WINDOW` clause at all, since a window function call can specify its window definition directly in its `OVER` clause. However, the `WINDOW` clause saves typing when the same window definition is needed for more than one window function.

Currently, `FOR NO KEY UPDATE`, `FOR UPDATE`, `FOR SHARE`, and `FOR KEY SHARE` cannot be specified with `WINDOW`.

See Window Expressions for more information about window functions.

The SELECT List

The `SELECT` list (between the key words `SELECT` and `FROM`) specifies expressions that form the output rows of the `SELECT` statement. The expressions can (and usually do) refer to columns computed in the `FROM` clause.

An expression in the `SELECT` list can be a constant value, a column reference, an operator invocation, a function call, an aggregate expression, a window expression, a scalar subquery, and so on. A number of constructs can be classified as an expression but do not follow any general syntax rules. These generally have the semantics of a function or operator. For information about SQL value expressions and function calls, see SQL: Querying Data in the *WarehousePG Administrator Guide*.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Just as in a table, every output column of a `SELECT` has a name. In a simple `SELECT` this name is just used to label the column for display, but when the `SELECT` is a sub-query of a larger query, the name is seen by the larger query as the column name of the virtual table produced by the sub-query. To specify the name to use for an output column, write `AS <output_name>` after the column's expression. (You can omit `AS`, but only if the desired output name does not match any SQL keyword. For protection against possible future keyword additions, you can always either write `AS` or double-quote the output name.) If you do not specify a column name, WarehousePG chooses a name automatically. If the column's expression is a simple column reference then the chosen name is the same as that column's name. In more complex cases, a function or type name may be used, or the system may fall back on a generated name such as `?column?` or `columnN`.

An output column's name can be used to refer to the column's value in `ORDER BY` and `GROUP BY` clauses, but not in the `WHERE` or `HAVING` clauses; there you must specify the expression instead.

Instead of an expression, you can specify `*` in the output list as a shorthand for all the columns of the selected rows. Also, you can specify `<table_name>.*` as a shorthand for the columns coming from just that table. In these cases it is not possible to specify new names with `AS`; the output column names will be the same as the table columns' names.

According to the SQL standard, the expressions in the output list should be computed before applying `DISTINCT`, `ORDER BY`, or `LIMIT`. This is obviously necessary when using `DISTINCT`, since otherwise it's not clear what values are being made distinct. However, in many cases it is convenient if output expressions are computed after `ORDER BY` and `LIMIT`; particularly if the output list contains any volatile or expensive functions. With that behavior, the order of function evaluations is more intuitive and there will not be evaluations corresponding to rows that never appear in the output. WarehousePG effectively evaluates output expressions after sorting and limiting, so long as those expressions are not referenced in `DISTINCT`, `ORDER BY`, or `GROUP BY`. (As a counterexample, `SELECT f(x) FROM tab ORDER BY 1` clearly must evaluate `f(x)` before sorting.) Output expressions that contain set-returning functions are effectively evaluated after sorting and before limiting, so that `LIMIT` will act to cut off the output from a set-returning function.

> **Note** WarehousePG versions prior to 7 did not provide any guarantees about the timing of evaluation of output expressions versus sorting and limiting; it depended on the form of the chosen query plan.

The DISTINCT Clause

If `SELECT DISTINCT` is specified, all duplicate rows are removed from the result set (one row is kept from each group of duplicates). `SELECT ALL` specifies the opposite: all rows are kept; that is the default.

`SELECT DISTINCT ON ( <expression> [, ...] )` keeps only the first row of each set of rows where the given expressions evaluate to equal. The `DISTINCT ON` expressions are interpreted using the same rules as for `ORDER BY` (see above). Note that the "first row" of each set is unpredictable unless `ORDER BY` is used to ensure that the desired row appears first. For example:

```
SELECT DISTINCT ON (location) location, time, report
    FROM weather_reports
    ORDER BY location, time DESC;
```

retrieves the most recent weather report for each location. But if we had not used `ORDER BY` to force descending order of time values for each location, we'd have gotten a report from an unpredictable time for each location.

The `DISTINCT ON` expression(s) must match the leftmost `ORDER BY` expression(s). The `ORDER BY` clause will normally contain additional expression(s) that determine the desired precedence of rows within each `DISTINCT ON` group.

Currently, `FOR NO KEY UPDATE`, `FOR UPDATE`, `FOR SHARE`, and `FOR KEY SHARE` cannot be specified with `DISTINCT`.

The UNION Clause

The `UNION` clause has this general form:

```
<select_statement> UNION [ALL | DISTINCT] <select_statement>
```

`<select_statement>` is any `SELECT` statement without an `ORDER BY`, `LIMIT`, `FOR NO KEY UPDATE`, `FOR UPDATE`, `FOR SHARE`, or `FOR KEY SHARE` clause. (`ORDER BY` and `LIMIT` can be attached to a subquery expression if it is enclosed in parentheses. Without parentheses, these clauses will be taken to apply to the result of the `UNION`, not to its right-hand input expression.)

The `UNION` operator computes the set union of the rows returned by the involved `SELECT` statements. A row is in the set union of two result sets if it appears in at least one of the result sets. The two `SELECT` statements that represent the direct operands of the `UNION` must produce the same number of columns, and corresponding columns must be of compatible data types.

The result of `UNION` does not contain any duplicate rows unless the `ALL` option is specified. `ALL` prevents elimination of duplicates. (Therefore, `UNION ALL` is usually significantly quicker than `UNION`; use `ALL` when you can.) `DISTINCT` can be specified to explicitly specify the default behavior of eliminating duplicate rows.

Multiple `UNION` operators in the same `SELECT` statement are evaluated left to right, unless otherwise indicated by parentheses.

Currently, `FOR NO KEY UPDATE`, `FOR UPDATE`, `FOR SHARE`, and `FOR KEY SHARE` cannot be specified either for a `UNION` result or for any input of a `UNION`.

The INTERSECT Clause

The `INTERSECT` clause has this general form:

```
<select_statement> INTERSECT [ALL | DISTINCT] <select_statement>
```

`<select_statement>` is any `SELECT` statement without an `ORDER BY`, `LIMIT`, `FOR NO KEY UPDATE`, `FOR UPDATE`, `FOR SHARE`, or `FOR KEY SHARE` clause.

The `INTERSECT` operator computes the set intersection of the rows returned by the involved `SELECT` statements. A row is in the intersection of two result sets if it appears in both result sets.

The result of `INTERSECT` does not contain any duplicate rows unless the `ALL` option is specified. With `ALL`, a row that has `<m>` duplicates in the left table and `<n>` duplicates in the right table will appear `min(<m>, <n>)` times in the result set. `DISTINCT` can be written to explicitly specify the default behavior of eliminating duplicate rows.

Multiple `INTERSECT` operators in the same `SELECT` statement are evaluated left to right, unless parentheses dictate otherwise. `INTERSECT` binds more tightly than `UNION`. That is, `A UNION B INTERSECT C` will be read as `A UNION (B INTERSECT C)`.

Currently, `FOR NO KEY UPDATE`, `FOR UPDATE`, `FOR SHARE`, and `FOR KEY SHARE` cannot be specified either for an `INTERSECT` result or for any input of an `INTERSECT`.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

The EXCEPT Clause

The `EXCEPT` clause has this general form:

```
<select_statement> EXCEPT [ALL | DISTINCT] <select_statement>
```

`<select_statement>` is any `SELECT` statement without an `ORDER BY`, `LIMIT`, `FOR NO KEY UPDATE`, `FOR UPDATE`, `FOR SHARE`, or `FOR KEY SHARE` clause.

The `EXCEPT` operator computes the set of rows that are in the result of the left `SELECT` statement but not in the result of the right one.

The result of `EXCEPT` does not contain any duplicate rows unless the `ALL` option is specified. With `ALL`, a row that has `<m>` duplicates in the left table and `<n>` duplicates in the right table will appear `max(<m>-<n>,0)` times in the result set. `DISTINCT` can be written to explicitly specify the default behavior of eliminating duplicate rows.

Multiple `EXCEPT` operators in the same `SELECT` statement are evaluated left to right, unless parentheses dictate otherwise. `EXCEPT` binds at the same level as `UNION`.

Currently, `FOR NO KEY UPDATE`, `FOR UPDATE`, `FOR SHARE`, and `FOR KEY SHARE` cannot be specified either for an `EXCEPT` result or for any input of an `EXCEPT`.

The ORDER BY Clause

The optional `ORDER BY` clause has this general form:

```
ORDER BY <expression> [ASC | DESC | USING <operator>] [NULLS {FIRST | LAST}] [,...]
```

The `ORDER BY` clause causes the result rows to be sorted according to the specified expression(s). If two rows are equal according to the left-most expression, they are compared according to the next expression and so on. If they are equal according to all specified expressions, they are returned in an implementation-dependent order.

Each `<expression>` can be the name or ordinal number of an output column (`SELECT` list item), or it can be an arbitrary expression formed from input-column values.

The ordinal number refers to the ordinal (left-to-right) position of the output column. This feature makes it possible to define an ordering on the basis of a column that does not have a unique name. This is never absolutely necessary because it is always possible to assign a name to an output column using the `AS` clause.

It is also possible to use arbitrary expressions in the `ORDER BY` clause, including columns that do not appear in the `SELECT` output list. Thus the following statement is valid:

```
SELECT name FROM distributors ORDER BY code;
```

A limitation of this feature is that an `ORDER BY` clause applying to the result of a `UNION`, `INTERSECT`, or `EXCEPT` clause may only specify an output column name or number, not an expression.

If an `ORDER BY` expression is a simple name that matches both an output column name and an input column name, `ORDER BY` will interpret it as the output column name. This is the opposite of the choice that `GROUP BY` will make in the same situation. This inconsistency is made to be compatible with the SQL standard.

Optionally one may add the key word `ASC` (ascending) or `DESC` (descending) after any expression in the `ORDER BY` clause. If not specified, `ASC` is assumed by default. Alternatively, a specific ordering operator name may be specified in the `USING` clause. `ASC` is usually equivalent to `USING <` and `DESC` is usually equivalent to `USING >`. (But the creator of a user-defined data type can define exactly what the default sort ordering is, and it might correspond to operators with other names.)

If `NULLS LAST` is specified, null values sort after all non-null values; if `NULLS FIRST` is specified, null values sort before all non-null values. If neither is specified, the default behavior is `NULLS LAST` when `ASC` is specified or implied, and `NULLS FIRST` when `DESC` is specified (thus, the default is to act as though nulls are larger than non-nulls). When `USING` is specified, the default nulls ordering depends upon whether the operator is a less-than or greater-than operator.

Note that ordering options apply only to the expression they follow; for example `ORDER BY x, y DESC` does not mean the same thing as `ORDER BY x DESC, y DESC`.

Character-string data is sorted according to the locale-specific collation order that was established when the database was created. You can override this at need by including a `COLLATE` clause in the expression, for example `ORDER BY mycolumn COLLATE "en_US"`.

Character-string data is sorted according to the collation that applies to the column being sorted. That can be overridden as needed by including a `COLLATE` clause in the expression, for example `ORDER BY mycolumn COLLATE "en_US"`. For information about defining collations, see CREATE COLLATION.

The LIMIT Clause

The `LIMIT` clause consists of two independent sub-clauses:

```
LIMIT {<count> | ALL}
OFFSET <start>
```

`<count>` specifies the maximum number of rows to return, while `<start>` specifies the number of rows to skip before starting to return rows. When both are specified, `<start>` rows are skipped before starting to count the `<count>` rows to be returned.

If the `<count>` expression evaluates to NULL, it is treated as `LIMIT ALL`, that is, no limit. If `<start>` evaluates to NULL, it is treated the same as `OFFSET 0`.

SQL:2008 introduced a different syntax to achieve the same result, which WarehousePG also supports. It is:

```
OFFSET <start> [ ROW | ROWS ]
    FETCH { FIRST | NEXT } [ <count> ] { ROW | ROWS } ONLY
```

In this syntax, the `<start>` or `<count>` value is required by the standard to be a literal constant, a parameter, or a variable name; as a WarehousePG extension, other expressions are allowed, but will generally need to be enclosed in parentheses to avoid ambiguity. If `<count>` is omitted in a `FETCH` clause, it defaults to 1. `ROW` and `ROWS` as well as `FIRST` and `NEXT` are noise words that don't influence the effects of these clauses. According to the standard, the `OFFSET` clause must come before the `FETCH` clause if both are present; but WarehousePG allows either order.

When using `LIMIT`, it is a good idea to use an `ORDER BY` clause that constrains the result rows into a unique order. Otherwise you will get an unpredictable subset of the query's rows — you may be asking for the tenth through twentieth rows, but tenth through twentieth in what ordering? You don't know what ordering unless you specify `ORDER BY`.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

The query optimizer takes `LIMIT` into account when generating a query plan, so you are very likely to get different plans (yielding different row orders) depending on what you use for `LIMIT` and `OFFSET`. Thus, using different `LIMIT/OFFSET` values to select different subsets of a query result will give inconsistent results unless you enforce a predictable result ordering with `ORDER BY`. This is not a defect; it is an inherent consequence of the fact that SQL does not promise to deliver the results of a query in any particular order unless `ORDER BY` is used to constrain the order.

It is even possible for repeated executions of the same `LIMIT` query to return different subsets of the rows of a table, if there is not an `ORDER BY` to enforce selection of a deterministic subset. Again, this is not a bug; WarehousePG does not guarantee determinism of the results in such a case.

The Locking Clause

`FOR UPDATE`, `FOR NO KEY UPDATE`, `FOR SHARE`, and `FOR KEY SHARE` are *locking clauses*; they affect how `SELECT` locks rows as they are obtained from the table. The Global Deadlock Detector affects the locking used by `SELECT` queries that contain a locking clause (`FOR <lock_strength>`). The Global Deadlock Detector is enabled by setting the gp_enable_global_deadlock_detector configuration parameter to `on`. See Global Deadlock Detector in the *WarehousePG Administrator Guide* for information about the Global Deadlock Detector.

The locking clause has the general form:

```
FOR <lock_strength> [OF <table_name> [ , ... ] ] [ NOWAIT | SKIP LOCKED ]
```

`<lock_strength>` can be one of these values:

- `UPDATE` - Locks the table with an `EXCLUSIVE` lock.
- `NO KEY UPDATE` - Locks the table with an `EXCLUSIVE` lock.
- `SHARE` - Locks the table with a `ROW SHARE` lock.
- `KEY SHARE` - Locks the table with a `ROW SHARE` lock.

When the Global Deadlock Detector is deactivated (the default), WarehousePG uses the specified lock.

When the Global Deadlock Detector is enabled, a `ROW SHARE` lock is used to lock the table for simple `SELECT` queries that contain a locking clause, and the query plans contain a `lockrows` node. Simple `SELECT` queries that contain a locking clause fulfill all the following conditions:

- The locking clause is in the top level `SELECT` context.
- The `FROM` clause contains a single table that is not a view or an append optimized table.
- The `SELECT` command does not contain a set operation such as `UNION` or `INTERSECT`.
- The `SELECT` command does not contain a sub-query.

Otherwise, table locking for a `SELECT` query that contains a locking clause behaves as if the Global Deadlock Detector is deactivated.

> **Note** The Global Deadlock Detector also affects the locking used by `DELETE` and `UPDATE` operations. By default, WarehousePG acquires an `EXCLUSIVE` lock on tables for `DELETE` and `UPDATE` operations on heap tables. When the Global Deadlock Detector is enabled, the lock mode for `DELETE` and `UPDATE` operations on heap tables is `ROW EXCLUSIVE`.

For more information on each row-level lock mode, refer to Explicit Locking in the PostgreSQL documentation.

To prevent the operation from waiting for other transactions to commit, use either the `NOWAIT` option or the `SKIP LOCKED` option. With `NOWAIT`, the statement reports an error, rather than waiting, if a selected row cannot be locked immediately. With `SKIP LOCKED`, any selected rows that cannot be immediately locked are skipped. Skipping locked rows provides an inconsistent view of the data, so this is not suitable for general purpose work, but can be used to avoid lock contention with multiple consumers accessing a queue-like table. Note that `NOWAIT` and `SKIP LOCKED` apply only to the row-level lock(s) — the required `ROW SHARE` table-level lock is still taken in the ordinary way. You can use LOCK with the `NOWAIT` option first, if you need to acquire the table-level lock without waiting.

If specific tables are named in a locking clause, then only rows coming from those tables are locked; any other tables used in the `SELECT` are simply read as usual. A locking clause without a table list affects all tables used in the statement. If a locking clause is applied to a view or sub-query, it affects all tables used in the view or sub-query. However, these clauses do not apply to `WITH` queries referenced by the primary query. If you want row locking to occur within a `WITH` query, specify a locking clause within the `WITH` query.

Multiple locking clauses can be written if it is necessary to specify different locking behavior for different tables. If the same table is mentioned (or implicitly affected) by both more than one locking clause, then it is processed as if it was only specified by the strongest one. Similarly, a table is processed as `NOWAIT` if that is specified in any of the clauses affecting it. Otherwise, it is processed as `SKIP LOCKED` if that is specified in any of the clauses affecting it.

The locking clauses cannot be used in contexts where returned rows cannot be clearly identified with individual table rows; for example they cannot be used with aggregation.

When a locking clause appears at the top level of a `SELECT` query, the rows that are locked are exactly those that are returned by the query; in the case of a join query, the rows locked are those that contribute to returned join rows. In addition, rows that satisfied the query conditions as of the query snapshot will be locked, although they will not be returned if they were updated after the snapshot and no longer satisfy the query conditions. If a `LIMIT` is used, locking stops once enough rows have been returned to satisfy the limit (but note that rows skipped over by `OFFSET` will get locked). Similarly, if a locking clause is used in a cursor's query, only rows actually fetched or stepped past by the cursor will be locked.

When a locking clause appears in a sub-`SELECT`, the rows locked are those returned to the outer query by the sub-query. This might involve fewer rows than inspection of the sub-query alone would suggest, since conditions from the outer query might be used to optimize execution of the sub-query. For example,

```
SELECT * FROM (SELECT * FROM mytable FOR UPDATE) ss WHERE col1 = 5;
```

will lock only rows having `col1 = 5`, even though that condition is not textually within the sub-query.

It is possible for a `SELECT` command running at the `READ COMMITTED` transaction isolation level and using `ORDER BY` and a locking clause to return rows out of order. This is because `ORDER BY` is applied first. The command sorts the result, but might then block trying to obtain a lock on one or more of the rows. Once the `SELECT` unblocks, some of the ordering column values might have been modified, leading to those rows appearing to be out of order (though they are in order in terms of the original column values). This can be worked around at need by placing the `FOR UPDATE/SHARE` clause in a sub-query, for example

```
SELECT * FROM (SELECT * FROM mytable FOR UPDATE) ss ORDER BY column1;
```

Note that this will result in locking all rows of `mytable`, whereas `FOR UPDATE` at the top level would lock only the actually returned rows. This can make for a significant performance difference, particularly if the `ORDER BY` is combined with `LIMIT` or other restrictions. So this technique is recommended only if concurrent updates of the ordering columns are expected and a strictly sorted result is required.

At the `REPEATABLE READ` or `SERIALIZABLE` transaction isolation level this would cause a serialization failure (with a `SQLSTATE` of `40001`), so there is no possibility of receiving rows out of order under these isolation levels.

The TABLE Command

The command

```
TABLE <name>
```

is equivalent to

```
SELECT * FROM <name>
```

It can be used as a top-level command or as a space-saving syntax variant in parts of complex queries. Only the `WITH`, `UNION`, `INTERSECT`, `EXCEPT`, `ORDER BY`, `LIMIT`, `OFFSET`, `FETCH`, and `FOR` locking clauses can be used with `TABLE`; the `WHERE` clause and any form of aggregation cannot be used.

Examples

To join the table `films` with the table `distributors`:

```
SELECT f.title, f.did, d.name, f.date_prod, f.kind
  FROM distributors d, JOIN films f USING (did);
```

To sum the column `length` of all films and group the results by `kind`:

```
SELECT kind, sum(length) AS total FROM films GROUP BY kind;
```

To sum the column `length` of all films, group the results by `kind`, and show those group totals that are less than 5 hours:

```
SELECT kind, sum(length) AS total FROM films GROUP BY kind
  HAVING sum(length) < interval '5 hours';
```

Calculate the subtotals and grand totals of all sales for movie `kind` and `distributor`.

```
SELECT kind, distributor, sum(prc*qty) FROM sales
GROUP BY ROLLUP(kind, distributor)
ORDER BY 1,2,3;
```

Calculate the rank of movie distributors based on total sales:

```
SELECT distributor, sum(prc*qty),
       rank() OVER (ORDER BY sum(prc*qty) DESC)
FROM sales
GROUP BY distributor ORDER BY 2 DESC;
```

The following two examples are identical ways of sorting the individual results according to the contents of the second column (`name`):

```
SELECT * FROM distributors ORDER BY name;
SELECT * FROM distributors ORDER BY 2;
```

The next example shows how to obtain the union of the tables `distributors` and `actors`, restricting the results to those that begin with the letter `W` in each table. Only distinct rows are wanted, so the key word `ALL` is omitted:

```
SELECT distributors.name
  FROM distributors
  WHERE distributors.name LIKE 'W%'
UNION
SELECT actors.name
  FROM actors
  WHERE actors.name LIKE 'W%';
```

This example shows how to use a function in the `FROM` clause, both with and without a column definition list:

```
CREATE FUNCTION distributors(int) RETURNS SETOF distributors
AS $$ SELECT * FROM distributors WHERE did = $1; $$ LANGUAGE
SQL;
SELECT * FROM distributors(111);

CREATE FUNCTION distributors_2(int) RETURNS SETOF record AS
$$ SELECT * FROM distributors WHERE did = $1; $$ LANGUAGE
SQL;
SELECT * FROM distributors_2(111) AS (dist_id int, dist_name text);
```

This example uses a function with an ordinality column added:

```
SELECT * FROM unnest(ARRAY['a','b','c','d','e','f']) WITH ORDINALITY;
```

This example uses a simple `WITH` clause:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
WITH test AS (
  SELECT random() as x FROM generate_series(1, 3)
  )
SELECT * FROM test
UNION ALL
SELECT * FROM test;
```

This example uses the `WITH` clause to display per-product sales totals in only the top sales regions.

```
WITH regional_sales AS
    SELECT region, SUM(amount) AS total_sales
    FROM orders
    GROUP BY region
  ), top_regions AS (
    SELECT region
    FROM regional_sales
    WHERE total_sales > (SELECT SUM(total_sales) FROM
       regional_sales)
  )
SELECT region, product, SUM(quantity) AS product_units,
   SUM(amount) AS product_sales
FROM orders
WHERE region IN (SELECT region FROM top_regions)
GROUP BY region, product;
```

The example could have been written without the `WITH` clause but would have required two levels of nested sub- `SELECT` statements.

This example uses the `WITH RECURSIVE` clause to find all subordinates (direct or indirect) of the employee Mary, and their level of indirectness, from a table that shows only direct subordinates:

```
WITH RECURSIVE employee_recursive(distance, employee_name, manager_name) AS (
    SELECT 1, employee_name, manager_name
    FROM employee
    WHERE manager_name = 'Mary'
  UNION ALL
    SELECT er.distance + 1, e.employee_name, e.manager_name
    FROM employee_recursive er, employee e
    WHERE er.employee_name = e.manager_name
  )
SELECT distance, employee_name FROM employee_recursive;
```

The typical form of a recursive query is an initial condition, followed by `UNION [ALL]`, followed by the recursive part of the query. Be sure that the recursive part of the query will eventually return no tuples, or else the query will loop indefinitely. See WITH Queries (Common Table Expressions)in the *WarehousePG Administrator Guide* for more examples.

This example uses `LATERAL` to apply a set-returning function `get_product_names()` for each row of the `manufacturers` table:

```
SELECT m.name AS mname, pname
  FROM manufacturers m, LATERAL get_product_names(m.id) pname;
```

Manufacturers not currently having any products would not appear in the result, since it is an inner join. If we wished to include the names of such manufacturers in the result, we could write the query as follows:

```
SELECT m.name AS mname, pname
  FROM manufacturers m LEFT JOIN LATERAL get_product_names(m.id) pname ON true;
```

Compatibility

The `SELECT` statement is compatible with the SQL standard, but there are some extensions and some missing features.

Omitted FROM Clauses

WarehousePG allows one to omit the `FROM` clause. It has a straightforward use to compute the results of simple expressions. For example:

```
SELECT 2+2;
```

Some other SQL databases cannot do this except by introducing a dummy one-row table from which to do the `SELECT`.

Note that if a `FROM` clause is not specified, the query cannot reference any database tables. For example, the following query is invalid:

```
SELECT distributors.* WHERE distributors.name = 'Westward';
```

In earlier releases, setting a server configuration parameter, `add_missing_from`, to true allowed WarehousePG to add an implicit entry to the query's `FROM` clause for each table referenced by the query. This is no longer allowed.

Empty SELECT Lists

The list of output expressions after `SELECT` can be empty, producing a zero-column result table. This is not valid syntax according to the SQL standard. WarehousePG allows it to be consistent with allowing zero-column tables. However, an empty list is not allowed when `DISTINCT` is used.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Omitting the AS Key Word

In the SQL standard, the optional key word `AS` can be omitted before an output column name whenever the new column name is a valid column name (that is, not the same as any reserved keyword). WarehousePG is slightly more restrictive: `AS` is required if the new column name matches any keyword at all, reserved or not. Recommended practice is to use `AS` or double-quote output column names, to prevent any possible conflict against future keyword additions.

In `FROM` items, both the standard and WarehousePG allow `AS` to be omitted before an alias that is an unreserved keyword. But this is impractical for output column names, because of syntactic ambiguities.

ONLY and Inheritance

The SQL standard requires parentheses around the table name when writing `ONLY`, for example:

```
SELECT * FROM ONLY (tab1), ONLY (tab2) WHERE ...
```

WarehousePG considers these parentheses to be optional.

WarehousePG allows a trailing `*` to be written to explicitly specify the non-`ONLY` behavior of including child tables. The standard does not allow this.

Note: The above points apply equally to all SQL commands supporting the `ONLY` option.

Function Calls in FROM

WarehousePG allows you to write a function call directly as a member of the `FROM` list. In the SQL standard it would be necessary to wrap such a function call in a sub-`SELECT`; that is, the syntax `FROM func(...) alias` is approximately equivalent to `FROM LATERAL (SELECT func(...)) alias`. Note that `LATERAL` is considered to be implicit; this is because the standard requires `LATERAL` semantics for an `UNNEST()` item in `FROM`. WarehousePG treats `UNNEST()` the same as other set-returning functions.

Namespace Available to GROUP BY and ORDER BY

In the SQL-92 standard, an `ORDER BY` clause may only use output column names or numbers, while a `GROUP BY` clause may only use expressions based on input column names. WarehousePG extends each of these clauses to allow the other choice as well (but it uses the standard's interpretation if there is ambiguity). WarehousePG also allows both clauses to specify arbitrary expressions. Note that names appearing in an expression are always taken as input-column names, not as output column names.

SQL:1999 and later use a slightly different definition which is not entirely upward compatible with SQL-92. In most cases, however, WarehousePG interprets an `ORDER BY` or `GROUP BY` expression the same way SQL:1999 does.

Functional Dependencies

WarehousePG recognizes functional dependency (allowing columns to be omitted from `GROUP BY`) only when a table's primary key is included in the `GROUP BY` list. The SQL standard specifies additional conditions that should be recognized.

LIMIT and OFFSET

The clauses `LIMIT` and `OFFSET` are WarehousePG-specific syntax, also used by MySQL. The SQL:2008 standard has introduced the clauses `OFFSET .. FETCH {FIRST|NEXT} ...` for the same functionality, as shown above in LIMIT Clause. This syntax is also used by IBM DB2. (Applications for Oracle frequently use a workaround involving the automatically generated `rownum` column, which is not available in WarehousePG, to implement the effects of these clauses.)

FOR NO KEY UPDATE, FOR UPDATE, FOR SHARE, and FOR KEY SHARE

Although `FOR UPDATE` appears in the SQL standard, the standard allows it only as an option of `DECLARE CURSOR`. WarehousePG allows it in any `SELECT` query as well as in sub-`SELECT`s, but this is an extension. The `FOR NO KEY UPDATE`, `FOR SHARE`, and `FOR KEY SHARE` variants, as well as the `NOWAIT` and `SKIP LOCKED` options, do not appear in the standard.

Data-Modifying Statements in WITH

WarehousePG allows `INSERT`, `UPDATE`, and `DELETE` to be used as `WITH` queries. This is not found in the SQL standard.

Nonstandard Clauses

The clause `DISTINCT ON` is not defined in the SQL standard.

`ROWS FROM( ... )` is an extension of the SQL standard.

The `MATERIALIZED` and `NOT MATERIALIZED` options of `WITH` are extensions of the SQL standard.

Limited Use of STABLE and VOLATILE Functions

To prevent data from becoming out-of-sync across the segments in WarehousePG, any function classified as `STABLE` or `VOLATILE` cannot be run at the segment database level if it contains SQL or modifies the database in any way. See CREATE FUNCTION for more information.

7.1.164 SELECT INTO

Defines a new table from the results of a query.

Synopsis

```
[ WITH [ RECURSIVE ] <with_query> [, ...] ]
SELECT [ALL | DISTINCT [ON ( <expression> [, ...] )]]
    * | <expression> [ [AS] <output_name> ] [, ...]
    INTO [TEMPORARY | TEMP | UNLOGGED ] [TABLE] <new_table>
    [FROM <from_item> [, ...]]
    [WHERE <condition>]
    [GROUP BY <expression> [, ...]]
    [HAVING <condition> [, ...]]
    [WINDOW <window_name> AS ( <window_definition> ) [, ...]]
    [{UNION | INTERSECT | EXCEPT} [ALL | DISTINCT ] <select>]
    [ORDER BY <expression> [ASC | DESC | USING <operator>] [NULLS {FIRST | LAST}] [, ...]]
    [LIMIT {<count> | ALL}]
    [OFFSET <start> [ ROW | ROWS ] ]
    [FETCH { FIRST | NEXT } [ <count> ] { ROW | ROWS } ONLY ]
    [FOR {UPDATE | SHARE} [OF <table_name> [, ...]] [NOWAIT] [...]]
```

Description

`SELECT INTO` creates a new table and fills it with data computed by a query. The data is not returned to the client, as it is with a normal `SELECT`. The new table's columns have the names and data types associated with the output columns of the `SELECT`.

Parameters

TEMPORARY TEMP If specified, the table is created as a temporary table. Refer to CREATE TABLE for details.

UNLOGGED If specified, the table is created as an unlogged table. Refer to CREATE TABLE for details.

new_table The name (optionally schema-qualified) of the table to be created.

All other parameters for `SELECT INTO` are described in detail on the SELECT reference page.

Notes

CREATE TABLE AS is functionally similar to `SELECT INTO`. `CREATE TABLE AS` is the recommended syntax, since this form of `SELECT INTO` is not available in ECPG or PL/pgSQL, because they interpret the `INTO` clause differently. Also, `CREATE TABLE AS` offers a superset of the functionality provided by `SELECT INTO`.

In contrast to `CREATE TABLE AS`, `SELECT INTO` does not allow specifying properties like a table's access method with `USING <method>` or the table's tablespace with `TABLESPACE <tablespace_name>`. Use CREATE TABLE AS if necessary. Therefore, the default table access method is chosen for the new table. See default_table_access_method for more information.

Examples

Create a new table `films_recent` consisting only of recent entries from the table `films`:

```
SELECT * INTO films_recent FROM films WHERE date_prod >= '2016-01-01';
```

Compatibility

The SQL standard uses `SELECT INTO` to represent selecting values into scalar variables of a host program, rather than creating a new table. The WarehousePG usage of `SELECT INTO` to represent table creation is historical. It is best to use CREATE TABLE AS for this purpose in new applications.

7.1.165 SET

Changes the value of a run-time WarehousePG configuration parameter.

Synopsis

```
SET [ SESSION | LOCAL ] <configuration_parameter> { TO | = } { <value> | '<value>' | DEFAULT }

SET [SESSION | LOCAL] TIME ZONE { <value> | '<value>' |  LOCAL | DEFAULT }
```

Description

The `SET` command changes server configuration parameters. Any configuration parameter classified as a session parameter can be changed on-the-fly with `SET`. (Some require superuser privileges to change, and others cannot be changed after server or session start.) `SET` affects only the value used by the current session.

If `SET` or `SET SESSION` is issued within a transaction that is later cancelled, the effects of the `SET` command disappear when the transaction is rolled back. Once the surrounding transaction is committed, the effects will persist until the end of the session, unless overridden by another `SET`.

The effects of `SET LOCAL` last only till the end of the current transaction, whether committed or not. A special case is `SET` followed by `SET LOCAL` within a single transaction: the `SET LOCAL` value will be seen until the end of the transaction, but afterwards (if the transaction is committed) the `SET` value will take effect.

The effects of `SET` or `SET LOCAL` are also canceled by rolling back to a savepoint that is earlier than the command.

If `SET LOCAL` is used within a function that includes a `SET` option for the same configuration parameter (see CREATE FUNCTION), the effects of the `SET LOCAL` command disappear at function exit; the value in effect when the function was called is restored anyway. This allows `SET LOCAL` to be used for dynamic or repeated changes of a parameter within a function, while retaining the convenience of using the `SET` option to save and restore the caller's value. Note that a regular `SET` command overrides any surrounding function's `SET` option; its effects persist unless rolled back.

See Server Configuration Parameters for information about server parameters.

Parameters

SESSION Specifies that the command takes effect for the current session. This is the default if neither `SESSION` nor `LOCAL` appears.

LOCAL Specifies that the command takes effect for only the current transaction. After `COMMIT` or `ROLLBACK`, the session-level setting takes effect again. Issuing this outside of a transaction block emits a warning and otherwise has no effect.

configuration_parameter The name of a settable WarehousePG run-time configuration parameter. Only parameters classified as *session* can be changed with `SET`. See Server Configuration Parameters for details.

value New value of the parameter. Values can be specified as string constants, identifiers, numbers, or comma-separated lists of these, as appropriate for the particular parameter. `DEFAULT` can be used to specify resetting the parameter to its default value (that is, whatever value it would have had if no `SET` had been issued in the current session). If specifying memory sizing or time units, enclose the value in single quotes.

There are a few configuration parameters that can only be adjusted using the `SET` command or that have a special syntax:

SCHEMA `SET SCHEMA '<value>'` is an alias for `SET <search_path> TO <value>`. Only one schema may be specified using this syntax.

NAMES `SET NAMES <value>` is an alias for `SET client_encoding TO <value>`.

SEED Sets the internal seed for the random number generator (the function `random()`). Allowed values are floating-point numbers between -1 and 1 inclusive.

You can also set the seed by invoking the `setseed()` function:

```
```
SELECT setseed(value);
```
```

TIME ZONE `SET TIME ZONE <value>` is an alias for `SET timezone TO <value>`. The syntax `SET TIME ZONE` allows special syntax for the time zone specification. Examples of valid values follow:

```
- `'PST8PDT'`
- `'Europe/Rome'`
- `-7` \(time zone 7 hours west from UTC\)
- `INTERVAL '-08:00' HOUR TO MINUTE` \(time zone 8 hours west from UTC\).

LOCAL
DEFAULT
Set the time zone to your local time zone \(that is, server's default value of timezone\).

See the [Time Zones](https://www.postgresql.org/docs/12/datatype-datetime.html#DATATYPE-TIMEZONES) section of the PostgreSQL documentation for more information
about time zones in WarehousePG.
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Examples

Set the schema search path:

```
SET search_path TO my_schema, public;
```

Increase the segment host memory per query to 200 MB:

```
SET statement_mem TO '200MB';
```

Set the style of date to traditional POSTGRES with "day before month" input convention:

```
SET datestyle TO postgres, dmy;
```

Set the time zone for San Mateo, California (Pacific Time):

```
SET TIME ZONE 'PST8PDT';
```

Set the time zone for Italy:

```
SET TIME ZONE 'Europe/Rome';
```

Compatibility

`SET TIME ZONE` extends syntax defined in the SQL standard. The standard allows only numeric time zone offsets while WarehousePG allows more flexible time-zone specifications. All other `SET` features are WarehousePG extensions.

7.1.166 SET CONSTRAINTS

Sets constraint check timing for the current transaction.

> **Note** Referential integrity syntax (foreign key constraints) is accepted but not enforced.

Synopsis

```
SET CONSTRAINTS { ALL | <name> [, ...] } { DEFERRED | IMMEDIATE }
```

Description

`SET CONSTRAINTS` sets the behavior of constraint checking within the current transaction. `IMMEDIATE` constraints are checked at the end of each statement. `DEFERRED` constraints are not checked until transaction commit. Each constraint has its own `IMMEDIATE` or `DEFERRED` mode.

Upon creation, a constraint is given one of three characteristics: `DEFERRABLE INITIALLY DEFERRED`, `DEFERRABLE INITIALLY IMMEDIATE`, or `NOT DEFERRABLE`. The third class is always `IMMEDIATE` and is not affected by the `SET CONSTRAINTS` command. The first two classes start every transaction in the indicated mode, but their behavior can be changed within a transaction by `SET CONSTRAINTS`.

`SET CONSTRAINTS` with a list of constraint names changes the mode of just those constraints (which must all be deferrable). Each constraint name can be schema-qualified. The current schema search path is used to find the first matching name if no schema name is specified. `SET CONSTRAINTS ALL` changes the mode of all deferrable constraints.

When `SET CONSTRAINTS` changes the mode of a constraint from `DEFERRED` to `IMMEDIATE`, the new mode takes effect retroactively: any outstanding data modifications that would have been checked at the end of the transaction are instead checked during the execution of the `SET CONSTRAINTS` command. If any such constraint is violated, the `SET CONSTRAINTS` fails (and does not change the constraint mode). Thus, `SET CONSTRAINTS` can be used to force checking of constraints to occur at a specific point in a transaction.

Currently, only `UNIQUE`, `PRIMARY KEY`, `REFERENCES` (foreign key), and `EXCLUDE` constraints are affected by this setting. `NOT NULL` and `CHECK` constraints are always checked immediately when a row is inserted or modified (*not* at the end of the statement). Uniqueness and exclusion constraints that have not been declared `DEFERRABLE` are also checked immediately.

The firing of triggers that are declared as "constraint triggers" is also controlled by this setting — they fire at the same time that the associated constraint should be checked.

Notes

Because WarehousePG does not require constraint names to be unique within a schema (but only per-table), it is possible that there is more than one match for a specified constraint name. In this case `SET CONSTRAINTS` will act on all matches. For a non-schema-qualified name, once a match or matches have been found in some schema in the search path, schemas appearing later in the path are not searched.

This command only alters the behavior of constraints within the current transaction. Issuing this outside of a transaction block emits a warning and otherwise has no effect.

Compatibility

This command complies with the behavior defined in the SQL standard, except for the limitation that, in WarehousePG, it does not apply to `NOT NULL` and `CHECK` constraints. Also, WarehousePG checks non-deferrable uniqueness constraints immediately, not at end of statement as the standard would suggest.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.1.167 SET ROLE

Sets the current role identifier of the current session.

Synopsis

```
SET [SESSION | LOCAL] ROLE <rolename>

SET [SESSION | LOCAL] ROLE NONE

RESET ROLE
```

Description

This command sets the current role identifier of the current SQL-session context to be rolename. The role name may be written as either an identifier or a string literal. After `SET ROLE`, permissions checking for SQL commands is carried out as though the named role were the one that had logged in originally.

The specified rolename must be a role that the current session user is a member of. If the session user is a superuser, any role can be selected.

The `NONE` and `RESET` forms reset the current role identifier to be the current session role identifier. These forms may be run by any user.

Parameters

SESSION Specifies that the command takes effect for the current session. This is the default.

LOCAL Specifies that the command takes effect for only the current transaction. After `COMMIT` or `ROLLBACK`, the session-level setting takes effect again. Note that `SET LOCAL` will appear to have no effect if it is run outside of a transaction.

rolename The name of a role to use for permissions checking in this session.

NONE RESET Reset the current role identifier to be the current session role identifier (that of the role used to log in).

Notes

Using this command, it is possible to either add privileges or restrict privileges. If the session user role has the `INHERITS` attribute, then it automatically has all the privileges of every role that it could `SET ROLE` to; in this case `SET ROLE` effectively drops all the privileges assigned directly to the session user and to the other roles it is a member of, leaving only the privileges available to the named role. On the other hand, if the session user role has the `NOINHERITS` attribute, `SET ROLE` drops the privileges assigned directly to the session user and instead acquires the privileges available to the named role.

In particular, when a superuser chooses to `SET ROLE` to a non-superuser role, they lose their superuser privileges.

`SET ROLE` has effects comparable to `SET SESSION AUTHORIZATION`, but the privilege checks involved are quite different. Also, `SET SESSION AUTHORIZATION` determines which roles are allowable for later `SET ROLE` commands, whereas changing roles with `SET ROLE` does not change the set of roles allowed to a later `SET ROLE`.

`SET ROLE` does not process session variables specified by the role's `ALTER ROLE` settings; the session variables are only processed during login.

Examples

```
SELECT SESSION_USER, CURRENT_USER;
 session_user | current_user
--------------+--------------
 peter        | peter

SET ROLE 'paul';

SELECT SESSION_USER, CURRENT_USER;
 session_user | current_user
--------------+--------------
 peter        | paul
```

Compatibility

WarehousePG allows identifier syntax (rolename), while the SQL standard requires the role name to be written as a string literal. SQL does not allow this command during a transaction; WarehousePG does not make this restriction. The `SESSION` and `LOCAL` modifiers are a WarehousePG extension, as is the `RESET` syntax.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

SET SESSION AUTHORIZATION

Parent topic: SQL Commands

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.1.168 SET SESSION AUTHORIZATION

Sets the session role identifier and the current role identifier of the current session.

Synopsis

```
SET [SESSION | LOCAL] SESSION AUTHORIZATION <rolename>

SET [SESSION | LOCAL] SESSION AUTHORIZATION DEFAULT

RESET SESSION AUTHORIZATION
```

Description

This command sets the session role identifier and the current role identifier of the current SQL-session context to be rolename. The role name may be written as either an identifier or a string literal. Using this command, it is possible, for example, to temporarily become an unprivileged user and later switch back to being a superuser.

The session role identifier is initially set to be the (possibly authenticated) role name provided by the client. The current role identifier is normally equal to the session user identifier, but may change temporarily in the context of `setuid` functions and similar mechanisms; it can also be changed by SET ROLE. The current user identifier is relevant for permission checking.

The session user identifier may be changed only if the initial session user (the authenticated user) had the superuser privilege. Otherwise, the command is accepted only if it specifies the authenticated user name.

The `DEFAULT` and `RESET` forms reset the session and current user identifiers to be the originally authenticated user name. These forms may be run by any user.

Parameters

SESSION Specifies that the command takes effect for the current session. This is the default.

LOCAL Specifies that the command takes effect for only the current transaction. After `COMMIT` or `ROLLBACK`, the session-level setting takes effect again. Note that `SET LOCAL` will appear to have no effect if it is run outside of a transaction.

rolename The name of the role to assume.

NONE RESET Reset the session and current role identifiers to be that of the role used to log in.

Examples

```
SELECT SESSION_USER, CURRENT_USER;
 session_user | current_user
--------------+--------------
 peter        | peter

SET SESSION AUTHORIZATION 'paul';

SELECT SESSION_USER, CURRENT_USER;
 session_user | current_user
--------------+--------------
 paul         | paul
```

Compatibility

The SQL standard allows some other expressions to appear in place of the literal rolename, but these options are not important in practice. WarehousePG allows identifier syntax (rolename), which SQL does not. SQL does not allow this command during a transaction; WarehousePG does not make this restriction. The `SESSION` and `LOCAL` modifiers are a WarehousePG extension, as is the `RESET` syntax.

7.1.169 SET TRANSACTION

Sets the characteristics of the current transaction.

Synopsis

```
SET TRANSACTION <transaction_mode> [, ...]
SET TRANSACTION SNAPSHOT <snapshot_id>
SET SESSION CHARACTERISTICS AS TRANSACTION <transaction_mode> [, ...]
     [READ ONLY | READ WRITE]
     [NOT] DEFERRABLE

where <transaction_mode> is one of:

    ISOLATION LEVEL {SERIALIZABLE | REPEATABLE READ | READ COMMITTED | READ UNCOMMITTED}
    READ WRITE | READ ONLY
    [NOT] DEFERRABLE

and <snapshot_id> is the id of the existing transaction whose snapshot you want this transaction to run with.
```

Description

The `SET TRANSACTION` command sets the characteristics of the current transaction. It has no effect on any subsequent transactions. `SET SESSION CHARACTERISTICS` sets the default transaction characteristics for subsequent transactions of a session. These defaults can be overridden by `SET TRANSACTION` for an individual transaction.

The available transaction characteristics are the transaction isolation level, the transaction access mode (read/write or read-only), and the deferrable mode. In addition, a snapshot can be selected, though only for the current transaction, not as a session default.

> **Note** Deferrable transactions require the transaction to be serializable. WarehousePG does not support serializable transactions, so including the `DEFERRABLE` clause has no effect.

The isolation level of a transaction determines what data the transaction can see when other transactions are running concurrently.

- **READ COMMITTED** — A statement can only see rows committed before it began. This is the default.
- **REPEATABLE READ** — All statements in the current transaction can only see rows committed before the first query or data-modification statement run in the transaction.

The SQL standard defines two additional levels, `READ UNCOMMITTED` and `SERIALIZABLE`. In WarehousePG, `READ UNCOMMITTED` is treated as `READ COMMITTED`. If you specify `SERIALIZABLE`, WarehousePG falls back to `REPEATABLE READ`.

The transaction isolation level cannot be changed after the first query or data-modification statement (`SELECT`, `INSERT`, `DELETE`, `UPDATE`, `FETCH`, or `COPY`) of a transaction has been run.

The transaction access mode determines whether the transaction is read/write or read-only. Read/write is the default. When a transaction is read-only, the following SQL commands are disallowed: `INSERT`, `UPDATE`, `DELETE`, and `COPY FROM` if the table they would write to is not a temporary table; all `CREATE`, `ALTER`, and `DROP` commands; `COMMENT`, `GRANT`, `REVOKE`, `TRUNCATE`; and `EXPLAIN ANALYZE` and `EXECUTE` if the command they would run is among those listed. This is a high-level notion of read-only that does not prevent all writes to disk.

The `DEFERRABLE` transaction property has no effect unless the transaction is also `SERIALIZABLE` and `READ ONLY`. When all of these properties are set on a transaction, the transaction may block when first acquiring its snapshot, after which it is able to run without the normal overhead of a `SERIALIZABLE` transaction and without any risk of contributing to or being cancelled by a serialization failure. This mode is well suited for long-running reports or backups. *Because WarehousePG does not support serializable transactions, the `DEFERRABLE` transaction property has no effect in WarehousePG.*

The `SET TRANSACTION SNAPSHOT` command allows a new transaction to run with the same snapshot as an existing transaction. The pre-existing transaction must have exported its snapshot with the `pg_export_snapshot()` function. That function returns a snapshot identifier, which must be given to `SET TRANSACTION SNAPSHOT` to specify which snapshot is to be imported. The identifier must be written as a string literal in this command, for example `'000003A1-1'`. `SET TRANSACTION SNAPSHOT` can only be executed at the start of a transaction, before the first query or data-modification statement (`SELECT`, `INSERT`, `DELETE`, `UPDATE`, `FETCH`, or `COPY`) of the transaction. Furthermore, the transaction must already be set to `SERIALIZABLE` or `REPEATABLE READ` isolation level (otherwise, the snapshot would be discarded immediately, since `READ COMMITTED` mode takes a new snapshot for each command). If the importing transaction uses `SERIALIZABLE` isolation level, then the transaction that exported the snapshot must also use that isolation level. Also, a non-read-only serializable transaction cannot import a snapshot from a read-only transaction.

Notes

If `SET TRANSACTION` is run without a prior START TRANSACTION or BEGIN, it emits a warning and otherwise has no effect.

It is possible to dispense with `SET TRANSACTION` by instead specifying the desired transaction_modes in `BEGIN` or `START TRANSACTION`. But that option is not available for `SET TRANSACTION SNAPSHOT`.

The session default transaction modes can also be set or examined via the configuration parametersdefault_transaction_isolation, default_transaction_read_only, and default_transaction_deferrable. (In fact `SET SESSION CHARACTERISTICS` is just a verbose equivalent for setting these variables with `SET`.) This means the defaults can be set in the configuration file, via `ALTER DATABASE`, etc.

The current transaction's modes can similarly be set or examined via the configuration parameterstransaction_isolation, transaction_read_only, and transaction_deferrable. Setting one of these parameters acts the same as the corresponding `SET TRANSACTION` option, with the same restrictions on when it can be done. However, these parameters cannot be set in the configuration file, or from any source other than live SQL.

Examples

To begin a new transaction with the same snapshot as an already existing transaction, first export the snapshot from the existing transaction. That will return the snapshot identifier, for example:

```
BEGIN TRANSACTION ISOLATION LEVEL REPEATABLE READ;
SELECT pg_export_snapshot();
 pg_export_snapshot
---------------------
 00000003-0000001B-1
(1 row)
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Then give the snapshot identifier in a `SET TRANSACTION SNAPSHOT` command at the beginning of the newly opened transaction:

```
BEGIN TRANSACTION ISOLATION LEVEL REPEATABLE READ;
SET TRANSACTION SNAPSHOT '00000003-0000001B-1';
```

Compatibility

These commands are defined in the SQL standard, except for the `DEFERRABLE` transaction mode and the `SET TRANSACTION SNAPSHOT` form, which are WarehousePG extensions.

`SERIALIZABLE` is the default transaction isolation level in the standard. In WarehousePG, the default is `READ COMMITTED`. Due to lack of predicate locking, WarehousePG does not fully support the `SERIALIZABLE` level, so it falls back to the `REPEATABLE READ` level when `SERIALIZABLE` is specified. Essentially, a predicate-locking system prevents phantom reads by restricting what is written, whereas a multi-version concurrency control model (MVCC) as used in WarehousePG prevents them by restricting what is read.

In the SQL standard, there is one other transaction characteristic that can be set with these commands: the size of the diagnostics area. This concept is specific to embedded SQL, and therefore is not implemented in the WarehousePG server.

The SQL standard requires commas between successive transaction_modes, but for historical reasons WarehousePG allows the commas to be omitted.

7.1.170 SHOW

Shows the value of a run-time system configuration parameter.

Synopsis

```
SHOW <name>

SHOW ALL
```

Description

`SHOW` displays the current settings of WarehousePG run-time system configuration parameters. You can set these parameters with the `SET` statement, by editing the `postgresql.conf` configuration file of the WarehousePG coordinator, through the `PGOPTIONS` environment variable (when using libpq or a libpq-based application), or through command-line flags when starting the WarehousePG server.

Parameters

name The name of a run-time system configuration parameter.

Some parameters viewable by `SHOW` are read-only — you can view their values but not set them:

```
SERVER_VERSION
Shows the version number of the WarehousePG server.

SERVER_ENCODING
Shows the server-side character set encoding. You can show, but not set, this parameter because the encoding is determined at database creation time.

LC_COLLATE
Shows the database's locale setting for collation (text ordering). You can show, but not set, this parameter because the setting is determined at database
creation time.

LC_CTYPE
Shows the database's locale setting for character classification; You can show, but not set, this parameter because the setting is determined at database creation
time.

IS_SUPERUSER
True if the current role has superuser privileges.
```

ALL Shows the current value of all configuration parameters, with descriptions.

Notes

The function `current_setting()` produces equivalent output; see System Administration Functions in the PostgreSQL documentation. Also, the pg_settings system view produces the same information.

Examples

Show the current setting of the parameter `DateStyle`:

```
SHOW DateStyle;
 DateStyle
-----------
 ISO, MDY
(1 row)
```

Show the current setting of the parameter `row_security`:

```
SHOW row_security;
 row_security
--------------
 on
(1 row)
```

Show the current setting of all parameters:

```
SHOW ALL;
       name       | setting |                  description
------------------+---------+-----------------------------------------------------
 application_name | psql    | Sets the application name to be reported in sta...

 ...

 xmlbinary        | base64  | Sets how binary values are to be encoded in XML.
 xmloption        | content | Sets whether XML data in implicit parsing and s...
(473 rows)
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Compatibility

The `SHOW` command is a WarehousePG extension.

7.1.171 START TRANSACTION

Starts a transaction block.

Synopsis

```
START TRANSACTION [<transaction_mode>] [, ...]

where <transaction_mode> is one of:

   ISOLATION LEVEL {SERIALIZABLE | REPEATABLE READ | READ COMMITTED | READ UNCOMMITTED}
   READ WRITE | READ ONLY
   [NOT] DEFERRABLE
```

Description

`START TRANSACTION` begins a new transaction block. If the isolation level, read/write mode, or deferrable mode is specified, the new transaction has those characteristics, as if SET TRANSACTION was run. This is the same as the BEGIN command.

Parameters

Refer to SET TRANSACTION for information on the meaning of the parameters to this statement.

Compatibility

In the standard, it is not necessary to issue `START TRANSACTION` to start a transaction block: any SQL command implicitly begins a block. WarehousePG's behavior can be seen as implicitly issuing a `COMMIT` after each command that does not follow `START TRANSACTION` (or `BEGIN`), and it is therefore often called 'autocommit'. Other relational database systems may offer an autocommit feature as a convenience.

The `DEFERRABLE` transaction_mode is a WarehousePG language extension.

The SQL standard requires commas between successive transaction_modes, but for historical reasons WarehousePG allows the commas to be omitted.

See also the compatibility section of SET TRANSACTION.

7.1.172 TRUNCATE

Empties a table or set of tables of all rows.

> **Note** WarehousePG does not enforce referential integrity syntax (foreign key constraints). `TRUNCATE` truncates a table that is referenced in a foreign key constraint even if the `CASCADE` option is omitted.

Synopsis

```
TRUNCATE [TABLE] [ONLY] <name> [ * ] [, ...]
    [ RESTART IDENTITY | CONTINUE IDENTITY ] [CASCADE | RESTRICT]
```

Description

`TRUNCATE` quickly removes all rows from a table or set of tables. It has the same effect as an unqualified DELETE on each table, but since it does not actually scan the tables it is faster. Furthermore, it reclaims disk space immediately, rather than requiring a subsequent VACUUM operation. This is most useful on large tables.

You must have the `TRUNCATE` privilege on the table to truncate it.

Parameters

name The name (optionally schema-qualified) of a table to truncate. If `ONLY` is specified before the table name, only that table is truncated. If `ONLY` is not specified, the table and all its descendant tables (if any) are truncated. Optionally, you can specify `*` after the table name to explicitly indicate that descendant tables are included.

RESTART IDENTITY Automatically restart sequences owned by columns of the truncated table(s).

CONTINUE IDENTITY Do not change the values of sequences. This is the default.

CASCADE Because this key word applies to foreign key references (which are not supported in WarehousePG) it has no effect.

RESTRICT Because this key word applies to foreign key references (which are not supported in WarehousePG) it has no effect.

Notes

`TRUNCATE` acquires an `ACCESS EXCLUSIVE` lock on each table that it operates on, which blocks all other concurrent operations on the table. When `RESTART IDENTITY` is specified, any sequences that are to be restarted are likewise locked exclusively. If you require concurrent access to a table, use the `DELETE` command instead.

`TRUNCATE` will not fire any user-defined `ON DELETE` triggers that might exist for the tables.

`TRUNCATE` will not truncate any tables that inherit from the named table. Only the named table is truncated, not its child tables.

`TRUNCATE` is not MVCC-safe. After truncation, the table will appear empty to concurrent transactions, if they are using a snapshot taken before the truncation occurred.

`TRUNCATE` is transaction-safe with respect to the data in the tables: the truncation will be safely rolled back if the surrounding transaction does not commit.

When `RESTART IDENTITY` is specified, the implied `ALTER SEQUENCE RESTART` operations are also done transactionally; that is, they will be rolled back if the surrounding transaction does not commit. Be aware that if any additional sequence operations are done on the restarted sequences before the transaction rolls back, the effects of these operations on the sequences will be rolled back.

`TRUNCATE` is not currently supported for foreign tables. This implies that if a specified table has any descendant tables that are foreign, the command will fail.

Examples

Empty the tables `films` and `distributors`:

```
TRUNCATE films, distributors;
```

The same, and also reset any associated sequence generators:

```
TRUNCATE films, distributors RESTART IDENTITY;
```

Compatibility

The SQL:2008 standard includes a `TRUNCATE` command with the syntax `TRUNCATE TABLE tablename`. The clauses `CONTINUE IDENTITY` / `RESTART IDENTITY` also appear in that standard, but have slightly different though related meanings. Some of the concurrency behavior of this command is left implementation-defined by the standard, so the above notes should be considered and compared with other implementations if necessary.

7.1.173 UNLISTEN

Stops listening for a notification.

Synopsis

```
UNLISTEN { <channel> | * }
```

Description

`UNLISTEN` is used to remove an existing registration for `NOTIFY` events. `UNLISTEN` cancels any existing registration of the current WarehousePG session as a listener on the notification channel named channel. The special wildcard `*` cancels all listener registrations for the current session.

NOTIFY contains a more extensive discussion of the use of `LISTEN` and `NOTIFY`.

Parameters

channel The name of a notification channel (any identifier).

- All current listen registrations for this session are cleared.

Notes

You can unlisten something you were not listening for; no warning or error will appear.

At the end of each session, `UNLISTEN *` is automatically executed.

A transaction that has executed `UNLISTEN` cannot be prepared for two-phase commit.

Examples

To make a registration:

```
LISTEN virtual;
NOTIFY virtual;
Asynchronous notification "virtual" received from server process with PID 8448.
```

Once `UNLISTEN` has been executed, further `NOTIFY` messages will be ignored:

```
UNLISTEN virtual;
NOTIFY virtual;
-- no NOTIFY event is received
```

Compatibility

There is no `UNLISTEN` statement in the SQL standard.

7.1.174 UPDATE

Updates rows of a table.

Synopsis

```
[ WITH [ RECURSIVE ] <with_query> [, ...] ]
UPDATE [ ONLY ] <table_name> [ [ AS ] <alias> ]
   SET { <column_name> = { <expression> | DEFAULT } |
       ( <column_name> [, ...] ) = [ ROW ] ( { <expression> | DEFAULT } [, ...] ) |
       ( <column_name> [, ...] ) = ( <sub-SELECT> )
       } [, ...]
   [ FROM <from_item> [, ...] ]
   [ WHERE <condition> | WHERE CURRENT OF <cursor_name> ]
   [ RETURNING * | <output_expression> [ [AS] <output_name> ] [, ...] ]
```

Description

`UPDATE` changes the values of the specified columns in all rows that satisfy the condition. Only the columns to be modified need be mentioned in the `SET` clause; columns not explicitly modified retain their previous values.

There are two ways to modify a table using information contained in other tables in the database: using sub-selects, or specifying additional tables in the `FROM` clause. Which technique is more appropriate depends on the specific circumstances.

The optional `RETURNING` clause causes `UPDATE` to compute and return value(s) based on each row actually updated. WarehousePG can compute any expression using the table's columns, and/or columns of other tables mentioned in `FROM`. The new (post-update) values of the table's columns are used. The syntax of the `RETURNING` list is identical to that of the output list of `SELECT`.

You must have the `UPDATE` privilege on the table, or at least on the column(s) that are listed to be updated. You must also have the `SELECT` privilege on any column whose values are read in the expressions or condition.

> **Note** As the default, WarehousePG acquires an `EXCLUSIVE` lock on tables for `UPDATE` operations on heap tables. When the Global Deadlock Detector is enabled, the lock mode for `UPDATE` operations on heap tables is `ROW EXCLUSIVE`. See Global Deadlock Detector.

Parameters

with_query The `WITH` clause allows you to specify one or more subqueries that can be referenced by name in the `UPDATE` query. See WITH Queries (Common Table Expressions) and SELECT for details.

For an `UPDATE` command that includes a `WITH` clause, the clause can only contain `SELECT` commands, the `WITH` clause cannot contain a data-modifying command (`INSERT`, `UPDATE`, or `DELETE`).

It is possible for the query (`SELECT` statement) to also contain a `WITH` clause. In such a case both sets of with_query can be referenced within the `UPDATE` query, but the second one takes precedence since it is more closely nested.

table_name The name (optionally schema-qualified) of the table to update. If `ONLY` is specified before the table name, matching rows are updated in the named table only. If `ONLY` is not specified, matching rows are also updated in any tables inheriting from the named table. Optionally, you can specify `*` after the table name to explicitly indicate that descendant tables are included.

alias A substitute name for the target table. When an alias is provided, it completely hides the actual name of the table. For example, given `UPDATE foo AS f`, the remainder of the `UPDATE` statement must refer to this table as `f` not `foo`.

column_name The name of a column in the table named by table_name. The column name can be qualified with a subfield name or array subscript, if needed. Do not include the table's name in the specification of a target column; for example, `UPDATE table_name SET table_name.col = 1` is invalid.

expression An expression to assign to the column. The expression may use the old values of this and other columns in the table.

DEFAULT Set the column to its default value (which will be NULL if no specific default expression has been assigned to it).

sub-SELECT A `SELECT` sub-query that produces as many output columns as are listed in the parenthesized column list preceding it. The sub-query must yield no more than one row when executed. If it yields one row, its column values are assigned to the target columns; if it yields no rows, NULL values are assigned to the target columns. The sub-query can refer to old values of the current row of the table being updated.

from_item A table expression allowing columns from other tables to appear in the `WHERE` condition and the update expressions. This uses the same syntax as the `FROM` clause of a SELECT statement; for example, you can specify an alias for the table name. Do not repeat the target table as a from_item unless you intend a self-join (in which case it must appear with an alias in the from_item).

condition An expression that returns a value of type `boolean`. Only rows for which this expression returns `true` will be updated.

cursor_name The name of the cursor to use in a `WHERE CURRENT OF` condition. The row to be updated is the one most recently fetched from the cursor. The cursor must be a non-grouping query on the `UPDATE`'s target table. Note that `WHERE CURRENT OF` cannot be specified together with a Boolean condition. See DECLARE for more information about using cursors with `WHERE CURRENT OF`.

The `UPDATE...WHERE CURRENT OF` statement can only be run on the server, for example in an interactive psql session or a script. Language extensions such as PL/pgSQL do not have support for updatable cursors.

output_expression An expression to be computed and returned by the `UPDATE` command after each row is updated. The expression may use any column names of the table named by table_name or table(s) listed in `FROM`. Write `*` to return all columns.

output_name A name to use for a returned column.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Outputs

On successful completion, an `UPDATE` command returns a command tag of the form:

```
UPDATE <count>
```

The count is the number of rows updated, including matched rows whose values did not change. If count is 0, no rows were updated by the query (this is not considered an error).

If the `UPDATE` command contains a `RETURNING` clause, the result will be similar to that of a `SELECT` statement containing the columns and values defined in the `RETURNING` list, computed over the row(s) updated by the command.

Notes

When a `FROM` clause is present, the target table is joined to the tables mentioned in the from_item list, and each output row of the join represents an update operation for the target table. When using `FROM` , ensure that the join produces at most one output row for each row to be modified. In other words, a target row should not join to more than one row from the other table(s). If it does, then only one of the join rows will be used to update the target row, but which one will be used is not readily predictable.

Because of this indeterminacy, referencing other tables only within sub-selects is safer, though often harder to read and slower than using a join.

For a partitioned table, all of the child tables are locked during the `UPDATE` operation when the Global Deadlock Detector is not enabled (the default). Only some of the leaf child tables are locked when the Global Deadlock Detector is enabled. For information about the Global Deadlock Detector, see Global Deadlock Detector.

In the case of a partitioned table, updating a row might cause it to no longer satisfy the partition constraint of the containing partition. In that case, if there is some other partition in the partition tree for which this row satisfies its partition constraint, then the row is moved to that partition. If there is no such partition, an error will occur. Behind the scenes, the row movement is actually a `DELETE` and `INSERT` operation.

There is a possibility that a concurrent `UPDATE` or `DELETE` on the row being moved will generate a serialization failure error. Suppose session 1 is performing an `UPDATE` on a partition key, and meanwhile a concurrent session 2 for which this row is visible performs an `UPDATE` or `DELETE` operation on this row. In such case, session 2's `UPDATE` or `DELETE` will detect the row movement and raise a serialization failure error (which always returns with an SQLSTATE code '40001'). Applications may wish to retry the transaction if this occurs. In the usual case where the table is not partitioned, or where there is no row movement, session 2 would have identified the newly updated row and carried out the `UPDATE/DELETE` on this new row version.

Note that while rows can be moved from local partitions to a foreign-table partition (provided the foreign data wrapper supports tuple routing), they cannot be moved from a foreign-table partition to another partition.

Examples

Change the word `Drama` to `Dramatic` in the column `kind` of the table `films` :

```
UPDATE films SET kind = 'Dramatic' WHERE kind = 'Drama';
```

Adjust temperature entries and reset precipitation to its default value in one row of the table `weather` :

```
UPDATE weather SET temp_lo = temp_lo+1, temp_hi =
temp_lo+15, prcp = DEFAULT
WHERE city = 'San Francisco' AND date = '2016-07-03';
```

Perform the same operation and return the updated entries:

```
UPDATE weather SET temp_lo = temp_lo+1, temp_hi = temp_lo+15, prcp = DEFAULT
  WHERE city = 'San Francisco' AND date = '2003-07-03'
  RETURNING temp_lo, temp_hi, prcp;
```

Use the alternative column-list syntax to do the same update:

```
UPDATE weather SET (temp_lo, temp_hi, prcp) = (temp_lo+1,
temp_lo+15, DEFAULT)
WHERE city = 'San Francisco' AND date = '2016-07-03';
```

Increment the sales count of the salesperson who manages the account for Acme Corporation, using the `FROM` clause syntax (assuming both tables being joined are distributed in WarehousePG on the `id` column):

```
UPDATE employees SET sales_count = sales_count + 1 FROM
accounts
WHERE accounts.name = 'Acme Corporation'
AND employees.id = accounts.id;
```

Perform the same operation, using a sub-select in the `WHERE` clause:

```
UPDATE employees SET sales_count = sales_count + 1 WHERE id =
  (SELECT id FROM accounts WHERE name = 'Acme Corporation');
```

Update contact names in an `accounts` table to match the currently assigned salesmen:

```
UPDATE accounts SET (contact_first_name, contact_last_name) =
    (SELECT first_name, last_name FROM salesmen
     WHERE salesmen.id = accounts.sales_id);
```

A similar result could be accomplished with a join:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
UPDATE accounts SET contact_first_name = first_name,
                    contact_last_name = last_name
  FROM salesmen WHERE salesmen.id = accounts.sales_id;
```

However, the second query may give unexpected results if `salesmen.id` is not a unique key, whereas the first query is guaranteed to raise an error if there are multiple `id` matches. Also, if there is no match for a particular `accounts.sales_id` entry, the first query will set the corresponding name fields to NULL, whereas the second query will not update that row at all.

Update statistics in a `summary` table to match the current data:

```
UPDATE summary s SET (sum_x, sum_y, avg_x, avg_y) =
    (SELECT sum(x), sum(y), avg(x), avg(y) FROM data d
     WHERE d.group_id = s.group_id);
```

Attempt to insert a new stock item along with the quantity of stock. If the item already exists, instead update the stock count of the existing item. To do this without failing the entire transaction, use savepoints.

```
BEGIN;
-- other operations
SAVEPOINT sp1;
INSERT INTO wines VALUES('Chateau Lafite 2003', '24');
-- Assume the above fails because of a unique key violation,
-- so now we issue these commands:
ROLLBACK TO sp1;
UPDATE wines SET stock = stock + 24 WHERE winename = 'Chateau
Lafite 2003';
-- continue with other operations, and eventually
COMMIT;
```

Compatibility

This command conforms to the SQL standard, except that the `FROM` and `RETURNING` clauses are WarehousePG extensions, as is the ability to use `WITH` with `UPDATE`.

Some other database systems offer a `FROM` option in which the target table is supposed to be listed again within `FROM`. That is not how WarehousePG interprets `FROM`. Be careful when porting applications that use this extension.

According to the standard, the source value for a parenthesized sub-list of target column names can be any row-valued expression yielding the correct number of columns. WarehousePG only allows the source value to be a row constructor or a sub-`SELECT`. You can specify an individual column's updated value as `DEFAULT` in the row-constructor case, but not inside a sub-`SELECT`.

7.1.175 VACUUM

Garbage-collects and optionally analyzes a database.

Synopsis

```
VACUUM [ (<option> [, ...]) ] [<table_name> [(<column_name> [, ...] )]]
VACUUM [FULL] [FREEZE] [VERBOSE] [ANALYZE]  [<table_name> [(<column_name> [, ...] )]]
where <option> can be one of:
    FULL [ <boolean> ]
    FREEZE [ <boolean> ]
    VERBOSE [ <boolean> ]
    ANALYZE [ <boolean> ]
    DISABLE_PAGE_SKIPPING [ <boolean> ]
    SKIP_LOCKED [ <boolean> ]
    INDEX_CLEANUP [ <boolean> ]
    TRUNCATE [ <boolean> ]
    SKIP_DATABASE_STATS [ <boolean> ]
    ONLY_DATABASE_STATS [ <boolean> ]
    AO_AUX_ONLY [ <boolean> ]
```

Description

`VACUUM` reclaims storage occupied by deleted tuples. In normal WarehousePG operation, tuples that are deleted or obsoleted by an update are not physically removed from their table; they remain present on disk until a `VACUUM` is done. Therefore it is necessary to perform `VACUUM` periodically, especially on frequently-updated tables.

When no table list is specified, `VACUUM` processes every table in the current database that the current user has permission to vacuum. When a table is specified, `VACUUM` processes only that table.

`VACUUM ANALYZE` performs a `VACUUM` and then an `ANALYZE` for each selected table. This is a handy combination form for routine maintenance scripts. See ANALYZE for more details about its processing.

`VACUUM` (without `FULL`) marks deleted and obsoleted data in tables and indexes for future reuse.

With heap tables, it reclaims for re-use only if the space is at the end of the table and an exclusive table lock can be easily obtained. Unused space at the start or middle of a table remains as is. This form of the command can operate in parallel with normal reading and writing of the table, as an exclusive lock is not obtained. However, extra space is not returned to the operating system (in most cases); it is just kept available for re-use within the same table. `VACUUM FULL` rewrites the entire contents of the table into a new disk file with no extra space, allowing unused space to be returned to the operating system. This form is much slower and requires an `ACCESS EXCLUSIVE` lock on each table while it is being processed.

With append-optimized tables, `VACUUM` compacts a table by first vacuuming the indexes, then compacting each segment file in turn, if applicable, and finally vacuuming auxiliary relations and updating statistics. On each segment, visible rows are copied from the current segment file to a new segment file, and then the current segment file is scheduled to be dropped and the new segment file is made available. Plain `VACUUM` of an append-optimized table allows scans, inserts, deletes, and updates of the table while a segment file is compacted. However, an `EXCLUSIVE` lock is taken briefly to drop the current segment file and activate the new segment file.

`VACUUM FULL` for append-optimized tables does more extensive processing, including moving of tuples across blocks to try to compact the table to the minimum number of disk blocks. However this may also happen for `VACUUM` (without `FULL`) based on how many hidden tuples there are. `VACUUM FULL` requires an `ACCESS EXCLUSIVE` lock on each table while it is being processed. The `ACCESS EXCLUSIVE` lock guarantees that the holder is the only transaction accessing the table in any way.

When the option list is surrounded by parentheses, the options can be written in any order. Without parentheses, options must be specified in exactly the order shown above. The parenthesized syntax was added in WarehousePG 6.0; the unparenthesized syntax is deprecated.

> **Important**
>
> For more important information on the use of `VACUUM`, `VACUUM FULL`, and `VACUUM ANALYZE`, see Notes.

Parameters

FULL

Selects a *full* vacuum, which may reclaim more space, but takes much longer and exclusively locks the table. This method also requires extra disk space, since it writes a new copy of the table and doesn't release the old copy until the operation is complete. Use this only when a significant amount of space needs to be reclaimed from within the table.

FREEZE

Selects aggressive *freezing* of tuples. Specifying `FREEZE` is equivalent to performing `VACUUM` with the vacuum_freeze_min_age and `vacuum_freeze_table_age` server configuration parameter set to zero. Aggressive freezing is always performed when the table is rewritten, so this option is redundant when `FULL` is specified.

VERBOSE

Prints a detailed vacuum activity report for each table.

ANALYZE

Updates statistics used by the planner to determine the most efficient way to run a query.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

DISABLE_PAGE_SKIPPING

Normally, `VACUUM` skips pages based on the visibility map. It always skips pages where all tuples are known to be frozen, and skips those where all tuples are known to be visible to all transactions except when performing an aggressive vacuum. Except when performing an aggressive vacuum, it skips some pages in order to avoid waiting for other sessions to finish using them. This option disables all page-skipping behavior, you may use this option only when the contents of the visibility map are suspect, which should happen only if there is a hardware or software issue causing database corruption.

SKIP_LOCKED

Specifies that `VACUUM` should not wait for any conflicting locks to be released when beginning work on a relation: if it cannot lock a relation immediately without waiting, it skips the relation. Note that even with this option, `VACUUM` may still block when opening the relation's indexes. Additionally, `VACUUM ANALYZE` may still block when acquiring sample rows from partitions, table inheritance children, and some types of foreign tables. Also, while `VACUUM` ordinarily processes all partitions of specified partitioned tables, this option will cause `VACUUM` to skip all partitions if there is a conflicting lock on the partitioned table.

INDEX_CLEANUP

Specifies that `VACUUM` should attempt to remove index entries pointing to dead tuples. This is normally the desired behavior and is the default unless you override it by setting the `vacuum_index_cleanup` server configuration parameter to `false` for the table you run `VACUUM` against. Setting this option to `false` may be useful when you need to make vacuum run as quickly as possible, for example, to avoid imminent transaction ID wraparound. However, if you do not perform index cleanup regularly, performance may suffer, because as the table is modified, indexes accumulate dead tuples and the table itself accumulates dead line pointers that cannot be removed until index cleanup completes. This option has no effect for tables that do not have an index and is ignored if the `FULL` option is specified.

TRUNCATE

Specifies that `VACUUM` should attempt to truncate any empty pages at the end of the table and allow the disk space for the truncated pages to be returned to the operating system. This is normally the desired behavior and is the default unless the `vacuum_truncate` option has been set to false for the table to be vacuumed. Setting this option to `false` may be useful to avoid `ACCESS EXCLUSIVE` lock on the table that the truncation requires. This option is ignored if the `FULL` option is specified.

SKIP_DATABASE_STATS

Specifies that `VACUUM` should skip updating the database-wide statistics about oldest unfrozen XIDs. `VACUUM` normally updates these statistics once at the end of the command. This operation may take a while in a database with a very large number of tables, and accomplishes nothing unless the table that had contained the oldest unfrozen XID was among those vacuumed. If multiple `VACUUM` commands are issued in parallel, only one of them can update the database-wide statistics at a time. Consequently, if an application intends to issue a series of many `VACUUM` commands, it may be helpful to set this option in all but the last such command; or set it in all the commands and separately issue `VACUUM (ONLY_DATABASE_STATS)` afterwards.

ONLY_DATABASE_STATS

Specifies that `VACUUM` do nothing except update the database-wide statistics about oldest unfrozen XIDs. When this option is specified, the `<table_and_columns>` list must be empty, and no other option may be enabled except `VERBOSE`.

AO_AUX_ONLY

Runs `VACUUM` against all auxiliary tables of an append-optimized table. It does not run `VACUUM` against the append-optimized table. If run against a non-append-optimized table with no child partitions, no action takes place. If run against a heap table with an append-optimized partition, `VACUUM` vacuums the auxiliary tables of this partition. You may also use `AO_AUX_ONLY` without specifying a table to run against all append-optimized tables in the database.

`<boolean>`

Specifies whether the selected option should be turned on or off. You can write `TRUE`, `ON`, or `1` to enable the option, and `FALSE`, `OFF`, or `0` to deactivate it. If the boolean value is omitted, `TRUE` is assumed.

`<ao_table>`

The name of a table whose auxiliary tables are to be vacuumed, most often an append-optimized table.

`<table_name>`

The name (optionally schema-qualified) of a specific table or materialized view to vacuum. If the specified table is a partitioned table, all of its leaf partitions are vacuumed. Defaults to all tables in the current database.

`<column_name>`

The name of a specific column to analyze. Defaults to all columns. If a column list is specified, `ANALYZE` must also be specified.

Outputs

When `VERBOSE` is specified, `VACUUM` emits progress messages to indicate which table is currently being processed. Various statistics about the tables are printed as well.

Notes

To vacuum a table, one must ordinarily be the table's owner or a superuser. However, database owners are allowed to vacuum all tables in their databases, except shared catalogs. (The restriction for shared catalogs implies that a true database-wide `VACUUM` can only be performed by a superuser.) `VACUUM` skips over any tables that the calling user does not have permission to vacuum.

`VACUUM` cannot be run inside a transaction block.

For tables with GIN indexes, `VACUUM` (in any form) also completes any pending index insertions, by moving pending index entries to the appropriate places in the main GIN index structure.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Vacuum active databases frequently (at least nightly), in order to remove expired rows. After adding or deleting a large number of rows, running the `VACUUM ANALYZE` command for the affected table might be useful. This updates the system catalogs with the results of all recent changes, and allows the WarehousePG query optimizer to make better choices in planning queries.

`VACUUM FULL` reclaims all expired row space, however it requires an exclusive lock on each table being processed, is a very expensive operation, and might take a long time to complete on large, distributed WarehousePG tables. Perform `VACUUM FULL` operations during database maintenance periods.

The `FULL` option is not recommended for routine use, but might be useful in special cases. An example is when you have deleted or updated most of the rows in a table and would like the table to physically shrink to occupy less disk space and allow faster table scans. `VACUUM FULL` usuallys shrink the table more than a plain `VACUUM` would.

As an alternative to `VACUUM FULL`, you can re-create the table with a `CREATE TABLE AS` statement and drop the old table.

`VACUUM` causes a substantial increase in I/O traffic, which might cause poor performance for other active sessions. Therefore, it is sometimes advisable to use the cost-based vacuum delay.

WarehousePG includes an *autovacuum* facility that you can use to automate routine vacuum maintenance. Refer to The Autovacuum Daemon PostgreSQL documentation for more information.

`VACUUM` commands skip external and foreign tables.

For append-optimized tables, `VACUUM` and `VACUUM FULL` require enough available disk space to accommodate the new segment file during the `VACUUM` or `VACUUM FULL` process. If the ratio of hidden rows to total rows in a segment file is less than a threshold value (10, by default), the segment file is not compacted. The threshold value can be configured with the `gp_appendonly_compaction_threshold` server configuration parameter. `VACUUM FULL` ignores the threshold and rewrites the segment file regardless of the ratio. `VACUUM` can be deactivated for append-optimized tables using the `gp_appendonly_compaction` server configuration parameter. See Server Configuration Parameters for information about the server configuration parameters.

If a concurrent serializable transaction is detected when an append-optimized table is being vacuumed, the current and subsequent segment files are not compacted. If a segment file has been compacted but a concurrent serializable transaction is detected in the transaction that drops the original segment file, the drop is skipped. This could leave one or two segment files in an "awaiting drop" state after the vacuum has completed.

For more information about concurrency control in WarehousePG, see Routine System Maintenance Tasks in the *WarehousePG Administrator Guide*.

Examples

To clean a single table `onek`, analyze it for the optimizer and print a detailed vacuum activity report:

```
VACUUM (VERBOSE, ANALYZE) onek;
```

Vacuum all tables in the current database:

```
VACUUM;
```

Vacuum a specific table only:

```
VACUUM (VERBOSE, ANALYZE) mytable;
```

Vacuum all tables in the current database and collect statistics for the query optimizer:

```
VACUUM ANALYZE;
```

Compatibility

There is no `VACUUM` statement in the SQL standard.

7.1.176 VALUES

Computes a set of rows.

Synopsis

```
VALUES ( <expression> [, ...] ) [, ...]
   [ORDER BY <sort_expression> [ ASC | DESC | USING <operator> ] [, ...] ]
   [LIMIT { <count> | ALL } ]
   [OFFSET <start> [ ROW | ROWS ] ]
   [FETCH { FIRST | NEXT } [<count> ] { ROW | ROWS } ONLY ]
```

Description

`VALUES` computes a row value or set of row values specified by value expressions. It is most commonly used to generate a "constant table" within a larger command, but it can be used on its own.

When more than one row is specified, all the rows must have the same number of elements. The data types of the resulting table's columns are determined by combining the explicit or inferred types of the expressions appearing in that column, using the same rules as for `UNION`.

Within larger commands, `VALUES` is syntactically allowed anywhere that `SELECT` is. Because it is treated like a `SELECT` by the grammar, it is possible to use the `ORDER BY`, `LIMIT` (or equivalent `FETCH FIRST`), and `OFFSET` clauses with a `VALUES` command.

Parameters

expression A constant or expression to compute and insert at the indicated place in the resulting table (set of rows). In a `VALUES` list appearing at the top level of an `INSERT`, an expression can be replaced by `DEFAULT` to indicate that the destination column's default value should be inserted. `DEFAULT` cannot be used when `VALUES` appears in other contexts.

sort_expression An expression or integer constant indicating how to sort the result rows. This expression may refer to the columns of the `VALUES` result as `column1`, `column2`, etc. For more details, see "The ORDER BY Clause" in the parameters for SELECT.

operator A sorting operator. For more details, see "The ORDER BY Clause" in the parameters forSELECT.

LIMIT count OFFSET start The maximum number of rows to return. For more details, see "The LIMIT Clause" in the parameters forSELECT.

Notes

`VALUES` lists with very large numbers of rows should be avoided, as you may encounter out-of-memory failures or poor performance. `VALUES` appearing within `INSERT` is a special case (because the desired column types are known from the `INSERT`'s target table, and need not be inferred by scanning the `VALUES` list), so it can handle larger lists than are practical in other contexts.

Examples

A bare `VALUES` command:

```
VALUES (1, 'one'), (2, 'two'), (3, 'three');
```

This will return a table of two columns and three rows. It is effectively equivalent to:

```
SELECT 1 AS column1, 'one' AS column2
UNION ALL
SELECT 2, 'two'
UNION ALL
SELECT 3, 'three';
```

More usually, `VALUES` is used within a larger SQL command. The most common use is in `INSERT`:

```
INSERT INTO films (code, title, did, date_prod, kind)
    VALUES ('T_601', 'Yojimbo', 106, '1961-06-16', 'Drama');
```

In the context of `INSERT`, entries of a `VALUES` list can be `DEFAULT` to indicate that the column default should be used here instead of specifying a value:

```
INSERT INTO films VALUES
    ('UA502', 'Bananas', 105, DEFAULT, 'Comedy', '82
minutes'),
    ('T_601', 'Yojimbo', 106, DEFAULT, 'Drama', DEFAULT);
```

`VALUES` can also be used where a sub-`SELECT` might be written, for example in a `FROM` clause:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
SELECT f.* FROM films f, (VALUES('MGM', 'Horror'), ('UA',
'Sci-Fi')) AS t (studio, kind) WHERE f.studio = t.studio AND
f.kind = t.kind;
UPDATE employees SET salary = salary * v.increase FROM
(VALUES(1, 200000, 1.2), (2, 400000, 1.4)) AS v (depno,
target, increase) WHERE employees.depno = v.depno AND
employees.sales >= v.target;
```

Note that an `AS` clause is required when `VALUES` is used in a `FROM` clause, just as is true for `SELECT`. It is not required that the `AS` clause specify names for all the columns, but it is good practice to do so. The default column names for `VALUES` are `column1`, `column2`, etc. in WarehousePG, but these names might be different in other database systems.

When `VALUES` is used in `INSERT`, the values are all automatically coerced to the data type of the corresponding destination column. When it is used in other contexts, it may be necessary to specify the correct data type. If the entries are all quoted literal constants, coercing the first is sufficient to determine the assumed type for all:

```
SELECT * FROM machines WHERE ip_address IN
(VALUES('192.168.0.1'::inet), ('192.168.0.10'),
('192.0.2.43'));
```

> **Note** For simple `IN` tests, it is better to rely on the list-of-scalars form of `IN` than to write a `VALUES` query as shown above. The list of scalars method requires less writing and is often more efficient.

Compatibility

`VALUES` conforms to the SQL standard. `LIMIT` and `OFFSET` are WarehousePG extensions; see also under SELECT.

7.1.177 ALTER RULE

Changes the definition of a rule.

Synopsis

```
ALTER RULE name ON <table_name> RENAME TO <new_name>
```

Description

`ALTER RULE` changes properties of an existing rule. Currently, the only available action is to change the rule's name.

To use `ALTER RULE`, you must own the table or view that the rule applies to.

Parameters

name The name of an existing rule to alter.

table_name The name (optionally schema-qualified) of the table or view that the rule applies to.

new_name The new name for the rule.

Examples

To rename an existing rule:

```
ALTER RULE notify_all ON emp RENAME TO notify_me;
```

Compatibility

`ALTER RULE` is a WarehousePG extension, as is the entire query rewrite system.

7.1.178 ALTER TRIGGER

Changes the definition of a trigger.

Synopsis

```
ALTER TRIGGER <name> ON <table> RENAME TO <newname>
```

Description

`ALTER TRIGGER` changes properties of an existing trigger. The `RENAME` clause changes the name of the given trigger without otherwise changing the trigger definition. You must own the table on which the trigger acts to be allowed to change its properties.

Parameters

name The name of an existing trigger to alter.

table The name of the table on which this trigger acts.

newname The new name for the trigger.

Notes

The ability to temporarily activate or deactivate a trigger is provided by ALTER TABLE, not by `ALTER TRIGGER`, because `ALTER TRIGGER` has no convenient way to express the option of activating or deactivating all of a table's triggers at once.

Note that WarehousePG has limited support of triggers in this release. See CREATE TRIGGER for more information.

Examples

To rename an existing trigger:

```
ALTER TRIGGER emp_stamp ON emp RENAME TO emp_track_chgs;
```

Compatibility

`ALTER TRIGGER` is a WarehousePG extension of the SQL standard.

See Also

ALTER TABLE, CREATE TRIGGER, DROP TRIGGER

Parent topic: SQL Commands

7.1.179 CREATE TRIGGER

Defines a new trigger. User-defined triggers are not supported in WarehousePG.

Synopsis

```
CREATE TRIGGER <name> {BEFORE | AFTER} {<event> [OR ...]}
       ON <table> [ FOR [EACH] {ROW | STATEMENT} ]
       EXECUTE PROCEDURE <funcname> ( <arguments> )
```

Description

`CREATE TRIGGER` creates a new trigger. The trigger will be associated with the specified table and will run the specified function when certain events occur. If multiple triggers of the same kind are defined for the same event, they will be fired in alphabetical order by name.

> *Important* Due to the distributed nature of a WarehousePG cluster, the use of triggers on data is very limited in WarehousePG. The function used in the trigger must be `IMMUTABLE`, meaning it cannot use information not directly present in its argument list. The function specified in the trigger also cannot run any SQL or modify distributed database objects in any way. Given that triggers are most often used to alter tables (for example, update these other rows when this row is updated), these limitations offer very little practical use of triggers in WarehousePG. For that reason, WarehousePG does not support the use of user-defined triggers in WarehousePG. Triggers cannot be used on append-optimized tables. Event Triggers, which capture only DDL events, *are* supported in WarehousePG. See the PostgreSQL documentation for Event Triggers for additional information.

SELECT does not modify any rows so you can not create `SELECT` triggers. Rules and views are more appropriate in such cases.

Parameters

name The name to give the new trigger. This must be distinct from the name of any other trigger for the same table.

BEFORE AFTER Determines whether the function is called before or after the event. If the trigger fires before the event, the trigger may skip the operation for the current row, or change the row being inserted (for `INSERT` and `UPDATE` operations only). If the trigger fires after the event, all changes, including the last insertion, update, or deletion, are visible to the trigger.

event Specifies the event that will fire the trigger (`INSERT`, `UPDATE`, or `DELETE`). Multiple events can be specified using OR.

table The name (optionally schema-qualified) of the table the trigger is for.

FOR EACH ROW FOR EACH STATEMENT This specifies whether the trigger procedure should be fired once for every row affected by the trigger event, or just once per SQL statement. If neither is specified, `FOR EACH STATEMENT` is the default. A trigger that is marked `FOR EACH ROW` is called once for every row that the operation modifies. In contrast, a trigger that is marked `FOR EACH STATEMENT` only runs once for any given operation, regardless of how many rows it modifies.

funcname A user-supplied function that is declared as `IMMUTABLE`, taking no arguments, and returning type `trigger`, which is run when the trigger fires. This function must not run SQL or modify the database in any way.

arguments An optional comma-separated list of arguments to be provided to the function when the trigger is run. The arguments are literal string constants. Simple names and numeric constants may be written here, too, but they will all be converted to strings. Please check the description of the implementation language of the trigger function about how the trigger arguments are accessible within the function; it may be different from normal function arguments.

Notes

To create a trigger on a table, the user must have the `TRIGGER` privilege on the table.

Examples

Declare the trigger function and then a trigger:

```
CREATE FUNCTION sendmail() RETURNS trigger AS
'$GPHOME/lib/emailtrig.so' LANGUAGE C IMMUTABLE;

CREATE TRIGGER t_sendmail AFTER INSERT OR UPDATE OR DELETE
ON mytable FOR EACH STATEMENT EXECUTE PROCEDURE sendmail();
```

Compatibility

The `CREATE TRIGGER` statement in WarehousePG implements a subset of the SQL standard. The following functionality is currently missing:

- WarehousePG has strict limitations on the function that is called by a trigger, which makes the use of triggers very limited in WarehousePG. For this reason, triggers are not officially supported in WarehousePG.
- SQL allows triggers to fire on updates to specific columns (e.g., `AFTER UPDATE OF col1, col2`).
- SQL allows you to define aliases for the 'old' and 'new' rows or tables for use in the definition of the triggered action (e.g., `CREATE TRIGGER ... ON tablename REFERENCING OLD ROW AS somename NEW ROW AS othername ...`). Since WarehousePG allows trigger procedures to be written in any number of user-defined languages, access to the data is handled in a language-specific way.
- WarehousePG only allows the execution of a user-defined function for the triggered action. The standard allows the execution of a number of other SQL commands, such as `CREATE TABLE` as the triggered action. This limitation is not hard to work around by creating a user-defined function that runs the desired commands.
- SQL specifies that multiple triggers should be fired in time-of-creation order. WarehousePG uses name order, which was judged to be more convenient.
- SQL specifies that `BEFORE DELETE` triggers on cascaded deletes fire after the cascaded `DELETE` completes. The WarehousePG behavior is for `BEFORE DELETE` to always fire before the delete action, even a cascading one. This is considered more consistent.
- The ability to specify multiple actions for a single trigger using `OR` is a WarehousePG extension of the SQL standard.

7.1.180 DROP TRIGGER

Removes a trigger.

Synopsis

```
DROP TRIGGER [IF EXISTS] <name> ON <table> [CASCADE | RESTRICT]
```

Description

`DROP TRIGGER` will remove an existing trigger definition. To run this command, the current user must be the owner of the table for which the trigger is defined.

Parameters

IF EXISTS Do not throw an error if the trigger does not exist. A notice is issued in this case.

name The name of the trigger to remove.

table The name (optionally schema-qualified) of the table for which the trigger is defined.

CASCADE Automatically drop objects that depend on the trigger.

RESTRICT Refuse to drop the trigger if any objects depend on it. This is the default.

Examples

Remove the trigger `sendmail` on table `expenses`;

```
DROP TRIGGER sendmail ON expenses;
```

Compatibility

The `DROP TRIGGER` statement in WarehousePG is not compatible with the SQL standard. In the SQL standard, trigger names are not local to tables, so the command is simply `DROP TRIGGER name`.

7.2 Data Types

WarehousePG has a rich set of native data types available to users. Users may also define new data types using the `CREATE TYPE` command. This reference shows all of the built-in data types. In addition to the types listed here, there are also some internally used data types, such as *oid* (object identifier), but those are not documented in this guide.

Additional modules that you register may also install new data types. The `hstore` module, for example, introduces a new data type and associated functions for working with key-value pairs. See hstore. The `citext` module adds a case-insensitive text data type. See citext.

The following data types are specified by SQL: *bit*, *bit varying*, *boolean*, *character varying*, *varchar*, *character*, *char*, *date*, *double precision*, *integer*, *interval*, *numeric*, *decimal*, *real*, *smallint*, *time* (with or without time zone), and *timestamp* (with or without time zone).

Each data type has an external representation determined by its input and output functions. Many of the built-in types have obvious external formats. However, several types are either unique to PostgreSQL (and WarehousePG), such as geometric paths, or have several possibilities for formats, such as the date and time types. Some of the input and output functions are not invertible. That is, the result of an output function may lose accuracy when compared to the original input.

Name	Alias	Size	Range	Description
bigint	int8	8 bytes	-9223372036854775808 to 9223372036854775807	large range integer
bigserial	serial8	8 bytes	1 to 9223372036854775807	large autoincrementing integer
bit [(n)]		*n* bits	bit string constant	fixed-length bit string
bit varying [(n)][1]	varbit	actual number of bits	bit string constant	variable-length bit string
boolean	bool	1 byte	true/false, t/f, yes/no, y/n, 1/0	logical boolean (true/false)
box		32 bytes	((x1,y1),(x2,y2))	rectangular box in the plane - not allowed in distribution key columns.
bytea[1]		1 byte + *binary string*	sequence of octets	variable-length binary string
character [(n)][1]	char [(n)]	1 byte + *n*	strings up to *n* characters in length	fixed-length, blank padded
character varying [(n)][1]	varchar [(n)]	1 byte + *string size*	strings up to *n* characters in length	variable-length with limit
cidr		12 or 24 bytes		IPv4 and IPv6 networks
circle		24 bytes	<(x,y),r> (center and radius)	circle in the plane - not allowed in distribution key columns.
date		4 bytes	4713 BC - 294,277 AD	calendar date (year, month, day)
decimal [(p, s)][1]	numeric [(p, s)]	variable	no limit	user-specified precision, exact
double precision	float8 float	8 bytes	15 decimal digits precision	variable-precision, inexact
inet		12 or 24 bytes		IPv4 and IPv6 hosts and networks
integer	int, int4	4 bytes	-2147483648 to +2147483647	usual choice for integer
interval [fields] [(p)]		16 bytes	-178000000 years to 178000000 years	time span
json		1 byte + json size	json of any length	variable unlimited length
jsonb		1 byte + binary string	json of any length in a decomposed binary format	variable unlimited length
lseg		32 bytes	((x1,y1),(x2,y2))	line segment in the plane - not allowed in distribution key columns.
macaddr		6 bytes		MAC addresses
macaddr8		8 bytes		MAC addresses (EUI-64 format)
money		8 bytes	-92233720368547758.08 to +92233720368547758.07	currency amount
path[1]		16+16n bytes	[(x1,y1),...]	geometric path in the plane - not allowed in distribution key columns.
point		16 bytes	(x,y)	geometric point in the plane - not allowed in distribution key columns.
polygon		40+16n bytes	((x1,y1),...)	closed geometric path in the plane - not allowed in distribution key columns.
real	float4	4 bytes	6 decimal digits precision	variable-precision, inexact
serial	serial4	4 bytes	1 to 2147483647	autoincrementing integer
smallint	int2	2 bytes	-32768 to +32767	small range integer
text[1]		1 byte + *string size*	strings of any length	variable unlimited length
time [(p)] [without time zone]		8 bytes	00:00:00[.000000] - 24:00:00[.000000]	time of day only
time [(p)] with time zone	timetz	12 bytes	00:00:00+1359 - 24:00:00-1359	time of day only, with time zone
timestamp [(p)] [without time zone]		8 bytes	4713 BC - 294,277 AD	both date and time
timestamp [(p)] with time zone	timestamptz	8 bytes	4713 BC - 294,277 AD	both date and time, with time zone
uuid		16 bytes		Universally Unique Identifiers according to RFC 4122, ISO/IEC 9834-8:2005
xml[1]		1 byte + *xml size*	xml of any length	variable unlimited length
txid_snapshot				user-level transaction ID snapshot

- Date/Time Types
- Pseudo-Types
- Text Search Data Types
- Range Types

Parent topic: WarehousePG Reference Guide

[1] For variable length data types, if the data is greater than or equal to 127 bytes, the storage overhead is 4 bytes instead of 1.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.2.1 Date/Time Types

WarehousePG supports the full set of SQL date and time types, shown in Table 1. The operations available on these data types are described in Date/Time Functions and Operators in the PostgreSQL documentation. Dates are counted according to the Gregorian calendar, even in years before that calendar was introduced (see History of Units in the PostgreSQL documentation for more information).

Name	Storage Size	Description	Low Value	High Value	Resolution
timestamp [(p)] [without time zone]	8 bytes	both date and time (no time zone)	4713 BC	294276 AD	1 microsecond / 14 digits
timestamp [(p)] with time zone	8 bytes	both date and time, with time zone	4713 BC	294276 AD	1 microsecond / 14 digits
date	4 bytes	date (no time of day)	4713 BC	5874897 AD	1 day
time [(p)] [without time zone]	8 bytes	time of day (no date)	00:00:00	24:00:00	1 microsecond / 14 digits
time [(p)] with time zone	12 bytes	times of day only, with time zone	00:00:00+1459	24:00:00-1459	1 microsecond / 14 digits
interval [fields] [(p)]	16 bytes	time interval	-178000000 years	178000000 years	1 microsecond / 14 digits

> **Note** The SQL standard requires that writing just `timestamp` be equivalent to `timestamp without time zone`, and WarehousePG honors that behavior. `timestamptz` is accepted as an abbreviation for `timestamp with time zone`; this is a PostgreSQL extension.

`time`, `timestamp`, and `interval` accept an optional precision value p which specifies the number of fractional digits retained in the seconds field. By default, there is no explicit bound on precision. The allowed range of p is from 0 to 6 for the `timestamp` and `interval` types.

> **Note** When `timestamp` values are stored as eight-byte integers (currently the default), microsecond precision is available over the full range of values. When `timestamp` values are stored as double precision floating-point numbers instead (a deprecated compile-time option), the effective limit of precision might be less than 6. `timestamp` values are stored as seconds before or after midnight 2000-01-01. When `timestamp` values are implemented using floating-point numbers, microsecond precision is achieved for dates within a few years of 2000-01-01, but the precision degrades for dates further away. Note that using floating-point datetimes allows a larger range of `timestamp` values to be represented than shown above: from 4713 BC up to 5874897 AD.

The same compile-time option also determines whether `time` and `interval` values are stored as floating-point numbers or eight-byte integers. In the floating-point case, large `interval` values degrade in precision as the size of the interval increases.

For the `time` types, the allowed range of p is from 0 to 6 when eight-byte integer storage is used, or from 0 to 10 when floating-point storage is used.

The `interval` type has an additional option, which is to restrict the set of stored fields by writing one of these phrases:

```
YEAR
MONTH
DAY
HOUR
MINUTE
SECOND
YEAR TO MONTH
DAY TO HOUR
DAY TO MINUTE
DAY TO SECOND
HOUR TO MINUTE
HOUR TO SECOND
MINUTE TO SECOND
```

Note that if both fields and p are specified, the fields must include `SECOND`, since the precision applies only to the seconds.

The type `time with time zone` is defined by the SQL standard, but the definition exhibits properties which lead to questionable usefulness. In most cases, a combination of `date`, `time`, `timestamp without time zone`, and `timestamp with time zone` should provide a complete range of date/time functionality required by any application.

The types `abstime` and `reltime` are lower precision types which are used internally. You are discouraged from using these types in applications; these internal types might disappear in a future release.

WarehousePG 6 and later releases do not automatically cast text from the deprecated timestamp format `YYYYMMDDHH24MISS`. The format could not be parsed unambiguously in previous WarehousePG releases.

For example, this command returns an error in WarehousePG 6. In previous releases, a timestamp is returned.

```
# select to_timestamp('20190905140000');
```

In WarehousePG 6, this command returns a timestamp.

```
# select to_timestamp('20190905140000','YYYYMMDDHH24MISS');
```

Date/Time Input

Date and time input is accepted in almost any reasonable format, including ISO 8601, SQL-compatible, traditional POSTGRES, and others. For some formats, ordering of day, month, and year in date input is ambiguous and there is support for specifying the expected ordering of these fields. Set the DateStyle parameter to `MDY` to select month-day-year interpretation, `DMY` to select day-month-year interpretation, or `YMD` to select year-month-day interpretation.

WarehousePG is more flexible in handling date/time input than the SQL standard requires. See Appendix B. Date/Time Support in the PostgreSQL documentation for the exact parsing rules of date/time input and for the recognized text fields including months, days of the week, and time zones.

Remember that any date or time literal input needs to be enclosed in single quotes, like text strings. SQL requires the following syntax

```
<type> [ (<p>) ] '<value>'
```

where p is an optional precision specification giving the number of fractional digits in the seconds field. Precision can be specified for `time`, `timestamp`, and `interval` types. The allowed values are mentioned above. If no precision is specified in a constant specification, it defaults to the precision of the literal value.

Dates

Table 2 shows some possible inputs for the `date` type.

Example	Description
1999-01-08	ISO 8601; January 8 in any mode (recommended format)
January 8, 1999	unambiguous in any datestyle input mode
1/8/1999	January 8 in `MDY` mode; August 1 in `DMY` mode
1/18/1999	January 18 in `MDY` mode; rejected in other modes
01/02/03	January 2, 2003 in `MDY` mode; February 1, 2003 in `DMY` mode; February 3, 2001 in `YMD` mode
1999-Jan-08	January 8 in any mode
Jan-08-1999	January 8 in any mode
08-Jan-1999	January 8 in any mode
99-Jan-08	January 8 in `YMD` mode, else error
08-Jan-99	January 8, except error in `YMD` mode
Jan-08-99	January 8, except error in `YMD` mode
19990108	ISO 8601; January 8, 1999 in any mode
990108	ISO 8601; January 8, 1999 in any mode
1999.008	year and day of year
J2451187	Julian date
January 8, 99 BC	year 99 BC

Times

The time-of-day types are `time [ (p) ] without time zone` and `time [ (p) ] with time zone`. `time` alone is equivalent to `time without time zone`.

Valid input for these types consists of a time of day followed by an optional time zone. (See Time Input and Time Zone Input.) If a time zone is specified in the input for `time without time zone`, it is silently ignored. You can also specify a date but it will be ignored, except when you use a time zone name that involves a daylight-savings rule, such as `America/New_York`. In this case specifying the date is required in order to determine whether standard or daylight-savings time applies. The appropriate time zone offset is recorded in the `time with time zone` value.

Time Input

Example	Description
`04:05:06.789`	ISO 8601
`04:05:06`	ISO 8601
`04:05`	ISO 8601
`040506`	ISO 8601
`04:05 AM`	same as 04:05; AM does not affect value
`04:05 PM`	same as 16:05; input hour must be <= 12
`04:05:06.789-8`	ISO 8601
`04:05:06-08:00`	ISO 8601
`04:05-08:00`	ISO 8601
`040506-08`	ISO 8601
`04:05:06 PST`	time zone specified by abbreviation
`2003-04-12 04:05:06 America/New_York`	time zone specified by full name

Time Zone Input

Example	Description
`PST`	Abbreviation (for Pacific Standard Time)
`America/New_York`	Full time zone name
`PST8PDT`	POSIX-style time zone specification
`-8:00`	ISO-8601 offset for PST
`-800`	ISO-8601 offset for PST
`-8`	ISO-8601 offset for PST
`zulu`	Military abbreviation for UTC
`z`	Short form of `zulu`

Refer to Time Zones for more information on how to specify time zones.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Time Stamps

Valid input for the time stamp types consists of the concatenation of a date and a time, followed by an optional time zone, followed by an optional `AD` or `BC`. (Alternatively, `AD`/`BC` can appear before the time zone, but this is not the preferred ordering.) Thus: `1999-01-08 04:05:06` and: `1999-01-08 04:05:06 -8:00` are valid values, which follow the ISO 8601 standard. In addition, the common format: `January 8 04:05:06 1999 PST` is supported.

The SQL standard differentiates `timestamp without time zone` and `timestamp with time zone` literals by the presence of a `+` or `-` symbol and time zone offset after the time. Hence, according to the standard, `TIMESTAMP '2004-10-19 10:23:54'` is a `timestamp without time zone`, while `TIMESTAMP '2004-10-19 10:23:54+02'` is a `timestamp with time zone`. WarehousePG never examines the content of a literal string before determining its type, and therefore will treat both of the above as `timestamp without time zone`. To ensure that a literal is treated as `timestamp with time zone`, give it the correct explicit type: `TIMESTAMP WITH TIME ZONE '2004-10-19 10:23:54+02'` In a literal that has been determined to be `timestamp without time zone`, WarehousePG will silently ignore any time zone indication. That is, the resulting value is derived from the date/time fields in the input value, and is not adjusted for time zone.

For `timestamp with time zone`, the internally stored value is always in UTC (Universal Coordinated Time, traditionally known as Greenwich Mean Time, GMT). An input value that has an explicit time zone specified is converted to UTC using the appropriate offset for that time zone. If no time zone is stated in the input string, then it is assumed to be in the time zone indicated by the system's `TimeZone` parameter, and is converted to UTC using the offset for the timezone zone.

When a `timestamp with time zone` value is output, it is always converted from UTC to the current timezone zone, and displayed as local time in that zone. To see the time in another time zone, either change timezone or use the `AT TIME ZONE` construct (see AT TIME ZONE in the PostgreSQL documentation).

Conversions between `timestamp without time zone` and `timestamp with time zone` normally assume that the `timestamp without time zone` value should be taken or given as timezone local time. A different time zone can be specified for the conversion using `AT TIME ZONE`.

Special Values

WarehousePG supports several special date/time input values for convenience, as shown in Special Date/Time Inputs. The values `infinity` and `-infinity` are specially represented inside the system and will be displayed unchanged; but the others are simply notational shorthands that will be converted to ordinary date/time values when read. (In particular, `now` and related strings are converted to a specific time value as soon as they are read.) All of these values need to be enclosed in single quotes when used as constants in SQL commands.

Special Date/Time Inputs

Input String	Valid Types	Description
`epoch`	`date`, `timestamp`	1970-01-01 00:00:00+00 (Unix system time zero)
`infinity`	`date`, `timestamp`	later than all other time stamps
`-infinity`	`date`, `timestamp`	earlier than all other time stamps
`now`	`date`, `time`, `timestamp`	current transaction's start time
`today`	`date`, `timestamp`	midnight today
`tomorrow`	`date`, `timestamp`	midnight tomorrow
`yesterday`	`date`, `timestamp`	midnight yesterday
`allballs`	`time`	00:00:00.00 UTC

The following SQL-compatible functions can also be used to obtain the current time value for the corresponding data type: `CURRENT_DATE`, `CURRENT_TIME`, `CURRENT_TIMESTAMP`, `LOCALTIME`, `LOCALTIMESTAMP`. The latter four accept an optional subsecond precision specification. (See Current Date/Time in the PostgreSQL documentation.) Note that these are SQL functions and are *not* recognized in data input strings.

Date/Time Output

The output format of the date/time types can be set to one of the four styles ISO 8601, SQL (Ingres), traditional POSTGRES (Unix `date` format), or German. The default is the ISO format. (The SQL standard requires the use of the ISO 8601 format. The name of the `SQL` output format is a historical accident.) Date/Time Output Styles shows examples of each output style. The output of the `date` and `time` types is generally only the date or time part in accordance with the given examples. However, the POSTGRES style outputs date-only values in ISO format.

Date/Time Output Styles

Style Specification	Description	Example
`ISO`	ISO 8601, SQL standard	`1997-12-17 07:37:16-08`
`SQL`	traditional style	`12/17/1997 07:37:16.00 PST`
`Postgres`	original style	`Wed Dec 17 07:37:16 1997 PST`
`German`	regional style	`17.12.1997 07:37:16.00 PST`

> **Note** ISO 8601 specifies the use of uppercase letter `T` to separate the date and time. WarehousePG accepts that format on input, but on output it uses a space rather than `T`, as shown above. This is for readability and for consistency with RFC 3339 as well as some other database systems.

In the SQL and POSTGRES styles, day appears before month if DMY field ordering has been specified, otherwise month appears before day. (See Date Input for how this setting also affects interpretation of input values.) Date Order Conventions shows examples.

Date Order Conventions

datestyle Setting	Input Ordering	Example Output
`SQL, DMY`	day/month/year	`17/12/1997 15:37:16.00 CET`
`SQL, MDY`	month/day/year	`12/17/1997 07:37:16.00 PST`
`Postgres, DMY`	day/month/year	`Wed 17 Dec 07:37:16 1997 PST`

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

The date/time style can be selected by the user using the `SET datestyle` command, the `DateStyle` parameter in the `postgresql.conf` configuration file, or the `PGDATESTYLE` environment variable on the server or client.

The formatting function `to_char` (see Data Type Formatting Functions) is also available as a more flexible way to format date/time output.

Time Zones

Time zones, and time-zone conventions, are influenced by political decisions, not just earth geometry. Time zones around the world became somewhat standardized during the 1900s, but continue to be prone to arbitrary changes, particularly with respect to daylight-savings rules. WarehousePG uses the widely-used IANA (Olson) time zone database for information about historical time zone rules. For times in the future, the assumption is that the latest known rules for a given time zone will continue to be observed indefinitely far into the future.

WarehousePG endeavors to be compatible with the SQL standard definitions for typical usage. However, the SQL standard has an odd mix of date and time types and capabilities. Two obvious problems are:

1. Although the `date` type cannot have an associated time zone, the `time` type can. Time zones in the real world have little meaning unless associated with a date as well as a time, since the offset can vary through the year with daylight-saving time boundaries.
2. The default time zone is specified as a constant numeric offset from UTC. It is therefore impossible to adapt to daylight-saving time when doing date/time arithmetic across DST boundaries.

To address these difficulties, we recommend using date/time types that contain both date and time when using time zones. We do*not* recommend using the type `time with time zone` (though it is supported by WarehousePG for legacy applications and for compliance with the SQL standard). WarehousePG assumes your local time zone for any type containing only date or time.

All timezone-aware dates and times are stored internally in UTC. They are converted to local time in the zone specified by the `TimeZone` configuration parameter before being displayed to the client.

WarehousePG allows you to specify time zones in three different forms:

1. A full time zone name, for example `America/New_York`. The recognized time zone names are listed in the `pg_timezone_names` view. WarehousePG uses the widely-used IANA time zone data for this purpose, so the same time zone names are also recognized by other software.
2. A time zone abbreviation, for example `PST`. Such a specification merely defines a particular offset from UTC, in contrast to full time zone names which can imply a set of daylight savings transition-date rules as well. The recognized abbreviations are listed in the `pg_timezone_abbrevs` view. You cannot set the configuration parameters TimeZone or log_timezone to a time zone abbreviation, but you can use abbreviations in date/time input values and with the `AT TIME ZONE` operator.
3. In addition to the timezone names and abbreviations, WarehousePG will accept POSIX-style time zone specifications of the form STDoffset or STDoffsetDST, where STD is a zone abbreviation, offset is a numeric offset in hours west from UTC, and DST is an optional daylight-savings zone abbreviation, assumed to stand for one hour ahead of the given offset. For example, if `EST5EDT` were not already a recognized zone name, it would be accepted and would be functionally equivalent to United States East Coast time. In this syntax, a zone abbreviation can be a string of letters, or an arbitrary string surrounded by angle brackets (`<>`). When a daylight-savings zone abbreviation is present, it is assumed to be used according to the same daylight-savings transition rules used in the IANA time zone database's entry. In a standard WarehousePG installation, is the same as `US/Eastern`, so that POSIX-style time zone specifications follow USA daylight-savings rules. If needed, you can adjust this behavior by replacing the file.

In short, this is the difference between abbreviations and full names: abbreviations represent a specific offset from UTC, whereas many of the full names imply a local daylight-savings time rule, and so have two possible UTC offsets. As an example, `2014-06-04 12:00 America/New_York` represents noon local time in New York, which for this particular date was Eastern Daylight Time (UTC-4). So `2014-06-04 12:00 EDT` specifies that same time instant. But `2014-06-04 12:00 EST` specifies noon Eastern Standard Time (UTC-5), regardless of whether daylight savings was nominally in effect on that date.

To complicate matters, some jurisdictions have used the same timezone abbreviation to mean different UTC offsets at different times; for example, in Moscow `MSK` has meant UTC+3 in some years and UTC+4 in others. WarehousePG interprets such abbreviations according to whatever they meant (or had most recently meant) on the specified date; but, as with the `EST` example above, this is not necessarily the same as local civil time on that date.

One should be wary that the POSIX-style time zone feature can lead to silently accepting bogus input, since there is no check on the reasonableness of the zone abbreviations. For example `SET TIMEZONE TO FOOBAR0` will work, leaving the system effectively using a rather peculiar abbreviation for UTC. Another issue to keep in mind is that in POSIX time zone names, positive offsets are used for locations of Greenwich. Everywhere else, WarehousePG follows the ISO-8601 convention that positive timezone offsets are of Greenwich.

In all cases, timezone names and abbreviations are recognized case-insensitively.

Neither timezone names nor abbreviations are hard-wired into the server; they are obtained from configuration files (see Configuring Localization Settings).

The `TimeZone` configuration parameter can be set in the file , or in any of the other standard ways for setting configuration parameters. There are also some special ways to set it:

1. The SQL command `SET TIME ZONE` sets the time zone for the session. This is an alternative spelling of `SET TIMEZONE TO` with a more SQL-spec-compatible syntax.
2. The `PGTZ` environment variable is used by `libpq` clients to send a `SET TIME ZONE` command to the server upon connection.

Interval Input

`interval` values can be written using the following verbose syntax:

```
<@> <quantity> <unit> <quantity> <unit>... <direction>
```

where quantity is a number (possibly signed); unit is `microsecond`, `millisecond`, `second`, `minute`, `hour`, `day`, `week`, `month`, `year`, `decade`, `century`, `millennium`, or abbreviations or plurals of these units; direction can be `ago` or empty. The at sign (`@`) is optional noise. The amounts of the different units are implicitly added with appropriate sign accounting. `ago` negates all the fields. This syntax is also used for interval output, if IntervalStyle is set to `postgres_verbose`.

Quantities of days, hours, minutes, and seconds can be specified without explicit unit markings. For example, `'1 12:59:10'` is read the same as `'1 day 12 hours 59 min 10 sec'`. Also, a combination of years and months can be specified with a dash; for example `'200-10'` is read the same as `'200 years 10 months'`. (These shorter forms are in fact the only ones allowed by the SQL standard, and are used for output when IntervalStyle is set to `sql_standard`.)

Interval values can also be written as ISO 8601 time intervals, using either the `format with designators` of the standard's section 4.4.3.2 or the `alternative format` of section 4.4.3.3. The format with designators looks like this:

```
P <quantity> <unit> <quantity> <unit> ...  T  <quantity> <unit> ...
```

The string must start with a `P`, and may include a `T` that introduces the time-of-day units. The available unit abbreviations are given in ISO 8601 Interval Unit Abbreviations. Units may be omitted, and may be specified in any order, but units smaller than a day must appear after `T`. In particular, the meaning of `M` depends on whether it is before or after `T`.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

ISO 8601 Interval Unit Abbreviations

Abbreviation	Meaning
Y	Years
M	Months (in the date part)
W	Weeks
D	Days
H	Hours
M	Minutes (in the time part)
S	Seconds

In the alternative format:

```
P  <years>-<months>-<days>   T <hours>:<minutes>:<seconds>
```

the string must begin with `P`, and a `T` separates the date and time parts of the interval. The values are given as numbers similar to ISO 8601 dates.

When writing an interval constant with a fields specification, or when assigning a string to an interval column that was defined with a fields specification, the interpretation of unmarked quantities depends on the fields. For example `INTERVAL '1' YEAR` is read as 1 year, whereas `INTERVAL '1'` means 1 second. Also, field values `to the right` of the least significant field allowed by the fields specification are silently discarded. For example, writing `INTERVAL '1 day 2:03:04' HOUR TO MINUTE` results in dropping the seconds field, but not the day field.

According to the SQL standard all fields of an interval value must have the same sign, so a leading negative sign applies to all fields; for example the negative sign in the interval literal `'-1 2:03:04'` applies to both the days and hour/minute/second parts. WarehousePG allows the fields to have different signs, and traditionally treats each field in the textual representation as independently signed, so that the hour/minute/second part is considered positive in this example. If IntervalStyle is set to `sql_standard` then a leading sign is considered to apply to all fields (but only if no additional signs appear). Otherwise the traditional WarehousePG interpretation is used. To avoid ambiguity, it's recommended to attach an explicit sign to each field if any field is negative.

In the verbose input format, and in some fields of the more compact input formats, field values can have fractional parts; for example `'1.5 week'` or `'01:02:03.45'`. Such input is converted to the appropriate number of months, days, and seconds for storage. When this would result in a fractional number of months or days, the fraction is added to the lower-order fields using the conversion factors 1 month = 30 days and 1 day = 24 hours. For example, `'1.5 month'` becomes 1 month and 15 days. Only seconds will ever be shown as fractional on output.

This table shows some examples of valid `interval` input.

Example	Description
1-2	SQL standard format: 1 year 2 months
3 4:05:06	SQL standard format: 3 days 4 hours 5 minutes 6 seconds
1 year 2 months 3 days 4 hours 5 minutes 6 seconds	Traditional Postgres format: 1 year 2 months 3 days 4 hours 5 minutes 6 seconds
P1Y2M3DT4H5M6S	ISO 8601 `format with designators`: same meaning as above
P0001-02-03T04:05:06	ISO 8601 `alternative format`: same meaning as above

Internally `interval` values are stored as months, days, and seconds. This is done because the number of days in a month varies, and a day can have 23 or 25 hours if a daylight savings time adjustment is involved. The months and days fields are integers while the seconds field can store fractions. Because intervals are usually created from constant strings or `timestamp` subtraction, this storage method works well in most cases, but can cause unexpected results: `SELECT EXTRACT(hours from '80 minutes'::interval); date_part ----------- 1 SELECT EXTRACT(days from '80 hours'::interval); date_part ----------- 0` Functions `justify_days` and `justify_hours` are available for adjusting days and hours that overflow their normal ranges.

Interval Output

The output format of the interval type can be set to one of the four styles `sql_standard`, `postgres`, `postgres_verbose`, or `iso_8601`, using the command `SET intervalstyle`. The default is the `postgres` format. Interval Output Style Examples shows examples of each output style.

The `sql_standard` style produces output that conforms to the SQL standard's specification for interval literal strings, if the interval value meets the standard's restrictions (either year-month only or day-time only, with no mixing of positive and negative components). Otherwise the output looks like a standard year-month literal string followed by a day-time literal string, with explicit signs added to disambiguate mixed-sign intervals.

The output of the `postgres` style matches the output of PostgreSQL releases prior to 8.4 when the DateStyle parameter was set to `ISO`.

The output of the `postgres_verbose` style matches the output of PostgreSQL releases prior to 8.4 when the DateStyle parameter was set to non-`ISO` output.

The output of the `iso_8601` style matches the `format with designators` described in section 4.4.3.2 of the ISO 8601 standard.

Interval Output Style Examples

Style Specification	Year-Month Interval	Day-Time Interval	Mixed Interval
`sql_standard`	1-2	3 4:05:06	-1-2 +3 -4:05:06
`postgres`	1 year 2 mons	3 days 04:05:06	-1 year -2 mons +3 days -04:05:06
`postgres_verbose`	@ 1 year 2 mons	@ 3 days 4 hours 5 mins 6 secs	@ 1 year 2 mons -3 days 4 hours 5 mins 6 secs ago
`iso_8601`	P1Y2M	P3DT4H5M6S	P-1Y-2M3DT-4H-5M-6S

7.2.2 Pseudo-Types

WarehousePG supports special-purpose data type entries that are collectively called *pseudo-types*. A pseudo-type cannot be used as a column data type, but it can be used to declare a function's argument or result type. Each of the available pseudo-types is useful in situations where a function's behavior does not correspond to simply taking or returning a value of a specific SQL data type.

Functions coded in procedural languages can use pseudo-types only as allowed by their implementation languages. The procedural languages all forbid use of a pseudo-type as an argument type, and allow only*void* and *record* as a result type.

A function with the pseudo-type *record* as a return data type returns an unspecified row type. The *record* represents an array of possibly-anonymous composite types. Since composite datums carry their own type identification, no extra knowledge is needed at the array level.

The pseudo-type *void* indicates that a function returns no value.

> **Note** WarehousePG does not support triggers and the pseudo-type *trigger*.

The types *anyelement*, *anyarray*, *anynonarray*, and *anyenum* are pseudo-types called polymorphic types. Some procedural languages also support polymorphic functions using the types*anyarray*, *anyelement*, *anyenum*, and *anynonarray*.

The pseudo-type *anytable* is a WarehousePG type that specifies a table expression—an expression that computes a table. WarehousePG allows this type only as an argument to a user-defined function. SeeTable Value Expressions for more about the *anytable* pseudo-type.

For more information about pseudo-types, see the PostgreSQL documentation aboutPseudo-Types.

Parent topic: Data Types

Polymorphic Types

Four pseudo-types of special interest are *anyelement*, *anyarray*, *anynonarray*, and *anyenum*, which are collectively called *polymorphic* types. Any function declared using these types is said to be a polymorphic function. A polymorphic function can operate on many different data types, with the specific data types being determined by the data types actually passed to it at runtime.

Polymorphic arguments and results are tied to each other and are resolved to a specific data type when a query calling a polymorphic function is parsed. Each position (either argument or return value) declared as*anyelement* is allowed to have any specific actual data type, but in any given call they must all be the same actual type. Each position declared as *anyarray* can have any array data type, but similarly they must all be the same type. If there are positions declared *anyarray* and others declared *anyelement*, the actual array type in the *anyarray* positions must be an array whose elements are the same type appearing in the *anyelement* positions. *anynonarray* is treated exactly the same as *anyelement*, but adds the additional constraint that the actual type must not be an array type. *anyenum* is treated exactly the same as *anyelement*, but adds the additional constraint that the actual type must be an `enum` type.

When more than one argument position is declared with a polymorphic type, the net effect is that only certain combinations of actual argument types are allowed. For example, a function declared as `equal(*anyelement*, *anyelement*)` takes any two input values, so long as they are of the same data type.

When the return value of a function is declared as a polymorphic type, there must be at least one argument position that is also polymorphic, and the actual data type supplied as the arqument determines the actual result type for that call. For example, if there were not already an array subscripting mechanism, one could define a function that implements subscripting as `subscript(*anyarray*, integer) returns *anyelement*` . This declaration constrains the actual first argument to be an array type, and allows the parser to infer the correct result type from the actual first argument's type. Another example is that a function declared as `myfunc(*anyarray*) returns *anyenum*` will only accept arrays of `enum` types.

Note that *anynonarray* and *anyenum* do not represent separate type variables; they are the same type as *anyelement*, just with an additional constraint. For example, declaring a function as `myfunc(*anyelement*, *anyenum*)` is equivalent to declaring it as `myfunc(*anyenum*, *anyenum*)` : both actual arguments must be the same `enum` type.

A variadic function (one taking a variable number of arguments) is polymorphic when its last parameter is declared as `VARIADIC *anyarray*` . For purposes of argument matching and determining the actual result type, such a function behaves the same as if you had declared the appropriate number of *anynonarray* parameters.

For more information about polymorphic types, see the PostgreSQL documentation aboutPolymorphic Arguments and Return Types.

Table Value Expressions

The *anytable* pseudo-type declares a function argument that is a table value expression. The notation for a table value expression is a `SELECT` statement enclosed in a `TABLE()` function. You can specify a distribution policy for the table by adding `SCATTER RANDOMLY` , or a `SCATTER BY` clause with a column list to specify the distribution key.

The `SELECT` statement is run when the function is called and the result rows are distributed to segments so that each segment runs the function with a subset of the result table.

For example, this table expression selects three columns from a table named `customer` and sets the distribution key to the first column:

```
TABLE(SELECT cust_key, name, address FROM customer SCATTER BY 1)
```

The `SELECT` statement may include joins on multiple base tables, `WHERE` clauses, aggregates, and any other valid query syntax.

The *anytable* type is only permitted in functions implemented in the C or C++ languages. The body of the function can access the table using the WarehousePG Server Programming Interface (SPI) or the WarehousePG Partner Connector (GPPC) API.

7.2.3 Text Search Data Types

WarehousePG provides two data types that are designed to support full text search, which is the activity of searching through a collection of natural-language *documents* to locate those that best match a *query*. The `tsvector` type represents a document in a form optimized for text search; the `tsquery` type similarly represents a text query. Using Full Text Search provides a detailed explanation of this facility, and Text Search Functions and Operators summarizes the related functions and operators.

The `tsvector` and `tsquery` types cannot be part of the distribution key of a WarehousePG table.

Parent topic: Data Types

tsvector

A `tsvector` value is a sorted list of distinct *lexemes*, which are words that have been *normalized* to merge different variants of the same word (see Using Full Text Search for details). Sorting and duplicate-elimination are done automatically during input, as shown in this example:

```
SELECT 'a fat cat sat on a mat and ate a fat rat'::tsvector;
                    tsvector
-----------------------------------------------------
 'a' 'and' 'ate' 'cat' 'fat' 'mat' 'on' 'rat' 'sat'
```

To represent lexemes containing whitespace or punctuation, surround them with quotes:

```
SELECT $$the lexeme '    ' contains spaces$$::tsvector;
               tsvector
-------------------------------------------
 '    ' 'contains' 'lexeme' 'spaces' 'the'
```

(We use dollar-quoted string literals in this example and the next one to avoid the confusion of having to double quote marks within the literals.) Embedded quotes and backslashes must be doubled:

```
SELECT $$the lexeme 'Joe''s' contains a quote$$::tsvector;
                   tsvector
------------------------------------------------
 'Joe''s' 'a' 'contains' 'lexeme' 'quote' 'the'
```

Optionally, integer *positions* can be attached to lexemes:

```
SELECT 'a:1 fat:2 cat:3 sat:4 on:5 a:6 mat:7 and:8 ate:9 a:10 fat:11 rat:12'::tsvector;
                                tsvector
-------------------------------------------------------------------------------
 'a':1,6,10 'and':8 'ate':9 'cat':3 'fat':2,11 'mat':7 'on':5 'rat':12 'sat':4
```

A position normally indicates the source word's location in the document. Positional information can be used for *proximity ranking*. Position values can range from 1 to 16383; larger numbers are silently set to 16383. Duplicate positions for the same lexeme are discarded.

Lexemes that have positions can further be labeled with a *weight*, which can be `A`, `B`, `C`, or `D`. `D` is the default and hence is not shown on output:

```
SELECT 'a:1A fat:2B,4C cat:5D'::tsvector;
          tsvector
----------------------------
 'a':1A 'cat':5 'fat':2B,4C
```

Weights are typically used to reflect document structure, for example by marking title words differently from body words. Text search ranking functions can assign different priorities to the different weight markers.

It is important to understand that the `tsvector` type itself does not perform any normalization; it assumes the words it is given are normalized appropriately for the application. For example,

```
select 'The Fat Rats'::tsvector;
      tsvector
--------------------
 'Fat' 'Rats' 'The'
```

For most English-text-searching applications the above words would be considered non-normalized, but tsvector doesn't care. Raw document text should usually be passed through `to_tsvector` to normalize the words appropriately for searching:

```
SELECT to_tsvector('english', 'The Fat Rats');
   to_tsvector
-----------------
 'fat':2 'rat':3
```

tsquery

A `tsquery` value stores lexemes that are to be searched for, and combines them honoring the Boolean operators `&` (AND), `|` (OR), and `!` (NOT). Parentheses can be used to enforce grouping of the operators:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
SELECT 'fat & rat'::tsquery;
    tsquery
---------------
 'fat' & 'rat'

SELECT 'fat & (rat | cat)'::tsquery;
          tsquery
----------------------------
 'fat' & ( 'rat' | 'cat' )

SELECT 'fat & rat & ! cat'::tsquery;
        tsquery
------------------------
 'fat' & 'rat' & !'cat'
```

In the absence of parentheses, `!` (NOT) binds most tightly, and `&` (AND) binds more tightly than `|` (OR).

Optionally, lexemes in a `tsquery` can be labeled with one or more weight letters, which restricts them to match only `tsvector` lexemes with matching weights:

```
SELECT 'fat:ab & cat'::tsquery;
    tsquery
------------------
 'fat':AB & 'cat'
```

Also, lexemes in a `tsquery` can be labeled with * to specify prefix matching:

```
SELECT 'super:*'::tsquery;
  tsquery
-----------
 'super':*
```

This query will match any word in a `tsvector` that begins with "super". Note that prefixes are first processed by text search configurations, which means this comparison returns true:

```
SELECT to_tsvector( 'postgraduate' ) @@ to_tsquery( 'postgres:*' );
 ?column?
----------
 t
(1 row)
```

because `postgres` gets stemmed to `postgr`:

```
SELECT to_tsquery('postgres:*');
 to_tsquery
------------
 'postgr':*
(1 row)
```

which then matches `postgraduate`.

Quoting rules for lexemes are the same as described previously for lexemes in `tsvector`; and, as with `tsvector`, any required normalization of words must be done before converting to the `tsquery` type. The `to_tsquery` function is convenient for performing such normalization:

```
SELECT to_tsquery('Fat:ab & Cats');
    to_tsquery
------------------
 'fat':AB & 'cat'
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.2.4 Range Types

Range types are data types representing a range of values of some element type (called the range's subtype). For instance, ranges of `timestamp` might be used to represent the ranges of time that a meeting room is reserved. In this case the data type is `tsrange` (short for "timestamp range"), and `timestamp` is the subtype. The subtype must have a total order so that it is well-defined whether element values are within, before, or after a range of values.

Range types are useful because they represent many element values in a single range value, and because concepts such as overlapping ranges can be expressed clearly. The use of time and date ranges for scheduling purposes is the clearest example; but price ranges, measurement ranges from an instrument, and so forth can also be useful.

Parent topic: Data Types

Built-in Range Types

WarehousePG comes with the following built-in range types:

- `int4range` -- Range of `integer`
- `int8range` -- Range of `bigint`
- `numrange` -- Range of `numeric`
- `tsrange` -- Range of `timestamp without time zone`
- `tstzrange` -- Range of `timestamp with time zone`
- `daterange` -- Range of `date`

In addition, you can define your own range types; see CREATE TYPE for more information.

Examples

```
CREATE TABLE reservation (room int, during tsrange);
INSERT INTO reservation VALUES
    (1108, '[2010-01-01 14:30, 2010-01-01 15:30)');

-- Containment
SELECT int4range(10, 20) @> 3;

-- Overlaps
SELECT numrange(11.1, 22.2) && numrange(20.0, 30.0);

-- Extract the upper bound
SELECT upper(int8range(15, 25));

-- Compute the intersection
SELECT int4range(10, 20) * int4range(15, 25);

-- Is the range empty?
SELECT isempty(numrange(1, 5));
```

See Range Functions and Operators for complete lists of operators and functions on range types.

Inclusive and Exclusive Bounds

Every non-empty range has two bounds, the lower bound and the upper bound. All points between these values are included in the range. An inclusive bound means that the boundary point itself is included in the range as well, while an exclusive bound means that the boundary point is not included in the range.

In the text form of a range, an inclusive lower bound is represented by `[` while an exclusive lower bound is represented by `(` . Likewise, an inclusive upper bound is represented by `]` , while an exclusive upper bound is represented by `)` . (See Range Functions and Operators for more details.)

The functions `lower_inc` and `upper_inc` test the inclusivity of the lower and upper bounds of a range value, respectively.

Infinite (Unbounded) Ranges

The lower bound of a range can be omitted, meaning that all points less than the upper bound are included in the range. Likewise, if the upper bound of the range is omitted, then all points greater than the lower bound are included in the range. If both lower and upper bounds are omitted, all values of the element type are considered to be in the range.

This is equivalent to considering that the lower bound is "minus infinity", or the upper bound is "plus infinity", respectively. But note that these infinite values are never values of the range's element type, and can never be part of the range. (So there is no such thing as an inclusive infinite bound -- if you try to write one, it will automatically be converted to an exclusive bound.)

Also, some element types have a notion of "infinity", but that is just another value so far as the range type mechanisms are concerned. For example, in timestamp ranges, `[today,]` means the same thing as `[today,)` . But `[today,infinity]` means something different from `[today,infinity)` -- the latter excludes the special `timestamp` value `infinity` .

The functions `lower_inf` and `upper_inf` test for infinite lower and upper bounds of a range, respectively.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Range Input/Output

The input for a range value must follow one of the following patterns:

```
(<lower-bound>,<upper-bound>)
(<lower-bound>,<upper-bound>]
[<lower-bound>,<upper-bound>)
[<lower-bound>,<upper-bound>]
empty
```

The parentheses or brackets indicate whether the lower and upper bounds are exclusive or inclusive, as described previously. Notice that the final pattern is `empty`, which represents an empty range (a range that contains no points).

The lower-bound may be either a string that is valid input for the subtype, or empty to indicate no lower bound. Likewise, upper-bound may be either a string that is valid input for the subtype, or empty to indicate no upper bound.

Each bound value can be quoted using `"` (double quote) characters. This is necessary if the bound value contains parentheses, brackets, commas, double quotes, or backslashes, since these characters would otherwise be taken as part of the range syntax. To put a double quote or backslash in a quoted bound value, precede it with a backslash. (Also, a pair of double quotes within a double-quoted bound value is taken to represent a double quote character, analogously to the rules for single quotes in SQL literal strings.) Alternatively, you can avoid quoting and use backslash-escaping to protect all data characters that would otherwise be taken as range syntax. Also, to write a bound value that is an empty string, write `""`, since writing nothing means an infinite bound.

Whitespace is allowed before and after the range value, but any whitespace between the parentheses or brackets is taken as part of the lower or upper bound value. (Depending on the element type, it might or might not be significant.)

Examples:

```
-- includes 3, does not include 7, and does include all points in between
SELECT '[3,7)'::int4range;

-- does not include either 3 or 7, but includes all points in between
SELECT '(3,7)'::int4range;

-- includes only the single point 4
SELECT '[4,4]'::int4range;

-- includes no points (and will be normalized to 'empty')
SELECT '[4,4)'::int4range;
```

Constructing Ranges

Each range type has a constructor function with the same name as the range type. Using the constructor function is frequently more convenient than writing a range literal constant, since it avoids the need for extra quoting of the bound values. The constructor function accepts two or three arguments. The two-argument form constructs a range in standard form (lower bound inclusive, upper bound exclusive), while the three-argument form constructs a range with bounds of the form specified by the third argument. The third argument must be one of the strings `()`, `(]`, `[)`, or `[]`. For example:

```
-- The full form is: lower bound, upper bound, and text argument indicating
-- inclusivity/exclusivity of bounds.
SELECT numrange(1.0, 14.0, '(]');

-- If the third argument is omitted, '[)' is assumed.
SELECT numrange(1.0, 14.0);

-- Although '(]' is specified here, on display the value will be converted to
-- canonical form, since int8range is a discrete range type (see below).
SELECT int8range(1, 14, '(]');

-- Using NULL for either bound causes the range to be unbounded on that side.
SELECT numrange(NULL, 2.2);
```

Discrete Range Types

A discrete range is one whose element type has a well-defined “step”, such as `integer` or `date`. In these types two elements can be said to be adjacent, when there are no valid values between them. This contrasts with continuous ranges, where it's always (or almost always) possible to identify other element values between two given values. For example, a range over the `numeric` type is continuous, as is a range over `timestamp`. (Even though `timestamp` has limited precision, and so could theoretically be treated as discrete, it's better to consider it continuous since the step size is normally not of interest.)

Another way to think about a discrete range type is that there is a clear idea of a “next” or “previous” value for each element value. Knowing that, it is possible to convert between inclusive and exclusive representations of a range's bounds, by choosing the next or previous element value instead of the one originally given. For example, in an integer range type `[4,8]` and `(3,9)` denote the same set of values; but this would not be so for a range over numeric.

A discrete range type should have a *canonicalization* function that is aware of the desired step size for the element type. The canonicalization function is charged with converting equivalent values of the range type to have identical representations, in particular consistently inclusive or exclusive bounds. If a canonicalization function is not specified, then ranges with different formatting will always be treated as unequal, even though they might represent the same set of values in reality.

The built-in range types `int4range`, `int8range`, and `daterange` all use a canonical form that includes the lower bound and excludes the upper bound; that is, `[)`. User-defined range types can use other conventions, however.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Defining New Range Types

Users can define their own range types. The most common reason to do this is to use ranges over subtypes not provided among the built-in range types. For example, to define a new range type of subtype `float8`:

```
CREATE TYPE floatrange AS RANGE (
    subtype = float8,
    subtype_diff = float8mi
);

SELECT '[1.234, 5.678]'::floatrange;
```

Because `float8` has no meaningful "step", we do not define a canonicalization function in this example.

Defining your own range type also allows you to specify a different subtype B-tree operator class or collation to use, so as to change the sort ordering that determines which values fall into a given range.

If the subtype is considered to have discrete rather than continuous values, the CREATE TYPE command should specify a `canonical` function. The canonicalization function takes an input range value, and must return an equivalent range value that may have different bounds and formatting. The canonical output for two ranges that represent the same set of values, for example the integer ranges `[1, 7]` and `[1, 8)`, must be identical. It doesn't matter which representation you choose to be the canonical one, so long as two equivalent values with different formattings are always mapped to the same value with the same formatting. In addition to adjusting the inclusive/exclusive bounds format, a canonicalization function might round off boundary values, in case the desired step size is larger than what the subtype is capable of storing. For instance, a range type over `timestamp` could be defined to have a step size of an hour, in which case the canonicalization function would need to round off bounds that weren't a multiple of an hour, or perhaps throw an error instead.

In addition, any range type that is meant to be used with GiST or SP-GiST indexes should define a subtype difference, or `subtype_diff`, function. (The index will still work without `subtype_diff`, but it is likely to be considerably less efficient than if a difference function is provided.) The subtype difference function takes two input values of the subtype, and returns their difference (i.e., X minus Y) represented as a `float8` value. In our example above, the function `float8mi` that underlies the regular `float8` minus operator can be used; but for any other subtype, some type conversion would be necessary. Some creative thought about how to represent differences as numbers might be needed, too. To the greatest extent possible, the `subtype_diff` function should agree with the sort ordering implied by the selected operator class and collation; that is, its result should be positive whenever its first argument is greater than its second according to the sort ordering.

A less-oversimplified example of a `subtype_diff` function is:

```
CREATE FUNCTION time_subtype_diff(x time, y time) RETURNS float8 AS
'SELECT EXTRACT(EPOCH FROM (x - y))' LANGUAGE sql STRICT IMMUTABLE;

CREATE TYPE timerange AS RANGE (
    subtype = time,
    subtype_diff = time_subtype_diff
);

SELECT '[11:10, 23:00]'::timerange;
```

See CREATE TYPE for more information about creating range types.

Indexing

GiST and SP-GiST indexes can be created for table columns of range types. For instance, to create a GiST index:

```
CREATE INDEX reservation_idx ON reservation USING GIST (during);
```

A GiST or SP-GiST index can accelerate queries involving these range operators: `=`, `&&`, `<@`, `@>`, `<<`, `>>`, `-|-`, `&<`, and `&>` (see Range Functions and Operators for more information).

In addition, B-tree and hash indexes can be created for table columns of range types. For these index types, basically the only useful range operation is equality. There is a B-tree sort ordering defined for range values, with corresponding `<` and `>` operators, but the ordering is rather arbitrary and not usually useful in the real world. Range types' B-tree and hash support is primarily meant to allow sorting and hashing internally in queries, rather than creation of actual indexes.

7.3 Summary of Built-in Functions

WarehousePG supports built-in functions and operators including analytic functions and window functions that can be used in window expressions. For information about using built-in WarehousePG functions see, "Using Functions and Operators" in the *WarehousePG Administrator Guide*.

- WarehousePG Function Types
- Built-in Functions and Operators
- JSON Functions and Operators
- Window Functions
- Advanced Aggregate Functions
- Text Search Functions and Operators
- Range Functions and Operators

Parent topic: WarehousePG Reference Guide

WarehousePG Function Types

WarehousePG evaluates functions and operators used in SQL expressions. Some functions and operators are only allowed to run on the coordinator since they could lead to inconsistencies in WarehousePG segment instances. This table describes the WarehousePG Function Types.

Function Type	WarehousePG Support	Description	Comments
IMMUTABLE	Yes	Relies only on information directly in its argument list. Given the same argument values, always returns the same result.	
STABLE	Yes, in most cases	Within a single table scan, returns the same result for same argument values, but results change across SQL statements.	Results depend on database lookups or parameter values. `current_timestamp` family of functions is `STABLE`; values do not change within an execution.
VOLATILE	Restricted	Function values can change within a single table scan. For example: `random()`, `timeofday()`.	Any function with side effects is volatile, even if its result is predictable. For example: `setval()`.

In WarehousePG, data is divided up across segments — each segment is a distinct PostgreSQL database. To prevent inconsistent or unexpected results, do not run functions classified as `VOLATILE` at the segment level if they contain SQL commands or modify the database in any way. For example, functions such as `setval()` are not allowed to run on distributed data in WarehousePG because they can cause inconsistent data between segment instances.

To ensure data consistency, you can safely use `VOLATILE` and `STABLE` functions in statements that are evaluated on and run from the coordinator. For example, the following statements run on the coordinator (statements without a `FROM` clause):

```
SELECT setval('myseq', 201);
SELECT foo();
```

If a statement has a `FROM` clause containing a distributed table *and* the function in the `FROM` clause returns a set of rows, the statement can run on the segments:

```
SELECT * from foo();
```

WarehousePG does not support functions that return a table reference (`rangeFuncs`) or functions that use the `refCursor` datatype.

Built-in Functions and Operators

The following table lists the categories of built-in functions and operators supported by PostgreSQL. All functions and operators are supported in WarehousePG as in PostgreSQL with the exception of `STABLE` and `VOLATILE` functions, which are subject to the restrictions noted in WarehousePG Function Types. See the Functions and Operators section of the PostgreSQL documentation for more information about these built-in functions and operators.

Operator/Function Category	VOLATILE Functions	STABLE Functions	Restrictions
Logical Operators			
Comparison Operators			
Mathematical Functions and Operators	random setseed		
String Functions and Operators	*All built-in conversion functions*	convert pg_client_encoding	
Binary String Functions and Operators			
Bit String Functions and Operators			
Pattern Matching			
Data Type Formatting Functions		to_char to_timestamp	
Date/Time Functions and Operators	timeofday	age current_date current_time current_timestamp localtime localtimestamp now

JSON Functions and Operators

This section describes:

- functions and operators for processing and creating JSON data
- the SQL/JSON path language

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Processing and Creating JSON Data

WarehousePG includes built-in functions and operators that create and manipulate JSON data:

- JSON Operators
- JSON Creation Functions
- JSON Aggregate Functions
- JSON Processing Functions

JSON Operators

This table describes the operators that are available for use with the `json` and `jsonb` data types.

Operator	Right Operand Type	Return Type	Description	Example	Example Result
`->`	`int`	`json` or `jsonb`	Get the JSON array element (indexed from zero, negative integers count from the end).	`'[{"a":"foo"},{"b":"bar"},{"c":"baz"}]'::json->2`	`{"c":"baz"}`
`->`	`text`	`json` or `jsonb`	Get the JSON object field by key.	`'{"a": {"b":"foo"}'::json->'a'`	`{"b":"foo"}`
`->>`	`int`	`text`	Get the JSON array element as `text`.	`'[1,2,3]'::json->>2`	`3`
`->>`	`text`	`text`	Get the JSON object field as `text`.	`'{"a":1,"b":2}'::json->>'b'`	`2`
`#>`	`text[]`	`json` or `jsonb`	Get the JSON object at the specified path.	`'{"a": {"b":{"c": "foo"}}'::json#>'{a,b}'`	`{"c": "foo"}`
`#>>`	`text[]`	`text`	Get the JSON object at the specified path as `text`.	`'{"a":[1,2,3],"b":[4,5,6]}'::json#>>'{a,2}'`	`3`

> **Note** There are parallel variants of these operators for both the `json` and `jsonb` data types. The field/element/path extraction operators return the same data type as their left-hand input (either `json` or `jsonb`), except for those specified as returning `text`, which coerce the value to `text`. The field/element/path extraction operators return `NULL`, rather than failing, if the JSON input does not have the right structure to match the request; for example if no such element exists. The field/element/path extraction operators that accept integer JSON array subscripts all support negative subscripting from the end of arrays.

These standard comparison operators are available for `jsonb`, but not for `json.` They follow the ordering rules for B-tree operations outlined at jsonb Indexing.

Operator	Description
`<`	less than
`>`	greater than
`<=`	less than or equal to
`>=`	greater than or equal to
`=`	equal
`<>` or `!=`	not equal

> **Note** The `!=` operator is converted to `<>` in the parser stage. It is not possible to implement `!=` and `<>` operators that do different things.

Operators that require the `jsonb` data type as the left operand are described in the following table. Many of these operators can be indexed by `jsonb` operator classes. For a full description of `jsonb` containment and existence semantics, refer to jsonb Containment and Existence. jsonb Indexing describes how these operators can be used to effectively index `jsonb` data.

Operator	Right Operand Type	Description	Example			
`@>`	`jsonb`	Does the left JSON value contain the right JSON path/value entries at the top level?	`'{"a":1, "b":2}'::jsonb @> '{"b":2}'::jsonb`			
`<@`	`jsonb`	Are the left JSON path/value enries contained at the top level within the right JSON value?	`'{"b":2}'::jsonb <@ '{"a":1, "b":2}'::jsonb`			
`?`	`text`	Does the *string* exist as a top-level key within the JSON value?	`'{"a":1, "b":2}'::jsonb ? 'b'`			
`?`	`text[]`	Do any of these array *strings* exist as a top-level key?	`'{"a":1, "b":2, "c":3}'::jsonb ?`	array['b', 'c']		
`?&`	`text[]`	Do all of these array *strings* exist as top-level keys?	`'["a", "b"]'::jsonb ?& array['a', 'b']`			
`||`	`jsonb`	Concatenate two `jsonb` values into a new `jsonb` value.	`'["a", "b"]'::jsonb`	`'["c", "d"]'::jsonb`		
`-`	`text`	Delete key/value pair or *string* elements from left operand. Key/value pairs are matched based on their key value.	`'{"a": "b"}'::jsonb - 'a'`			
`-`	`text[]`	Delete multiple key/value pairs or *string* elements from left operand. Key/value pairs are matched based on their key value.	`'{"a": "b", "c": "d"}'::jsonb - '{a,c}'::text[]`			
`-`	`integer`	Delete the array element with specified index (Negative integers count from the end). Throws an error if top level container is not an array.	`'["a", "b"]'::jsonb - 1`			
`#-`	`text[]`	Delete the field or element with specified path (for JSON arrays, negative integers count from the end)	`'["a", {"b":1}]'::jsonb #- '{1,b}'`			
`@?`	`jsonpath`	Does JSON path return any item for the specified JSON value?	`'{"a":[1,2,3,4,5]}'::jsonb @? '$.a[*] ? (@ > 2)'`			
`@@`	`jsonpath`	Returns the result of JSON path predicate check for the specified JSON value. Only the first item of the result is taken into account. If the result is not Boolean, then `null` is returned.	`'{"a":[1,2,3,4,5]}'::jsonb @@ '$.a[*] > 2'`			

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

> **Note** The `||` operator concatenates two JSON objects by generating an object containing the union of their keys, taking the second object's value when there are duplicate keys. All other cases produce a JSON array: first, any non-array input is converted into a single-element array, and then the two arrays are concatenated. It does not operate recursively; only the top-level array or object structure is merged.

> **Note** The `@?` and `@@` operators suppress the following errors: lacking object field or array element, unexpected JSON item type, and numeric errors. This behavior might be helpful while searching over JSON document collections of varying structure.

JSON Creation Functions

This table describes the functions that create `json` and `jsonb` data type values. (There are no equivalent functions for `jsonb` for `row_to_json()` and `array_to_json()`. However, the `to_jsonb()` function supplies much the same functionality as these functions would.)

Function	Description	Example	Example Result
`to_json(anyelement)` `to_jsonb(anyelement)`	Returns the value as a `json` or `jsonb` object. Arrays and composites are converted (recursively) to arrays and objects; otherwise, if the input contains a cast from the type to `json`, the cast function is used to perform the conversion; otherwise, a scalar value is produced. For any scalar type other than a number, a Boolean, or a null value, the text representation will be used, in such a fashion that it is a valid `json` or `jsonb` value.	`to_json('Fred said "Hi."'::text)`	`"Fred said \"Hi.\""`
`array_to_json(anyarray [, pretty_bool])`	Returns the array as a JSON array. A multidimensional array becomes a JSON array of arrays. Line feeds will be added between dimension-1 elements if `pretty_bool` is true.	`array_to_json('{1,5},{99,100}'::int[])`	`[[1,5],[99,100]]`
`row_to_json(record [, pretty_bool])`	Returns the row as a JSON object. Line feeds will be added between level-1 elements if `pretty_bool` is true.	`row_to_json(row(1,'foo'))`	`{"f1":1,"f2":"foo"}`
`json_build_array(VARIADIC "any")`	Builds a possibly-heterogeneously-typed JSON array out of a `VARIADIC` argument list.	`json_build_array(1,2,'3',4,5)`	`[1, 2, "3", 4, 5]`
`json_build_object(VARIADIC "any")`	Builds a JSON object out of a `VARIADIC` argument list. The argument list is taken in order and converted to a set of key/value pairs.	`json_build_object('foo',1,'bar',2)`	`{"foo": 1, "bar": 2}`
`json_object(text[])`	Builds a JSON object out of a text array. The array must have either exactly one dimension with an even number of members, in which case they are taken as alternating key/value pairs, or two dimensions such that each inner array has exactly two elements, which are taken as a key/value pair.	`json_object('{a, 1, b, "def", c, 3.5}')` `json_object('{a, 1},{b, "def"},{c, 3.5}')`	`{"a": "1", "b": "def", "c": "3.5"}`
`json_object(keys text[], values text[])`	Builds a JSON object out of a text array. This form of `json_object` takes keys and values pairwise from two separate arrays. In all other respects it is identical to the one-argument form.	`json_object('{a, b}', '{1,2}')`	`{"a": "1", "b": "2"}`

> **Note** `array_to_json()` and `row_to_json()` have the same behavior as `to_json()` except for offering a pretty-printing option. The behavior described for `to_json()` likewise applies to each individual value converted by the other JSON creation functions.

> **Note** The hstore extension has a cast from `hstore` to `json`, so that `hstore` values converted via the JSON creation functions will be represented as JSON objects, not as primitive string values.

JSON Aggregate Functions

This table shows the functions that aggregate records to an array of JSON objects and pairs of values to a JSON object

Function	Argument Types	Return Type	Description
`json_agg(record)` `jsonb_agg(record)`	`record`	`json`	Aggregates records as a JSON array of objects.
`json_object_agg(name, value)` `jsonb_object_agg(name, value)`	`("any", "any")`	`json`	Aggregates name/value pairs as a JSON object.

JSON Processing Functions

This table shows the functions that are available for processing `json` and `jsonb` values.

Many of these processing functions and operators convert Unicode escapes in JSON strings to the appropriate single character. This is a not an issue if the input data type is `jsonb`, because the conversion was already done. However, for `json` data type input, this might result in an error being thrown as described inAbout JSON Data.

Table 8. JSON Processing Functions

Function	Return Type	Description	Example	Example Result
`json_array_length(json)` `jsonb_array_length(jsonb)`	`int`	Returns the number of elements in the outermost JSON array.	`json_array_length('[1,2,3,{"f1":1,"f2":[5,6]},4]')`	`5`

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Function	Return Type	Description	Example	Example Result

`json_each(json)`
`jsonb_each(jsonb)`
	`setof key text, value json`
	`setof key text, value jsonb`
		Expands the outermost JSON object into a set of key/value pairs.	`select * from json_each('{"a":"foo", "b":"bar"}')`	`key | value`
				`-----+-------`
				`a   | "foo"`
				`b   | "bar"`

`json_each_text(json)`
`jsonb_each_text(jsonb)`
	`setof key text, value text`	Expands the outermost JSON object into a set of key/value pairs. The returned values will be of type `text`.	`select * from json_each_text('{"a":"foo", "b":"bar"}')`	`key | value`
				`-----+-------`
				`a   | foo`
				`b   | bar`

`json_extract_path(from_json json, VARIADIC path_elems text[])` `jsonb_extract_path(from_json jsonb, VARIADIC path_elems text[])`	`json` `jsonb`	Returns the JSON value pointed to by `path_elems` (equivalent to `#>` operator).	`json_extract_path('{"f2": {"f3":1},"f4": {"f5":99,"f6":"foo"}','f4')`	`{"f5":99,"f6":"foo"}`
`json_extract_path_text(from_json json, VARIADIC path_elems text[])` `jsonb_extract_path_text(from_json jsonb, VARIADIC path_elems text[])`	`text`	Returns the JSON value pointed to by `path_elems` as text (equivalent to `#>>` operator).	`json_extract_path_text('{"f2": {"f3":1},"f4": {"f5":99,"f6":"foo"}','f4', 'f6')`	`foo`

`json_object_keys(json)`
`jsonb_object_keys(jsonb)`
	`setof text`	Returns set of keys in the outermost JSON object.	`json_object_keys('{"f1":"abc","f2":{"f3":"a", "f4":"b"}')`	`json_object_keys`
				`------------------`
				`f1`
				`f2`

`json_populate_record(base anyelement, from_json json)`
`jsonb_populate_record(base anyelement, from_json jsonb)`
	`anyelement`	Expands the object in `from_json` to a row whose columns match the record type defined by `base`. See the Note 1.	`select * from json_populate_record(null::myrowtype, '{"a": 1, "b": ["2", "a b"], "c": {"d": 4, "e": "a b c"}')`	`a |   b       |      c`
				`---+-----------+-------------`
				`1 | {2,"a b"} | (4,"a b c")`

`json_populate_recordset(base anyelement, from_json json)`
`jsonb_populate_recordset(base anyelement, from_json jsonb)`
	`setof anyelement`	Expands the outermost array of objects in `from_json` to a set of rows whose columns match the record type defined by `base`. See the Note 1.	`select * from json_populate_recordset(null::myrowtype, '[{"a":1,"b":2}, {"a":3,"b":4}]')`	`a | b`
				`---+---`
				`1 | 2`
				`3 | 4`

`json_array_elements(json)`
`jsonb_array_elements(jsonb)`
	`setof json`
	`setof jsonb`
		Expands a JSON array to a set of JSON values.	`select * from json_array_elements('[1,true, [2,false]]')`	`value`
				`-----------`
				`1`
				`true`
				`[2,false]`

`json_array_elements_text(json)`
`jsonb_array_elements_text(jsonb)`
	`setof text`	Expands a JSON array to a set of `text` values.	`select * from json_array_elements_text('["foo", "bar"]')`	`value`
				`-----------`
				`foo`
				`bar`

`json_typeof(json)` `jsonb_typeof(jsonb)`	`text`	Returns the type of the outermost JSON value as a text string. Possible types are `object`, `array`, `string`, `number`, `boolean`, and `null`.	`json_typeof('-123.4')`	`number`

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Function	Return Type	Description	Example	Example Result

`json_to_record(json)`
`jsonb_to_record(jsonb)`
	`record`	Builds an arbitrary record from a JSON object. See the Note 1.
		As with all functions returning record, the caller must explicitly define the structure of the record with an `AS` clause.
			`select * from json_to_record('{"a":1,"b":[1,2,3],"c":[1,2,3],"e":"bar","r": {"a":123, "b": "a b c"}') as x(a int, b text, c int[], d text, r myrowtype)`	`a | b | c | d | r`
				`---+---------+---------+---+--------------`
				`1 | [1,2,3] | {1,2,3} | | (123,"a b c")`

`json_to_recordset(json)`
`jsonb_to_recordset(jsonb)`
	`setof record`	Builds an arbitrary set of records from a JSON array of objects See the Note 1.
		As with all functions returning record, the caller must explicitly define the structure of the record with an `AS` clause.
			`select * from json_to_recordset('[{"a":1,"b":"foo"},{"a":"2","c":"bar"}]') as x(a int, b text);`	`a | b`
				`---+-----`
				`1 | foo`
				`2 |`

`json_strip_nulls(from_json json)` `jsonb_strip_nulls(from_json jsonb)`	`json` `jsonb`	Returns *from_json* with all object fields that have null values omitted. Other null values are untouched.	`json_strip_nulls('[{"f1":1,"f2":null},2,null,3]')`	`[{"f1":1},2,null,3]`
`jsonb_set(target jsonb, path text[], new_value jsonb [, create_missing boolean])`	`jsonb`	Returns *target* with the section designated by *path* replaced by *new_value*, or with *new_value* added if *create_missing* is true (default is `true`) and the item designated by *path* does not exist. As with the path oriented operators, negative integers that appear in *path* count from the end of JSON arrays.	`jsonb_set('[{"f1":1,"f2":null},2,null,3]', '{0,f1}','[2,3,4]', false)` `jsonb_set('[{"f1":1,"f2":null},2]', '{0,f3}','[2,3,4]')`	`[{"f1":[2,3,4],"f2":null},2,null,3]` `[{"f1": 1, "f2": null, "f3": [2, 3, 4]}, 2]`
`jsonb_insert(target jsonb, path text[], new_value jsonb [, insert_after boolean])`	`jsonb`	Returns *target* with *new_value* inserted. If *target* section designated by *path* is in a JSONB array, *new_value* will be inserted before target or after if *insert_after* is true (default is `false`). If *target* section designated by *path* is in JSONB object, *new_value* will be inserted only if *target* does not exist. As with the path oriented operators, negative integers that appear in *path* count from the end of JSON arrays.	`jsonb_insert('{"a": [0,1,2]}', '{a, 1}', '"new_value"')` `jsonb_insert('{"a": [0,1,2]}', '{a, 1}', '"new_value"', true)`	`{"a": [0, "new_value", 1, 2]}` `{"a": [0, 1, "new_value", 2]}`

`jsonb_pretty(from_json jsonb)`	`text`	Returns *from_json* as indented JSON text.	`jsonb_pretty('[{"f1":1,"f2":null},2,null,3]')`	`[`
				`{`
				`"f1": 1,`
				`"f2": null`
				`},`
				`2,`
				`null,`
				`3`
				`]`

`jsonb_path_exists(target jsonb, path jsonpath [, vars jsonb [, silent bool]])`	`boolean`	Checks whether JSON path returns any item for the specified JSON value.	`jsonb_path_exists('{"a":[1,2,3,4,5]}', '$.a[*] ? (@ >= $min && @ <= $max)', '{"min":2,"max":4}')`	`true`
`jsonb_path_match(target jsonb, path jsonpath [, vars jsonb [, silent bool]])`	`boolean`	Returns the result of JSON path predicate check for the specified JSON value. Only the first item of the result is taken into account. If the result is not Boolean, then `null` is returned.	`jsonb_path_match('{"a":[1,2,3,4,5]}', 'exists($.a[*] ? (@ >= $min && @ <= $max))', '{"min":2,"max":4}')`	`true`

`jsonb_path_query(target jsonb, path jsonpath [, vars jsonb [, silent bool]])`	`setof jsonb`	Gets all JSON items returned by JSON path for the specified JSON value.	`select * from jsonb_path_query('{"a":[1,2,3,4,5]}', '$.a[*] ? (@ >= $min && @ <= $max)', '{"min":2,"max":4}');`	`jsonb_path_query`
				`------------------`
				`2`
				`3`
				`4`

`jsonb_path_query_array(target jsonb, path jsonpath [, vars jsonb [, silent bool]])`	`jsonb`	Gets all JSON items returned by JSON path for the specified JSON value and wraps result into an array.	`jsonb_path_query_array('{"a":[1,2,3,4,5]}', '$.a[*] ? (@ >= $min && @ <= $max)', '{"min":2,"max":4}')`	`[2, 3, 4]`

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Function	Return Type	Description	Example	Example Result
`jsonb_path_query_first(target jsonb, path jsonpath [, vars jsonb [, silent bool]])`	`jsonb`	Gets the first JSON item returned by JSON path for the specified JSON value. Returns `NULL` on no results.	`jsonb_path_query_first('{"a":[1,2,3,4,5]}', '$.a[*] ? (@ >= $min && @ <= $max)', '{"min":2,"max":4}')`	`2`

Notes on JSON processing functions examples

1. The functions `json[b]_populate_record()`, `json[b]_populate_recordset()`, `json[b]_to_record()` and `json[b]_to_recordset()` operate on a JSON object, or array of objects, and extract the values associated with keys whose names match column names of the output row type. Object fields that do not correspond to any output column name are ignored, and output columns that do not match any object field will be filled with nulls. To convert a JSON value to the SQL type of an output column, the following rules are applied in sequence:

    - A JSON null value is converted to a SQL null in all cases.
    - If the output column is of type `json` or `jsonb`, the JSON value is just reproduced exactly.
    - If the output column is a composite (row) type, and the JSON value is a JSON object, the fields of the object are converted to columns of the output row type by recursive application of these rules.
    - Likewise, if the output column is an array type and the JSON value is a JSON array, the elements of the JSON array are converted to elements of the output array by recursive application of these rules.
    - Otherwise, if the JSON value is a string literal, the contents of the string are fed to the input conversion function for the column's data type.
    - Otherwise, the ordinary text representation of the JSON value is fed to the input conversion function for the column's data type.

    While the examples for these functions use constants, the typical use would be to reference a table in the `FROM` clause and use one of its `json` or `jsonb` columns as an argument to the function. Extracted key values can then be referenced in other parts of the query, like `WHERE` clauses and target lists. Extracting multiple values in this way can improve performance over extracting them separately with per-key operators.

2. All the items of the `path` parameter of `jsonb_set()` as well as `jsonb_insert()` except the last item must be present in the target. If `create_missing` is false, all items of the `path` parameter of `jsonb_set()` must be present. If these conditions are not met the target is returned unchanged.

    If the last path item is an object key, it will be created if it is absent and given the new value. If the last path item is an array index, if it is positive the item to set is found by counting from the left, and if negative by counting from the right - `-1` designates the rightmost element, and so on. If the item is out of the range -array_length .. array_length -1, and create_missing is true, the new value is added at the beginning of the array if the item is negative, and at the end of the array if it is positive.

3. The `json_typeof` function's `null` return value should not be confused with a SQL NULL. While calling `json_typeof('null'::json)` will return `null`, calling `json_typeof(NULL::json)` will return a SQL NULL.

4. If the argument to `json_strip_nulls()` contains duplicate field names in any object, the result could be semantically somewhat different, depending on the order in which they occur. This is not an issue for `jsonb_strip_nulls()` since `jsonb` values never have duplicate object field names.

5. The `jsonb_path_exists()`, `jsonb_path_match()`, `jsonb_path_query()`, `jsonb_path_query_array()`, and `jsonb_path_query_first()` functions have optional `vars` and `silent` arguments.

    If the `vars` argument is specified, it provides an object containing named variables to be substituted into a `jsonpath` expression.

    If the `silent` argument is specified and has the `true` value, these functions suppress the same errors as the `@?` and `@@` operators.

The SQL/JSON Path Language

SQL/JSON path expressions specify the items to be retrieved from the JSON data, similar to XPath expressions used for SQL access to XML. In WarehousePG, path expressions are implemented as the `jsonpath` data type and can use any elements described in jsonpath Type.

JSON query functions and operators pass the provided path expression to the *path engine* for evaluation. If the expression matches the queried JSON data, the corresponding SQL/JSON item is returned. Path expressions are written in the SQL/JSON path language and can also include arithmetic expressions and functions. Query functions treat the provided expression as a text string, so it must be enclosed in single quotes.

A path expression consists of a sequence of elements allowed by the `jsonpath` data type. The path expression is evaluated from left to right, but you can use parentheses to change the order of operations. If the evaluation is successful, a sequence of SQL/JSON items (*SQL/JSON sequence*) is produced, and the evaluation result is returned to the JSON query function that completes the specified computation.

To refer to the JSON data to be queried (the *context item*), use the `$` sign in the path expression. It can be followed by one or more accessor operators, which go down the JSON structure level by level to retrieve the content of context item. Each operator that follows deals with the result of the previous evaluation step.

For example, suppose you have some JSON data from a GPS tracker that you would like to parse, such as:

```
{
  "track": {
    "segments": [
      {
        "location"[ 47.763, 13.4034 ],
        "start time": "2018-10-14 10:05:14",
        "HR": 73
      },
      {
        "location"[ 47.706, 13.2635 ],
        "start time": "2018-10-14 10:39:21",
        "HR": 135
      }
    ]
  }
}
```

To retrieve the available track segments, you need to use the `.<key>` accessor operator for all the preceding JSON objects:

```
'$.track.segments'
```

If the item to retrieve is an element of an array, you have to unnest this array using the `[*]` operator. For example, the following path will return location coordinates for all the available track segments:

```
'$.track.segments[*].location'
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

To return the coordinates of the first segment only, you can specify the corresponding subscript in the `[]` accessor operator. Note that the SQL/JSON arrays are 0-relative:

```
'$.track.segments[0].location'
```

The result of each path evaluation step can be processed by one or more `jsonpath` operators and methods listed in SQL/JSON Path Operators and Methods below. Each method name must be preceded by a dot. For example, you can get an array size:

```
'$.track.segments.size()'
```

For more examples of using `jsonpath` operators and methods within path expressions, see SQL/JSON Path Operators and Methods below.

When defining the path, you can also use one or more *filter expressions* that work similar to the `WHERE` clause in SQL. A filter expression begins with a question mark and provides a condition in parentheses:

```
? (condition)
```

Filter expressions must be specified right after the path evaluation step to which they are applied. The result of this step is filtered to include only those items that satisfy the provided condition. SQL/JSON defines three-valued logic, so the condition can be `true`, `false`, or `unknown`. The `unknown` value plays the same role as SQL `NULL` and can be tested for with the is `unknown` predicate. Further path evaluation steps use only those items for which filter expressions return `true`.

Functions and operators that can be used in filter expressions are listed in jsonpath Filter Expression Elements. The path evaluation result to be filtered is denoted by the `@` variable. To refer to a JSON element stored at a lower nesting level, add one or more accessor operators after `@`.

Suppose you would like to retrieve all heart rate values higher than 130. You can achieve this using the following expression:

```
'$.track.segments[*].HR ? (@ > 130)'
```

To get the start time of segments with such values instead, you have to filter out irrelevant segments before returning the start time, so the filter expression is applied to the previous step, and the path used in the condition is different:

```
'$.track.segments[*] ? (@.HR > 130)."start time"'
```

You can use several filter expressions on the same nesting level, if required. For example, the following expression selects all segments that contain locations with relevant coordinates and high heart rate values:

```
'$.track.segments[*] ? (@.location[1] < 13.4) ? (@.HR > 130)."start time"'
```

Using filter expressions at different nesting levels is also allowed. The following example first filters all segments by location, and then returns high heart rate values for these segments, if available:

```
'$.track.segments[*] ? (@.location[1] < 13.4).HR ? (@ > 130)'
```

You can also nest filter expressions within each other:

```
'$.track ? (exists(@.segments[*] ? (@.HR > 130))).segments.size()'
```

This expression returns the size of the track if it contains any segments with high heart rate values, or an empty sequence otherwise.

Deviations from Standard

WarehousePG's implementation of SQL/JSON path language has the following deviations from the SQL/JSON standard:

- `.datetime()` item method is not implemented yet mainly because immutable `jsonpath` functions and operators cannot reference session timezone, which is used in some datetime operations. Datetime support will be added to `jsonpath` in future versions of WarehousePG.
- A path expression can be a Boolean predicate, although the SQL/JSON standard allows predicates only in filters. This is necessary for implementation of the `@@` operator. For example, the following `jsonpath` expression is valid in WarehousePG:

  ```
  '$.track.segments[*].HR < 70'
  ```

- There are minor differences in the interpretation of regular expression patterns used in `like_regex` filters as described in Regular Expressions.

Strict And Lax Modes

When you query JSON data, the path expression may not match the actual JSON data structure. An attempt to access a non-existent member of an object or element of an array results in a structural error. SQL/JSON path expressions have two modes of handling structural errors:

- lax (default) — the path engine implicitly adapts the queried data to the specified path. Any remaining structural errors are suppressed and converted to empty SQL/JSON sequences.
- strict — if a structural error occurs, an error is raised.

The lax mode facilitates matching of a JSON document structure and path expression if the JSON data does not conform to the expected schema. If an operand does not match the requirements of a particular operation, it can be automatically wrapped as an SQL/JSON array or unwrapped by converting its elements into an SQL/JSON sequence before performing this operation. Besides, comparison operators automatically unwrap their operands in the lax mode, so you can compare SQL/JSON arrays out-of-the-box. An array of size 1 is considered equal to its sole element. Automatic unwrapping is not performed only when:

- The path expression contains `type()` or `size()` methods that return the type and the number of elements in the array, respectively.
- The queried JSON data contain nested arrays. In this case, only the outermost array is unwrapped, while all the inner arrays remain unchanged. Thus, implicit unwrapping can only go one level down within each path evaluation step.

For example, when querying the GPS data listed above, you can abstract from the fact that it stores an array of segments when using the lax mode:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
'lax $.track.segments.location'
```

In the strict mode, the specified path must exactly match the structure of the queried JSON document to return an SQL/JSON item, so using this path expression will cause an error. To get the same result as in the lax mode, you have to explicitly unwrap the segments array:

```
'strict $.track.segments[*].location'
```

The `.**` accessor can lead to surprising results when using the lax mode. For instance, the following query selects every HR value twice:

```
lax $.**.HR
```

This happens because the `.**` accessor selects both the segments array and each of its elements, while the `.HR` accessor automatically unwraps arrays when using the lax mode. To avoid surprising results, we recommend using the `.**` accessor only in the strict mode. The following query selects each HR value just once:

```
strict $.**.HR
```

Regular Expressions

SQL/JSON path expressions allow matching text to a regular expression with the `like_regex` filter. For example, the following SQL/JSON path query would case-insensitively match all strings in an array that starts with an English vowel:

```
'$[*] ? (@ like_regex "^[aeiou]" flag "i")'
```

The optional flag string may include one or more of the characters `i` for case-insensitive match, `m` to allow `^` and `$` to match at newlines, `s` to allow `.` to match a newline, and `q` to quote the whole pattern (reducing the behavior to a simple substring match).

The SQL/JSON standard borrows its definition for regular expressions from the `LIKE_REGEX` operator, which in turn uses the XQuery standard. WarehousePG does not currently support the `LIKE_REGEX` operator. Therefore, the `like_regex` filter is implemented using the POSIX regular expression engine as described in POSIX Regular Expressions. This leads to various minor discrepancies from standard SQL/JSON behavior which are catalogued in Differences From XQuery (LIKE_REGEX). Note, however, that the flag-letter incompatibilities described there do not apply to SQL/JSON, as it translates the XQuery flag letters to match what the POSIX engine expects.

Keep in mind that the pattern argument of `like_regex` is a JSON path string literal, written according to the rules given in jsonpath Type. This means in particular that any backslashes you want to use in the regular expression must be doubled. For example, to match string values of the root document that contain only digits:

```
$.* ? (@ like_regex "^\\d+$")
```

SQL/JSON Path Operators and Methods

The following table describes the operators and methods available in `jsonpath`:

Operator/Method	Description	Example JSON	Example Query	Result
`+` (unary)	Plus operator that iterates over the SQL/JSON sequence	`{"x": [2.85, -14.7, -9.4]}`	`+ $.x.floor()`	`2, -15, -10`
`-` (unary)	Minus operator that iterates over the SQL/JSON sequence	`{"x": [2.85, -14.7, -9.4]}`	`- $.x.floor()`	`-2, 15, 10`
`+` (binary)	Addition	`[2]`	`2 + $[0]`	`4`
`-` (binary)	Subtraction	`[2]`	`4 - $[0]`	`2`
`*`	Multiplication	`[4]`	`2 * $[0]`	`8`
`/`	Division	`[8]`	`$[0] / 2`	`4`
`%`	Modulus	`[32]`	`$[0] % 10`	`2`
`type()`	Type of the SQL/JSON item	`[1, "2", {}]`	`$[*].type()`	`"number", "string", "object"`
`size()`	Size of the SQL/JSON item	`{"m": [11, 15]}`	`$.m.size()`	`2`
`double()`	Approximate floating-point number converted from an SQL/JSON number or a string	`{"len": "1.9"}`	`$.len.double() * 2`	`3.8`
`ceiling()`	Nearest integer greater than or equal to the SQL/JSON number	`{"h": 1.3}`	`$.h.ceiling()`	`2`
`floor()`	Nearest integer less than or equal to the SQL/JSON number	`{"h": 1.3}`	`$.h.floor()`	`1`
`abs()`	Absolute value of the SQL/JSON number	`{"z": -0.3}`	`$.z.abs()`	`0.3`
`keyvalue()`	Sequence of object's key-value pairs represented as array of items containing three fields (`"key"`, `"value"`, and `"id"`). `"id"` is a unique identifier of the object key-value pair belongs to.	`{"x": "20", "y": 32}`	`$.keyvalue()`	`{"key": "x", "value": "20", "id": 0}, {"key": "y", "value": 32, "id": 0}`

SQL/JSON Filter Expression Elements

The following table describes the available filter expressions elements for `jsonpath`:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Value/Predicate	Description	Example JSON	Example Query	Result
`==`	Equality operator	`[1, 2, 1, 3]`	`$[*] ? (@ == 1)`	`1, 1`
`!=`	Non-equality operator	`[1, 2, 1, 3]`	`$[*] ? (@ != 1)`	`2, 3`
`<>`	Non-equality operator (same as `!=`)	`[1, 2, 1, 3]`	`$[*] ? (@ <> 1)`	`2, 3`
`<`	Less-than operator	`[1, 2, 3]`	`$[*] ? (@ < 2)`	`1`
`<=`	Less-than-or-equal-to operator	`[1, 2, 3]`	`$[*] ? (@ <= 2)`	`1, 2`
`>`	Greater-than operator	`[1, 2, 3]`	`$[*] ? (@ > 2)`	`3`
`>=`	Greater-than-or-equal-to operator	`[1, 2, 3]`	`$[*] ? (@ >= 2)`	`2, 3`
`true`	Value used to perform comparison with JSON `true` literal	`[{"name": "John", "parent": false}, {"name": "Chris", "parent": true}]`	`$[*] ? (@.parent == true)`	`{"name": "Chris", "parent": true}`
`false`	Value used to perform comparison with JSON `false` literal	`[{"name": "John", "parent": false}, {"name": "Chris", "parent": true}]`	`$[*] ? (@.parent == false)`	`{"name": "John", "parent": false}`
`null`	Value used to perform comparison with JSON `null` value	`[{"name": "Mary", "job": null}, {"name": "Michael", "job": "driver"}]`	`$[*] ? (@.job == null) .name`	`"Mary"`
`&&`	Boolean AND	`[1, 3, 7]`	`$[*] ? (@ > 1 && @ < 5)`	`3`
`||`	Boolean OR	`[1, 3, 7]`	`$[*] ? (@ < 1 || @ > 5)`	`7`
`!`	Boolean NOT	`[1, 3, 7]`	`$[*] ? (!(@ < 5))`	`7`
`like_regex`	Tests whether the first operand matches the regular expression given by the second operand, optionally with modifications described by a string of `flag` characters.	`["abc", "abd", "aBdC", "abdacb", "babc"]`	`$[*] ? (@ like_regex "^ab.*c" flag "i")`	`"abc", "aBdC", "abdacb"`
`starts with`	Tests whether the second operand is an initial substring of the first operand	`["John Smith", "Mary Stone", "Bob Johnson"]`	`$[*] ? (@ starts with "John")`	`"John Smith"`
`exists`	Tests whether a path expression matches at least one SQL/JSON item	`{"x": [1, 2], "y": [2, 4]}`	`strict $.* ? (exists (@ ? (@[*] > 2)))`	`2, 4`
`is unknown`	Tests whether a Boolean condition is `unknown`	`[-1, 2, 7, "infinity"]`	`$[*] ? ((@ > 0) is unknown)`	`"infinity"`

Window Functions

The following are WarehousePG built-in window functions. All window functions are *immutable*. For more information about window functions, see "Window Expressions" in the *WarehousePG Administrator Guide*.

Function	Return Type	Full Syntax	Description	
`cume_dist()`	`double precision`	`CUME_DIST() OVER ( [PARTITION BY` expr `] ORDER BY` expr `)`	Calculates the cumulative distribution of a value in a group of values. Rows with equal values always evaluate to the same cumulative distribution value.	
`dense_rank()`	`bigint`	`DENSE_RANK () OVER ( [PARTITION BY` expr `] ORDER BY` expr `)`	Computes the rank of a row in an ordered group of rows without skipping rank values. Rows with equal values are given the same rank value.	
`first_value(*expr*)`	same as input expr type	`FIRST_VALUE(` expr `) OVER ( [PARTITION BY` expr `] ORDER BY` expr `[ROWS`	RANGE `frame\_expr ])`	Returns the first value in an ordered set of values.
`lag(*expr* [,*offset*] [,*default* ])`	same as input *expr* type	`LAG(` *expr* `[,` *offset* `] [,` *default* `]) OVER ( [PARTITION BY` *expr* `] ORDER BY` *expr* `)`	Provides access to more than one row of the same table without doing a self join. Given a series of rows returned from a query and a position of the cursor, `LAG` provides access to a row at a given physical offset prior to that position. The default `offset` is 1. *default* sets the value that is returned if the offset goes beyond the scope of the window. If *default* is not specified, the default value is null.	
`last_value(*expr*)`	same as input *expr* type	`LAST_VALUE(`*expr*`) OVER ( [PARTITION BY` *expr*`] ORDER BY` *expr* `[ROWS`	RANGE *frame_expr*`])`	Returns the last value in an ordered set of values.
`lead(*expr* [,*offset*] [,*default* ])`	same as input *expr* type	`LEAD(*expr*[,*offset*] [,*expr***default*]) OVER ( [PARTITION BY *expr*] ORDER BY *expr* )`	Provides access to more than one row of the same table without doing a self join. Given a series of rows returned from a query and a position of the cursor, `lead` provides access to a row at a given physical offset after that position. If *offset* is not specified, the default offset is 1. *default* sets the value that is returned if the offset goes beyond the scope of the window. If *default* is not specified, the default value is null.	
`ntile(*expr*)`	`bigint`	`NTILE(*expr*) OVER ( [PARTITION BY *expr*] ORDER BY *expr* )`	Divides an ordered data set into a number of buckets (as defined by *expr*) and assigns a bucket number to each row.	
`percent_rank()`	`double precision`	`PERCENT_RANK () OVER ( [PARTITION BY *expr*] ORDER BY *expr*)`	Calculates the rank of a hypothetical row `R` minus 1, divided by 1 less than the number of rows being evaluated (within a window partition).	
`rank()`	`bigint`	`RANK () OVER ( [PARTITION BY *expr*] ORDER BY *expr*)`	Calculates the rank of a row in an ordered group of values. Rows with equal values for the ranking criteria receive the same rank. The number of tied rows are added to the rank number to calculate the next rank value. Ranks may not be consecutive numbers in this case.	
`row_number()`	`bigint`	`ROW_NUMBER () OVER ( [PARTITION BY *expr*] ORDER BY *expr*)`	Assigns a unique number to each row to which it is applied (either each row in a window partition or each row of the query).

Advanced Aggregate Functions

The following built-in advanced analytic functions are WarehousePG extensions of the PostgreSQL database. Analytic functions are *immutable*.

Note The WarehousePG MADlib Extension for Analytics provides additional advanced functions to perform statistical analysis and machine learning with WarehousePG data. See MADlib Extension for Analytics.

Table 10. Advanced Aggregate Functions

Function	Return Type	Full Syntax	Description

`gp_array_agg (anyarray)`	same as the argument data type	`gp_array_agg (anyarray)`
		Example:
		`CREATE TABLE intarr_tbl (a int, arr int[]);`
		`INSERT INTO intarr_tbl SELECT i, array[i, i] FROM generate_series(1, 5)i;`
		`INSERT INTO intarr_tbl SELECT 6, '{6, NULL}'::int[];`
		`INSERT INTO intarr_tbl SELECT 8, '{NULL, 7}'::int[];`
		`SELECT gp_array_agg(arr ORDER BY arr) FROM intarr_tbl;`
			A parallel version of `array_agg(anyarray)`. Concatenates input arrays to create an array of one higher dimension. The inputs must all have the same dimensions, and they cannot be empty or null.

`gp_array_agg (anynonarray)`	array of the argument type	`gp_array_agg (anynonarray)`
		Example:
		`CREATE TABLE table1(a int4, b int4);`
		`INSERT INTO table1 VALUES (4,5), (2,1), (1,3), (3,null), (3,7);`
		`SELECT gp_array_agg(a ORDER BY b NULLS FIRST) FROM table1;`
			An parallel version of `array_agg(anynonarray)`. Creates an array by concatenating input values, including nulls.

`MEDIAN (expr)`	`timestamp, timestamptz, interval, float`	`MEDIAN (expression)`
		Example:
		`SELECT department_id, MEDIAN(salary)`
		`FROM employees`
		`GROUP BY department_id;`
			Can take a two-dimensional array as input. Treats such arrays as matrices.

`PERCENTILE_CONT (expr) WITHIN GROUP (ORDER BY expr [DESC/ASC])`	`timestamp, timestamptz, interval, float`	`PERCENTILE_CONT(percentage) WITHIN GROUP (ORDER BY expression)`
		Example:
		`SELECT department_id,`
		`PERCENTILE_CONT (0.5) WITHIN GROUP (ORDER BY salary DESC)`
		`"Median_cont";`
		`FROM employees GROUP BY department_id;`
			Performs an inverse distribution function that assumes a continuous distribution model. It takes a percentile value and a sort specification and returns the same datatype as the numeric datatype of the argument. This returned value is a computed result after performing linear interpolation. Null are ignored in this calculation.

`PERCENTILE_DISC (expr) WITHIN GROUP (ORDER BY expr [DESC/ASC])`	`timestamp, timestamptz, interval, float`	`PERCENTILE_DISC(percentage) WITHIN GROUP (ORDER BY expression)`
		Example:
		`SELECT department_id,`
		`PERCENTILE_DISC (0.5) WITHIN GROUP (ORDER BY salary DESC)`
		`"Median_desc";`
		`FROM employees GROUP BY department_id;`
			Performs an inverse distribution function that assumes a discrete distribution model. It takes a percentile value and a sort specification. This returned value is an element from the set. Null are ignored in this calculation.

`sum(array[])`	`smallint[]int[], bigint[], float[]`	`sum(array[[1,2],[3,4]])`
		Example:
		`CREATE TABLE mymatrix (myvalue int[]);`
		`INSERT INTO mymatrix VALUES (array[[1,2],[3,4]]);`
		`INSERT INTO mymatrix VALUES (array[[0,1],[1,0]]);`
		`SELECT sum(myvalue) FROM mymatrix;`
		` sum`
		`---------------`
		` {1,3},{4,4}`
			Performs matrix summation. Can take as input a two-dimensional array that is treated as a matrix.

`pivot_sum (label[], label, expr)`	`int[], bigint[], float[]`	`pivot_sum( array['A1','A2'], attr, value)`	A pivot aggregation using sum to resolve duplicate entries.
`unnest (array[])`	set of `anyelement`	`unnest( array['one', 'row', 'per', 'item'])`	Transforms a one dimensional array into rows. Returns a set of `anyelement`, a polymorphic pseudotype in PostgreSQL.

Text Search Functions and Operators

The following tables summarize the functions and operators that are provided for full text searching. See Using Full Text Search for a detailed explanation of WarehousePG's text search facility.

Operator	Description	Example	Result

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Operator	Description	Example	Result
`@@`	`tsvector` matches `tsquery` ?	`to_tsvector('fat cats ate rats') @@ to_tsquery('cat & rat')`	`t`
`@@@`	deprecated synonym for `@@`	`to_tsvector('fat cats ate rats') @@@ to_tsquery('cat & rat')`	`t`
`		`	concatenate `tsvector` s	`'a':1 b:2'::tsvector	'c:1 d:2 b:3'::tsvector`	`'a':1 'b':2,5 'c':3 'd':4`
`&&`	AND `tsquery` s together	`'fat	rat'::tsquery && 'cat'::tsquery`	`('fat'	'rat') & 'cat'`
`		`	OR `tsquery` s together	`'fat	rat'::tsquery	'cat'::tsquery`	`('fat' | 'rat')	'cat'`
`!!`	negate a `tsquery`	`!! 'cat'::tsquery`	`!'cat'`
`@>`	`tsquery` contains another ?	`'cat'::tsquery @> 'cat & rat'::tsquery`	`f`
`<@`	`tsquery` is contained in ?	`'cat'::tsquery <@ 'cat & rat'::tsquery`	`t`

Note The `tsquery` containment operators consider only the lexemes listed in the two queries, ignoring the combining operators.

In addition to the operators shown in the table, the ordinary B-tree comparison operators (=, <, etc) are defined for types `tsvector` and `tsquery`. These are not very useful for text searching but allow, for example, unique indexes to be built on columns of these types.

Function	Return Type	Description	Example	Result
`get_current_ts_config()`	regconfig	get default text search configuration	get_current_ts_config()	english
`length(tsvector)`	integer	number of lexemes in tsvector	length('fat:2,4 cat:3 rat:5A'::tsvector)	3
`numnode(tsquery)`	integer	number of lexemes plus operators in tsquery	numnode('(fat & rat) | cat'::tsquery)	5
`plainto_tsquery([ config regconfig , ] querytext)`	tsquery	produce tsquery ignoring punctuation	plainto_tsquery('english', 'The Fat Rats')	'fat' & 'rat'
`querytree(query tsquery)`	text	get indexable part of a tsquery	querytree('foo & ! bar'::tsquery)	'foo'
`setweight(tsvector, "char")`	tsvector	assign weight to each element of tsvector	setweight('fat:2,4 cat:3 rat:5B'::tsvector, 'A')	'cat':3A 'fat':2A,4A 'rat':5A
`strip(tsvector)`	tsvector	remove positions and weights from tsvector	strip('fat:2,4 cat:3 rat:5A'::tsvector)	'cat' 'fat' 'rat'
`to_tsquery([ config regconfig , ] query text)`	tsquery	normalize words and convert to tsquery	to_tsquery('english', 'The & Fat & Rats')	'fat' & 'rat'
`to_tsvector([ config regconfig , ] documenttext)`	tsvector	reduce document text to tsvector	to_tsvector('english', 'The Fat Rats')	'fat':2 'rat':3
`ts_headline([ config regconfig, ] documenttext, query tsquery [, options text ])`	text	display a query match	ts_headline('x y z', 'z'::tsquery)	x y z
`ts_rank([ weights float4[], ] vector tsvector,query tsquery [, normalization integer ])`	float4	rank document for query	ts_rank(textsearch, query)	0.818
`ts_rank_cd([ weights float4[], ] vectortsvector, query tsquery [, normalizationinteger ])`	float4	rank document for query using cover density	ts_rank_cd('{0.1, 0.2, 0.4, 1.0}', textsearch, query)	2.01317
`ts_rewrite(query tsquery, target tsquery,substitute tsquery)`	tsquery	replace target with substitute within query	ts_rewrite('a & b'::tsquery, 'a'::tsquery, 'foo|bar'::tsquery)	'b' & ('foo' | 'bar')
`ts_rewrite(query tsquery, select text)`	tsquery	replace using targets and substitutes from a SELECTcommand	SELECT ts_rewrite('a & b'::tsquery, 'SELECT t,s FROM aliases')	'b' & ('foo' | 'bar')
`tsvector_update_trigger()`	trigger	trigger function for automatic tsvector column update	CREATE TRIGGER ... tsvector_update_trigger(tsvcol, 'pg_catalog.swedish', title, body)	
`tsvector_update_trigger_column()`	trigger	trigger function for automatic tsvector column update	CREATE TRIGGER ... tsvector_update_trigger_column(tsvcol, configcol, title, body)	

Note All the text search functions that accept an optional `regconfig` argument will use the configuration specified by default_text_search_config when that argument is omitted.

The functions in the following table are listed separately because they are not usually used in everyday text searching operations. They are helpful for development and debugging of new text search configurations.

Function	Return Type	Description	Example	Result
`ts_debug([ *config* regconfig, ] *document* text, OUT *alias* text, OUT *description* text, OUT *token* text, OUT *dictionaries* regdictionary[], OUT *dictionary* regdictionary, OUT *lexemes* text[])`	`setof record`	test a configuration	`ts_debug('english', 'The Brightest supernovaes')`	`(asciiword,"Word, all ASCII",The, {english_stem},english_stem, {}) ...`
`ts_lexize(*dict* regdictionary, *token* text)`	`text[]`	test a dictionary	`ts_lexize('english_stem', 'stars')`	`{star}`
`ts_parse(*parser\_name* text, *document* text, OUT *tokid* integer, OUT *token* text)`	`setof record`	test a parser	`ts_parse('default', 'foo - bar')`	`(1,foo) ...`
`ts_parse(*parser\_oid* oid, *document* text, OUT *tokid* integer, OUT *token* text)`	`setof record`	test a parser	`ts_parse(3722, 'foo - bar')`	`(1,foo) ...`

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Function	Return Type	Description	Example	Result
`ts_token_type(*parser\_name* text, OUT *tokid* integer, OUT *alias* text, OUT description text)`	`setof record`	get token types defined by parser	`ts_token_type('default')`	`(1,asciiword,"Word, all ASCII") ...`
`ts_token_type(*parser\_oid* oid, OUT *tokid* integer, OUT *alias* text, OUT *description* text)`	`setof record`	get token types defined by parser	`ts_token_type(3722)`	`(1,asciiword,"Word, all ASCII") ...`
`ts_stat(*sqlquery* text, [ *weights* text, ] OUT *word* text, OUT *ndocinteger*, OUT *nentry* integer)`	`setof record`	get statistics of a tsvectorcolumn	`ts_stat('SELECT vector from apod')`	`(foo,10,15) ...`

Range Functions and Operators

See Range Types for an overview of range types.

The following table shows the operators available for range types.

Operator	Description	Example	Result
`=`	equal	`int4range(1,5) = '[1,4]'::int4range`	`t`
`<>`	not equal	`numrange(1.1,2.2) <> numrange(1.1,2.3)`	`t`
`<`	less than	`int4range(1,10) < int4range(2,3)`	`t`
`>`	greater than	`int4range(1,10) > int4range(1,5)`	`t`
`<=`	less than or equal	`numrange(1.1,2.2) <= numrange(1.1,2.2)`	`t`
`>=`	greater than or equal	`numrange(1.1,2.2) >= numrange(1.1,2.0)`	`t`
`@>`	contains range	`int4range(2,4) @> int4range(2,3)`	`t`
`@>`	contains element	`'[2011-01-01,2011-03-01)'::tsrange @> '2011-01-10'::timestamp`	`t`
`<@`	range is contained by	`int4range(2,4) <@ int4range(1,7)`	`t`
`<@`	element is contained by	`42 <@ int4range(1,7)`	`f`
`&&`	overlap (have points in common)	`int8range(3,7) && int8range(4,12)`	`t`
`<<`	strictly left of	`int8range(1,10) << int8range(100,110)`	`t`
`>>`	strictly right of	`int8range(50,60) >> int8range(20,30)`	`t`
`&<`	does not extend to the right of	`int8range(1,20) &< int8range(18,20)`	`t`
`&>`	does not extend to the left of	`int8range(7,20) &> int8range(5,10)`	`t`
`-`	-`	is adjacent to	`numrange(1.1,2.2) - - numrange(2.2,3.3)`	`t`
`+`	union	`numrange(5,15) + numrange(10,20)`	`[5,20)`
`*`	intersection	`int8range(5,15) * int8range(10,20)`	`[10,15)`
`-`	difference	`int8range(5,15) - int8range(10,20)`	`[5,10)`

The simple comparison operators `<`, `>`, `<=`, and `>=` compare the lower bounds first, and only if those are equal, compare the upper bounds. These comparisons are not usually very useful for ranges, but are provided to allow B-tree indexes to be constructed on ranges.

The left-of/right-of/adjacent operators always return false when an empty range is involved; that is, an empty range is not considered to be either before or after any other range.

The union and difference operators will fail if the resulting range would need to contain two disjoint sub-ranges, as such a range cannot be represented.

The following table shows the functions available for use with range types.

Function	Return Type	Description	Example	Result
`lower(anyrange)`	range's element type	lower bound of range	`lower(numrange(1.1,2.2))`	`1.1`
`upper(anyrange)`	range's element type	upper bound of range	`upper(numrange(1.1,2.2))`	`2.2`
`isempty(anyrange)`	`boolean`	is the range empty?	`isempty(numrange(1.1,2.2))`	`false`
`lower_inc(anyrange)`	`boolean`	is the lower bound inclusive?	`lower_inc(numrange(1.1,2.2))`	`true`
`upper_inc(anyrange)`	`boolean`	is the upper bound inclusive?	`upper_inc(numrange(1.1,2.2))`	`false`
`lower_inf(anyrange)`	`boolean`	is the lower bound infinite?	`lower_inf('(,)'::daterange)`	`true`
`upper_inf(anyrange)`	`boolean`	is the upper bound infinite?	`upper_inf('(,)'::daterange)`	`true`
`range_merge(anyrange, anyrange)`	`anyrange`	the smallest range which includes both of the given ranges	`range_merge('[1,2)'::int4range, '[3,4)'::int4range)`	`[1,4)`

The `lower` and `upper` functions return null if the range is empty or the requested bound is infinite. The `lower_inc`, `upper_inc`, `lower_inf`, and `upper_inf` functions all return false for an empty range.

7.4 Additional Supplied Modules

WarehousePG (WHPG) extends the core capabilities of Postgres with a suite of additional modules designed for enterprise-scale data warehousing. These modules provide specialized functionality for performance, security, and integration, and are categorized into three primary types:

- **Postgres Sourced Modules**: These are standard "contrib" modules that are part of the official PostgreSQL distribution. WarehousePG includes these to ensure developers can use familiar, high-quality Postgres tools for data manipulation and query analysis.
- **WHPG Open Source Modules**: These are open-source extensions specifically developed or optimized for the WarehousePG MPP ecosystem.
- **EDB Provided Modules**: These are specialized enhancements provided by EDB to deliver enterprise-grade security, governance, and support for business-critical environments.

The following WarehousePG and PostgreSQL `contrib` modules are installed; refer to the linked module documentation for usage instructions.

- auto_explain Provides a means for logging execution plans of slow statements automatically.
- btree_gin - Provides sample generalized inverted index (GIN) operator classes that implement B-tree equivalent behavior for certain data types.
- citext - Provides a case-insensitive, multibyte-aware text data type.
- dblink - Provides connections to other WarehousePGs.
- diskquota - Allows administrators to set disk usage quotas for WarehousePG roles and schemas.
- fuzzystrmatch - Determines similarities and differences between strings.
- gp_exttable_fdw - Built-in foreign-data wrapper that internally converts an external table to a foreign table.
- gp_legacy_string_agg - Implements a legacy, single-argument `string_agg()` aggregate function that was present in WarehousePG 5.
- gp_sparse_vector - Implements a WarehousePG data type that uses compressed storage of zeros to make vector computations on floating point numbers faster.
- hstore - Provides a data type for storing sets of key/value pairs within a single PostgreSQL value.
- ip4r - Provides data types for operations on IPv4 and IPv6 IP addresses.
- ltree - Provides data types for representing labels of data stored in a hierarchical tree-like structure.
- orafce - Provides WarehousePG-specific Oracle SQL compatibility functions.
- pageinspect - Provides functions for low level inspection of the contents of database pages; available to superusers only.
- pg_buffercache - Provides access to five views for obtaining cluster-wide shared buffer metrics.
- pg_cron - Provides a cron-based job scheduler that runs inside the database.
- pg_stat_statements - Provides a means for tracking execution statistics of all SQL statements executed by WarehousePG.
- pg_trgm - Provides functions and operators for determining the similarity of alphanumeric text based on trigram matching. The module also provides index operator classes that support fast searching for similar strings.
- pgcrypto - Provides cryptographic functions for WarehousePG.
- postgresml - Provides functions for using tens of thousands of pre-trained open source AI/machine learning models in WarehousePG.
- postgres_fdw - Provides a foreign data wrapper (FDW) for accessing data stored in an external PostgreSQL or WarehousePG.
- postgresql-hll - Provides HyperLogLog data types for PostgreSQL and WarehousePG.
- sslinfo - Provides information about the SSL certificate that the current client provided when connecting to WarehousePG.
- tablefunc - Provides various functions that return tables (multiple rows).
- timestamp9 - Provides an efficient nanosecond-precision timestamp data type for WarehousePG.
- tsm_system_rows - Implements the `SYSTEM_ROWS` table sampling method.
- tsm_system_time - implements the `SYSTEM_TIME` table sampling method.
- uuid-ossp - Provides functions to generate universally unique identifiers (UUIDs).

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.4.1 EDB provided modules

EDB-provided modules deliver a suite of enterprise-grade extensions specifically engineered to enhance the security, performance, and manageability of your WarehousePG cluster. Backed by 24x7 expert support, these modules ensure your environment meets the rigorous demands of business-critical, petabyte-scale data warehousing.

EDB provides the following modules:

- PGAA - Enables distributed analytical queries against object storage directly from WarehousePG, with support for Parquet, Delta Lake, and Iceberg formats.
- pgAudit - Provides detailed session and object audit logging for WarehousePG.
- PGFS - Provides the storage layer for object storage connectivity, including credential management for S3, GCS, and Azure. Required dependency of PGAA.
- pgvector - Provides vector similarity search capabilities for WarehousePG that enable searching, storing, and querying machine language-generated embeddings at large scale.
- user_profile - Provides password quality checking and policy definition for WarehousePG.
- whpg-anonymizer - Provides dynamic data masking and static data anonymization for WarehousePG.
- whpg_fdw - Provides a foreign data wrapper (FDW) for accessing data stored in a remote WarehousePG cluster.

Downloading and installing an extension

You must install the extension on each host in your WarehousePG cluster.

1. From the coordinator, download the package from the EDB repository:

```
```bash
export EDB_SUBSCRIPTION_TOKEN=<your-token>
export EDB_REPO=gpsupp
curl -1sSLf "https://downloads.enterprisedb.com/$EDB_SUBSCRIPTION_TOKEN/$EDB_REPO/setup.rpm.sh" | sudo -E bash
sudo dnf download edb-whpg<major_version>-<extension_name>
```

```bash
export EDB_SUBSCRIPTION_TOKEN=<your-token>
export EDB_REPO=gpsupp
curl -1sSLf "https://downloads.enterprisedb.com/$EDB_SUBSCRIPTION_TOKEN/$EDB_REPO/setup.rpm.sh" | sudo -E bash
sudo yumdownloader edb-whpg<major_version>-<extension_name>
```

Where:
- `<your-token>` is the token you received when you registered for the EDB subscription.
- `<major_version>` is your WHPG version (6 or 7).
- `<extension_name>` is the name of the extension you want to install.
```

1. Create a file `all_hosts` on your WHPG coordinator, which lists all hosts in the WHPG cluster. For example:

   ```
   cdw
   scdw
   sdw1
   sdw2
   sdw3
   ```

2. From the coordinator, use the `gpsync` utility to transfer the package to all hosts in the cluster and then use the `gpssh` utility to install the package:

```
```bash
gpsync -f all_hosts <package-name> =:/tmp
gpssh -f all_hosts -e 'sudo dnf install -y /tmp/<package-name>'
```

```bash
gpsync -f all_hosts <package-name> =:/tmp
gpssh -f all_hosts -e 'sudo yum install -y /tmp/<package-name>'
```
```

Where `<package-name>` is the name of the package file you downloaded.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.4.1.1 Postgres Analytics Accelerator (PGAA)

The Postgres Analytics Accelerator (PGAA) extension enables WarehousePG to run distributed analytical queries directly against data in object storage, without requiring ETL or data movement into the cluster. PGAA supports Parquet, Delta Lake, and Iceberg formats, and integrates with Iceberg REST catalogs and Apache Spark.

PGAA requires the PGFS extension as a dependency, which is installed automatically when you install PGAA.

Installing PGAA

For full installation instructions, including prerequisites, package names, and cluster configuration, seeInstalling PGAA on WarehousePG.

Using PGAA

For guidance on querying object storage, connecting to Iceberg catalogs, and accelerating queries with Spark, see Scaling with WarehousePG.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.4.1.2 pgAudit

The PostgreSQL Audit Extension (pgAudit) provides detailed session and object audit logging via the standard PostgreSQL logging facility. It produces the forensic audit trails required to comply with various government, financial, and ISO certifications.

While standard PostgreSQL statement logging (`log_statement = all`) provides a basic history, it often lacks the granular detail required for deep forensics. pgAudit focuses on the specific internal actions taken by the database to satisfy a request, rather than just the request itself.

Downloading, installing, and loading the extension

Refer to Downloading and installing an extension for installation and setup instructions.

Once installed, you must load the pgAudit extension as a shared library before you can use it within your databases.

1. Load the extension as a shared library before you can use it within your databases. Check for existing shared libraries:

```
gpconfig -s
shared_preload_libraries
```

2. Use the output of the previous command to enable the new extension, along any other shared libraries, and restart WHPG:

```
gpconfig -c shared_preload_libraries -v '<other_libraries>,
pgAudit'
gpstop -ar
```

3. Create the extension in your database:

```
CREATE EXTENSION
pgaudit;
```

Configuring pgAudit settings

These settings control pgAudit behavior and can only be modified by a superuser. Settings can be applied globally (via `postgresql.conf` or using `ALTER SYSTEM`), at the database level (`ALTER DATABASE`), or at the role level (`ALTER ROLE`).

- `pgaudit.log` : Specifies the classes of statements to log. The supported values are:
    - `READ` : `SELECT` and `COPY` when the source is a relation or a query.
    - `WRITE` : `INSERT` , `UPDATE` , `DELETE` , `TRUNCATE` , and `COPY` when the target is a relation.
    - `FUNCTION` : Function calls and DO blocks.
    - `ROLE` : Statements related to roles and privileges, such as `GRANT` , `REVOKE` , `CREATE/ALTER/DROP ROLE` .
    - `DDL` : All other DDL statements not included in the `ROLE` class.
    - `MISC` : Miscellaneous commands, such as `DISCARD` , `FETCH` , `CHECKPOINT` , `VACUUM` , and `SET` .
    - `MISC_SET` : Miscellaneous `SET` commands. For example, `SET ROLE` .
    - `ALL` : Include all of the above.
    - `NONE` : (Default) Log nothing.
- `pgaudit.log_catalog` : Logs statements where all relations are in `pg_catalog` . Default is `on` . Disable this setting to reduce system noise.
- `pgaudit.log_client` : Determines if audit messages are visible to the client process, such as `psql` . Default is `off` . Leave this setting disabled to reduce noise, but consider enabling it for debugging purposes.
- `pgaudit.log_level` : Specifies the log level for entries. See Message Severity Levels for supported values. Note that `ERROR` , `FATAL` , and `PANIC` are not supported. This setting `pgaudit.log_level` is only enabled when `pgaudit.log_client` is enabled. The default value is `LOG` .
- `pgaudit.log_parameter` : Includes statement parameters in CSV format following the statement text. Default is `off` .
- `pgaudit.log_relation` : Creates a separate entry for each relation referenced in a statement. Enable this parameter for exhaustive logging without using object audit logging. Default is `off` .
- `pgaudit.log_statement_once` : Logs statement text only once per statement/substatement pair to reduce verbosity. Default is `off` .
- `pgaudit.role` : Specifies the master role to use for object audit logging. There is no default value.

Using pgAudit

pgAudit supports two main auditing methods: **session audit logging** and **object audit logging**.

Session audit logging

Session auditing captures statements executed by a specific user or backend. You define which classes of statements to log using the `pgaudit.log` parameter.

Examples

- Log all DDL and `WRITE` statements:

```
SET pgaudit.log = 'write,
ddl';
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

- Create a separate log entry for every table referenced in a statement:

```
SET pgaudit.log_relation = on;
```

- Log everything except miscellaneous commands:

```
SET pgaudit.log = 'all, -
misc';
```

- Report audit log messages as `NOTICE`:

```
SET pgaudit.log_level = notice;
```

Object audit logging

Object auditing allows for granular logging of specific tables, views, or columns. This method uses the PostgreSQL role system to trigger logging, which is often more efficient for targeted tracking of sensitive data.

> **Note**
>
> pgAudit object logging only supports `SELECT`, `INSERT`, `UPDATE`, and `DELETE` statements.

To configure object audit logging:

1. Create an auditor role: Define a dedicated role for auditing and set `pgaudit.role` to include this role.

```
CREATE ROLE auditor WITH
NOLOGIN;
SET pgaudit.role =
'auditor';
```

2. Grant target permissions: Grant the `auditor` role the permissions you wish to track on objects.

```
GRANT <permission> ON <object> TO
auditor;
```

Examples

- Audit all reads on a table:

```
GRANT SELECT ON public.payroll TO
auditor;
```

- Audit updates to a specific column:

```
GRANT UPDATE (password) ON public.users TO
auditor;
```

Interpreting audit logs

Audit entries are sent to the PostgreSQL standard logger (`stderr` or `csvlog`). WarehousePG stores these logs within the `pg_log` directory of each segment's data directory. Each entry is prefixed with `AUDIT`.

A typical log entry follows this format:

```
AUDIT: SESSION,1,1,DDL,CREATE TABLE,TABLE,public.test_table,CREATE TABLE test_table (id int),<not logged>
```

The audit logs contain the following columns:

- `AUDIT_TYPE`: Indicates if the log was triggered by a `SESSION` or an `OBJECT` setting.
- `STATEMENT_ID`: A unique ID for the statement in this session (sequential). There may be multiple entries for a statement ID when more than one relation is logged.
- `SUBSTATEMENT_ID`: Sequential ID for sub-statements (e.g., function calls within a query).
- `CLASS`: The category of the statement, defined by `pgaudit.log` (`READ`, `WRITE`, `DDL`, etc.).
- `COMMAND`: The specific SQL command executed.
- `OBJECT_TYPE`: Type of object accessed (`TABLE`, `INDEX`, `VIEW`).
- `OBJECT_NAME`: Fully-qualified name of the object.
- `STATEMENT`: The full text of the SQL query.
- `PARAMETER`: Statement parameters if `pgaudit.log_parameter` is enabled.

Usage considerations

When implementing pgAudit in your environment, keep the following operational behaviors in mind:

- **Object renaming:** When an object is renamed, pgAudit logs the event using the new name (the target name). For example, if you execute `ALTER TABLE test RENAME TO test2;`, the audit entry will record the object name as `public.test2`.
- **Duplicate entries:** Certain commands may trigger multiple log entries for a single action. For instance, creating a table with a primary key will generate independent log entries for both the table and the underlying index. However, these related entries are grouped under a single `STATEMENT_ID`, allowing you to correlate them during an audit review.
- **Superuser auditing limitations:** It is not possible to reliably audit superuser accounts with pgAudit, as superusers have the necessary permissions to modify or bypass the extension's settings. We recommend to restrict the use of superuser accounts for daily operations.
- **Automated maintenance tasks:** Operations performed by Autovacuum and Autoanalyze processes are not captured in the audit log, as they are system-level background tasks.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

- **Aborted transactions:** Statements attempted after a transaction has entered an `aborted` state (due to a previous error) are not captured by pgAudit. However the standard PostgreSQL logging facility will still record the initial error that caused the abort, along with any subsequent failed attempts, as standard `ERROR` messages.

Best practices

- **Manage log volume:** In analytical (OLAP) environments, audit logging can generate enormous volumes of data. Assess disk space and performance impact before enabling exhaustive logging on large fact tables.
- **Filter system noise:** Set `pgaudit.log_catalog = off` to prevent logging the internal queries generated by administration tools.
- **Capture prepared statements:** Set `pgaudit.log_parameter = on` to see the actual values being passed into the query.
- **Storage management:** Use object auditing for fact tables in WarehousePG. Auditing every `INSERT` in a multi-terabyte table via session auditing can exhaust disk space rapidly.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.4.1.3 Postgres File System (PGFS)

The Postgres File System (PGFS) extension provides the storage layer for object storage connectivity in WarehousePG. It handles credential management and abstracts access to S3, Google Cloud Storage (GCS), and Azure, and is a required dependency of the Postgres Analytics Accelerator (PGAA) extension.

Installing PGFS

PGFS is installed automatically as a dependency when you install PGAA. For full installation instructions, see Installing PGAA on WarehousePG.

Using PGFS

PGFS is used through PGAA. For full documentation, see Scaling with WarehousePG.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.4.1.4 pgvector

The pgvector module provides high-performance vector similarity search capabilities for WarehousePG (WHPG). By representing complex data (like text, images, or audio) as machine-learning-generated embeddings, you can perform semantic and syntactic searches at scale.

The WarehousePG pgvector module is equivalent to version 0.7.4. of the pgvector module used with PostgreSQL. SeeLimitations to understand the limitations of the WarehousePG version of the module.

Downloading, installing, and loading the extension

Refer to Downloading and installing an extension for installation and setup instructions.

Once installed, create the extension in your database:

```
CREATE EXTENSION vector;
```

About the vector types, operators, and functions

pgvector introduces the `vector` data type along with specialized index access methods `ivfflat` and `hnsw`. These tools enable both exact and approximate nearest neighbor (ANN) searches using various distance metrics.

vector data type

The `vector` data type represents an n-dimensional coordinate. Each `vector` takes `4 * dimensions + 8` bytes of storage. Each element is a single precision floating-point number (similar to the `real` type in WarehousePG), and all of the elements must be finite (no `NaN`, `Infinity`, or `-Infinity`). Vectors can have up to 16,000 dimensions.

vector operators

pgvector provides the following operators for the `vector` data type:

Operator	Description
+	Element-wise addition
-	Element-wise subtraction
*	Element-wise multiplication
<->	Euclidean distance
<#>	Negative inner product
<=>	Cosine distance

> **Note**
>
> Because WarehousePG supports only `ASC` (ascending) order, the `<#>` returns the negative inner product to ensure the smallest value appears first.

vector functions

pgvector provides the following functions for the `vector` data type:

Function name	Return type	Description
`cosine_distance(vector, vector)`	`double precision`	Computes the cosine distance
`inner_product(vector, vector)`	`double precision`	Computes the inner product
`l2_distance(vector, vector)`	`double precision`	Computes the Euclidean distance
`l1_distance(vector, vector)`	`double precision`	Computes the taxicab distance
`vector_dims(vector)`	`integer`	Returns the number of dimensions
`vector_norm(vector)`	`double precision`	Computes the Euclidean norm

vector aggregate functions

pgvector provides the following aggregate functions for the `vector` data type:

Function	Return type	Description
`avg(vector)`	`vector`	Computes the arithmetic mean
`sum(vector)`	`vector`	Computes the sum of the vector elements

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Using the pgvector module

You can use pgvector to search, store, and query embeddings in WarehousePG.

Storing embeddings

You can define `vector` columns with a specific dimension count to ensure data integrity.

- Create a table with a `vector` column with three dimensions:

```
CREATE TABLE items (id bigserial PRIMARY KEY, embedding
vector(1536));
```

- Add a column to an existing table:

```
ALTER TABLE items ADD COLUMN embedding vector(3);
```

Performing common DML operations

- Insert data:

```
INSERT INTO items (embedding) VALUES ('[1,2,3]'),
('[4,5,6]');
```

- Upsert:

```
INSERT INTO items (id, embedding) VALUES (1,
'[1,2,3]')
    ON CONFLICT (id) DO UPDATE SET embedding =
EXCLUDED.embedding;
```

- Update and delete data:

```
UPDATE items SET embedding = '[1,2,3]' WHERE id = 1;
DELETE FROM items WHERE id = 1;
```

- Insert and update data:

```
INSERT INTO items (embedding) VALUES ('[1.1, 2.2,
3.3]');
UPDATE items SET embedding = '[4.4, 5.5, 6.6]' WHERE id = 1;
```

Querying embeddings

- Get the nearest neighbors to a `vector` by L2 distance:

```
SELECT * FROM items ORDER BY embedding <-> '[3,1,2]' LIMIT 5;
```

- Get the nearest neighbors to a row:

```
SELECT * FROM items WHERE id != 1
  ORDER BY embedding <-> (SELECT embedding FROM items WHERE id = 1) LIMIT
5;
```

- Filter by a certain distance:

```
SELECT * FROM items WHERE embedding <-> '[3,1,2]' < 5;
```

Evaluating embedding distance

- Inner product (multiply by -1):

```
SELECT (embedding <#> '[3,1,2]') * -1 AS inner_product FROM
items;
```

- Cosine similarity (1 - distance):

```
SELECT 1 - (embedding <=> '[3,1,2]') AS cosine_similarity FROM
items;
```

Aggregating embeddings

- Average the vectors in a table:

```
SELECT AVG(embedding) FROM
items;
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

- Average a group of vectors in a table:

```
SELECT category_id, AVG(embedding) FROM items GROUP BY category_id;
```

Indexing embeddings

By default, pgvector performs an exact nearest neighbor search, which guarantees perfect recall. To trade some recall for performance, you can use an Approximate Nearest Neighbor (ANN) index.

> **Note**
>
> Unlike typical indexes, adding an approximate index may change query results.

When you create an index for an embedding, you use the `lists` parameter to specify the number of clusters created during index creation. Each cluster is a partition of the data set.

For optimal search accuracy:

- Create the index after the table has data.
- Choose an appropriate `lists` value. Use `rows / 1000` for up to 1M rows and `sqrt(rows)` for over 1M rows.
- pgvector provides a `probes` parameter that you can set at query time to specify the number of regions to search during a query. When querying, specify an appropriate number of `probes`. A high number is better for recall, a low number is better for speed. A reasonable initial value is `sqrt(lists)`.

Inverted File Flat (IVFFlat) indexes

IVFFlat indexes are best for large datasets where memory is limited. It partitions vectors into clusters (lists). You can index a `vector` that has up to 2,000 dimensions.

- Create an index on the L2 distance:

```
CREATE INDEX ON items USING ivfflat (embedding vector_l2_ops) WITH (lists =
100);
```

- Create an index on the inner product:

```
CREATE INDEX ON items USING ivfflat (embedding vector_ip_ops) WITH (lists =
100);
```

- Create an index on the cosine distance:

```
CREATE INDEX ON items USING ivfflat (embedding vector_cosine_ops) WITH (lists =
100);
```

- Specify the number of `probes` (1 by default) to specify how many regions to search.

```
SET ivfflat.probes =
10;
```

- Use `SET LOCAL` inside a transaction block to set `probes` for a single query:

```
BEGIN;
SET LOCAL ivfflat.probes =
10;
SELECT ... --- your queries
COMMIT;
```

Hierarchical navigable small world (HNSW) indexes

HNSW indexes build a graph for faster search and higher recall than IVFFlat, supporting up to 2,000 dimensions.

- Create an index on the L2 distance:

```
CREATE INDEX ON items USING hnsw (embedding vector_l2_ops);
```

- Create an index on the inner product:

```
CREATE INDEX ON items USING hnsw (embedding vector_ip_ops);
```

- Create an index on the cosine distance:

```
CREATE INDEX ON items USING hnsw (embedding
vector_cosine_ops);
```

HNSW indexes support the following parameters:

- `m`: Specifies the maximum number of connections per layer (16 by default).
- `ef_construction`: Specifies the size of the dynamic candidate list for constructing the graph (64 by default).

For example:

```
CREATE INDEX ON items USING hnsw (embedding vector_l2_ops) WITH (m = 16, ef_construction =
64);
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

You can specify a custom size for the dynamic candidate list for a search:

```
SET hnsw.ef_search =
100;
```

Higher value provides better recall at the cost of speed. The default size of the candidate list is 40. For example:

```
BEGIN;
SET LOCAL hnsw.ef_search =
100;
SELECT ... --- your queries
COMMIT;
```

Advanced usage

Parallel index creation

WarehousePG version 7.3.1 and later supports parallel index creation for HNSW and IVFFlat indexes through the `max_parallel_maintenance_workers` configuration parameter. By default, `max_parallel_maintenance_workers` is set to `2`, which allows two parallel workers to run per segment during index creation. To disable parallel workers, set `max_parallel_maintenance_workers` to `0`.

Viewing indexing progress

You can check index creation progress in WarehousePG as described in CREATE INDEX Progress Reporting:

```
SELECT phase, tuples_done, tuples_total FROM
gp_stat_progress_create_index;
```

Filtering

Index nearest neighbor queries with a `WHERE` clause:

```
SELECT * FROM items WHERE category_id = 123 ORDER BY embedding <-> '[3,1,2]' LIMIT
5;
```

For approximate search, create a partial index on the `vector` column:

```
CREATE INDEX ON items USING ivfflat (embedding vector_l2_ops) WITH (lists =
100)
    WHERE (category_id = 123);
```

Use partitioning to perform an approximate search on many different values of the `WHERE` columns:

```
CREATE TABLE items (embedding vector(3), category_id int) PARTITION BY
LIST(category_id);
```

Performing hybrid search

Use pgvector together with full-text search for a hybrid search:

```
SELECT id, content FROM items, to_tsquery('hello & search')
query
  WHERE textsearch @@ query ORDER BY ts_rank_cd(textsearch, query) DESC LIMIT 5;
```

Performance tuning and debugging

Use `EXPLAIN ANALYZE` to debug performance:

```
EXPLAIN ANALYZE SELECT * FROM items ORDER BY embedding <-> '[3,1,2]' LIMIT 5;
```

If vectors are normalized to length 1, use inner product for the best performance:

```
SELECT * FROM items ORDER BY embedding <#> '[3,1,2]' LIMIT 5;
```

To speed up queries with an index, increase the number of inverted `lists` (at the expense of recall):

```
CREATE INDEX ON items USING ivfflat (embedding vector_l2_ops) WITH (lists =
1000);
```

Limitations

pgvector for WarehousePG has the following limitations:

- The WarehousePG query optimizer (ORCA) doesn't support `ivfflat` and `hnsw` indexes. Queries using these indexes will fall back to the Postgres-based planner.
- The size of a vector index can be larger than the size of the base table.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.4.1.5 user_profile

WarehousePG (WHPG) allows database superusers to manage password policies and account security via the `user_profile` extension.

Downloading, installing, and loading the extension

Refer to Downloading and installing an extension for installation and setup instructions.

Once installed, you must load the user_profile extension as a shared library before you can use it within your databases.

1. Load the extension as a shared library before you can use it within your databases. Check for existing shared libraries:

   ```
   gpconfig -s
   shared_preload_libraries
   ```

2. Use the output of the previous command to enable the new extension, along any other shared libraries, and restart WHPG:

   ```
   gpconfig -c shared_preload_libraries -v '<other_libraries>,
   user_profile'
   gpstop -ar
   ```

3. Create the extension in your database:

   ```
   CREATE EXTENSION user_profile;
   ```

Understanding the user_profile parameters

A profile is a set of security attributes applied to a group of roles to enforce authentication rules such as password complexity, expiration, and lockout policies.

Each profile defines password management policies designed to strengthen authentication security. These profiles allow you to:

- Track failed login attempts.
- Lock accounts automatically after a specified threshold of failures.
- Enforce password expiration and grace periods for renewals.
- Define complexity requirements to ensure strong credentials.
- Restrict password reuse to prevent credential cycling.

After creating a profile, you can associate it with one or more user roles. When a user initiates a connection, the WarehousePG (WHPG) server acts as the enforcement engine, applying the specific security rules defined in the profile associated with that user's login role.

Although a single WHPG cluster can support multiple profiles, these profiles are cluster-wide resources. This means a profile is shared by all databases within the cluster; a user accessing different databases under the same cluster will always be subject to the same profile constraints.

To update your security requirements, you only need to modify the profile. The WHPG server will then automatically apply those updated standards to every user associated with that profile across the entire cluster.

By default, WHPG creates a system profile named `default`. When a new role is created, the server automatically assigns it to the `default` profile unless an alternative is explicitly specified. Upon installing the `user_profile` extension, all existing roles are retroactively assigned to the `default` profile to ensure immediate coverage. The `default` profile is a mandatory system component and cannot be deleted.

Each profile consists of several parameters that govern how passwords and logins are handled:

Parameter Name	Description	Supported values
`FAILED_LOGIN_ATTEMPTS`	The maximum number of failed login attempts permitted before the server locks the account for the duration defined by `PASSWORD_LOCK_TIME`.	`INTEGER` > 0, or `UNLIMITED` (no lockout threshold).
`PASSWORD_LOCK_TIME`	The number of days an account remains locked after exceeding `FAILED_LOGIN_ATTEMPTS`.	`NUMERIC` >= 0 (supports decimals for partial days), or `UNLIMITED` (requires superuser unlock).
`PASSWORD_LIFE_TIME`	The password's validity period in days. If used with `PASSWORD_GRACE_TIME`, the user can still connect during the grace period but must change their password before executing commands.	`NUMERIC` >= 0 (supports decimals for partial days), or `UNLIMITED` (no expiration).
`PASSWORD_GRACE_TIME`	The grace period in days starting after password expiration. During this time, users can connect but are restricted from executing commands until the password is updated.	`NUMERIC` >= 0 (supports decimals for partial days), or `UNLIMITED` (infinite grace period).
`PASSWORD_REUSE_TIME`	The minimum number of days that must pass before a previous password can be reused. Works in conjunction with `PASSWORD_REUSE_MAX`. If both parameters are set to `UNLIMITED`, there are no restrictions on password reuse.	`NUMERIC` >= 0 (supports decimals for partial days), or `UNLIMITED` (no time restriction).
`PASSWORD_REUSE_MAX`	The number of password changes required before a previous password can be reused. Works in conjunction with `PASSWORD_REUSE_TIME`. If both parameters are set to `UNLIMITED`, there are no restrictions on password reuse.	`INTEGER` >= 0, or `UNLIMITED` (no count restriction)..
`PASSWORD_MINIMUM_LENGTH`	The minimum character count required for a password.	`INTEGER` >= 1, or `UNLIMITED` (no length check).
`PASSWORD_REQUIRE_UPPER`	Enforces the inclusion of at least one uppercase character in the password string.	`TRUE` (required) or `FALSE` (optional).
`PASSWORD_REQUIRE_LOWER`	Enforces the inclusion of at least one lowercase character in the password string.	`TRUE` (required) or `FALSE` (optional).
`PASSWORD_REQUIRE_NUMBER`	Enforces the inclusion of at least one numeric character (0-9) in the password string.	`TRUE` (required) or `FALSE` (optional).
`PASSWORD_SPECIAL_CHARS`	Defines a set of special characters; the password must contain at least one character from this specified string.	A string of characters, or '' (empty string) for no restriction.

The `default` profile initially has all parameters set to `UNLIMITED` or `FALSE`.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Creating a new profile

Use the `up_create_profile()` User Defined Function (UDF) to create a new profile:

```
up_create_profile( <profile_name>
      [<param1>, <value1>, <param2>, <value2> ... ]);
```

Where:

- `profile_name` specifies the name of the profile.
- `parameter` specifies the attribute limited by the profile.
- `value` specifies the parameter limit.

Examples

The following command creates a profile named `acctg`. The profile specifies that if a user doesn't authenticate with the correct password in five attempts, the account is locked for one day:

```
SELECT up_create_profile('acctg',
        'FAILED_LOGIN_ATTEMPTS', '5',
        'PASSWORD_LOCK_TIME', '1');
```

The following command creates a profile named `sales`. The profile specifies that a user must change their password every 90 days:

```
SELECT up_create_profile('sales',
        'PASSWORD_LIFE_TIME', '90',
        'PASSWORD_GRACE_TIME', '3');
```

The following command creates a profile named `accts`. The profile specifies that a user can't reuse a password within `180` days of the last use of the password and must change their password at least five times before reusing the password:

```
SELECT up_create_profile('accts',
        'PASSWORD_REUSE_TIME', '180',
        'PASSWORD_REUSE_MAX', '5');
```

The following command creates a profile named `resources`. When a user associated with this profile wants to change the password, the password must contain at least one number character and one special character:

```
SELECT up_create_profile('resource',
        'PASSWORD_REQUIRE_NUMBER', 'TRUE',
        'PASSWORD_SPECIAL_CHARS', '!@#$%^&*');
```

Altering a profile

Use the `up_alter_profile()` UDF to modify a user profile:

```
up_alter_profile( <profile_name>
      [<param1>, <value1>, <param2>, <value2> ... ]);
```

Where:

- `profile_name` specifies the name of the profile.
- `parameter` specifies the attribute limited by the profile. Use `name` to rename the profile.
- `value` specifies the parameter limit.

A database superuser can use the `up_alter_profile()` UDF to modify the values specified by the `default` profile.

Examples

The following command modifies a profile named `acctg_profile` to specify that if a user doesn't successfully authenticate whitin three attempts, the account is locked for one day.

```
SELECT up_alter_profile('acctg_profile',
        'FAILED_LOGIN_ATTEMPTS', '3',
        'PASSWORD_LOCK_TIME', '1');
```

The following command changes the name of `acctg_profile` to `payables_profile`:

```
SELECT up_alter_profile('acctg_profile', 'name', 'payables_profile');
```

Inspecting a profile

Use the `up_show_profile()` UDF to list one or all profiles:

```
up_show_profile( [profile_name] );
```

Where:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

- `profile_name` specifies the name of the profile. `NULL` lists all profiles.

Dropping a profile

Use the `up_drop_profile()` UDF to drop a profile:

```
up_drop_profile(<profile_name>);
```

Where:

- `profile_name` specifies the name of the profile being dropped.

You cannot drop a profile if there are one or more users associated with it.

Examples

The following command drops a profile named `acctg_profile`:

```
SELECT
up_drop_profile('acctg_profile');
```

Associating a profile with an existing role

Use the `up_alter_role_profile()` UDF to associate a profile with an existing role:

```
up_alter_role_profile(<role_name|role_id>, <profile_name>);
```

Where:

- `role_id` or `role_name` specify the role to associate the profile with.
- `profile_name` specifies the name of the profile.

Only a database superuser can use the `up_alter_role_profile()` UDF.

Each login role can have only one profile. To discover the profile that's currently associated with a login role, use the `up_show_role_info()` UDF:

```
up_show_role_info([role_name|role_id])
```

Where:

- `role_id` or `role_name` specify the specific role to show (use `NULL` to show all roles).

Examples

The following command associates a profile named `acctg` with a user named `john`:

```
SELECT up_alter_role_profile('john', 'acctg');
```

Locking and unlocking a role

A database superuser can use the `up_lock()` and `up_unlock()` UDFs to lock or unlock a role:

```
up_lock(<role_name|role_id>)
up_unlock(<role_name|role_id>)
```

Where:

- `role_name` or `role_id` specifies the role to be locked or unlocked.

Use `up_lock()` to immediately lock a user role. Once locked, a role's `LOGIN` functionality is disabled. The role remains in this locked state until a superuser restores access using the `ACCOUNT UNLOCK` clause of the `ALTER ROLE` statement (or uses the `up_unlock()` UDF).

Use the `up_unlock()` clause to unlock a role that was locked by `up_lock()`, or a role that was locked through the profile `FAILED_LOGIN_ATTEMPTS` setting.

Examples

The following command locks a role named `john`. The account remains locked until the account is unlocked by calling `up_unlock()`.

```
SELECT up_lock('john');
```

The following command unlocks a role named `john`:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
SELECT up_unlock('john');
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.4.1.6 whpg-anonymizer

The whpg-anonymizer extension provides powerful data masking and anonymization capabilities directly within the WarehousePG (WHPG) engine. It allows organizations to conceal sensitive Personally Identifiable Information (PII) to comply with privacy regulations such as GDPR, HIPAA, and CCPA.

Data anonymization is the process of altering personal data so that individuals can no longer be identified, typically to protect user privacy. The extension supports two primary strategies for protecting data:

- **Irreversible anonymization:** Irreversibly altering data in the underlying tables.
- **Dynamic pseudonymization:** Real-time transformation of data based on the role of the user querying the database.

Downloading, installing, and loading the extension

Refer to Downloading and installing an extension for installation and setup instructions.

Once installed, you must load the whpg-anonymizer extension as a shared library before you can use it within your databases.

1. Load the extension as a shared library before you can use it within your databases. Check for existing shared libraries:

```
gpconfig -s
shared_preload_libraries
```

2. Use the output of the previous command to enable the new extension, along any other shared libraries, and restart WHPG:

```
gpconfig -c shared_preload_libraries -v '<other_libraries>,
anon'
gpstop -ar
```

3. Create the extension in your database and initialize it:

```
CREATE EXTENSION anon;
SELECT anon.init();
```

Performing dynamic masking and anonymization

To implement data masking or anonymization in WarehousePG, follow these steps:

1. **Start the masking engine:** Dynamic masking isn't active by default to prevent performance overhead on administrative tasks. Explicitly enable the dynamic masking engine for the current session or database:

```
SELECT
anon.start_dynamic_masking();
```

2. **Define the masking policies:** Use `SECURITY LABEL` statements to map specific columns to masking static values or functions.

    - **Static value masking:** This method replaces every row in a column with the exact same string.

```
SECURITY LABEL FOR anon ON COLUMN <table_name>.<column_name>
    IS 'MASKED WITH VALUE $$<replacement_text>$$';
```

    - **Functional masking:** This method uses a mathematical function to transform the original data. It allows the masked data to maintain its original format, length, or uniqueness without revealing the actual identity.

```
SECURITY LABEL FOR anon ON COLUMN <table_name>.<column_name>
IS 'MASKED WITH FUNCTION <function_name>
(<column_name>)';
```

3. **Assign subject roles:** Identify the database roles that must see masked data and label them as `MASKED`.

```
SECURITY LABEL FOR anon ON ROLE <role_name> IS 'MASKED';
```

4. **Remove or update policies:** If you need to change a rule or stop masking a specific column, use the `NULL` label or drop the rule.

```
-- Remove a masking rule from a
column
SECURITY LABEL FOR anon ON COLUMN <table_name>.<column_name> IS NULL;

-- Remove the masking requirement from a
user
SECURITY LABEL FOR anon ON ROLE <role_name> IS NULL;
```

Implementation example

The following example demonstrates how to conceal employee phone numbers and names from a specific user.

1. Enable the dynamic masking engine:

```
SELECT
anon.start_dynamic_masking();
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

2. Create a sample table and populate it with sensitive data:

```
CREATE TABLE employees
(
    id SERIAL PRIMARY
KEY,
    name TEXT,
    phone TEXT,
    salary
NUMERIC
);

INSERT INTO employees (name, phone, salary)
VALUES
('Alice', '13812345678', 25000),
('Bob', '13987654321', 18000);
```

3. Apply a static string rule, which masks names with a static string:

```
SECURITY LABEL FOR anon ON COLUMN employees.name
IS 'MASKED WITH VALUE $$CONFIDENTIAL$$';
```

4. Apply a functional masking rule, which masks phone numbers using a partial MD5 hash:

```
SECURITY LABEL FOR anon ON COLUMN employees.phone
IS 'MASKED WITH FUNCTION
pg_catalog.substring(pg_catalog.md5(phone),0,12)';
```

5. Assign the `MASKED` label to the `analyst` role:

```
CREATE ROLE analyst
LOGIN;
GRANT SELECT ON employees TO
analyst;
SECURITY LABEL FOR anon ON ROLE analyst IS 'MASKED';
```

6. When logged in as the `analyst` role, the PII is automatically concealed:

```
SELECT * FROM employees;
id |     name     |    phone    | salary
----+--------------+-------------+--------
1 | CONFIDENTIAL | 4c0115d39dd |
25000
2 | CONFIDENTIAL | 16d4b6356cc |
18000
(2 rows)
```

Limitations

Because WarehousePG utilizes a Massively Parallel Processing (MPP) architecture, certain features of PostgreSQL `postgresql_anonymizer` are restricted.

Unsupported functions

The `anon.fake_*` family of functions, such as `anon.fake_first_name()`, is not supported in WarehousePG for dynamic masking.

These functions rely on secondary table lookups to fetch pre-generated data. In an MPP environment, segment nodes can't perform secondary relation lookups during the execution of a primary query. Attempting to use them will result in a cross-slice execution error:

```
ERROR:  function cannot execute on a QE slice because it accesses relation
<relation>
```

Standard masking functions that do not require external table lookups are fully supported. Examples include:

- `anon.random_zip()`
- `anon.random_date_between()`
- `anon.partial()`
- Standard Postgres hashing and string manipulation functions

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.4.1.7 whpg_fdw

The WarehousePG (WHPG) `whpg_fdw` extension is a Foreign Data Wrapper (FDW) that you can use to run federated queries between two WarehousePG clusters. It allows you to query data stored in a remote WarehousePG database as if it were part of your local database.

The `whpg_fdw` extension is based on the PostgreSQL Foreign Data Wrapper framework, leveraging its capabilities to connect and interact with remote WarehousePG databases seamlessly.

Downloading, installing, and loading the extension

Refer to Downloading and installing an extension for installation and setup instructions.

Once installed, create the extension in your database:

```
CREATE EXTENSION whpg_fdw;
```

Using the extension

Perform the following tasks to access data that resides in a remote WHPG cluster with `whpg_fdw`:

1. Create a foreign server to represent each remote WHPG database to which you want to connect.
2. Create a user mapping for the local WHPG database user that you want to allow to access each server.
3. Create a foreign table for each remote WHPG table that you want to access, or import a foreign schema.
4. Import a foreign schema to import multiple foreign tables from the remote database at once.
5. Construct and run queries.

Creating a foreign server

To access a remote WarehousePG database, you must first create a foreign server which specifies the connection details of the remote database. You provide these connection parameters in the `OPTIONS` clause of the `CREATE SERVER` command. A `whpg_fdw` foreign server accepts the same options as a `postgres_fdw` foreign server. Refer to the postgres_fdw documentation for more details.

`whpg_fdw` also supports the following additional options when creating a foreign server:

- `mpp_execute`: Determines where the foreign scan is executed. The default value is `coordinator`, which means that the foreign scan runs only on the remote coordinator. Set it to `all segments` instead, to leverage the fulll Massively Parallel Processing (MPP) power of WarehousePG. This enables parallel execution across all remote segments.
- `num_segments`: Defines the number of segments in the remote cluster. This option is required only when `mpp_execute` is set to `all segments`. The default value is the total number of segments in the local WarehousePG cluster. If the local and remote clusters have different number of segments, you must manually set this value to ensure proper data distribution.
- `fetch_size`: Specifies the number of rows retrieved from the remote segments during each round trip. The default value is 100.

The following is an example of creating a `whpg_fdw` foreign server:

```
CREATE SERVER
remote_whpg
FOREIGN DATA WRAPPER
whpg_fdw
OPTIONS (host 'remote_host', port '5432', dbname
'remote_db',
         mpp_execute 'all segments', num_segments '4', fetch_size
'200');
```

Creating a user mapping

To allow your local database roles to access the remote server, you must define a user mapping that maps a local role to the credentials on the remote WarehousePG database. This follows the standard PostgreSQL Foreign Data Wrapper (FDW) syntax through the `CREATE USER MAPPING` command.

User mappings that you create can include the following `OPTIONS`:

- `user`: Specifies the name of the remote WarehousePG database user to connect as. The remote user must have the right permissions to access the required tables of the remote database.
- `password`: Specifies the password for the user. Only a superuser can connect to the remote WarehousePG database without a password.

The following is an example of creating a user mapping:

```
CREATE USER MAPPING FOR local_user
SERVER
remote_whpg
OPTIONS (user 'remote_user', password
'remote_password');
```

Creating a foreign table

Use the `CREATE FOREIGN TABLE` command to create a foreign table that represents the remote table in your local WarehousePG database.

The column data types that you specify when you create the foreign table must exactly match those in the referenced remote table. We recommend that the columns are declared with exactly the same collations, if applicable, as the referenced columns of the remote table. Because `whpg_fdw` matches foreign table columns to the remote table by name, not position, you can create a foreign table with fewer columns, or with a different column order, than the underlying remote table.

Foreign tables include the following `OPTIONS`:

- `schema_name`: Specifies the name of the schema in which the remote WarehousePG table resides.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

- `table_name` : Specifies the name of the remote WarehousePG database.

`whpg_fdw` also supports the following additional options when creating a foreign table:

- `mpp_execute` : Determines where the foreign scan is executed. The default value is the one set for the foreign server. Set this parameter to override the one specified by the foreign server creation.
- `fetch_size` : Specifies the number of rows retrieved from the remote segments during each round trip. The default value is the one set for the foreign server. Set this parameter to override the one specified by the foreign server creation.

The following is an example of creating a foreign table:

```
CREATE FOREIGN TABLE remote_table (id INT, name TEXT, age
INT)
SERVER
remote_whpg
OPTIONS (schema_name 'public', table_name 'employees');
```

Importing a foreign schema

With WarehousePG 7, you can also use the `IMPORT FOREIGN SCHEMA` command to import multiple foreign tables from the remote database at once. `whpg_fdw` supports the same options for the `IMPORT FOREIGN SCHEMA` command as `postgres_fdw`.

The following is an example of importing a foreign schema:

```
IMPORT FOREIGN SCHEMA public
FROM SERVER
remote_whpg
INTO local_schema;
```

This command creates foreign tables in the `local_schema` schema in the local database for all tables in the `public` schema in the remote database.

Constructing and running queries

Query the foreign tables using the same SQL commands as you would to query local tables. The `whpg_fdw` handles the communication with the remote WarehousePG database and retrieves the data.

```
SELECT * FROM remote_table WHERE age >
30;
```

`whpg_fdw` minimizes the data transfer between the local and remote databases by pushing down filters and projections to the remote side whenever possible. See About predicate pushdown for details. Run the `EXPLAIN VERBOSE` command to see the query plan and verify the clauses being pushed down.

```
EXPLAIN VERBOSE SELECT * FROM remote_table WHERE age >
30;
```

By default, all foreign tables created using `whpg_fdw` are updatable. You can modify this behavior by setting the `updatable` option to `false` for the foreign table or server.

> **Note**
>
> `whpg_fdw` only supports `INSERT` operations on foreign tables. `UPDATE` and `DELETE` operations are not supported.

About predicate pushdown

`whpg_fdw` for WarehousePG 7 supports predicate pushdown, which minimizes the amount of data transferred between the WarehousePG clusters by sending a query filter condition to the remote WarehousePG server where it is applied there.

> **Note**
>
> Predicate pushdown is only supported when using Postgres Planner and is not currently supported with ORCA Optimizer.

The following operations are supported for pushdown:

- `SELECT` with column projection
- `SELECT` with `WHERE` clause (filter pushdown)
- `JOIN` operations
- `LIMIT` and `OFFSET` clauses
- `ORDER BY` clause
- Aggregation functions (`MAX` , `COUNT` , `AVG` , etc.)

Limitations

- The `UPDATE` and `DELETE` operations on foreign tables are not supported.
- Pushdown for grouping sets and window aggregation is not supported.
- Triggers on foreign tables are not supported.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.4.2 auto_explain

The `auto_explain` module provides a means for logging execution plans of slow statements automatically, without having to run `EXPLAIN` by hand.

The WarehousePG `auto_explain` module was runs only on the WarehousePG coordinator segment host. It is otherwise equivalent in functionality to the PostgreSQL `auto_explain` module.

Loading the Module

The `auto_explain` module provides no SQL-accessible functions. To use it, simply load it into the server. You can load it into an individual session by entering this command as a superuser:

```
LOAD 'auto_explain';
```

More typical usage is to preload it into some or all sessions by including `auto_explain` in `session_preload_libraries` or `shared_preload_libraries` in `postgresql.conf`. Then you can track unexpectedly slow queries no matter when they happen. However, this does introduce overhead for all queries.

Module Documentation

See auto_explain in the PostgreSQL documentation for detailed information about the configuration parameters that control this module's behavior.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.4.3 btree_gin

The `btree_gin` module provides sample generalized inverted index (GIN) operator classes that implement B-tree equivalent behavior for certain data types.

The WarehousePG `btree_gin` module is equivalent to the PostgreSQL `btree_gin` module. There are no WarehousePG or MPP-specific considerations for the module.

Installing and Registering the Module

The `btree_gin` module is installed when you install WarehousePG. Before you can use any of the functions defined in the module, you must register the `btree_gin` extension in each database in which you want to use the functions:

```
CREATE EXTENSION btree_gin;
```

Refer to Installing Extensions for more information.

Module Documentation

See btree_gin in the PostgreSQL documentation for detailed information about the individual functions in this module.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.4.4 citext

The citext module provides a case-insensitive character string data type, `citext`. Essentially, it internally calls the `lower()` function when comparing values. Otherwise, it behaves almost exactly like the `text` data type.

The WarehousePG `citext` module is equivalent to the PostgreSQL `citext` module. There are no WarehousePG or MPP-specific considerations for the module.

Installing and Registering the Module

The `citext` module is installed when you install WarehousePG. Before you can use any of the data types, operators, or functions defined in the module, you must register the `citext` extension in each database in which you want to use the objects. Refer to Installing Extensions for more information.

Module Documentation

See citext in the PostgreSQL documentation for detailed information about the data types, operators, and functions defined in this module.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.4.5 dblink

The `dblink` module supports connections to other WarehousePG databases from within a database session. These databases can reside in the same WarehousePG cluster, or in a remote system.

WarehousePG supports `dblink` connections between databases in WarehousePG installations with the same major version number. You can also use `dblink` to connect to other WarehousePG installations that use compatible `libpq` libraries.

> **Note** `dblink` is intended for database users to perform short ad hoc queries in other databases. `dblink` is not intended for use as a replacement for external tables.

The WarehousePG `dblink` module is a modified version of the PostgreSQL `dblink` module. There are some restrictions and limitations when you use the module in WarehousePG.

Installing and Registering the Module

The `dblink` module is installed when you install WarehousePG. Before you can use any of the functions defined in the module, you must register the `dblink` extension in each database in which you want to use the functions. Refer to Installing Extensions for more information.

WarehousePG Considerations

In this release of WarehousePG, statements that modify table data cannot use named or implicit `dblink` connections. Instead, you must provide the connection string directly in the `dblink()` function. For example:

```
gpadmin=# CREATE TABLE testdbllocal (a int, b text) DISTRIBUTED BY (a);
CREATE TABLE
gpadmin=# INSERT INTO testdbllocal select * FROM dblink('dbname=postgres', 'SELECT * FROM testdblink') AS dbltab(id int, product text);
INSERT 0 2
```

The WarehousePG version of `dblink` deactivates the following asynchronous functions:

- `dblink_send_query()`
- `dblink_is_busy()`
- `dblink_get_result()`

Using dblink

The following procedure identifies the basic steps for configuring and using `dblink` in WarehousePG. The examples use `dblink_connect()` to create a connection to a database and `dblink()` to run an SQL query.

1. Begin by creating a sample table to query using the `dblink` functions. These commands create a small table in the `postgres` database, which you will later query from the `testdb` database using `dblink`:

   ```
   $ psql -d postgres
   psql (9.4.20)
   Type "help" for help.

   postgres=# CREATE TABLE testdblink (a int, b text) DISTRIBUTED BY (a);
   CREATE TABLE
   postgres=# INSERT INTO testdblink VALUES (1, 'Cheese'), (2, 'Fish');
   INSERT 0 2
   postgres=# \q
   $
   ```

2. Log into a different database as a superuser. In this example, the superuser `gpadmin` logs into the database `testdb`. If the `dblink` functions are not already available, register the `dblink` extension in the database:

   ```
   $ psql -d testdb
   psql (9.4beta1)
   Type "help" for help.

   testdb=# CREATE EXTENSION dblink;
   CREATE EXTENSION
   ```

3. Use the `dblink_connect()` function to create either an implicit or a named connection to another database. The connection string that you provide should be a `libpq` -style keyword/value string. This example creates a connection named `mylocalconn` to the `postgres` database on the local WarehousePG cluster:

   ```
   testdb=# SELECT dblink_connect('mylocalconn', 'dbname=postgres user=gpadmin');
    dblink_connect
   ----------------
    OK
   (1 row)
   ```

   > **Note** If a `user` is not specified, `dblink_connect()` uses the value of the `PGUSER` environment variable when WarehousePG was started. If `PGUSER` is not set, the default is the system user that started WarehousePG.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4. Use the `dblink()` function to query a database using a configured connection. Keep in mind that this function returns a record type, so you must assign the columns returned in the `dblink()` query. For example, the following command uses the named connection to query the table you created earlier:

```
testdb=# SELECT * FROM dblink('mylocalconn', 'SELECT * FROM testdblink') AS dbltab(id int, product text);
 id | product
----+---------
  1 | Cheese
  2 | Fish
(2 rows)
```

To connect to the local database as another user, specify the `user` in the connection string. This example connects to the database as the user `test_user`. Using `dblink_connect()`, a superuser can create a connection to another local database without specifying a password.

```
testdb=# SELECT dblink_connect('localconn2', 'dbname=postgres user=test_user');
```

To make a connection to a remote database system, include host and password information in the connection string. For example, to create an implicit `dblink` connection to a remote system:

```
testdb=# SELECT dblink_connect('host=remotehost port=5432 dbname=postgres user=gpadmin password=secret');
```

Using dblink as a Non-Superuser

To make a connection to a database with `dblink_connect()`, non-superusers must include host, user, and password information in the connection string. The host, user, and password information must be included even when connecting to a local database. For example, the user `test_user` can create a `dblink` connection to the local system `cdw` with this command:

```
testdb=> SELECT dblink_connect('host=cdw port=5432 dbname=postgres user=test_user password=secret');
```

If non-superusers need to create `dblink` connections that do not require a password, they can use the `dblink_connect_u()` function. The `dblink_connect_u()` function is identical to `dblink_connect()`, except that it allows non-superusers to create connections that do not require a password.

`dblink_connect_u()` is initially installed with all privileges revoked from `PUBLIC`, making it un-callable except by superusers. In some situations, it may be appropriate to grant `EXECUTE` permission on `dblink_connect_u()` to specific users who are considered trustworthy, but this should be done with care.

> **Caution** If a WarehousePG cluster has configured users with an authentication method that does not involve a password, then impersonation and subsequent escalation of privileges can occur when a non-superuser runs `dblink_connect_u()`. The `dblink` connection will appear to have originated from the user specified by the function. For example, a non-superuser can run `dblink_connect_u()` and specify a user that is configured with `trust` authentication.

Also, even if the `dblink` connection requires a password, it is possible for the password to be supplied from the server environment, such as a `~/.pgpass` file belonging to the server's user. It is recommended that any `~/.pgpass` file belonging to the server's user not contain any records specifying a wildcard host name.

1. As a superuser, grant the `EXECUTE` privilege on the `dblink_connect_u()` functions in the user database. This example grants the privilege to the non-superuser `test_user` on the functions with the signatures for creating an implicit or a named `dblink` connection. The server and database will be identified through a standard `libpq` connection string and optionally, a name can be assigned to the connection.

   ```
   testdb=# GRANT EXECUTE ON FUNCTION dblink_connect_u(text) TO test_user;
   testdb=# GRANT EXECUTE ON FUNCTION dblink_connect_u(text, text) TO test_user;
   ```

2. Now `test_user` can create a connection to another local database without a password. For example, `test_user` can log into the `testdb` database and run this command to create a connection named `testconn` to the local `postgres` database.

   ```
   testdb=> SELECT dblink_connect_u('testconn', 'dbname=postgres user=test_user');
   ```

   > **Note** If a `user` is not specified, `dblink_connect_u()` uses the value of the `PGUSER` environment variable when WarehousePG was started. If `PGUSER` is not set, the default is the system user that started WarehousePG.

3. `test_user` can use the `dblink()` function to run a query using a `dblink` connection. For example, this command uses the `dblink` connection named `testconn` created in the previous step. `test_user` must have appropriate access to the table.

   ```
   testdb=> SELECT * FROM dblink('testconn', 'SELECT * FROM testdblink') AS dbltab(id int, product text);
   ```

Using dblink with SSL-Encrypted Connections to WarehousePG

When you use `dblink` to connect to WarehousePG over an encrypted connection, you must specify the `sslmode` property in the connection string. Set `sslmode` to at least `require` to disallow unencrypted transfers. For example:

```
testdb=# SELECT dblink_connect('greenplum_con_sales', 'dbname=sales host=gpcoordinator user=gpadmin sslmode=require');
```

Refer to SSL Client Authentication for information about configuring WarehousePG to use SSL.

Additional Module Documentation

Refer to the dblink PostgreSQL documentation for detailed information about the individual functions in this module.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.4.6 diskquota

The diskquota module allows WarehousePG administrators to limit the amount of disk space used by schemas, roles, or tablespaces in a database.

This topic includes the following sections:

- Installing and Registering the Module (First Use)
- About the diskquota Module
- Understanding How diskquota Monitors Disk Usage
- About the diskquota Functions and Views
- Configuring the diskquota Module
- Using the diskquota Module
- Known Issues and Limitations
- Notes
- Upgrading the Module
- Examples

Installing and Registering the Module (First Use)

The `diskquota` module is installed when you install WarehousePG.

Before you can use the module, you must perform these steps:

1. Create the `diskquota` database. The `diskquota` module uses this database to store the list of databases where the module is enabled.

   ```
   $ createdb diskquota;
   ```

2. Add the `diskquota` shared library to the WarehousePG `shared_preload_libraries` server configuration parameter and restart WarehousePG. Be sure to retain the previous setting of the configuration parameter. For example:

   ```
   $ gpconfig -s shared_preload_libraries
   Values on all segments are consistent
   GUC              : shared_preload_libraries
   Coordinator value: auto_explain
   Segment     value: auto_explain
   $ gpconfig -c shared_preload_libraries -v 'auto_explain,diskquota-2.2'
   $ gpstop -ar
   ```

3. Register the `diskquota` extension in each database in which you want to enforce disk usage quotas. You can register `diskquota` in up to ten databases.

   ```
   $ psql -d testdb -c "CREATE EXTENSION diskquota"
   ```

4. Run the `diskquota.init_table_size_table()` UDF in the database. In a database with many files, this can take some time. The `diskquota` module cannot be used until the initialization is complete.

   ```
   =# SELECT diskquota.init_table_size_table();
   ```

   > **Note** You must run the `diskquota.init_table_size_table()` UDF for `diskquota` to work.

About the diskquota Module

The disk usage for a table includes the table data, indexes, toast tables, and free space map. For append-optimized tables, the calculation includes the visibility map and index, and the block directory table.

The `diskquota` module allows a WarehousePG administrator to limit the amount of disk space used by tables in schemas or owned by roles in up to 50 databases. The administrator can also use the module to limit the amount of disk space used by schemas and roles on a per-tablespace basis, as well as to limit the disk space used per WarehousePG segment for a tablespace.

> **Note** A role-based disk quota cannot be set for the WarehousePG cluster owner (the user that creates the WarehousePG cluster).

You can set the following quotas with the `diskquota` module:

- A *schema disk quota* sets a limit on the disk space that can used by all tables in a database that reside in a specific schema. The disk usage of a schema is defined as the total of disk usage on all segments for all tables in the schema.
- A *role disk quota* sets a limit on the disk space that can be used by all tables in a database that are owned by a specific role. The disk usage for a role is defined as the total of disk usage on all segments for all tables the role owns. Although a role is a cluster-level database object, the disk usage for roles is calculated separately for each database.
- A *schema tablespace disk quota* sets a limit on the disk space that can used by all tables in a database that reside in a specific schema and tablespace.
- A *role tablespace disk quota* sets a limit on the disk space that can used by all tables in a database that are owned by a specific role and reside in a specific tablespace.
- A *per-segment tablespace disk quota* sets a limit on the disk space that can be used by a Greeplum Database segment when a tablespace quota is set for a schema or role.

Understanding How diskquota Monitors Disk Usage

A single `diskquota` launcher process runs on the active WarehousePG coordinator node. The diskquota launcher process creates and launches a diskquota worker process on the coordinator for each diskquota-enabled database. A worker process is responsible for monitoring the disk usage of tablespaces, schemas, and roles in the target database, and communicates with the WarehousePG segments to obtain the sizes of active tables. The worker process also performs quota enforcement, placing tablespaces, schemas, or roles on a denylist when they reach their quota.

When a query plan for a data-adding query is generated, and the tablespace, schema, or role into which data would be loaded is on the denylist, `diskquota` cancels the query before it starts executing, and reports an error message that the quota has been exceeded.

A query that does not add data, such as a simple `SELECT` query, is always allowed to run, even when the tablespace, role, or schema is on the denylist.

Diskquota can enforce both *soft limits* and *hard limits* for disk usage:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

- By default, `diskquota` always enforces soft limits. `diskquota` checks quotas before a query runs. If quotas are not exceeded when a query is initiated, `diskquota` allows the query to run, even if it were to eventually cause a quota to be exceeded.
- When hard limit enforcement of disk usage is enabled, `diskquota` also monitors disk usage during query execution. If a query exceeds a disk quota during execution, `diskquota` terminates the query.

  Administrators can enable enforcement of a disk usage hard limit by setting the `diskquota.hard_limit` server configuration parameter as described in Activating/Deactivating Hard Limit Disk Usage Enforcement.

There is some delay after a quota has been reached before the schema or role is added to the denylist. Other queries could add more data during the delay. The delay occurs because `diskquota` processes that calculate the disk space used by each table run periodically with a pause between executions (two seconds by default). The delay also occurs when disk usage falls beneath a quota, due to operations such as `DROP`, `TRUNCATE`, or `VACUUM FULL` that remove data. Administrators can change the amount of time between disk space checks by setting the `diskquota.naptime` server configuration parameter as described in Setting the Delay Between Disk Usage Updates.

Diskquota can operate in both *static* and *dynamic* modes:

- When the number of databases in which the `diskquota` extension is registered is less than or equal to the maximum number of `diskquota` worker processes, `diskquota` operates in static mode; it assigns a background worker (bgworker) process to monitor each database, and the bgworker process exits only when the `diskquota` extension is dropped from the database.
- When the number of databases in which the `diskquota` extension is registered is greater than the maximum number of `diskquota` worker processes, `diskquota` operates in dynamic mode. In dynamic mode, for every monitored database every `diskquota.naptime` seconds, `diskquota` creates a bgworker process to collect disk usage information for the database, and then stops the bgworker process immediately after data collection completes. In this mode, `diskquota` dynamically starts and stops bgworker processes as needed for all monitored databases.

  Administrators can change the maximum number of worker processes configured for `diskquota` by setting the `diskquota.max_workers` server configuration parameter as described in Specifying the Maximum Number of Active diskquota Worker Processes.

If a query is unable to run because the tablespace, schema, or role has been denylisted, an administrator can increase the exceeded quota to allow the query to run. The module provides views that you can use to find the tablespaces, schemas, or roles that have exceeded their limits.

About the diskquota Functions and Views

The `diskquota` module provides user-defined functions (UDFs) and views that you can use to manage and monitor disk space usage in your WarehousePG deployment.

The functions and views provided by the `diskquota` module are available in the WarehousePG schema named `diskquota`.

> **Note** You may be required to prepend the schema name (`diskquota.`) to any UDF or view that you access.

User-defined functions provided by the module include:

Function Signature	Description
void init_table_size_table()	Sizes the existing tables in the current database.
void set_role_quota(role_name text, quota text)	Sets a disk quota for a specific role in the current database. > **Note** A role-based disk quota cannot be set for the WarehousePG cluster owner.
void set_role_tablespace_quota(role_name text, tablespace_name text, quota text)	Sets a disk quota for a specific role and tablespace combination in the current database. > **Note** A role-based disk quota cannot be set for the WarehousePG cluster owner.
void set_schema_quota(schema_name text, quota text)	Sets a disk quota for a specific schema in the current database.
void set_schema_tablespace_quota(schema_name text, tablespace_name text, quota text)	Sets a disk quota for a specific schema and tablespace combination in the current database.
void set_per_segment_quota(tablespace_name text, ratio float4)	Sets a per-segment disk quota for a tablespace in the current database.
void pause()	Instructs the module to continue to count disk usage for the current database, but pause and cease emitting an error when the limit is exceeded.
void resume()	Instructs the module to resume emitting an error when the disk usage limit is exceeded in the current database.
status() RETURNS table	Displays the `diskquota` binary and schema versions and the status of soft and hard limit disk usage enforcement in the current database.

Views available in the `diskquota` module include:

View Name	Description
show_fast_database_size_view	Displays the disk space usage in the current database.
show_fast_role_quota_view	Lists active quotas for roles in the current database.
show_fast_role_tablespace_quota_view	List active quotas for roles per tablespace in the current database.
show_fast_schema_quota_view	Lists active quotas for schemas in the current database.
show_fast_schema_tablespace_quota_view	Lists active quotas for schemas per tablespace in the current database.
show_segment_ratio_quota_view	Displays the per-segment disk quota ratio for any per-segment tablespace quotas set in the current database.

Configuring the diskquota Module

`diskquota` exposes server configuration parameters that allow you to control certain module functionality:

- diskquota.naptime - Controls how frequently (in seconds) that `diskquota` recalculates the table sizes.
- diskquota.max_active_tables - Identifies the maximum number of relations (including tables, indexes, etc.) that the `diskquota` module can monitor at the same time.
- diskquota.hard_limit - Activates or deactivates the hard limit enforcement of disk usage.
- diskquota.max_workers - Specifies the maximum number of diskquota worker processes that may be running at any one time.
- diskquota.max_table_segments - Specifies the maximum number of *table segments* in the cluster.

You use the `gpconfig` command to set these parameters in the same way that you would set any WarehousePG server configuration parameter.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Setting the Delay Between Disk Usage Updates

The `diskquota.naptime` server configuration parameter specifies how frequently (in seconds) `diskquota` recalculates the table sizes. The smaller the `naptime` value, the less delay in detecting changes in disk usage. This example sets the `naptime` to ten seconds and restarts WarehousePG:

```
$ gpconfig -c diskquota.naptime -v 10
$ gpstop -ar
```

About Shared Memory and the Maximum Number of Relations

The `diskquota` module uses shared memory to save the denylist and to save the active table list.

The denylist shared memory can hold up to one million database objects that exceed the quota limit. If the denylist shared memory fills, data may be loaded into some schemas or roles after they have reached their quota limit.

Active table shared memory holds up to one million of active tables by default. Active tables are tables that may have changed sizes since `diskquota` last recalculated the table sizes. `diskquota` hook functions are called when the storage manager on each WarehousePG segment creates, extends, or truncates a table file. The hook functions store the identity of the file in shared memory so that its file size can be recalculated the next time the table size data is refreshed.

The `diskquota.max_active_tables` server configuration parameter identifies the maximum number of relations (including tables, indexes, etc.) that the `diskquota` module can monitor at the same time. The default value is `300 * 1024`. This value should be sufficient for most WarehousePG installations. Should you change the value of this configuration parameter, you must restart the WarehousePG server.

Activating/Deactivating Hard Limit Disk Usage Enforcement

When you enable enforcement of a hard limit of disk usage, `diskquota` checks the quota during query execution. If at any point a currently running query exceeds a quota limit, `diskquota` terminates the query.

By default, hard limit disk usage enforcement is deactivated for all databases. To activate hard limit enforcement for all databases, set the `diskquota.hard_limit` server configuration parameter to `'on'`, and then reload the WarehousePG configuration:

```
$ gpconfig -c diskquota.hard_limit -v 'on'
$ gpstop -u
```

Run the following query to view the hard limit enforcement setting:

```
SELECT * from diskquota.status();
```

Specifying the Maximum Number of Active diskquota Worker Processes

The `diskquota.max_workers` server configuration parameter specifies the maximum number of diskquota worker processes (not including the `diskquota` launcher process) that may be running at any one time. The default number of maximum worker processes is `10`, and the maximum value that you can specify is `20`.

You must set this parameter at WarehousePG server start time.

> **Note** Setting `diskquota.max_workers` to a value that is larger than `max_worker_processes` has no effect; `diskquota` workers are taken from the pool of worker processes established by that WarehousePG server configuration parameter setting.

Specifying the Maximum Number of Table Segments (Shards)

A WarehousePG table (including a partitioned table's child tables) is distributed to all segments as a shard. `diskquota` counts each table shard as a *table segment*. The `diskquota.max_table_segments` server configuration parameter identifies the maximum number of *table segments* in the WarehousePG cluster, which in turn can gate the maximum number of tables that `diskquota` can monitor.

The runtime value of `diskquota.max_table_segments` equals <max_number_tables> * ⌈ {<number_segments> + 1}/{100} ⌉ * 100. The default value is `10 * 1024 * 1024`.

Using the diskquota Module

You can perform the following tasks with the `diskquota` module:

- View the diskquota Status
- Pause and Resume Disk Quota Exceeded Notifications
- Set a Schema or Role Disk Quota
- Set a Tablespace Disk Quota for a Schema or Role
- Set a Per-Segment Tablespace Disk Quota
- Display Disk Quotas and Disk Usage
- Temporarily Deactivate Disk Quota Monitoring

Viewing the diskquota Status

To view the `diskquota` module and schema version numbers, and the state of soft and hard limit enforcement in the current database, invoke the `status()` command:

```
SELECT diskquota.status();
          name          | status
------------------------+---------
 soft limits            | on
 hard limits            | on
 current binary version | 2.0.1
 current schema version | 2.0
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Pausing and Resuming Disk Quota Exceeded Notifications

If you do not care to be notified of disk quota exceeded events for a period of time, you can pause and resume error notification in the current database as shown below:

```
SELECT diskquota.pause();
-- perform table operations where you do not care to be notified
-- when a disk quota exceeded
SELECT diskquota.resume();
```

> **Note** The pause operation does not persist through a WarehousePG cluster restart; you must invoke `diskquota.pause()` again when the cluster is back up and running.

Setting a Schema or Role Disk Quota

Use the `diskquota.set_schema_quota()` and `diskquota.set_role_quota()` user-defined functions in a database to set, update, or delete disk quota limits for schemas and roles in the database. The functions take two arguments: the schema or role name, and the quota to set. You can specify the quota in units of MB, GB, TB, or PB; for example, `'2TB'`.

The following example sets a 250GB quota for the `acct` schema:

```
SELECT diskquota.set_schema_quota('acct', '250GB');
```

This example sets a 500MB disk quota for the `nickd` role:

```
SELECT diskquota.set_role_quota('nickd', '500MB');
```

To change a quota, invoke the `diskquota.set_schema_quota()` or `diskquota.set_role_quota()` function again with the new quota value.

To remove a schema or role quota, set the quota value to `'-1'` and invoke the function.

Setting a Tablespace Disk Quota

Use the `diskquota.set_schema_tablespace_quota()` and `diskquota.set_role_tablespace_quota()` user-defined functions in a database to set, update, or delete per-tablespace disk quota limits for schemas and roles in the current database. The functions take three arguments: the schema or role name, the tablespace name, and the quota to set. You can specify the quota in units of MB, GB, TB, or PB; for example, `'2TB'`.

The following example sets a 50GB disk quota for the tablespace named `tspaced1` and the `acct` schema:

```
SELECT diskquota.set_schema_tablespace_quota('acct', 'tspaced1', '250GB');
```

This example sets a 500MB disk quota for the `tspaced2` tablespace and the `nickd` role:

```
SELECT diskquota.set_role_tablespace_quota('nickd', 'tspaced2', '500MB');
```

To change a quota, invoke the `diskquota.set_schema_tablespace_quota()` or `diskquota.set_role_tablespace_quota()` function again with the new quota value.

To remove a schema or role tablespace quota, set the quota value to `'-1'` and invoke the function.

Setting a Per-Segment Tablespace Disk Quota

When an administrator sets a tablespace quota for a schema or a role, they may also choose to define a per-segment disk quota for the tablespace. Setting a per-segment quota limits the amount of disk space on a single WarehousePG segment that a single tablespace may consume, and may help prevent a segment's disk from filling due to data skew.

You can use the `diskquota.set_per_segment_quota()` function to set, update, or delete a per-segment tablespace disk quota limit. The function takes two arguments: the tablespace name and a ratio. The ratio identifies how much more of the disk quota a single segment can use than the average segment quota. A ratio that you specify must be greater than zero.

You can calculate the average segment quota as follows:

```
avg_seg_quota = tablespace_quota / number_of_segments
```

For example, if your WarehousePG cluster has 8 segments and you set the following schema tablespace quota:

```
SELECT diskquota.set_schema_tablespace_quota( 'accts', 'tspaced1', '800GB' );
```

The average segment quota for the `tspaced1` tablespace is `800GB / 8 = 100GB`.

If you set the following per-segment tablespace quota:

```
SELECT diskquota.set_per_segment_quota( 'tspaced1', '2.0' );
```

You can calculate the maximum allowed disk usage per segment allowed as follows:

```
max_disk_usage_per_seg = average_segment_quota * ratio
```

In this example, the maximum disk usage allowed per segment is `100GB * 2.0 = 200GB`.

`diskquota` will allow a query to run if the disk usage on all segments for all tables that are in tablespace `tblspc1` and that are goverend by a role or schema quota does not exceed `200GB`.

You can change the per-segment tablespace quota by invoking the `diskquota.set_per_segment_quota()` function again with the new quota value.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

To remove a per-segment tablespace quota, set the quota value to `'-1'` and invoke the function.

To view the per-segment quota ratio set for a tablespace, display the `show_segment_ratio_quota_view` view. For example:

```
SELECT tablespace_name, per_seg_quota_ratio
  FROM diskquota.show_segment_ratio_quota_view WHERE tablespace_name in ('tspaced1');
  tablespace_name  | per_seg_quota_ratio
-------------------+---------------------
 tspaced1          |                   2
(1 rows)
```

Identifying the diskquota-Monitored Databases

Run the following SQL commands to obtain a list of the `diskquota` -monitored databases in your WarehousePG cluster:

```
\c diskquota
SELECT d.datname FROM diskquota_namespace.database_list q, pg_database
d
    WHERE q.dbid = d.oid ORDER BY
d.datname;
```

Displaying Disk Quotas and Disk Usage

The `diskquota` module provides four views to display active quotas and the current computed disk space used.

The `diskquota.show_fast_schema_quota_view` view lists active quotas for schemas in the current database. The `nspsize_in_bytes` column contains the calculated size for all tables that belong to the schema.

```
SELECT * FROM diskquota.show_fast_schema_quota_view;
 schema_name | schema_oid | quota_in_mb | nspsize_in_bytes
-------------+------------+-------------+------------------
 acct        |      16561 |      256000 |           131072
 analytics   |      16519 |  1073741824 |        144670720
 eng         |      16560 |     5242880 |        117833728
 public      |       2200 |         250 |          3014656
(4 rows)
```

The `diskquota.show_fast_role_quota_view` view lists the active quotas for roles in the current database. The `rolsize_in_bytes` column contains the calculated size for all tables that are owned by the role.

```
SELECT * FROM diskquota.show_fast_role_quota_view;
 role_name | role_oid | quota_in_mb | rolsize_in_bytes
-----------+----------+-------------+------------------
 mdach     |    16558 |         500 |           131072
 adam      |    16557 |         300 |        117833728
 nickd     |    16577 |         500 |        144670720
(3 rows)
```

You can view the per-tablespace disk quotas for schemas and roles with the `diskquota.show_fast_schema_tablespace_quota_view` and `diskquota.show_fast_role_tablespace_quota_view` views. For example:

```
SELECT schema_name, tablespace_name, quota_in_mb, nspsize_tablespace_in_bytes
   FROM diskquota.show_fast_schema_tablespace_quota_view
   WHERE schema_name = 'acct' and tablespace_name ='tblspc1';
 schema_name | tablespace_name | quota_in_mb | nspsize_tablespace_in_bytes
-------------+-----------------+-------------+-----------------------------
 acct        | tspaced1        |      250000 |                      131072
(1 row)
```

About Temporarily Deactivating diskquota

You can temporarily deactivate the `diskquota` module by removing the shared library from `shared_preload_libraries` . For example::

```
$ gpconfig -s shared_preload_libraries
Values on all segments are consistent
GUC              : shared_preload_libraries
Coordinator value: auto_explain,diskquota-2.0
Segment     value: auto_explain,diskquota-2.0
$ gpconfig -c shared_preload_libraries -v 'auto_explain'
$ gpstop -ar
```

> **Note** When you deactivate the `diskquota` module in this manner, disk quota monitoring ceases. To re-initiate disk quota monitoring in this scenario, you must:

1. Re-add the library to `shared_preload_libraries` .
2. Restart WarehousePG.
3. Re-size the existing tables in the database by running: `SELECT diskquota.init_table_size_table();`
4. Restart WarehousePG again.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Known Issues and Limitations

The `diskquota` module has the following limitations and known issues:

- `diskquota` does not automatically work on a segment when the segment is replaced by a mirror. You must manually restart WarehousePG in this circumstance.
- `diskquota` cannot enforce a hard limit on `ALTER TABLE ADD COLUMN DEFAULT` operations.
- If WarehousePG restarts due to a crash, you must run `SELECT diskquota.init_table_size_table();` to ensure that the disk usage statistics are accurate.
- To avoid the chance of deadlock, you must first pause the `diskquota` extension before you drop the extension in any database:

  ```
  SELECT diskquota.pause();
  DROP EXTENSION diskquota;
  ```

- `diskquota` may record an incorrect table size after `ALTER TABLESPACE`, `TRUNCATE`, or other operations that modify the `relfilenode` of the table.

  Cause: `diskquota` does not acquire any locks on a relation when computing the table size. If another session is updating the table's tablespace while `diskquota` is calculating the table size, an error can occur.

  In most cases, you can ignore the difference; `diskquota` will update the size when new data is next ingested. To immediately ensure that the disk usage statistics are accurate, invoke:

  ```
  SELECT diskquota.init_table_size_table();
  ```

  And then restart WarehousePG.

- In rare cases, a `VACUUM FULL` operation may exceed a quota limit. To remedy the situation, pause `diskquota` before the operation and then resume `diskquota` after:

  ```
  SELECT diskquota.pause();
  -- perform the VACUUM FULL
  SELECT diskquota.resume();
  ```

  If you do not want to pause/resume `diskquota`, you may choose to temporarily set a higher quota for the operation and then set it back when the `VACUUM FULL` completes. Consider the following:

  - If you `VACUUM FULL` only a single table, set the quota to be no smaller than the size of that table.
  - If you `VACUUM FULL` all tables, set the quota to be no smaller than the size of the largest table in the database.

- The size of uncommitted tables are not counted in quota views. Even though the `diskquota.show_fast_role_quota_view` view may display a smaller used quota than the quota limit, a new query may trigger a quota exceeded condition in the following circumstance:

  - Hard limit enforcement of disk usage is deactivated.
  - A long-running query in a session has consumed the full disk quota. `diskquota` does update the denylist in this scenario, but the `diskquota.show_fast_role_quota_view` may not represent the actual used quota because the long-running query is not yet committed. If you execute a new query while the original is still running, the new query will trigger a quota exceeded error.

- When `diskquota` is operating in *static mode*, it may fail to monitor some databases when `diskquota.max_workers` is greater than the available number of bgworker processes. In *dynamic mode*, `diskquota` works correctly when there is at least one available bgworker process.

Notes

The `diskquota` module can detect a newly created table inside of an uncommitted transaction. The size of the new table is included in the disk usage calculated for the corresponding schema or role. Hard limit enforcement of disk usage must enabled for a quota-exceeding operation to trigger a `quota exceeded` error in this scenario.

Deleting rows or running `VACUUM` on a table does not release disk space, so these operations cannot alone remove a schema or role from the `diskquota` denylist. The disk space used by a table can be reduced by running `VACUUM FULL` or `TRUNCATE TABLE`.

The `diskquota` module supports high availability features provided by the background worker framework. The `diskquota` launcher process only runs on the active coordinator node. The postmaster on the standby coordinator does not start the `diskquota` launcher process when it is in standby mode. When the coordinator is down and the administrator runs thegpactivatestandby command, the standby coordinator changes its role to coordinator and the `diskquota` launcher process is forked automatically. Using the `diskquota` -enabled database list in the `diskquota` database, the `diskquota` launcher creates the `diskquota` worker processes that manage disk quotas for each database.

When you expand the WarehousePG cluster, each table consumes more table segments, which may then reduce the maximum number of tables that `diskquota` can support. If you encounter the following warning, try increasing the `diskquota.max_table_segments` value, and then restart WarehousePG:

```
[diskquota] the number of tables exceeds the limit, please increase the GUC value for diskquota.max_table_segments.
```

Upgrading the Module to Version 2.x

The `diskquota` 2.2 module is installed when you install or upgrade WarehousePG. Versions 1.x, 2.0.x, and 2.1.x of the module will continue to work after you upgrade WarehousePG.

> **Note** `diskquota` will be paused during the upgrade procedure and will be automatically resumed when the upgrade completes.

Perform the following procedure to upgrade the `diskquota` module:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

1. Replace the `diskquota-<n>` shared library in the WarehousePG `shared_preload_libraries` server configuration parameter setting and restart WarehousePG. Be sure to retain the other libraries. For example:

```
$ gpconfig -s shared_preload_libraries
Values on all segments are consistent
GUC              : shared_preload_libraries
Coordinator value: auto_explain,diskquota-2.1
Segment     value: auto_explain,diskquota-2.1

$ gpconfig -c shared_preload_libraries -v 'auto_explain,diskquota-2.2'
$ gpstop -ar
```

2. Update the `diskquota` extension in every database in which you registered the module:

```
$ psql -d testdb -c "ALTER EXTENSION diskquota UPDATE TO '2.2'";
```

3. Restart WarehousePG:

```
$ gpstop -ar
```

After upgrade, your existing disk quota rules continue to be enforced, and you can define new tablespace or per-segment rules. You can also utilize the new pause/resume disk quota enforcement functions.

Examples

Setting a Schema Quota

This example demonstrates how to configure a schema quota and then observe `diskquota` soft limit behavior as data is added to the schema. The example assumes that the `diskquota` processes are configured and running.

1. Create a database named `testdb` and connect to it.

```
$ createdb testdb
$ psql -d testdb
```

2. Create the diskquota extension in the database.

```
CREATE EXTENSION diskquota;
```

3. Create a schema named `s1`:

```
CREATE SCHEMA s1;
```

4. Set a 1MB disk quota for the `s1` schema.

```
SELECT diskquota.set_schema_quota('s1', '1MB');
```

5. Run the following commands to create a table in the `s1` schema and insert a small amount of data into it. The schema has no data yet, so it is not on the denylist.

```
SET search_path TO s1;
CREATE TABLE a(i int);
INSERT INTO a SELECT generate_series(1,100);
```

6. Insert a large amount of data, enough to exceed the 1MB quota that was set for the schema. Before the `INSERT` command, the `s1` schema is still not on the denylist, so this command should be allowed to run with only soft limit disk usage enforcement in effect, even though the operation will exceed the limit set for the schema.

```
INSERT INTO a SELECT generate_series(1,10000000);
```

7. Attempt to insert a small amount of data. Because the previous command exceeded the schema's disk quota soft limit, the schema should be denylisted and any data loading command should be cancelled.

```
INSERT INTO a SELECT generate_series(1,100);
ERROR:  schema's disk space quota exceeded with name: s1
```

8. Remove the quota from the `s1` schema by setting it to `-1` and again inserts a small amount of data. A 5-second sleep before the `INSERT` command ensures that the `diskquota` table size data is updated before the command is run.

```
SELECT diskquota.set_schema_quota('s1', '-1');
-- Wait for 5 seconds to ensure that the denylist is updated
SELECT pg_sleep(5);
INSERT INTO a SELECT generate_series(1,100);
```

Enabling Hard Limit Disk Usage Enforcement and Exceeding Quota

In this example, we enable hard limit enforcement of disk usage, and re-run commands from the previous example.

1. Enable hard limit disk usage enforcement:

```
$ gpconfig -c diskquota.hard_limit -v 'on'
$ gpstop -u
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

2. Run the following query to view the hard limit enforcement setting:

```
SELECT * from diskquota.status();
```

3. Re-set a 1MB disk quota for the `s1` schema.

```
SELECT diskquota.set_schema_quota('s1', '1MB');
```

4. Insert a large amount of data, enough to exceed the 1MB quota that was set for the schema. Before the `INSERT` command, the `s1` schema is still not on the denylist, so this command should be allowed to start. When the operation exceeds the schema quota, `diskquota` will terminate the query.

```
INSERT INTO a SELECT generate_series(1,10000000);
[hardlimit] schema's disk space quota exceeded
```

5. Remove the quota from the `s1` schema:

```
SELECT diskquota.set_schema_quota('s1', '-1');
```

Setting a Per-Segment Tablespace Quota

This example demonstrates how to configure tablespace and per-segment tablespace quotas. In addition to using the `testdb` database and the `s1` schema that you created in the previous example, this example assumes the following:

- Hard limit enforcement of disk usage is enabled (as in the previous example).
- The WarehousePG cluster has 8 primary segments.
- A tablespace named `tbsp1` has been created in the cluster.

Procedure:

1. Set a disk quota of `1 MB` for the tablespace named `tbsp1` and the schema named `s1`:

```
SELECT diskquota.set_schema_tablespace_quota('s1', 'tbsp1', '1MB');
```

2. Set a per-segment ratio of `2` for the `tbsp1` tablespace:

```
SELECT diskquota.set_per_segment_quota('tbsp1', 2);
```

   With this ratio setting, the average segment quota is `1MB / 8 = 125KB`, and the max per-segment disk usage for the tablespace is `125KB * 2 = 250KB`.

3. Create a new table named `b` and insert some data:

```
CREATE TABLE b(i int);
INSERT INTO b SELECT generate_series(1,100);
```

4. Insert a large amount of data into the table, enough to exceed the 250KB per-segment quota that was set for the tablespace. When the operation exceeds the per-segment tablespace quota, `diskquota` will terminate the query.

```
INSERT INTO b SELECT generate_series(1,10000000);
ERROR:  tablespace: tbsp1, schema: s1 diskquota exceeded per segment quota
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.4.7 fuzzystrmatch

The `fuzzystrmatch` module provides functions to determine similarities and distance between strings based on various algorithms.

The WarehousePG `fuzzystrmatch` module is equivalent to the PostgreSQL `fuzzystrmatch` module. There are no WarehousePG or MPP-specific considerations for the module.

Installing and Registering the Module

The `fuzzystrmatch` module is installed when you install WarehousePG. Before you can use any of the functions defined in the module, you must register the `fuzzystrmatch` extension in each database in which you want to use the functions. Refer to Installing Extensions for more information.

Module Documentation

See fuzzystrmatch in the PostgreSQL documentation for detailed information about the individual functions in this module.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.4.8 gp_exttable_fdw

The `gp_exttable_fdw` module is a built-in foreign-data wrapper that converts an external table to a foreign table.

Refer to Understanding the External Table to Foreign Table Mapping for more information about the conversion and runtime implications.

> **Important** Do not register nor directly use the `gp_exttable_fdw` module.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.4.9 gp_legacy_string_agg

The `gp_legacy_string_agg` module re-introduces the single-argument `string_agg()` function that was present in WarehousePG 5.

The `gp_legacy_string_agg` module is a WarehousePG extension.

> **Note** Use this module to aid migration from WarehousePG 5 to the native, two-argument `string_agg()` function included in WarehousePG 6.

Installing and Registering the Module

The `gp_legacy_string_agg` module is installed when you install WarehousePG. Before you can use the function defined in the module, you must register the `gp_legacy_string_agg` extension in each database where you want to use the function. Refer to Installing Extensions for more information about registering the module.

Using the Module

The single-argument `string_agg()` function has the following signature:

```
string_agg( text )
```

You can use the function to concatenate non-null input values into a string. For example:

```
SELECT string_agg(a) FROM (VALUES('aaaa'),('bbbb'),('cccc'),(NULL)) g(a);
WARNING:  Deprecated call to string_agg(text), use string_agg(text, text) instead
  string_agg
--------------
 aaaabbbbcccc
(1 row)
```

The function concatenates each string value until it encounters a null value, and then returns the string. The function returns a null value when no rows are selected in the query.

`string_agg()` produces results that depend on the ordering of the input rows. The ordering is unspecified by default; you can control the ordering by specifying an `ORDER BY` clause within the aggregate. For example:

```
CREATE TABLE table1(a int, b text);
INSERT INTO table1 VALUES(4, 'aaaa'),(2, 'bbbb'),(1, 'cccc'), (3, NULL);
SELECT string_agg(b ORDER BY a) FROM table1;
WARNING:  Deprecated call to string_agg(text), use string_agg(text, text) instead
  string_agg
--------------
 ccccbbbb
(1 row)
```

Migrating to the Two-Argument string_agg() Function

WarehousePG 6 includes a native, two-argument, text input `string_agg()` function:

```
string_agg( text, text )
```

The following function invocation is equivalent to the single-argument `string_agg()` function that is provided in this module:

```
string_agg( text, '' )
```

You can use this conversion when you are ready to migrate from this contrib module.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.4.10 gp_sparse_vector

The `gp_sparse_vector` module implements a WarehousePG data type and associated functions that use compressed storage of zeros to make vector computations on floating point numbers faster.

The `gp_sparse_vector` module is a WarehousePG extension.

Installing and Registering the Module

The `gp_sparse_vector` module is installed when you install WarehousePG. Before you can use any of the functions defined in the module, you must register the `gp_sparse_vector` extension in each database where you want to use the functions. Refer to Installing Extensions for more information.

Using the gp_sparse_vector Module

When you use arrays of floating point numbers for various calculations, you will often have long runs of zeros. This is common in scientific, retail optimization, and text processing applications. Each floating point number takes 8 bytes of storage in memory and/or disk. Saving those zeros is often impractical. There are also many computations that benefit from skipping over the zeros.

For example, suppose the following array of `double` s is stored as a `float8[]` in WarehousePG:

```
'{0, 33, <40,000 zeros>, 12, 22 }'::float8[]
```

This type of array arises often in text processing, where a dictionary may have 40-100K terms and the number of words in a particular document is stored in a vector. This array would occupy slightly more than 320KB of memory/disk, most of it zeros. Any operation that you perform on this data works on 40,001 fields that are not important.

The WarehousePG built-in `array` datatype utilizes a bitmap for null values, but it is a poor choice for this use case because it is not optimized for `float8[]` or for long runs of zeros instead of nulls, and the bitmap is not run-length-encoding- (RLE) compressed. Even if each zero were stored as a `NULL` in the array, the bitmap for nulls would use 5KB to mark the nulls, which is not nearly as efficient as it could be.

The WarehousePG `gp_sparse_vector` module defines a data type and a simple RLE-based scheme that is biased toward being efficient for zero value bitmaps. This scheme uses only 6 bytes for bitmap storage.

> **Note** The sparse vector data type defined by the `gp_sparse_vector` module is named `svec` . `svec` supports only `float8` vector values.

You can construct an `svec` directly from a float array as follows:

```
SELECT ('{0, 13, 37, 53, 0, 71 }'::float8[])::svec;
```

The `gp_sparse_vector` module supports the vector operators `<` , `>` , `*` , `**` , `/` , `=` , `+` , `sum()` , `vec_count_nonzero()` , and so on. These operators take advantage of the efficient sparse storage format, making computations on `svec` s faster.

The plus (`+`) operator adds each of the terms of two vectors of the same dimension together. For example, if vector `a = {0,1,5}` and vector `b = {4,3,2}` , you would compute the vector addition as follows:

```
SELECT ('{0,1,5}'::float8[]::svec + '{4,3,2}'::float8[]::svec)::float8[];
 float8
---------
 {4,4,7}
```

A vector dot product (`%*%`) between vectors `a` and `b` returns a scalar result of type `float8` . Compute the dot product (`(0*4+1*3+5*2)=13`) as follows:

```
SELECT '{0,1,5}'::float8[]::svec %*% '{4,3,2}'::float8[]::svec;
 ?column?
----------
       13
```

Special vector aggregate functions are also useful. `sum()` is self explanatory. `vec_count_nonzero()` evaluates the count of non-zero terms found in a set of `svec` and returns an `svec` with the counts. For instance, for the set of vectors `{0,1,5},{10,0,3},{0,0,3},{0,1,0}` , the count of non-zero terms would be `{1,2,3}` . Use `vec_count_nonzero()` to compute the count of these vectors:

```
CREATE TABLE listvecs( a svec );

INSERT INTO listvecs VALUES ('{0,1,5}'::float8[]),
    ('{10,0,3}'::float8[]),
    ('{0,0,3}'::float8[]),
    ('{0,1,0}'::float8[]);

SELECT vec_count_nonzero( a )::float8[] FROM listvecs;
 count_vec
-----------
 {1,2,3}
(1 row)
```

Additional Module Documentation

Refer to the `gp_sparse_vector` README s in the WarehousePG github repository for additional information about this module.

Apache MADlib includes an extended implementation of sparse vectors. See the MADlib Documentation for a description of this MADlib module.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Example

A text classification example that describes a dictionary and some documents follows. You will create WarehousePG tables representing a dictionary and some documents. You then perform document classification using vector arithmetic on word counts and proportions of dictionary words in each document.

Suppose that you have a dictionary composed of words in a text array. Create a table to store the dictionary data and insert some data (words) into the table. For example:

```
CREATE TABLE features (dictionary text[][]) DISTRIBUTED RANDOMLY;
INSERT INTO features
    VALUES ('{am,before,being,bothered,corpus,document,i,in,is,me,never,now,'
            'one,really,second,the,third,this,until}');
```

You have a set of documents, also defined as an array of words. Create a table to represent the documents and insert some data into the table:

```
CREATE TABLE documents(docnum int, document text[]) DISTRIBUTED RANDOMLY;
INSERT INTO documents VALUES
    (1,'{this,is,one,document,in,the,corpus}'),
    (2,'{i,am,the,second,document,in,the,corpus}'),
    (3,'{being,third,never,really,bothered,me,until,now}'),
    (4,'{the,document,before,me,is,the,third,document}');
```

Using the dictionary and document tables, find the dictionary words that are present in each document. To do this, you first prepare a *Sparse Feature Vector*, or SFV, for each document. An SFV is a vector of dimension *N*, where *N* is the number of dictionary words, and each SFV contains a count of each dictionary word in the document.

You can use the `gp_extract_feature_histogram()` function to create an SFV from a document. `gp_extract_feature_histogram()` outputs an `svec` for each document that contains the count of each of the dictionary words in the ordinal positions of the dictionary.

```
SELECT gp_extract_feature_histogram(
    (SELECT dictionary FROM features LIMIT 1), document)::float8[], document
        FROM documents ORDER BY docnum;

     gp_extract_feature_histogram        |                    document
-----------------------------------------+-----------------------------------------------
 {0,0,0,0,1,1,0,1,1,0,0,0,1,0,0,1,0,1,0} | {this,is,one,document,in,the,corpus}
 {1,0,0,0,1,1,1,1,0,0,0,0,0,0,1,2,0,0,0} | {i,am,the,second,document,in,the,corpus}
 {0,0,1,1,0,0,0,0,0,1,1,1,0,1,0,0,1,0,1} | {being,third,never,really,bothered,me,until,now}
 {0,1,0,0,0,2,0,0,1,1,0,0,0,0,0,2,1,0,0} | {the,document,before,me,is,the,third,document}

SELECT * FROM features;
                                          dictionary
-----------------------------------------------------------------------------------------------
 {am,before,being,bothered,corpus,document,i,in,is,me,never,now,one,really,second,the,third,this,until}
```

The SFV of the second document, "i am the second document in the corpus", is `{1,3*0,1,1,1,1,6*0,1,2}`. The word "am" is the first ordinate in the dictionary, and there is `1` instance of it in the SFV. The word "before" has no instances in the document, so its value is `0`; and so on.

`gp_extract_feature_histogram()` is very speed optimized - it is a single routine version of a hash join that processes large numbers of documents into their SFVs in parallel at the highest possible speeds.

For the next part of the processing, generate a sparse vector of the dictionary dimension (19). The vectors that you generate for each document are referred to as the *corpus*.

```
CREATE table corpus (docnum int, feature_vector svec) DISTRIBUTED RANDOMLY;

INSERT INTO corpus
    (SELECT docnum,
        gp_extract_feature_histogram(
            (select dictionary FROM features LIMIT 1), document) from documents);
```

Count the number of times each feature occurs at least once in all documents:

```
SELECT (vec_count_nonzero(feature_vector))::float8[] AS count_in_document FROM corpus;

           count_in_document
-----------------------------------------
 {1,1,1,1,2,3,1,2,2,2,1,1,1,1,1,3,2,1,1}
```

Count all occurrences of each term in all documents:

```
SELECT (sum(feature_vector))::float8[] AS sum_in_document FROM corpus;

            sum_in_document
-----------------------------------------
 {1,1,1,1,2,4,1,2,2,2,1,1,1,1,1,5,2,1,1}
```

The remainder of the classification process is vector math. The count is turned into a weight that reflects *Term Frequency / Inverse Document Frequency* (tf/idf). The calculation for a given term in a given document is:

```
#_times_term_appears_in_this_doc * log( #_docs / #_docs_the_term_appears_in )
```

`#_docs` is the total number of documents (4 in this case). Note that there is one divisor for each dictionary word and its value is the number of times that word appears in the document.

For example, the term "document" in document 1 would have a weight of `1 * log( 4/3 )`. In document 4, the term would have a weight of `2 * log( 4/3 )`. Terms that appear in every document would have weight `0`.

This single vector for the whole corpus is then scalar product multiplied by each document SFV to produce the tf/idf.

Calculate the tf/idf:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
SELECT docnum, (feature_vector*logidf)::float8[] AS tf_idf
    FROM (SELECT log(count(feature_vector)/vec_count_nonzero(feature_vector)) AS logidf FROM corpus)
    AS foo, corpus ORDER BY docnum;
 docnum |                                                
```

7.4.11 hstore

The `hstore` module implements a data type for storing sets of (key,value) pairs within a single WarehousePG data field. This can be useful in various scenarios, such as rows with many attributes that are rarely examined, or semi-structured data.

The WarehousePG `hstore` module is equivalent to the PostgreSQL `hstore` module. There are no WarehousePG or MPP-specific considerations for the module.

Installing and Registering the Module

The `hstore` module is installed when you install WarehousePG. Before you can use any of the data types or functions defined in the module, you must register the `hstore` extension in each database in which you want to use the objects. Refer to Installing Extensions for more information.

Module Documentation

See hstore in the PostgreSQL documentation for detailed information about the data types and functions defined in this module.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.4.12 ip4r

The `ip4r` module provides IPv4 and IPv6 data types, IPv4 and IPv6 range index data types, and related functions and operators.

The WarehousePG `ip4r` module is equivalent to version 2.4.2 of the `ip4r` module used with PostgreSQL. There are no WarehousePG or MPP-specific considerations for the module.

Installing and Registering the Module

The `ip4r` module is installed when you install WarehousePG. Before you can use any of the data types defined in the module, you must register the `ip4r` extension in each database in which you want to use the types:

```
CREATE EXTENSION ip4r;
```

Refer to Installing Extensions for more information.

Module Documentation

Refer to the ip4r github documentation for detailed information about using the module.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.4.13 ltree

The `ltree` module implements a data type named `ltree` that you can use to represent labels of data stored in a hierarchical tree-like structure. The module also provides extensive facilities for searching through label trees.

The WarehousePG `ltree` module is based on the `ltree` module used with PostgreSQL. The WarehousePG version of the module differs as described in theWarehousePG Considerations topic.

Installing and Registering the Module

The `ltree` module is installed when you install WarehousePG. Before you can use any of the data types, functions, or operators defined in the module, you must register the `ltree` extension in each database in which you want to use the objects:

```
CREATE EXTENSION ltree;
```

Refer to Installing Extensions for more information.

Module Documentation

Refer to the ltree PostgreSQL documentation for detailed information about the data types, functions, and operators defined in this module.

WarehousePG Considerations

Because this extension does not provide a hash operator class, columns defined with the data type `ltree` can not be used as the distribution key for a WarehousePG table.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.4.14 orafce

The `orafce` module provides Oracle Compatibility SQL functions in WarehousePG. These functions target PostgreSQL but can also be used in WarehousePG.

The WarehousePG `orafce` module is a modified version of the open source Orafce PostgreSQL module extension. The modified `orafce` source files for WarehousePG can be found in the `gpcontrib/orafce` directory in the WarehousePG open source project. The source reflects the Orafce 3.6.1 release and additional commits to 3af70a28f6.

There are some restrictions and limitations when you use the module in WarehousePG.

Installing and Registering the Module

> **Note** Always use the Oracle Compatibility Functions module included with your WarehousePG version. Before upgrading to a new WarehousePG version, uninstall the compatibility functions from each of your databases, and then, when the upgrade is complete, reinstall the compatibility functions from the new WarehousePG release. See the WarehousePG release notes for upgrade prerequisites and procedures.

The `orafce` module is installed when you install WarehousePG. Before you can use any of the functions defined in the module, you must register the `orafce` extension in each database in which you want to use the functions. Refer to Installing Extensions for more information.

WarehousePG Considerations

The following functions are available by default in WarehousePG and do not require installing the Oracle Compatibility Functions:

- sinh()
- tanh()
- cosh()
- decode() (See WarehousePG Implementation Differences for more information.)

WarehousePG Implementation Differences

There are differences in the implementation of the compatibility functions in WarehousePG from the original PostgreSQL `orafce` module extension implementation. Some of the differences are as follows:

- The original `orafce` module implementation performs a decimal round off, the WarehousePG implementation does not:
  - 2.00 becomes 2 in the original module implementation
  - 2.00 remains 2.00 in the WarehousePG implementation
- The provided Oracle compatibility functions handle implicit type conversions differently. For example, using the `decode` function:

  ```
  decode(<expression>, <value>, <return> [,<value>, <return>]...
              [, default])
  ```

  The original `orafce` module implementation automatically converts expression and each value to the data type of the first value before comparing. It automatically converts return to the same data type as the first result.

  The WarehousePG implementation restricts return and `default` to be of the same data type. The expression and value can be different types if the data type of value can be converted into the data type of the expression. This is done implicitly. Otherwise, `decode` fails with an `invalid input syntax` error. For example:

  ```
  SELECT decode('a','M',true,false);
  CASE
  ------
   f
  (1 row)
  SELECT decode(1,'M',true,false);
  ERROR: Invalid input syntax for integer:*"M"
  *LINE 1: SELECT decode(1,'M',true,false);
  ```

- Numbers in `bigint` format are displayed in scientific notation in the original `orafce` module implementation but not in the WarehousePG implementation:
  - 9223372036854775 displays as 9.2234E+15 in the original implementation
  - 9223372036854775 remains 9223372036854775 in the WarehousePG implementation
- The default date and timestamp format in the original `orafce` module implementation is different than the default format in the WarehousePG implementation. If the following code is run:

  ```
  CREATE TABLE TEST(date1 date, time1 timestamp, time2
                    timestamp with time zone);
  INSERT INTO TEST VALUES ('2001-11-11','2001-12-13
                   01:51:15','2001-12-13 01:51:15 -08:00');
  SELECT DECODE(date1, '2001-11-11', '2001-01-01') FROM TEST;
  ```

  The WarehousePG implementation returns the row, but the original implementation returns no rows.

  > **Note** The correct syntax when using the original `orafce` implementation to return the row is:

  ```
  SELECT DECODE(to_char(date1, 'YYYY-MM-DD'), '2001-11-11',
               '2001-01-01') FROM TEST
  ```

- The functions in the Oracle Compatibility Functions `dbms_alert` package are not implemented for WarehousePG.
- The `decode()` function is removed from the WarehousePG Oracle Compatibility Functions. The WarehousePG parser internally converts a `decode()` function call to a `CASE` statement.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Using orafce

Some Oracle Compatibility Functions reside in the `oracle` schema. To access them, set the search path for the database to include the `oracle` schema name. For example, this command sets the default search path for a database to include the `oracle` schema:

```
ALTER DATABASE <db_name> SET <search_path> = "$user", public, oracle;
```

Note the following differences when using the Oracle Compatibility Functions with PostgreSQL vs. using them with WarehousePG:

- If you use validation scripts, the output may not be exactly the same as with the original `orafce` module implementation.
- The functions in the Oracle Compatibility Functions `dbms_pipe` package run only on the WarehousePG coordinator host.
- The upgrade scripts in the Orafce project do not work with WarehousePG.

Additional Module Documentation

Refer to the README and WarehousePG orafce documentation in the WarehousePG github repository for detailed information about the individual functions and supporting objects provided in this module.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.4.15 pageinspect

The `pageinspect` module provides functions for low level inspection of the contents of database pages. `pageinspect` is available only to WarehousePG superusers.

The WarehousePG `pageinspect` module is based on the PostgreSQL `pageinspect` module. The WarehousePG version of the module differs as described in the WarehousePG Considerations topic.

Installing and Registering the Module

The `pageinspect` module is installed when you install WarehousePG. Before you can use any of the functions defined in the module, you must register the `pageinspect` extension in each database in which you want to use the functions:

```
CREATE EXTENSION pageinspect;
```

Refer to Installing Extensions for more information.

Upgrading the Module

If you are currently using `pageinspect` in your WarehousePG installation and you want to access newly-released module functionality, you must update the `pageinspect` extension in every database in which it is currently registered:

```
ALTER EXTENSION pageinspect UPDATE;
```

Module Documentation

See pageinspect in the PostgreSQL documentation for detailed information about the majority of functions in this module.

The next topic includes documentation for WarehousePG-added `pageinspect` functions.

WarehousePG Considerations

When using this module with WarehousePG, consider the following:

- The WarehousePG version of the `pageinspect` does not allow inspection of pages belonging to append-optimized or external relations.
- For `pageinspect` functions that read data from a database, the function reads data only from the segment instance where the function is run. For example, the `get_raw_page()` function returns a `block number out of range` error when you try to read data from a user-defined table on the WarehousePG coordinator because there is no data in the table on the coordinator segment. The function will read data from a system catalog table on the coordinator segment.

WarehousePG-Added Functions

In addition to the functions specified in the PostgreSQL documentation, WarehousePG provides these additional `pageinspect` functions for inspecting bitmap index pages:

Function Name	Description
bm_metap(relname text) returns record	Returns information about a bitmap index's meta page.
bm_bitmap_page_header(relname text, blkno int) returns record	Returns the header information for a bitmap page; this corresponds to the opaque section from the page header.
bm_lov_page_items(relname text, blkno int) returns setof record	Returns the list of value (LOV) items present in a bitmap LOV page.
bm_bitmap_page_items(relname text, blkno int) returns setof record	Returns the content words and their compression statuses for a bitmap page.
bm_bitmap_page_items(page bytea) returns setof record	Returns the content words and their compression statuses for a page image obtained by `get_raw_page()`.

Examples

WarehousePG-added `pageinspect` function usage examples follow.

Obtain information about the meta page of the bitmap index named `i1`:

```
testdb=# SELECT * FROM bm_metap('i1');
   magic    | version | auxrelid | auxindexrelid | lovlastblknum
------------+---------+----------+---------------+---------------
 1112101965 |       2 |   169980 |        169982 |             1
(1 row)
```

Display the header information for the second block of the bitmap index named `i1`:

```
testdb=# SELECT * FROM bm_bitmap_page_header('i1', 2);
 num_words | next_blkno | last_tid
-----------+------------+----------
 3         | 4294967295 | 65536
(1 row)
```

Display the LOV items located in the first block of the bitmap index named `i1`:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
testdb=# SELECT * FROM bm_lov_page_items('i1', 1) ORDER BY itemoffset;
 itemoffset | lov_head_blkno | lov_tail_blkno | last_complete_word      | last_word               | last_tid | last_setbit_tid | is_last_complete_word_fill |
is_last_word_fill
------------+----------------+----------------+-------------------------+-------------------------+----------+-----------------+----------------------------+-------
-------
 1          | 4294967295     | 4294967295     | ff ff ff ff ff ff ff ff | 00 00 00 00 00 00 00 00 | 0        | 0               | f                          | f
 2          | 2              | 2              | 80 00 00 00 00 00 00 01 | 00 00 00 00 07 ff ff ff | 65600    | 65627           | t                          | f
 3          | 3              | 3              | 80 00 00 00 00 00 00 02 | 00 3f ff ff ff ff ff ff | 131200   | 131254          | t                          | f
(3 rows)
```

Return the content words located in the second block of the bitmap index named `i1`:

```
testdb=# SELECT * FROM bm_bitmap_page_items('i1', 2) ORDER BY word_num;
 word_num | compressed | content_word
----------+------------+-------------------------
 0        | t          | 80 00 00 00 00 00 00 0e
 1        | f          | 00 00 00 00 00 00 1f ff
 2        | t          | 00 00 00 00 00 00 03 f1
(3 rows)
```

Alternatively, return the content words located in the heap page image of the same bitmap index and block:

```
testdb=# SELECT * FROM bm_bitmap_page_items(get_raw_page('i1', 2)) ORDER BY word_num;
 word_num | compressed | content_word
----------+------------+-------------------------
 0        | t          | 80 00 00 00 00 00 00 0e
 1        | f          | 00 00 00 00 00 00 1f ff
 2        | t          | 00 00 00 00 00 00 03 f1
(3 rows)
```

7.4.16 pg_buffercache

The `pg_buffercache` module provides five views for obtaining cluster-wide shared buffer metrics:

- `gp_buffercache`
- `gp_buffercache_summary`
- `gp_buffercache_usage_counts`
- `gp_buffercache_summary_aggregated`
- `gp_buffercache_usage_counts_aggregated`

The `gp_buffercache` view is a cluster-wide view that displays the `pg_buffercache` information from the coordinator and every primary segment for each buffer in the shared cache.

The `gp_buffercache_summary` view is a cluster-wide view that displays the `pg_buffercache_summary` information from the coordinator and each primary segment, summarized as one row per segment. Similar and more detailed information is provided by `gp_buffercache`, but `gp_buffercache_summary` is significantly better performance-wise.

The `gp_buffercache_usage_counts` view is a cluster-wide view that displays the `pg_puffercache_usage_counts` information from the coordinator and each primary segment returning summarized states of all shared buffers, aggregated over the possible usage count values. Similar and more detailed information is provided by `gp_buffercache`, but `gp_buffercache_usage_counts` is significantly better performance-wise.

The `gp_buffercache_summary_aggregated` view returns a single row with the aggregated output of `gp_buffercache_summary`.

The `gp_buffercache_usage_counts_aggregated` view returns a single row with the aggregated output of `gp_buffercache_usage_counts`.

Installing and Registering the Module

The `pg_buffercache` module is installed when you install WarehousePG. Before you can use any of the functions defined in the module, you must register the `pg_buffercache` extension in each database in which you want to use the functions:

```
CREATE EXTENSION pg_buffercache;
```

Refer to Installing Extensions for more information.

Module Documentation

See pg_buffercache in the PostgreSQL documentation for detailed information about the individual functions in this module.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.4.17 pg_cron

The `pg_cron` module is a cron-based job scheduler that runs inside the database.

Installing and Registering the Module

The `pg_cron` module is installed when you install WarehousePG. Before you can use it, you must perform the following steps:

You can only install the `pg_cron` module in one database per WarehousePG cluster. First, set the database where you want `pg_cron` to create its metadata tables, by default it uses the `postgres` database. In order to change it, run the following command and restart WarehousePG:

```
gpconfig -c cron.database_name -v 'db_name' --skipvalidation
```

Enable the extension as a preloaded library. First, check if there are any preloaded shared libraries by running the `gpconfig` command. The following example shows that the `auto_explain` libraries are already enabled for the cluster:

```
gpconfig -s shared_preload_libraries
Values on all segments are consistent
GUC              : shared_preload_libraries
Coordinator value: auto_explain
Segment     value: auto_explain
```

Use the output of the above command to enable the `pg_cron` module, along any other shared libraries, and restart WarehousePG:

```
gpconfig -c shared_preload_libraries -v 'auto_explain,pg_cron'
gpstop -ar
```

Register the `pg_cron` extension in the desired database. You can only install `pg_cron` in one database per cluster.

```
CREATE EXTENSION pg_cron;
```

Optionally, grant usage to specific users:

```
GRANT USAGE ON SCHEMA cron TO user1;
```

Refer to Installing Extensions for more information.

Upgrading the Module

The `pg_cron` module is installed when you install or upgrade WarehousePG. A previous version of the extension will continue to work in existing databases after you upgrade WarehousePG. To upgrade to the most recent version of the extension, you must:

```
ALTER EXTENSION pg_cron UPDATE TO '1.6.2';
```

Using the pg_cron Module

Use the user-defined functions (UDFs) under the `cron` schema to schedule cron jobs in your default database. For example, configure a job that deletes old database data every Saturday at 3:30am (GMT):

```
SELECT cron.schedule('30 3 * * 6', $$DELETE FROM events WHERE event_time < now() - interval '1 week'$$);
 schedule
----------
       42
```

Optionally, you may update the database column for the job that you just created so that it runs in another database within your WarehousePG cluster. Run the following command as a user with the superuser role:

```
UPDATE cron.job SET database = 'database1' WHERE jobid = 106;
SELECT cron.reload_job();
```

You may use the UDF `cron.schedule_in_database()` to schedule jobs in multiple databases. Below are the function arguments:

```
cron.schedule_in_database(job_name text,
schedule text,
command text,
database text,
username text default null,
active boolean default 'true')
```

For example, run `VACUUM` every Sunday at 4:00am (GMT) in a database other than the one `pg_cron` is installed on:

```
SELECT cron.schedule_in_database('weekly-vacuum', '0 4 * * 0', 'VACUUM', 'some_other_database');
 schedule
----------
       44
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

> **Important** Since the `TRIGGER` statement is not supported in WarehousePG, if a user runs an `UPDATE` or `INSERT` statement, or manually deletes any of the cron jobs instead of using the UDFs in the `cron` schema, you must run the following UDF to update the `pg_cron` cache:
>
> ```
> SELECT cron.reload_job();
> ```

> **Note** The server configuration parameter `cron.use_background_workers` is not supported on WarehousePG 6.

Module Documentation

Refer to the pg_cron github documentation for more information about using the module.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.4.18 pg_stat_statements

`pg_stat_statements` is a core PostgreSQL module that provides a means to track planning and execution statistics of all SQL statements executed by the server.

In WarehousePG (WHPG) distributed architecture, query execution is parallelized across the coordinator and multiple segments. The WHPG implementation of this module provides cluster-wide visibility, collecting performance metrics from every segment node. This allows administrators to analyze buffer usage, I/O operations, and execution patterns across the entire distributed cluster rather than just the coordinator.

By extending standard functionality into the parallel execution layer, `pg_stat_statements` enables:

- Comprehensive distributed tracking across all query executors.
- Unified visibility through specialized system views for both raw and aggregated data.
- Centralized management for resetting performance metrics across the entire cluster simultaneously.

Loading the module

`pg_stat_statements` is shipped with WarehousePG 7.4 and later. You must load the extension as a shared library before you can use it within your databases.

1. Load the extension as a shared library before you can use it within your databases. Check for existing shared libraries:

   ```
   gpconfig -s
   shared_preload_libraries
   ```

2. Use the output of the previous command to enable `pg_stat_statements1, along any other shared libraries, and restart WHPG:

   ```
   gpconfig -c shared_preload_libraries -v '<other_libraries>,
   pg_stat_statements'
   gpstop -ar
   ```

3. Create the extension in your database:

   ```
   CREATE EXTENSION
   pg_stat_statements;
   ```

Analyzing performance with distributed views

The statistics gathered by the module are made available via two specialized views:

whpg_stat_statements

This view displays raw statistics from the coordinator and all segments in a single table.

```
SELECT * FROM
whpg_stat_statements;
```

Column	Type	Description
`gp_segment_id`	`integer`	Segment identifier: `-1` for the coordinator, `0...N-1` for segments.
`userid`	`oid`	OID of the user who executed the statement.
`dbid`	`oid`	OID of the database in which the statement was executed.
`queryid`	`bigint`	Internal hash code computed from the statement's parse tree.
`query`	`text`	Normalized representative query text.
`plans`	`bigint`	Number of times the statement was planned.
`total_plan_time`	`double precision`	Total time spent planning the statement (milliseconds).
`calls`	`bigint`	Number of times the statement was executed.
`total_exec_time`	`double precision`	Total time spent executing the statement (milliseconds).
`rows`	`bigint`	Total number of rows retrieved or affected by the statement.
`shared_blks_hit`	`bigint`	Total number of shared block cache hits.
`shared_blks_read`	`bigint`	Total number of shared blocks read from disk.
`shared_blks_dirtied`	`bigint`	Total number of shared blocks dirtied.
`shared_blks_written`	`bigint`	Total number of shared blocks written to disk.
`local_blks_hit`	`bigint`	Total number of local block cache hits.
`local_blks_read`	`bigint`	Total number of local blocks read from disk.
`temp_blks_read`	`bigint`	Total number of temporary blocks read from disk.
`temp_blks_written`	`bigint`	Total number of temporary blocks written to disk.
`blk_read_time`	`double precision`	Total time spent reading blocks (if `track_io_timing` is enabled).
`blk_write_time`	`double precision`	Total time spent writing blocks (if `track_io_timing` is enabled).
`wal_records`	`bigint`	Total number of WAL records generated by the statement.
`wal_bytes`	`numeric`	Total number of WAL bytes generated by the statement.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

whpg_stat_statements_aggregated

This view provides a unified summary of total resource consumption per query across the entire cluster.

```
SELECT * FROM whpg_stat_statements_aggregated;
```

Column	Type	Description
`userid`	`oid`	OID of the user.
`dbid`	`oid`	OID of the database.
`queryid`	`bigint`	Internal hash code.
`query`	`text`	Normalized representative query text.
`calls`	`bigint`	Total number of executions.
`total_time`	`double precision`	Total time spent executing.
`min_time`	`double precision`	Minimum time spent executing.
`max_time`	`double precision`	Maximum time spent executing.
`mean_time`	`double precision`	Mean time spent executing.
`stddev_time`	`double precision`	Population standard deviation of execution time.
`rows`	`bigint`	Total rows retrieved/affected.
`shared_blks_hit`	`bigint`	Total shared block cache hits.
`shared_blks_read`	`bigint`	Total shared blocks read from disk.
`shared_blks_dirtied`	`bigint`	Total shared blocks dirtied.
`shared_blks_written`	`bigint`	Total shared blocks written to disk.
`local_blks_hit`	`bigint`	Total local block cache hits.
`local_blks_read`	`bigint`	Total local blocks read from disk.
`local_blks_dirtied`	`bigint`	Total local blocks dirtied.
`local_blks_written`	`bigint`	Total local blocks written to disk.
`temp_blks_read`	`bigint`	Total temporary blocks read from disk.
`temp_blks_written`	`bigint`	Total temporary blocks written to disk.
`blk_read_time`	`double precision`	Total block read time.
`blk_write_time`	`double precision`	Total block write time.

To provide a consolidated view of cluster performance, the metrics in this view are processed as follows:

- Buffer and I/O statistics (`shared_blks_*` , `local_blks_*` , `temp_blks_*` , `blk_*_time`) are summed across all nodes to show total cluster effort.
- Timing statistics (`total_time` , `min_time` , `max_time` , `mean_time`) reflect the values recorded at the coordinator level, representing the actual duration experienced by the user.

Managing statistics globally

The `pg_stat_statements` module includes functions to manage and clear gathered performance data.

whpg_stat_statements_reset

Resets all collected statistics on the coordinator and all segments simultaneously.

```
-- Global reset for all users and
databases
SELECT
whpg_stat_statements_reset();

-- Targeted reset for specific user, database, or
query
SELECT whpg_stat_statements_reset(userid, dbid,
queryid);
```

Parameter	Type	Description
`p_userid`	`Oid`	Reset entries for a specific user (use `0` for all users).
`p_dbid`	`Oid`	Reset entries for a specific database (use `0` for all databases).
`p_queryid`	`bigint`	Reset a specific query signature (use `0` for all queries).

> **Note**
>
> This function requires superuser privileges.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Examples

View per-segment buffer usage

Check if specific segments are performing significantly more physical reads than others, which often indicates poor data distribution.

```
SELECT

gp_segment_id,
    query,
    shared_blks_read,

shared_blks_hit,
    blk_read_time
FROM whpg_stat_statements
WHERE query LIKE '%my_table%'
ORDER BY
gp_segment_id;
```

Get aggregated statistics

Identify queries consuming the most total I/O time summed across the entire cluster.

```
SELECT
    query,

calls,
    rows,

shared_blks_hit,
    blk_read_time + blk_write_time AS
total_io_time_ms
FROM
whpg_stat_statements_aggregated
ORDER BY total_io_time_ms
DESC
LIMIT 10;
```

Reset statistics before benchmarking

To ensure accurate results for a new workload, reset all cluster statistics first.

```
-- 1. Clear cluster-wide
history
SELECT
whpg_stat_statements_reset();

-- 2. Run
workload
-- [Queries]

-- 3. Analyze aggregated cluster costs
SELECT * FROM whpg_stat_statements_aggregated;
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.4.19 pg_trgm

The `pg_trgm` module provides functions and operators for determining the similarity of alphanumeric text based on trigram matching. The module also provides index operator classes that support fast searching for similar strings.

The WarehousePG `pg_trgm` module is equivalent to the PostgreSQL `pg_trgm` module. There are no WarehousePG or MPP-specific considerations for the module.

Installing and Registering the Module

The `pg_trgm` module is installed when you install WarehousePG. Before you can use any of the functions defined in the module, you must register the `pg_trgm` extension in each database in which you want to use the functions:

```
CREATE EXTENSION pg_trgm;
```

Refer to Installing Extensions for more information.

Module Documentation

See pg_trgm in the PostgreSQL documentation for detailed information about the individual functions in this module.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.4.20 pgcrypto

WarehousePG is installed with an optional module of encryption/decryption functions called `pgcrypto`. The `pgcrypto` functions allow database administrators to store certain columns of data in encrypted form. This adds an extra layer of protection for sensitive data, as data stored in WarehousePG in encrypted form cannot be read by anyone who does not have the encryption key, nor can it be read directly from the disks.

> **Note** The `pgcrypto` functions run inside the database server, which means that all the data and passwords move between `pgcrypto` and the client application in clear-text. For optimal security, consider also using SSL connections between the client and the WarehousePG coordinator server.

Installing and Registering the Module

The `pgcrypto` module is installed when you install WarehousePG. Before you can use any of the functions defined in the module, you must register the `pgcrypto` extension in each database in which you want to use the functions. Refer to Installing Extensions for more information.

Configuring FIPS Encryption

Starting with WarehousePG 6.22, the `pgcrypto` extension provides a module-specific configuration parameter, `pgcrypto.fips`. This parameter configures WarehousePG support for a limited set of FIPS encryption functionality (*Federal Information Processing Standard* (FIPS) 140-2). For information about FIPS, see https://www.nist.gov/itl/popular-links/federal-information-processing-standards-fips. The default setting is `off`, FIPS encryption is not enabled.

Before enabling this parameter, ensure that FIPS is enabled on all WarehousePG cluster hosts.

When this parameter is enabled, these changes occur:

- FIPS mode is initialized in the OpenSSL library
- The functions `digest()` and `hmac()` allow only the SHA encryption algorithm (MD5 is not allowed)
- The functions for the crypt and gen_salt algorithms are disabled
- PGP encryption and decryption functions support only AES and 3DES encryption algorithms (other algorithms such as blowfish are not allowed)
- RAW encryption and decryption functions support only AES and 3DES (other algorithms such as blowfish are not allowed)

To enable `pgcrypto.fips`

1. Enable the `pgcrypto` functions as an extension if it is not enabled. See Installing Extensions. This example `psql` command creates the `pgcrypto` extension in the database `testdb`.

   ```
   psql -d testdb -c 'CREATE EXTENSION pgcrypto'
   ```

2. Configure the WarehousePG server configuration parameter `shared_preload_libraries` to load the `pgcrypto` library. This example uses the `gpconfig` utility to update the parameter in the WarehousePG `postgresql.conf` files.

   ```
   gpconfig -c shared_preload_libraries -v '$libdir/pgcrypto'
   ```

   This command displays the value of `shared_preload_libraries`.

   ```
   gpconfig -s shared_preload_libraries
   ```

3. Restart the WarehousePG cluster.

   ```
   gpstop -ra
   ```

4. Set the `pgcrypto.fips` server configuration parameter to `on` for each database that uses FIPS encryption. For example, these commands set the parameter to `on` for the database `testdb`.

   ```
   psql -d postgres
   ```

   ```
   ALTER DATABASE testdb SET pgcrypto.fips TO on;
   ```

   > **Important** You must use the `ALTER DATABASE` command to set the parameter. You cannot use the `SET` command that updates the parameter for a session, or use the `gpconfig` utility that updates `postgresql.conf` files.

5. After setting the parameter, reconnect to the database to enable encryption support for a session. This example uses the `psql` meta command `\c` to connect to the `testdb` database.

   ```
   \c testdb
   ```

To disable `pgcrypto.fips`

1. If the database does not use `pgcrypto` functions, disable the `pgcrypto` extension. This example `psql` command drops the `pgcrypto` extension in the database `testdb`.

   ```
   psql -d testdb -c 'DROP EXTENSION pgcrypto'
   ```

2. Remove `\$libdir/pgcrypto` from the `shared_preload_libraries` parameter, and restart WarehousePG. This `gpconfig` command displays the value of the parameter from the WarehousePG `postgresql.conf` files.

   ```
   gpconfig -s shared_preload_libraries
   ```

   Use the `gpconfig` utility with the `-c` and `-v` options to change the value of the parameter. Use the `-r` option to remove the parameter.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

3. Restart the WarehousePG cluster.

```
gpstop -ra
```

Additional Module Documentation

Refer to pgcrypto in the PostgreSQL documentation for more information about the individual functions in this module.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.4.21 postgresml

PostgresML is a machine learning extension for PostgreSQL that enables you to perform training and inference on text and tabular data using SQL queries. With PostgresML, you can seamlessly integrate machine learning models into your WarehousePG and harness the power of cutting-edge algorithms to process data efficiently.

The `postgresml` module provides PostgresML functions for using tens of thousands of pre-trained open source AI/machine learning models in WarehousePG. The models are provided by theHugging Face AI data science platform.

Before Registering the `postgresml` Module

Before registering the `postgresml` module, you must install the Data Science bundle for Python3.11, add the `pgml` library to the set of libraries the WarehousePG server loads at startup, and set the Python virtual environment:

1. Install the Data Science bundle for Python 3.11.
2. Add the `postgresml` library to preload when the WarehousePG server starts, using the `shared_preload_libraries` server configuration parameter and then restart the cluster.

   For example:

   ```
   gpconfig -c shared_preload_libraries -v 'xxx, pgml'
   ```

   where xxx represents any existing preloaded libraries.
3. Set the Python virtual environment.

   At the session level:

   ```
   SET pgml.venv='$GPHOME/ext/DataSciencePython3.11';
   ```

   To last beyond a session:

   ```
   gpconfig -c pgml.venv -v '$GPHOME/ext/DataSciencePython3.11'
   gpstop -u
   ```

> **Note** If this yields the error message, `[CRITICAL]:-not a valid GUC: pgml.venv` it means you failed to run Step 2, including restarting the cluster, beforehand.

Proceed to the next section to register the `postgresml` module.

Registering the Module

The `postgresml` module is installed when you install WarehousePG. Before you can use any of the data types, functions, or operators defined in the module, you must register the `postgresml` extension in each database in which you want to use the objects:

```
CREATE EXTENSION pgml;
```

Refer to Installing Extensions for more information.

Upgrading the Module

The `PostgresML` module is installed when you install or upgrade WarehousePG. A previous version of the extension will continue to work in existing databases after you upgrade WarehousePG. To upgrade to the most recent version of the extension, you must:

```
ALTER EXTENSION pgml UPDATE TO '2.7.13+greenplum.1.0.0';
```

in **every** database in which you registered/use the extension.

User-Defined Functions

The `postgresml` extension currently supports just a subset of all of the user-defined functions provided by PostgresML. They are these three:

- `pgml.load_dataset()` : Loads a dataset into tables in WarehousePG using the `INSERT` SQL command. Read more about loading data here.
- `pgml.embed()` - Generates an embedding for the dataset. Read more about PostgresML embeddings here.
- `pgml.transform()` : Applies a pre-trained transformer to process data. Read more about PostgresML pre-trained models here.
- `pgml.train()` : Handles different training tasks which are configurable with the function parameters. Read more about supervised learning here.
- `pgml.predict()` : Provides online predictions using the best, automatically deployed model for a project. Read more about supervised learning here.

additional PostgresML functions may be available in the future based on demand

pgml.load_dataset()

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Syntax

```
pgml.load_dataset(
    source TEXT,
    subset TEXT,
    limit bigint,
    kwargs JSONB
)
```

where:

`source` is the name of the data source. `subset` is a subset of the data source. The default is `NULL`. `limit` is a user-defined limit on the number of imported rows. The default is `NULL`. `kwargs` is a a JSONB object containing optional arguments. The default is an empty object (`{}`).

pgml.embed()

Syntax

```
pgml.embed(
    transformer TEXT,
    inputs TEXT or TEXT[],
    kwargs JSONB
)
```

where:

- `transformer` is the huggingface sentence-transformer name.
- `inputs` are the text(s) to embed. It can be a single text string or an array of texts.
- `kwargs` is a JSONB object containing optional arguments.

pgml.transform()

Syntax

```
pgml.transform(
    task TEXT or JSONB,
    call JSONB,
    inputs TEXT[] or BYTEA[]
)
```

where:

- `task` is the task name passed as either a simple text string or, for a more complex task setup, a JSONB object containing a full pipeline and initializer arguments.
- `call` is a JSONB object containing call arguments passed alongside the `inputs` values.
- `inputs` is a `TEXT[]` or `BYTEA[]` array containing inputs for inference.

> **Note** You must explicitly specify a model when calling `pgml.transform()`; default models are not yet supported.

pgml.train()

Syntax

```
pgml.train(
    project_name TEXT,
    task TEXT DEFAULT NULL,
    relation_name TEXT DEFAULT NULL,
    y_column_name TEXT DEFAULT NULL,
    algorithm TEXT DEFAULT 'linear',
    hyperparams JSONB DEFAULT '{}'::JSONB,
    search TEXT DEFAULT NULL,
    search_params JSONB DEFAULT '{}'::JSONB,
    search_args JSONB DEFAULT '{}'::JSONB,
    test_size REAL DEFAULT 0.25,
    test_sampling TEXT DEFAULT 'random',
    preprocess JSONB DEFAULT '{}'::JSONB
)
```

where

- `project_name` is an easily recognizable identifier to organize your work.
- `task` is the objective of the experiment: `regression`, `classification`, or `cluster`.
- `relation_name` is the Postgres table or view where the training data is stored or defined.
- `y_column_name` is the name of the label column in the training table.
- `algorithm` is the algorithm to train on the dataset, the available algorithms are `regression`, `classification`, and `clustering`.
- `hyperparams` are the hyperparameters to pass to the algorithm for training, JSON formatted.
- `search` indicates, if set, whether or not PostgresML performs a hyperparameter search to find the best hyperparameters for the algorithm.
- `search_params` are the search parameters used in the `hyperparameter` search, using the scikit-learn notation, JSON formatted.
- `search_args` are the configuration parameters for the `search`, JSON formatted. Currently only `n_iter` is supported for `random` search.
- `test_size` is the fraction of the dataset to use for the test set and algorithm validation.
- `test_sampling` is the algorithm used to fetch test data from the dataset: `random`, `first`, or `last`.
- `preprocess` are the preprocessing steps to impute NULLS, encode categoricals and scale inputs.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

For more information about the available algorithms, hyperparameter search, and data pre-processing, visit the officialPostgresML Documentation.

pgml.predict()

Syntax

```
select pgml.predict (
    project_name TEXT,
    features REAL[]
)
```

where

- `project_name` is the project name used to train models in pgml.train().
- `features` is an aggregate of feature vectors used to predict novel data points

Examples

The following example:

1. Downloads a dataset from the internet and creates a table to contain the data.
2. Generates an embedding for the text.
3. Downloads and runs pre-trained models.

```
# Download the dataset from the internet and create table for it

SELECT pgml.load_dataset('tweet_eval', 'sentiment');

# Generate an embedding for the text

SELECT pgml.embed('distilbert-base-uncased', 'Star Wars christmas special is on Disney')::vector AS embedding;
-----------------------------------------------------------------------------------------------

SELECT text, pgml.embed('distilbert-base-uncased', text)

FROM pgml.tweet_eval limit 5;

-----------------------------------------------------------------------------------------------

CREATE TABLE tweet_embeddings AS

SELECT text, pgml.embed('distilbert-base-uncased', text) AS embedding

FROM pgml.tweet_eval limit 5;

# Download and run pre-trained models

SELECT pgml.transform(
    'translation_en_to_fr',
    inputs => ARRAY[
        'Welcome to the future!',
        'Where have you been all this time?'
    ]
) AS french;
```

The following example:

1. Obtains training data.
2. Trains a model.
3. Performs a prediction.

```
# Obtain training data from a dataset

SELECT * FROM pgml.load_dataset('digits');
SELECT target, image
FROM pgml.digits LIMIT 5;

# Train a model using an algorithm using the default linear algorithm

SELECT * FROM pgml.train(
'Handwritten Digit Image Classifier',
'classification',
'pgml.digits',
'target'
);

# Predict

SELECT
target,
pgml.predict('Handwritten Digit Image Classifier', image) AS prediction
FROM pgml.digits
LIMIT 10;
```

7.4.22 postgres_fdw

The `postgres_fdw` module is a foreign-data wrapper (FDW) that you can use to access data stored in a remote PostgreSQL or WarehousePG.

The WarehousePG `postgres_fdw` module is a modified version of the PostgreSQL `postgres_fdw` module. The module behaves as described in the PostgreSQL postgres_fdw documentation when you use it to access a single remote PostgreSQL database. The WarehousePG `postgres_fdw` module also includes enhancements that allow you to access multiple remote PostgreSQL servers from a single foreign table.

> **Note** There are some restrictions and limitations when you use this foreign-data wrapper module, described below.

Installing and Registering the Module

The `postgres_fdw` module is installed when you install WarehousePG. Before you can use the foreign-data wrapper, you must register the `postgres_fdw` extension in each database in which you want to use the foreign-data wrapper. Refer to Installing Extensions for more information.

Using postgres_fdw to Access Multiple Remote PostgreSQL Servers

Before you create a foreign table using the `postgres_fdw` foreign-data wrapper, you must configure a server with the CREATE SERVER command. You can use a `postgres_fdw` foreign table to access data that is distributed across multiple remote PostgreSQL servers when you set certain WarehousePG and `postgres_fdw` -specific options on the `CREATE SERVER` command:

Option Name	Description	Value
mpp_execute	WarehousePG option that identifies the host(s) from which `postgres_fdw` reads or writes data.	Set to `'all segments'`, which, when specified for `postgres_fdw`, translates to all remote PostgreSQL servers specified in `multi_hosts`.
num_segments[1]	WarehousePG option that identifies the number of query executors that WarehousePG spawns on the source WarehousePG cluster.	Set to the number of remote PostgreSQL servers. If this option is not set, defaults to the number of segments in the local WarehousePG cluster.
multi_hosts	Space-separated list of remote PostgreSQL server host names.	You must specify exactly `num_segments` number of hosts in the list.
multi_ports	Space-separated list of port numbers for the PostgreSQL servers.	You must specify exactly one port number for each host specified in `multi_hosts`, in order.

[1] The WarehousePG query optimizer (GPORCA) can plan and optimize queries only when `num_segments` is equal to the number of segments in the local WarehousePG cluster. When `num_segments` is any other value, a query always falls back to the Postgres-based planner.

Setting these options instructs `postgres_fdw` to treat a foreign table that you create that specifes this `SERVER` as a *distributed* foreign table. That is, a foreign table whose underlying data is stored on multiple remote PostgreSQL servers. `postgres_fdw` directs a query on such a foreign table to each PostgreSQL server specified in `multi_hosts`.

An example `CREATE SERVER` command that configures access to PostgreSQL servers running on `pghost1` and `pghost2` follows:

```
CREATE SERVER
dist_pgserver
  FOREIGN DATA WRAPPER postgres_fdw
OPTIONS (multi_hosts 'pghost1 pghost2', multi_ports '5432 5555', num_segments '2', mpp_execute 'all
segments');
```

About Aggregate Pushdown Support

`postgres_fdw` supports partial aggregate pushdown for a *distributed* query under the following conditions:

- The aggregate contains no `DISTINCT` or `ORDER BY` clauses.
- The aggregate does not contain `HAVING` clause.
- The aggregate function is not `array_agg()`.
- The query contains no `LIMIT` or `JOIN` clauses.

> **Note** `postgres_fdw` does not support partial aggregate pushdown when the WarehousePG query optimizer (GPORCA) is enabled for a query.

About Limit Pushdown Support

`postgres_fdw` supports limit pushdown for a *distributed* query under the following conditions:

- The query contains no `OFFSET` clause.
- The query contains no aggregates.

Distributed postgres_fdw Limitations

When you use the foreign-data wrapper to access multiple remote PostgreSQL servers, WarehousePG `postgres_fdw` has the following limitations:

- You must set the `gp_enable_minmax_optimization` server configuration parameter to `off` to enable partial aggregate pushdown.
- `INSERT`, `UPDATE`, and `DELETE` operations on distributed foreign tables are not supported.
- `IMPORT FOREIGN SCHEMA` is not supported.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

WarehousePG Limitations

When you use the foreign-data wrapper to access WarehousePG, `postgres_fdw` has the following limitations:

- The `ctid` is not guaranteed to uniquely identify the physical location of a row within its table. For example, the following statements may return incorrect results when the foreign table references a WarehousePG table:

```
INSERT INTO rem1(f2) VALUES ('test') RETURNING ctid;
SELECT * FROM ft1, t1 WHERE t1.ctid = '(0,2)';
```

- `postgres_fdw` does not support local or remote triggers when you use it to access a foreign table that references a WarehousePG table.
- `UPDATE` or `DELETE` operations on a foreign table that references a WarehousePG table are not guaranteed to work correctly.

Additional Module Documentation

For more information about using foreign tables in WarehousePG, seeAccessing External Data with Foreign Tables.

For detailed information about this module, refer to the postgres_fdw PostgreSQL documentation.

The `postgres_fdw` foreign-data wrapper is included in the WarehousePG open source github repository. You can view the source code for the module which is located in the `contrib/` directory.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.4.23 postgresql-hll

The `postgresql-hll` module provides native HyperLogLog data types and relation functions, operators, and aggregates.

The WarehousePG `postgresql-hll` module is equivalent to version 2.16 of the `postgresql-hll` used with PostgreSQL. There are no WarehousePG or MPP-specific considerations for the module.

Installing and Registering the Module

The `postgresql-hll` module is installed when you install WarehousePG. Before you can use the data types defined in the module, you must register the `hll` extension in each database in which you want to use the types:

```
CREATE EXTENSION hll;
```

Refer to Installing Extensions for more information.

Module Documentation

Refer to the postgresql-hll github documentation for detailed information about using the module.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.4.24 sslinfo

The `sslinfo` module provides information about the SSL certificate that the current client provided when connecting to WarehousePG. Most functions in this module return NULL if the current connection does not use SSL.

The WarehousePG `sslinfo` module is equivalent to the PostgreSQL `sslinfo` module. There are no WarehousePG or MPP-specific considerations for the module.

Installing and Registering the Module

The `sslinfo` module is installed when you install WarehousePG. Before you can use any of the functions defined in the module, you must register the `sslinfo` extension in each database in which you want to use the functions. Refer to Installing Extensions for more information.

Module Documentation

See sslinfo in the PostgreSQL documentation for detailed information about the individual functions in this module.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.4.25 tablefunc

The `tablefunc` module provides various functions that return tables (that is, multiple rows).

The WarehousePG `tablefunc` module is equivalent to the PostgreSQL `tablefunc` module. There are no WarehousePG or MPP-specific considerations for the module.

Installing and Registering the Module

The `tablefunc` module is installed when you install WarehousePG. Before you can use any of the functions defined in the module, you must register the `tablefunc` extension in each database in which you want to use the functions:

```
CREATE EXTENSION tablefunc;
```

Module Documentation

See tablefunc in the PostgreSQL documentation for detailed information about the individual functions in this module.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.4.26 timestamp9

The `timestamp9` module provides an efficient, nanosecond-precision timestamp data type and related functions and operators.

The WarehousePG `timestamp9` module is based on version 1.2.0 of the `timestamp9` module used with PostgreSQL.

Installing and Registering the Module

The `timestamp9` module is installed when you install WarehousePG. Before you can use the data type defined in the module, you must register the `timestamp9` extension in each database in which you want to use the type:

```
CREATE EXTENSION timestamp9;
```

Refer to Installing Extensions for more information.

Supported Data Types

The WarehousePG `timestamp9` extension supports three kinds of datatatypes: `TIMESTAMP9`, `TIMESTAMP9_LTZ` and `TIMESTAMP9_NTZ`. (The `TIMESTAMP9_LTZ` data type is an alias for `TIMESTAMP9` data type.)

The following table summarizes key information about the `timestamp9` data types:

Data Type	Storage Size	Description	Max Value	Min Value	Resolution
`TIMESTAMP9`	8 bytes	Like TIMESTAMP9_LTZ. Timestamp with local time zone.	2261-12-31 23:59:59.999999999 +0000	1700-01-01 00:00:00.000000000 +0000	1 nanosecond
`TIMESTAMP9_LTZ`	8 bytes	Timestamp with local time zone.	2261-12-31 23:59:59.999999999 +0000	1700-01-01 00:00:00.000000000 +0000	1 nanosecond
`TIMESTAMP9_NTZ`	8 bytes	Timestamp without time zone.	2261-12-31 23:59:59.999999999 +0000	1700-01-01 00:00:00.000000000 +0000	1 nanosecond

More about `TIMESTAMP9`

The `TIMESTAMP9` data type is identical to the `TIMESTAMP9_LTZ` data type. Please see the next section for details.

More about `TIMESTAMP9_LTZ`

`LTZ` is an abbreviation for "Local Time Zone." WarehousePG stores `TIMESTAMP9_LTZ` internally in UTC (Universal Coordinated Time, traditionally known as Greenwich Mean Time or GMT) time. An input value that has an explicit time zone specified is converted to UTC using the appropriate offset for that time zone.

If no time zone is specified in the input string, then it is presumed to be in the time zone indicated by the system's `TIMEZONE` server configuration parameter and is converted to UTC using the offset for the time zone.

See TIMESTAMP9_LTZ Examples for examples using this data type.

More about `TIIMESTAMP9_NTZ`

`NTZ` is an abbreviation of 'No Time Zone.' WarehousePG stores UTC time internally without considering any time zone information. If a time zone is embedded in the timestamp string, WarehousePG will simply ignore it.

See TIMESTAMP9_NTZ Examples for examples using this data type.

Supported Type Conversions

The following table summarizes the `timestamp9` module's supported type conversions.

From	To	Description
`BIGINT`	`TIMESTAMP9_LTZ`	WarehousePG treats the `BIGINT` value as the number of nanoseconds started from '1970-01-01 00:00:00 +0000'.
`DATE`	`TIMESTAMP9_LTZ`	WarehousePG treats the `DATE` value as in the current session time zone. This behavior is identical to converting from from `DATE` to `TIMESTAMPTZ`.
`TIMESTAMP WITHOUT TIME ZONE/TIMESTAMP`	`TIMESTAMP9_LTZ`	WarehousePG treats the `TIMESTAMP` value as in the current session time zone. This behavior is identical to converting from `TIMESTAMP` to `TIMESTAMPTZ`.
`TIMESTAMP WITH TIME ZONE/TIMESTAMPTZ`	`TIMESTAMP9_LTZ`	For this conversion, WarehousePG only extends the fractional part to nanosecond precision.
`TIMESTAMP9_LTZ`	`BIGINT`	The result of this conversion is the nanoseconds since '1970-01-01 00:00:00.000000000 +0000' to the given `TIMESTAMP9_LTZ` value. If the given `TIMESTAMP9_LTZ` value is before '1970-01-01 00:00:00.000000000 +0000', the result is negative.
`TIMESTAMP9_LTZ`	`DATE`	The result of this conversion depends on the date of the given `TIMESTAMP9_LTZ` value in the time zone of the current session. The behavior is like doing conversion from `TIMESTAMPTZ` to `DATE`.
`TIMESTAMP9_LTZ`	`TIMESTAMP WITHOUT TIME ZONE/TIMESTAMP`	The result of this conversion is a timestamp without time zone. The resulting timestamp's value is determined by the value of `TIMESTAMP9_LTZ` in the current session time zone. Note that the fractional part of `TIMESTAMP` type has 6 digits, while `TIMESTAMP9_LTZ` has 9 digits in its fractional part. When converting `TIMESTAMP9_LTZ` to `TIMESTAMP`, the fractional part is truncated instead of being rounded off.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

From	To	Description
`TIMESTAMP9_LTZ`	`TIMESTAMP WITH TIME ZONE/TIMESTAMP`	When performing this conversion, WarehousePG truncates the fractional part to only 6 digits.
`BIGINT`	`TIMESTAMP9_NTZ`	When performing this conversion, WarehousePG treats the BIGINT value as the number of nanoseconds started from '1970-01-01 00:00:00'.
`DATE`	`TIMESTAMP9_NTZ`	When performing this conversion, the resulting timestamp is '00:00:00.000000000' on the given date.
`TIMESTAMP WITHOUT TIME ZONE/TIMESTAMP`	`TIMESTAMP9_NTZ`	When peforming this conversion, WarehousePG only extends the fractional part to nanosecond precision.
`TIMESTAMP WITH TIME ZONE/TIMESTAMP`	`TIMESTAMP9_NTZ`	The resulting timestamp's value is determined by the value of `TIMESTAMPTZ` in the current session time zone.
`TIMESTAMP9_NTZ`	`BIGINT`	The result of this conversion is the nanoseconds since '1970-01-01 00:00:00.000000000' to the given `TIMESTAMP9_NTZ` value. If the given `TIMESTAMP9_NTZ` value is before '1970-01-01 00:00:00.000000000', the result is negative.
`TIMESTAMP9_NTZ`	`DATE`	When performing this conversion, WarehousePG truncatest the time portion and preserves the date portion.
`TIMESTAMP9_NTZ`	`TIMESTAMP WITHOUT TIME ZONE/TIMESTAMP`	When performing this conversion, WarehousePG truncates only the fractional part to 6 digits.
`TIMESTAMP9_NTZ`	`TIMESTAMP WITH TIME ZONE/TIMESTAMP`	When performing this conversion, WarehousePG only truncates the fractional part to 6 digits and add the time zone of the current session.
`TIMESTAMP9_LTZ`	`TIMESTAMP9_NTZ`	The resulting `TIMESTAMP9_NTZ` value is determined by the value of `TIMESTAMP9_LTZ` in the current session's time zone.
`TIMESTAMP9_NTZ`	`TIMESTAMP9_LTZ`	When performing this conversion, WarehousePG adds the timezone of the current sesion.

Type Conversion Examples

Convert `BIGINT` to `TIMESTAMP9_LTZ`

```
=# SHOW TIMEZONE;

   TimeZone
--------------
Asia/Shanghai
(1 row)

=# SELECT 0::BIGINT::TIMESTAMP9_LTZ;

           timestamp9_ltz
-------------------------------------
1970-01-01 08:00:00.000000000 +0800
(1 row)
```

Convert `DATE` to `TIMESTAMP9_LTZ`

```
=# SHOW TIMEZONE;

   TimeZone
--------------
Asia/Shanghai
(1 row)

 =# SELECT '2023-01-01'::DATE::TIMESTAMP9_LTZ;

           timestamp9_ltz
-------------------------------------
2023-01-01 00:00:00.000000000 +0800
(1 row)

=# SELECT '2023-01-01'::DATE::TIMESTAMPTZ;

      timestamptz
------------------------
2023-01-01 00:00:00+08
(1 row)
```

Convert `TIMESTAMP WITHOUT TIME ZONE/TIMESTAMP` to `TIMESTAMP9_LTZ`

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
=# SHOW TIMEZONE;

   TimeZone
---------------
Asia/Shanghai
(1 row)

Time: 0.411 ms
=# SELECT '2023-01-01 00:00:00'::TIMESTAMP::TIMESTAMP9_LTZ;

           timestamp9_ltz
---------------------------------------
2023-01-01 00:00:00.000000000 +0800
(1 row)

Time: 0.691 ms
=# SELECT '2023-01-01 00:00:00'::TIMESTAMP::TIMESTAMPTZ;

      timestamptz
------------------------
2023-01-01 00:00:00+08
(1 row)
```

Convert `TIMESTAMP WITH TIME ZONE/TIMESTAMP` to `TIMESTAMP9_LTZ`

```
=# SELECT '2023-01-01 00:00:00.123456'::TIMESTAMPTZ::TIMESTAMP9_LTZ;

           timestamp9_ltz
---------------------------------------
2023-01-01 00:00:00.123456000 +0800
(1 row)
```

Convert `TIMESTAMP9_LTZ` to `BIGINT`

```
=# SELECT '2023-01-01 00:00:00.123456 Asia/Shanghai'::TIMESTAMP9_LTZ::BIGINT;

        int8
---------------------
1672502400123456000
(1 row)

=# SELECT '1969-01-01 00:00:00.123456 Asia/Shanghai'::TIMESTAMP9_LTZ::BIGINT;

        int8
--------------------
-31564799876544000
(1 row)
```

Convert `TIMESTAMP9_LTZ` to `DATE`

```
=# SET TIMEZONE TO 'Asia/Shanghai';
SET
=# SELECT '2023-01-02 02:59:59 Asia/Shanghai'::TIMESTAMPTZ::DATE;
    date
------------
2023-01-02
(1 row)

=# SET TIMEZONE TO 'UTC+0';
SET
=# SELECT '2023-01-02 02:59:59 Asia/Shanghai'::TIMESTAMPTZ::DATE;
    date
------------
2023-01-01
(1 row)
```

Convert `TIMESTAMP9_LTZ` to `TIMESTAMP WITHOUT TIME ZONE/TIMESTAMP`

Example 1

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
=# SET TIMEZONE TO 'Asia/Shanghai';
SET
=# SELECT '2023-01-02 02:59:59 Asia/Shanghai'::TIMESTAMP9_LTZ::TIMESTAMP;

      timestamp
---------------------
2023-01-02 02:59:59
(1 row)

=# SET TIMEZONE TO 'UTC+0';

SET
=# SELECT '2023-01-02 02:59:59 Asia/Shanghai'::TIMESTAMP9_LTZ::TIMESTAMP;

      timestamp
---------------------
2023-01-01 18:59:59
(1 row)
```

Example 2 -- Truncation of the fractional part

```
=# SET TIMEZONE TO 'Asia/Shanghai';
SET
=# SELECT '2023-01-02 02:59:59.123456789 Asia/Shanghai'::TIMESTAMP9_LTZ::TIMESTAMP;

         timestamp
----------------------------
2023-01-02 02:59:59.123456
(1 row)
```

Convert `TIMESTAMP9_LTZ` to `TIMESTAMP WITH TIME ZONE/TIMESTAMP`

```
=# SET TIMEZONE TO 'Asia/Shanghai';
=# SELECT '2023-01-02 02:59:59.123456789 Asia/Shanghai'::TIMESTAMP9_LTZ::TIMESTAMPTZ;
          timestamptz
-------------------------------
2023-01-02 02:59:59.123456+08
(1 row)
```

Convert `BIGINT` to `TIMESTAMP9_NTZ`

```
=# SELECT 0::BIGINT::TIMESTAMP9_NTZ;
        timestamp9_ntz
-------------------------------

1970-01-01 00:00:00.000000000
(1 row)
```

Convert `DATE` to `TIMESTAMP9_NTZ`

```
=# SELECT '2023-01-01'::DATE::TIMESTAMP9_NTZ;
        timestamp9_ntz
-------------------------------
2023-01-01 00:00:00.000000000
(1 row)
```

Convert `TIMESTAMP WITHOUT TIME ZONE/TIMESTAMP` to `TIMESTAMP9_NTZ`

```
=# SELECT '2023-01-01 00:00:00.123456'::TIMESTAMP::TIMESTAMP9_NTZ;
        timestamp9_ntz

-------------------------------
2023-01-01 00:00:00.123456000
(1 row)
```

Convert `TIMESTAMP WITH TIME ZONE/TIMESTAMP` to `TIMESTAMP9_NTZ`

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
=# SET TIMEZONE TO 'Asia/Shanghai';
SET
=# SELECT '2023-01-01 00:00:00.123456 Asia/Shanghai'::TIMESTAMPTZ::TIMESTAMP9_NTZ;
        timestamp9_ntz
-------------------------------
2023-01-01 00:00:00.123456000
(1 row)

           timestamp9_ltz
-------------------------------------
2023-01-01 23:00:00.123456789 +0000
(1 row)
```

The TimeZone Configuration Parameter and `timestamp9`

You can set the TimeZone server configuration parameter to specify the time zone that WarehousePG uses when it prints a `timestamp9` timestamp. When you set this parameter, WarehousePG displays the timestamp value in that time zone. For example:

```
testdb=# SELECT
now()::timestamp9;

now
-------------------------------------
 2022-08-24 18:08:01.729360000 +0800
(1 row)

testdb=# SET timezone TO
'UTC+2';
SET
testdb=# SELECT
now()::timestamp9;

now
-------------------------------------
 2022-08-24 08:08:12.995542000 -0200

```

Support For Date/Time Functions

The `timestamp9` module defines two server configuration parameters that you set to enable date/time functions defined in the `pg_catalog` schema on `timestamp` types. Visit the PostgreSQL Documentation for a list of the supported date/time functions. The parameters are:

- `timestamp9.enable_implicit_cast_timestamp9_ltz_to_timestamptz` : when enabled, casting a `timestamp9_ltz` value to `timestamp with time zone` becomes implicit.
- `timestamp9.enable_implicit_cast_timestamp9_ntz_to_timestamp` : when enabled, casting a `timestamp9_ntz` value to `timestamp without time zone` becomes implicit.

The default value for both configuration parameters is `off`. For example, if you try use the `date` function with `timestamp9` and `timestamp9.enable_implicit_cast_timestamp9_ltz_to_timestamptz` is set to `off`:

```
postgres=# SELECT date('2022-01-01'::timestamp9_ltz);
ERROR:  implicitly cast timestamp9_ltz to timestamptz is not allowed
HINT:  either set 'timestamp9.enable_implicit_cast_timestamp9_ltz_to_timestamptz' to 'on' or do it explicitly
```

Enable the configuration parameter in order to use the `date` function:

```
postgres=# SET timestamp9.enable_implicit_cast_timestamp9_ltz_to_timestamptz TO 'ON';
SET
postgres=# SELECT date('2022-01-01'::timestamp9_ltz);
    date
------------
 01-01-2022
(1 row)
```

Note that enabling these configuration parameters will also result in multiple casting paths from `timestamp9` types and built-in `timestamp` types. You may encounter error messages such as:

```
postgres=# select '2019-09-19'::timestamp9_ltz <= '2019-09-20'::timestamptz;
ERROR:  operator is not unique: timestamp9_ltz <= timestamp with time zone
LINE 1: select '2019-09-19'::timestamp9_ltz <= '2019-09-20'::timesta...
HINT:  Could not choose a best candidate operator. You might need to add explicit type casts.
```

In this situation, cast the type explicitly:

```
postgres=# select '2019-09-19'::timestamp9_ntz <= '2019-09-20'::timestamptz::timestamp9_ntz;
?column?
----------
 t
(1 row)
```

Alternatively, cast the `timestamp9_ntz` value to the `timestamptz` value:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
postgres=# select '2019-09-19'::timestamp9_ntz::timestamptz <= '2019-09-20'::timestamptz;
?column?
----------
 t
(1 row)
```

Support For Date/Time Functions

The `timestamp9` module defines two server configuration parameters that you set to enable date/time functions defined in the `pg_catalog` schema on `timestamp` types. Visit the PostgreSQL Documentation for a list of the supported date/time functions. The parameters are:

- `timestamp9.enable_implicit_cast_timestamp9_ltz_to_timestamptz` : when enabled, casting a `timestamp9_ltz` value to `timestamp with time zone` becomes implicit.
- `timestamp9.enable_implicit_cast_timestamp9_ntz_to_timestamp` : when enabled, casting a `timestamp9_ntz` value to `timestamp without time zone` becomes implicit.

The default value for both configuration parameters is `off` . For example, if you try use the `date` function with `timestamp9` and `timestamp9.enable_implicit_cast_timestamp9_ltz_to_timestamptz` is set to `off` :

```
postgres=# SELECT date('2022-01-01'::timestamp9_ltz);
ERROR:  implicitly cast timestamp9_ltz to timestamptz is not allowed
HINT:  either set 'timestamp9.enable_implicit_cast_timestamp9_ltz_to_timestamptz' to 'on' or do it explicitly
```

Enable the configuration parameter in order to use the `date` function:

```
postgres=# SET timestamp9.enable_implicit_cast_timestamp9_ltz_to_timestamptz TO 'ON';
SET
postgres=# SELECT date('2022-01-01'::timestamp9_ltz);
    date
------------
 01-01-2022
(1 row)
```

Note that enabling these configuration parameters will also result in multiple casting paths from `timestamp9` types and built-in `timestamp` types. You may encounter error messages such as:

```
postgres=# select '2019-09-19'::timestamp9_ltz <= '2019-09-20'::timestamptz;
ERROR:  operator is not unique: timestamp9_ltz <= timestamp with time zone
LINE 1: select '2019-09-19'::timestamp9_ltz <= '2019-09-20'::timesta...
HINT:  Could not choose a best candidate operator. You might need to add explicit type casts.
```

In this situation, cast the type explicitly:

```
postgres=# select '2019-09-19'::timestamp9_ntz <= '2019-09-20'::timestamptz::timestamp9_ntz;
?column?
----------
 t
(1 row)
```

Alternatively, cast the `timestamp9_ntz` value to the `timestamptz` value:

```
postgres=# select '2019-09-19'::timestamp9_ntz::timestamptz <= '2019-09-20'::timestamptz;
?column?
----------
 t
(1 row)
```

Examples

`TIMESTAMP9_LTZ` Examples

Valid input for `TIMESTAMP9_LTZ`

Valid input for the `TIMESTAMP9_LTZ` consists of the concatenation of a date and a time, followed by an optional time zone. Users can specify the fractional part of second up to 9 digits (in nanosecond precision).

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
The current system's TIMEZONE parameter is 'Asia/Shanghai'

SELECT '2023-02-20 00:00:00.123456789 +0200'::TIMESTAMP9_LTZ;

           timestamp9_ltz

---------------------------------------
2023-02-20 06:00:00.123456789 +0800
(1 row)

 If the input string doesn't have explicit time zone information, the timestamp is presumed to be in the time zone indicated by the system's TIMEZONE parameter.

SELECT '2023-02-20 00:00:00.123456789'::TIMESTAMP9_LTZ;

           timestamp9_ltz
---------------------------------------
2023-02-20 00:00:00.123456789 +0800
(1 row)
```

TIMESTAMP9_LTZ also accepts numbers as valid input. It's interpreted as the number of nanoseconds since the UTC time '1970-01-01 00:00:00.000000000'.

```
SELECT '123456789'::TIMESTAMP9_LTZ;

           timestamp9_ltz
---------------------------------------
1970-01-01 08:00:00.123456789 +0800
(1 row)
```

`TIMESTAMP9_NTZ` Examples

Valid input for `TIMESTAMP9_NTZ`

As with `TIMESTAMP9_LTZ`, valid input for the `TIMESTAMP9_NTZ` data type consists of the concatenation of a date and a time, followed by an optional time zone. Users can specify the fractional part of second up to 9 digits (in nanosecond precision). The difference is that, if the user specifies time zone in the input string, `TIMESTAMP9_NTZ` will ignore it and store the remaining timestamp as UTC time without applying any time zone offset.

The current system's TIMEZONE parameter is 'Asia/Shanghai'

```
=# SELECT '2023-02-20 00:00:00.123456789 +0200'::TIMESTAMP9_NTZ;
        timestamp9_ntz
-------------------------------
2023-02-20 00:00:00.123456789
(1 row)
=# SELECT '2023-02-20 00:00:00.123456789'::TIMESTAMP9_NTZ;
        timestamp9_ntz
-------------------------------
2023-02-20 00:00:00.123456789
(1 row)
```

Limitations

The `timestamp9` data type does not support arithmetic calculations with nanoseconds.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.4.27 uuid-ossp

The `uuid-ossp` module provides functions to generate universally unique identifiers (UUIDs) using one of several standard algorithms. The module also includes functions to produce certain special UUID constants.

The WarehousePG `uuid-ossp` module is equivalent to the PostgreSQL `uuid-ossp` module. There are no WarehousePG or MPP-specific considerations for the module.

Installing and Registering the Module

The `uuid-ossp` module is installed when you install WarehousePG. Before you can use any of the functions defined in the module, you must register the `uuid-ossp` extension in each database in which you want to use the functions:

```
CREATE EXTENSION "uuid-ossp";
```

Refer to Installing Extensions for more information.

Module Documentation

See the PostgreSQL uuid-ossp documentation for detailed information about this module.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.4.28 isn

The `isn` module provides support for the international product numbering standards EAN13, UPC, ISBN (books), ISMN (music), and ISSN (serials).

The WarehousePG `isn` module is equivalent to version 1.2 of the `isn` module used with PostgreSQL. There are no WarehousePG or MPP-specific considerations for the module.

Installing and Registering the Module

The `isn` module is installed when you install WarehousePG. Before you can use any of the numbering standards defined in the module, you must register the `isn` extension in each database in which you want to use the standards:

```
CREATE EXTENSION isn;
```

Refer to Installing Extensions for more information.

Module Documentation

Refer to the isn Postgres documentation for detailed information about using the module.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.4.29 tsm_system_rows

The `tsm_system_rows` module implements the `SYSTEM_ROWS` table sampling method. This method is used in the `TABLESAMPLE` clause of a `SELECT` command.

The `tsm_system_rows` module is a WarehousePG extension.

Installing and Registering the Module

The `tsm_system_rows` module is installed when you install WarehousePG. Before you can use any of the functions defined in the module, you must register the `tsm_system_rows` extension in each database where you want to use the functions. Refer to Installing Extensions for more information.

Using the tsm_system_rows Module

The `SYSTEM ROWS` table sampling method accepts a single integer argument that is the maximum number of rows to read. The resulting sample will always contain exactly that many rows, unless the table does not contain enough rows, in which case the whole table is selected.

Like the built-in `SYSTEM` sampling method, `SYSTEM_ROWS` performs block-level sampling, so that the sample is not completely random but may be subject to clustering effects, especially if only a small number of rows are requested.

Example

The following command returns a sample of 75 rows from the table `tableA`, unless the table does not have 75 visible rows; in this case, the command returns all table rows:

```
SELECT * FROM tableA TABLESAMPLE SYSTEM_ROWS(75);
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.4.30 tsm_system_time

The `tsm_system_time` module implements the `SYSTEM_TIME` table sampling method. This method is used in the `TABLESAMPLE` clause of a `SELECT` command.

The `tsm_system_time` module is a WarehousePG extension.

Installing and Registering the Module

The `tsm_system_time` module is installed when you install WarehousePG. Before you can use any of the functions defined in the module, you must register the `tsm_system_time` extension in each database where you want to use the functions. Refer to Installing Extensions for more information.

Using the tsm_system_time Module

The `SYSTEM_TIME` table sampling method takes a single floating-point argument that specifies the maximum number of milliseconds to spend reading the table. This allows you to control how long the query takes; the tradeoff is that the size of the sample becomes hard to predict. The resulting sample will contain as many rows as could be read in the specified time, unless the whole table has been read first.

Like the built-in `SYSTEM` sampling method, `SYSTEM_TIME` performs block-level sampling, so that, rather than being completely random, the sample may be subject to clustering effects, particularly when a small number of rows are selected.

Example

The following command return as large a sample of `tableA` as it can read in 1/2 second (500 milliseconds). If the entire table can be read in under 1 second, all of its rows will be returned.

```
SELECT * FROM tableA TABLESAMPLE SYSTEM_TIME(500);
```

7.5 Character Set Support

The character set support in WarehousePG allows you to store text in a variety of character sets, including single-byte character sets such as the ISO 8859 series and multiple-byte character sets such as EUC (Extended Unix Code), UTF-8, and Mule internal code. All supported character sets can be used transparently by clients, but a few are not supported for use within the server (that is, as a server-side encoding). The default character set is selected while initializing your WarehousePG cluster using `gpinitsystem`. It can be overridden when you create a database, so you can have multiple databases each with a different character set.

Name	Description	Language	Server?	Bytes/Char	Aliases
BIG5	Big Five	Traditional Chinese	No	1-2	WIN950, Windows950
EUC_CN	Extended UNIX Code-CN	Simplified Chinese	Yes	1-3	
EUC_JP	Extended UNIX Code-JP	Japanese	Yes	1-3	
EUC_KR	Extended UNIX Code-KR	Korean	Yes	1-3	
EUC_TW	Extended UNIX Code-TW	Traditional Chinese, Taiwanese	Yes	1-3

Parent topic: WarehousePG Reference Guide

Setting the Character Set

`gpinitsystem` defines the default character set for a WarehousePG cluster by reading the setting of the `ENCODING` parameter in the `gp_init_config` file at initialization time. The default character set is `UNICODE` or `UTF8`.

You can create a database with a different character set besides what is used as the system-wide default. For example:

```
=> CREATE DATABASE korean WITH ENCODING 'EUC_KR';
```

> **Important** Although you can specify any encoding you want for a database, it is unwise to choose an encoding that is not what is expected by the locale you have selected. The `LC_COLLATE` and `LC_CTYPE` settings imply a particular encoding, and locale-dependent operations (such as sorting) are likely to misinterpret data that is in an incompatible encoding.

Since these locale settings are frozen by `gpinitsystem`, the apparent flexibility to use different encodings in different databases is more theoretical than real.

One way to use multiple encodings safely is to set the locale to `C` or `POSIX` during initialization time, thus deactivating any real locale awareness.

Character Set Conversion Between Server and Client

WarehousePG supports automatic character set conversion between server and client for certain character set combinations. The conversion information is stored in the coordinator*pg_conversion* system catalog table. WarehousePG comes with some predefined conversions or you can create a new conversion using the SQL command `CREATE CONVERSION`.

Server Character Set	Available Client Character Sets
BIG5	not supported as a server encoding
EUC_CN	EUC_CN, MULE_INTERNAL, UTF8
EUC_JP	EUC_JP, MULE_INTERNAL, SJIS, UTF8
EUC_KR	EUC_KR, MULE_INTERNAL, UTF8
EUC_TW	EUC_TW, BIG5, MULE_INTERNAL, UTF8
GB18030	not supported as a server encoding
GBK	not supported as a server encoding
ISO_8859_5	ISO_8859_5, KOI8, MULE_INTERNAL, UTF8, WIN866, WIN1251
ISO_8859_6	ISO_8859_6, UTF8
ISO_8859_7	ISO_8859_7, UTF8
ISO_8859_8	ISO_8859_8, UTF8
JOHAB	JOHAB, UTF8
KOI8	KOI8, ISO_8859_5, MULE_INTERNAL, UTF8, WIN866, WIN1251
LATIN1	LATIN1, MULE_INTERNAL, UTF8
LATIN2	LATIN2, MULE_INTERNAL, UTF8, WIN1250
LATIN3	LATIN3, MULE_INTERNAL, UTF8
LATIN4	LATIN4, MULE_INTERNAL, UTF8
LATIN5	LATIN5, UTF8
LATIN6	LATIN6, UTF8
LATIN7	LATIN7, UTF8
LATIN8	LATIN8, UTF8
LATIN9	LATIN9, UTF8
LATIN10	LATIN10, UTF8
MULE_INTERNAL	MULE_INTERNAL, BIG5, EUC_CN, EUC_JP, EUC_KR, EUC_TW, ISO_8859_5, KOI8, LATIN1 to LATIN4, SJIS, WIN866, WIN1250, WIN1251
SJIS	not supported as a server encoding
SQL_ASCII	not supported as a server encoding
UHC	not supported as a server encoding
UTF8	all supported encodings
WIN866	WIN866
ISO_8859_5	KOI8, MULE_INTERNAL, UTF8, WIN1251
WIN874	WIN874, UTF8
WIN1250	WIN1250, LATIN2, MULE_INTERNAL, UTF8
WIN1251	WIN1251, ISO_8859_5, KOI8, MULE_INTERNAL, UTF8, WIN866
WIN1252	WIN1252, UTF8
WIN1253	WIN1253, UTF8
WIN1254	WIN1254, UTF8
WIN1255	WIN1255, UTF8
WIN1256	WIN1256, UTF8
WIN1257	WIN1257, UTF8
WIN1258	WIN1258, UTF8

To enable automatic character set conversion, you have to tell WarehousePG the character set (encoding) you would like to use in the client. There are several ways to accomplish this:

- Using the `\encoding` command in `psql`, which allows you to change client encoding on the fly.
- Using `SET client_encoding TO`.

  To set the client encoding, use the following SQL command:

  ```
  => SET CLIENT_ENCODING TO '*value*';
  ```

  To query the current client encoding:

  ```
  => SHOW client_encoding;
  ```

  To return to the default encoding:

  ```
  => RESET client_encoding;
  ```

- Using the `PGCLIENTENCODING` environment variable. When `PGCLIENTENCODING` is defined in the client's environment, that client encoding is automatically selected when a connection to the server is made. (This can subsequently be overridden using any of the other methods mentioned above.)
- Setting the configuration parameter `client_encoding`. If `client_encoding` is set in the coordinator `postgresql.conf` file, that client encoding is automatically selected when a connection to WarehousePG is made. (This can subsequently be overridden using any of the other methods mentioned above.)

If the conversion of a particular character is not possible (suppose you chose `EUC_JP` for the server and `LATIN1` for the client, then some Japanese characters do not have a representation in `LATIN1`) then an error is reported.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

If the client character set is defined as `SQL_ASCII`, encoding conversion is deactivated, regardless of the server's character set. The use of `SQL_ASCII` is unwise unless you are working with all-ASCII data. `SQL_ASCII` is not supported as a server encoding.

[1] Not all APIs support all the listed character sets. For example, the JDBC driver does not support MULE_INTERNAL, LATIN6, LATIN8, and LATIN10.[2] The SQL_ASCII setting behaves considerably differently from the other settings. Byte values 0-127 are interpreted according to the ASCII standard, while byte values 128-255 are taken as uninterpreted characters. If you are working with any non-ASCII data, it is unwise to use the SQL_ASCII setting as a client encoding. SQL_ASCII is not supported as a server encoding.

7.6 Server Configuration Parameters

There are many WarehousePG server configuration parameters that affect the behavior of the WarehousePG cluster. Many of these configuration parameters have the same names, settings, and behaviors as in a regular PostgreSQL database system.

- Parameter Types and Values describes the parameter data types and values.
- Setting Parameters describes limitations on who can change them and where or when they can be set.
- Parameter Categories organizes parameters by functionality.
- Configuration Parameters lists the parameter descriptions in alphabetic order.

Parameter Types and Values

All parameter names are case-insensitive. Every parameter takes a value of one of the following types: `Boolean`, `integer`, `floating point`, `enum`, or `string`.

Boolean values may be specified as `ON`, `OFF`, `TRUE`, `FALSE`, `YES`, `NO`, `1`, `0` (all case-insensitive).

Enum-type parameters are specified in the same manner as string parameters, but are restricted to a limited set of values. Enum parameter values are case-insensitive.

Some settings specify a memory size or time value. Each of these has an implicit unit, which is either kilobytes, blocks (typically eight kilobytes), milliseconds, seconds, or minutes. Valid memory size units are `kB` (kilobytes), `MB` (megabytes), and `GB` (gigabytes). Valid time units are `ms` (milliseconds), `s` (seconds), `min` (minutes), `h` (hours), and `d` (days). Note that the multiplier for memory units is 1024, not 1000. A valid time expression contains a number and a unit. When specifying a memory or time unit using the `SET` command, enclose the value in quotes. For example:

```
SET statement_mem TO '200MB';
```

> **Note** There is no space between the value and the unit names.

Setting Parameters

> **Note** WarehousePG does not support using the `ALTER SYSTEM` command to set server configuration parameters.

Many of the configuration parameters have limitations on who can change them and where or when they can be set. For example, to change certain parameters, you must be a WarehousePG superuser. Other parameters require a restart of the system for the changes to take effect. A parameter that is classified as *session* can be set at the system level (in the `postgresql.conf` file), at the database-level (using `ALTER DATABASE`), at the role-level (using `ALTER ROLE`), at the database- and role-level (`ALTER ROLE...IN DATABASE...SET`, or at the session-level (using `SET`). System parameters can only be set in the `postgresql.conf` file.

In WarehousePG, the coordinator and each segment instance has its own `postgresql.conf` file (located in their respective data directories). Some parameters are considered *local* parameters, meaning that each segment instance looks to its own `postgresql.conf` file to get the value of that parameter. You must set local parameters on every instance in the system (coordinator and segments). Others parameters are considered *coordinator* parameters. Coordinator parameters need only be set at the coordinator instance.

This table describes the values in the Settable Classifications column of the table in the description of a server configuration parameter.

Set Classification	Description
coordinator or local	A *coordinator* parameter only needs to be set in the `postgresql.conf` file of the WarehousePG coordinator instance. The value for this parameter is then either passed to (or ignored by) the segments at run time. A local parameter must be set in the `postgresql.conf` file of the coordinator AND each segment instance. Each segment instance looks to its own configuration to get the value for the parameter.
session or system	*Session* parameters can be changed on the fly within a database session, and can have a hierarchy of settings: at the system level (`postgresql.conf`), at the database level (`ALTER DATABASE...SET`), at the role level (`ALTER ROLE...SET`), at the database and role level (`ALTER ROLE...IN DATABASE...SET`), or at the session level (`SET`). If the parameter is set at multiple levels, then the most granular setting takes precedence (for example, session overrides database and role, database and role overrides role, role overrides database, and database overrides system). A *system* parameter can only be changed via the `postgresql.conf` file(s).
restart or reload	When changing parameter values in the postgresql.conf file(s), some require a *restart* of WarehousePG for the change to take effect. Other parameter values can be refreshed by just reloading the server configuration file (using `gpstop -u`), and do not require stopping the system.
superuser	These session parameters can only be set by a database superuser. Regular database users cannot set this parameter.
read only	These parameters are not settable by database users or superusers. The current value of the parameter can be shown but not altered.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.6.1 Configuration Parameters

Descriptions of the WarehousePG server configuration parameters listed alphabetically.

application_name

Sets the application name for a client session. For example, if connecting via `psql`, this will be set to `psql`. Setting an application name allows it to be reported in log messages and statistics views.

Value Range	Default	Set Classifications
string		coordinator, session, reload

array_nulls

This controls whether the array input parser recognizes unquoted NULL as specifying a null array element. By default, this is on, allowing array values containing null values to be entered. WarehousePG versions before 3.0 did not support null values in arrays, and therefore would treat NULL as specifying a normal array element with the string value 'NULL'.

Value Range	Default	Set Classifications
Boolean	on	coordinator, session, reload

authentication_timeout

Maximum time to complete client authentication. This prevents hung clients from occupying a connection indefinitely.

Value Range	Default	Set Classifications
Any valid time expression (number and unit)	1min	local, system, restart

autovacuum

When enabled, WarehousePG starts up the autovacuum daemon, which operates at the database level. When the daemon is running, WarehousePG:

- Automatically vacuums catalog tables and possibly auxiliary tables (determined by the gp_autovacuum_scope configuration parameter setting).
- Automatically analyzes the vacuumed tables.

Value Range	Default	Set Classifications
Boolean	on	coordinator, system, restart

autovacuum_analyze_scale_factor

Specifies a fraction of the table size to add to `autovacuum_analyze_threshold` when deciding whether or not to trigger an `ANALYZE`. The default is 0.1 (10% of table size). This parameter may be set only in the `postgresql.conf file` or on the server command line; but the setting can be overridden for individual tables by changing table storage parameters.

Value Range	Default	Set Classifications
Floating point	0.1	coordinator, system, restart

autovacuum_analyze_threshold

Specifies the minimum number of inserted, updated or deleted tuples needed to trigger an `ANALYZE` in any one table. The default is 50 tuples. This parameter may be set only in the `postgresql.conf` file or on the server command line; but the setting can be overridden for individual tables by changing table storage parameters.

Value Range	Default	Set Classifications
Integer	50	coordinator, system, restart

autovacuum_freeze_max_age

Specifies the maximum age at which to automatically vacuum a table to prevent transaction ID wraparound. Note that the system will launch autovacuum processes to prevent wraparound even wher `autovacuum=off`. The default value is 200 million transactions.

Value Range	Default	Set Classifications
100000 < integer < 2000000000	200000000	local, system, restart

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

autovacuum_max_workers

Specifies the maximum number of autovacuum processes (other than the autovacuum launcher) that may be running at any one time. The default is three. This parameter may be set only at server start.

Value Range	Default	Set Classifications
Integer	3	coordinator, system, restart

autovacuum_multixact_freeze_max_age

Specifies the maximum age (in multixacts) that a table's `pg_class.relminmxid` field can attain before a `VACUUM` operation is forced to prevent multixact ID wraparound within the table. Note that the system will launch autovacuum processes to prevent wraparound even when autovacuum is otherwise disabled.

Vacuuming multixacts also allows removal of old files from the `pg_multixact/members` and `pg_multixact/offsets subdirectories`, which is why the default is a relatively low 400 million multixacts. This parameter may be set only at server start, but the setting can be reduced for individual tables by changing table storage parameters.

Value Range	Default	Set Classifications
Integer	400000000	coordinator, system, restart

autovacuum_naptime

When `autovacuum=on` (the default), specifies the minimum delay between autovacuum runs. In each round, the daemon issues `VACUUM` and `ANALYZE` commands as needed for catalog (and possibly auxiliary) tables.

A value without units is taken to be seconds. The default is one minute.

This parameter may be set only in the `postgresql.conf` file or on the server command line.

Value Range	Default	Set Classifications
1 < integer < INT_MAX/1000	60	coordinator, system, restart

autovacuum_vacuum_cost_delay

Specifies the cost delay value in milliseconds for automatic vacuum operations. If set to -1, the value of this parameter is the set by `vacuum_cost_delay`.

A value without units is taken to be milliseconds. The default is 2 milliseconds. This parameter may be set only in the `postgresql.conf` file or on the server command line.

Value Range	Default	Set Classifications
floating point < 100	2	local, system, reload

autovacuum_vacuum_cost_limit

Specifies the cost limit value that will be used in automatic `VACUUM` operations. If -1 is specified (which is the default), the regular `vacuum_cost_limit` value will be used. Note that the value is distributed proportionally among the running autovacuum workers, if there is more than one, so that the sum of the limits for each worker does not exceed the value of this variable. This parameter may be set only in the `postgresql.conf` file or on the server command line; but the setting can be overridden for individual tables by changing table storage parameters.

Value Range	Default	Set Classifications
Integer	-1	local, system, reload

autovacuum_vacuum_scale_factor

Specifies a fraction of the table size to add to `autovacuum_vacuum_threshold` when deciding whether to trigger a `VACUUM`. The default is 0.2 (20% of table size). This parameter may be set only in the `postgresql.conf` file or on the server command line.

Value Range	Default	Set Classifications
floating point (%)	0.05	local, system, reload

autovacuum_vacuum_threshold

Specifies the minimum number of updated or deleted tuples needed to trigger a `VACUUM` in any one table. The default is 50 tuples. This parameter can only be set in the postgresql.conf file or on the server command line.

Value Range	Default	Set Classifications
0 < integer < INT_MAX	500	local, system, reload

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

backslash_quote

This controls whether a quote mark can be represented by \' in a string literal. The preferred, SQL-standard way to represent a quote mark is by doubling it (') but PostgreSQL has historically also accepted \'. However, use of \' creates security risks because in some client character set encodings, there are multibyte characters in which the last byte is numerically equivalent to ASCII \.

Value Range	Default	Set Classifications
on (allow \' always), off (reject always), safe_encoding (allow only if client encoding does not allow ASCII \ within a multibyte character)	safe_encoding	coordinator, session, reload

block_size

Reports the size of a disk block.

Value Range	Default	Set Classifications
number of bytes	32768	read only

bonjour_name

Specifies the Bonjour broadcast name. By default, the computer name is used, specified as an empty string. This option is ignored if the server was not compiled with Bonjour support.

Value Range	Default	Set Classifications
string	unset	coordinator, system, restart

check_function_bodies

When set to off, deactivates validation of the function body string during `CREATE FUNCTION`. Deactivating validation is occasionally useful to avoid problems such as forward references when restoring function definitions from a dump.

Value Range	Default	Set Classifications
Boolean	on	coordinator, session, reload

checkpoint_completion_target

Specifies the target of checkpoint completion, as a fraction of the total time between checkpoints. The default is `0.5`.

You can set this parameter only in the `postgresql.conf` file or on the server command line.

Value Range	Default	Set Classifications
0.0 - 1.0 (floating point)	0.5	local, system, reload

checkpoint_flush_after

Specifies the number of pages after which WarehousePG flushes previously performed writes to disk. Whenever more than the specified amount of data has been written while performing a checkpoint, WarehousePG attempts to force the operating system to issue these writes to the underlying storage. Doing so limits the amount of dirty data in the kernel's page cache, reducing the likelihood of stalls when an `fsync` is issued at the end of the checkpoint, or when the OS writes data back in larger batches in the background. Often that results in greatly reduced transaction latency, but note that there are some cases where performance may degrade, especially with workloads that are bigger than shared_buffers, but smaller than the OS's page cache.

If you specify this value without units, it is taken as blocks, that is `BLCKSZ` bytes (typically 32kB). The valid range is between `0`, which disables forced writeback, and `256`. The default is `32`.

You can set this parameter only in the `postgresql.conf` file or on the server command line.

Value Range	Default	Set Classifications
0 - 256 (integer)	32	local, system, reload

checkpoint_timeout

Specifies the maximum time between automatic WAL checkpoints.

If you specify this value without units, it is taken as seconds. The valid range is between 30 seconds and one day. The default value is five minutes `5min` or `300`).

Increasing this parameter can increase the amount of time needed for crash recovery.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Value Range	Default	Set Classifications
30 - 86400 (integer)	300	local, system, reload

checkpoint_warning

Enables warnings if checkpoint segments are filled more frequently than the specified value. WarehousePG writes a message to the server log if checkpoints caused by the filling of WAL segment files happen closer together than this amount of time (which suggests that you should raise max_wal_size).

If you specify this value without units, it is taken as seconds. The default is 30 seconds (`30`). The value zero (`0`) disables the warning.

WarehousePG generates no warnings if checkpoint_timeout is less than `checkpoint_warning`.

You can set this parameter only in the `postgresql.conf` file or on the server command line.

Value Range	Default	Set Classifications
0 - `INT_MAX` (integer)	30	local, system, reload

client_connection_check_interval

Sets the time interval between optional checks that the client is still connected, while running queries. 0 deactivates connection checks.

Value Range	Default	Set Classifications
number of milliseconds	0	coordinator, session, reload

client_encoding

Sets the client-side encoding (character set). The default is to use the same as the database encoding. See Supported Character Sets in the PostgreSQL documentation.

Value Range	Default	Set Classifications
character set	UTF8	coordinator, session, reload

client_min_messages

Controls which message levels are sent to the client. Each level includes all the levels that follow it. The later the level, the fewer messages are sent.

Value Range	Default	Set Classifications
DEBUG5, DEBUG4, DEBUG3, DEBUG2, DEBUG1, LOG, NOTICE, WARNING, ERROR, FATAL, PANIC	NOTICE	coordinator, session, reload

`INFO` level messages are always sent to the client.

cpu_index_tuple_cost

For the Postgres-based planner, sets the estimate of the cost of processing each index row during an index scan. This is measured as a fraction of the cost of a sequential page fetch.

Value Range	Default	Set Classifications
floating point	0.005	coordinator, session, reload

cpu_operator_cost

For the Postgres-based planner, sets the estimate of the cost of processing each operator in a WHERE clause. This is measured as a fraction of the cost of a sequential page fetch.

Value Range	Default	Set Classifications
floating point	0.0025	coordinator, session, reload

cpu_tuple_cost

For the Postgres-based planner, Sets the estimate of the cost of processing each row during a query. This is measured as a fraction of the cost of a sequential page fetch.

Value Range	Default	Set Classifications
floating point	0.01	coordinator, session, reload

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

cursor_tuple_fraction

Tells the Postgres-based planner how many rows are expected to be fetched in a cursor query, thereby allowing the Postgres-based planner to use this information to optimize the query plan. The default of 1 means all rows will be fetched.

Value Range	Default	Set Classifications
integer	1	coordinator, session, reload

data_checksums

Reports whether checksums are enabled for heap data storage in the database system. Checksums for heap data are enabled or deactivated when the database system is initialized and cannot be changed.

Heap data pages store heap tables, catalog tables, indexes, and database metadata. Append-optimized storage has built-in checksum support that is unrelated to this parameter.

WarehousePG uses checksums to prevent loading data corrupted in the file system into memory managed by database processes. When heap data checksums are enabled, WarehousePG computes and stores checksums on heap data pages when they are written to disk. When a page is retrieved from disk, the checksum is verified. If the verification fails, an error is generated and the page is not permitted to load into managed memory.

If the `ignore_checksum_failure` configuration parameter has been set to on, a failed checksum verification generates a warning, but the page is allowed to be loaded into managed memory. If the page is then updated, it is flushed to disk and replicated to the mirror. This can cause data corruption to propagate to the mirror and prevent a complete recovery. Because of the potential for data loss, the `ignore_checksum_failure` parameter should only be enabled when needed to recover data. See ignore_checksum_failure for more information.

Value Range	Default	Set Classifications
Boolean	on	read only

DateStyle

Sets the display format for date and time values, as well as the rules for interpreting ambiguous date input values. This variable contains two independent components: the output format specification and the input/output specification for year/month/day ordering.

Value Range	Default	Set Classifications
<format>, <date style> where: <format> is ISO, Postgres, SQL, or German <date style> is DMY, MDY, or YMD	ISO, MDY	coordinator, session, reload

db_user_namespace

This enables per-database user names. If on, you should create users as *username@dbname*. To create ordinary global users, simply append @ when specifying the user name in the client.

Value Range	Default	Set Classifications
Boolean	off	local, system, restart

deadlock_timeout

The time to wait on a lock before checking to see if there is a deadlock condition. On a heavily loaded server you might want to raise this value. Ideally the setting should exceed your typical transaction time, so as to improve the odds that a lock will be released before the waiter decides to check for deadlock.

Value Range	Default	Set Classifications
Any valid time expression (number and unit)	1s	local, system, restart

debug_assertions

Turns on various assertion checks.

Value Range	Default	Set Classifications
Boolean	off	local, system, restart

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

debug_pretty_print

Indents debug output to produce a more readable but much longer output format. *client_min_messages* or *log_min_messages* must be DEBUG1 or lower.

Value Range	Default	Set Classifications
Boolean	on	coordinator, session, reload

debug_print_parse

For each query run, prints the resulting parse tree. *client_min_messages* or *log_min_messages* must be DEBUG1 or lower.

Value Range	Default	Set Classifications
Boolean	off	coordinator, session, reload

debug_print_plan

For each query run, prints the WarehousePG parallel query execution plan. *client_min_messages* or *log_min_messages* must be DEBUG1 or lower.

Value Range	Default	Set Classifications
Boolean	off	coordinator, session, reload

debug_print_prelim_plan

For each query run, prints the preliminary query plan. *client_min_messages* or *log_min_messages* must be DEBUG1 or lower.

Value Range	Default	Set Classifications
Boolean	off	coordinator, session, reload

debug_print_rewritten

For each query run, prints the query rewriter output. *client_min_messages* or *log_min_messages* must be DEBUG1 or lower.

Value Range	Default	Set Classifications
Boolean	off	coordinator, session, reload

debug_print_slice_table

For each query run, prints the WarehousePG query slice plan. *client_min_messages* or *log_min_messages* must be DEBUG1 or lower.

Value Range	Default	Set Classifications
Boolean	off	coordinator, session, reload

debug_shareinput_xslice

Prints cross-slice share input scan information to the server log.

Value Range	Default	Set Classifications
Boolean	off	coordinator, session, reload, superuser

default_statistics_target

Sets the default statistics sampling target (the number of values that are stored in the list of common values) for table columns that have not had a column-specific target set via `ALTER TABLE SET STATISTICS`. Larger values may improve the quality of the Postgres-based planner estimates, particularly for columns with irregular data distributions, at the expense of consuming more space in `pg_statistic` and slightly more time to compute the estimates. Conversely, a lower limit might be sufficient for columns with simple data distributions. The default is 100.

For more information on the use of statistics by the Postgres-based planner, refer to Statistics Used by the Planner in the PostgreSQL documentation.

Value Range	Default	Set Classifications
0 > Integer > 10000	100	coordinator, session, reload

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

default_table_access_method

Sets the default table access method when a `CREATE TABLE` command does not explicitly specify an access method.

Value Range	Default	Set Classifications
heap, ao_row, ao_column	heap	coordinator, session

default_tablespace

The default tablespace in which to create objects (tables and indexes) when a `CREATE` command does not explicitly specify a tablespace.

Value Range	Default	Set Classifications
name of a tablespace	unset	coordinator, session, reload

default_text_search_config

Selects the text search configuration that is used by those variants of the text search functions that do not have an explicit argument specifying the configuration. See Using Full Text Search for further information. The built-in default is `pg_catalog.simple`, but `initdb` will initialize the configuration file with a setting that corresponds to the chosen `lc_ctype` locale, if a configuration matching that locale can be identified.

Value Range	Default	Set Classifications
The name of a text search configuration.	`pg_catalog.simple`	coordinator, session, reload

default_transaction_deferrable

When running at the `SERIALIZABLE` isolation level, a deferrable read-only SQL transaction may be delayed before it is allowed to proceed. However, once it begins running it does not incur any of the overhead required to ensure serializability; so serialization code will have no reason to force it to abort because of concurrent updates, making this option suitable for long-running read-only transactions.

This parameter controls the default deferrable status of each new transaction. It currently has no effect on read-write transactions or those operating at isolation levels lower than `SERIALIZABLE`. The default is `off`.

> **Note** Setting `default_transaction_deferrable` to `on` has no effect in WarehousePG. Only read-only, `SERIALIZABLE` transactions can be deferred. However, WarehousePG does not support the `SERIALIZABLE` transaction isolation level. See SET TRANSACTION.

Value Range	Default	Set Classifications
Boolean	off	coordinator, session, reload

default_transaction_isolation

Controls the default isolation level of each new transaction. WarehousePG treats `read uncommitted` the same as `read committed`, and treats `serializable` the same as `repeatable read`.

Value Range	Default	Set Classifications
read committed, read uncommitted, repeatable read, serializable	read committed	coordinator, session, reload

default_transaction_read_only

Controls the default read-only status of each new transaction. A read-only SQL transaction cannot alter non-temporary tables.

Value Range	Default	Set Classifications
Boolean	off	coordinator, session, reload

dynamic_library_path

If a dynamically loadable module needs to be opened and the file name specified in the `CREATE FUNCTION` or `LOAD` command does not have a directory component (i.e. the name does not contain a slash), the system will search this path for the required file. The compiled-in PostgreSQL package library directory is substituted for $libdir. This is where the modules provided by the standard PostgreSQL distribution are installed.

Value Range	Default	Set Classifications
a list of absolute directory paths separated by colons	$libdir	local, system, reload

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

effective_cache_size

Sets the assumption about the effective size of the disk cache that is available to a single query for the Postgres-based planner. This is factored into estimates of the cost of using an index; a higher value makes it more likely index scans will be used, a lower value makes it more likely sequential scans will be used. When setting this parameter, you should consider both WarehousePG's shared buffers and the portion of the kernel's disk cache that will be used for data files (though some data might exist in both places). Take also into account the expected number of concurrent queries on different tables, since they will have to share the available space. This parameter has no effect on the size of shared memory allocated by a WarehousePG server instance, nor does it reserve kernel disk cache; it is used only for estimation purposes.

Set this parameter to a number of block_size blocks (default 32K) with no units; for example, `262144` for 8GB. You can also directly specify the size of the effective cache; for example, `'1GB'` specifies a size of 32768 blocks. The `gpconfig` utility and `SHOW` command display the effective cache size value in units such as 'GB', 'MB', or 'kB'.

Value Range	Default	Set Classifications
1 - INT_MAX *or* number and unit	524288 (16GB)	coordinator, session, reload

enable_bitmapscan

Activates or deactivates the use of bitmap-scan plan types by the Postgres-based planner. Note that this is different than a Bitmap Index Scan. A Bitmap Scan means that indexes will be dynamically converted to bitmaps in memory when appropriate, giving faster index performance on complex queries against very large tables. It is used when there are multiple predicates on different indexed columns. Each bitmap per column can be compared to create a final list of selected tuples.

Value Range	Default	Set Classifications
Boolean	on	coordinator, session, reload

enable_groupagg

Activates or deactivates the use of group aggregation plan types by the Postgres-based planner.

Value Range	Default	Set Classifications
Boolean	on	coordinator, session, reload

enable_hashagg

Activates or deactivates the use of hash aggregation plan types by the Postgres-based planner.

Value Range	Default	Set Classifications
Boolean	on	coordinator, session, reload

enable_hashjoin

Activates or deactivates the use of hash-join plan types by the Postgres-based planner.

Value Range	Default	Set Classifications
Boolean	on	coordinator, session, reload

enable_indexscan

Activates or deactivates the use of index-scan plan types by the Postgres-based planner.

Value Range	Default	Set Classifications
Boolean	on	coordinator, session, reload

enable_mergejoin

Activates or deactivates the use of merge-join plan types by the Postgres-based planner. Merge join is based on the idea of sorting the left- and right-hand tables into order and then scanning them in parallel. So, both data types must be capable of being fully ordered, and the join operator must be one that can only succeed for pairs of values that fall at the 'same place' in the sort order. In practice this means that the join operator must behave like equality.

Value Range	Default	Set Classifications
Boolean	off	coordinator, session, reload

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

enable_nestloop

Activates or deactivates the use of nested-loop join plans by the Postgres-based planner. It's not possible to suppress nested-loop joins entirely, but turning this variable off discourages the Postgres-based planner from using one if there are other methods available.

Value Range	Default	Set Classifications
Boolean	off	coordinator, session, reload

enable_partition_pruning

Enables or disables the query planner's ability to eliminate a partitioned table's partitions from query plans. This also controls the planner's ability to generate query plans which allow the query executor to remove (ignore) partitions during query execution.

Value Range	Default	Set Classifications
Boolean	on	coordinator, session, reload

enable_seqscan

Activates or deactivates the use of sequential scan plan types by the Postgres-based planner. It's not possible to suppress sequential scans entirely, but turning this variable off discourages the Postgres-based planner from using one if there are other methods available.

Value Range	Default	Set Classifications
Boolean	on	coordinator, session, reload

enable_sort

Activates or deactivates the use of explicit sort steps by the Postgres-based planner. It's not possible to suppress explicit sorts entirely, but turning this variable off discourages the Postgres-based planner from using one if there are other methods available.

Value Range	Default	Set Classifications
Boolean	on	coordinator, session, reload

enable_tidscan

Activates or deactivates the use of tuple identifier (TID) scan plan types by the Postgres-based planner.

Value Range	Default	Set Classifications
Boolean	on	coordinator, session, reload

escape_string_warning

When on, a warning is issued if a backslash (\) appears in an ordinary string literal ('...' syntax). Escape string syntax (E'...') should be used for escapes, because in future versions, ordinary strings will have the SQL standard-conforming behavior of treating backslashes literally.

Value Range	Default	Set Classifications
Boolean	on	coordinator, session, reload

explain_pretty_print

Determines whether EXPLAIN VERBOSE uses the indented or non-indented format for displaying detailed query-tree dumps.

Value Range	Default	Set Classifications
Boolean	on	coordinator, session, reload

extra_float_digits

Adjusts the number of digits displayed for floating-point values, including float4, float8, and geometric data types. The parameter value is added to the standard number of digits. The value can be set as high as 3, to include partially-significant digits; this is especially useful for dumping float data that needs to be restored exactly. Or it can be set negative to suppress unwanted digits.

Value Range	Default	Set Classifications
integer (-15 to 3)	0	coordinator, session, reload

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

from_collapse_limit

The Postgres-based planner will merge sub-queries into upper queries if the resulting FROM list would have no more than this many items. Smaller values reduce planning time but may yield inferior query plans.

Value Range	Default	Set Classifications
1-*n*	20	coordinator, session, reload

gin_pending_list_limit

Sets the maximum size of a GIN index's pending list, which is used when `fastupdate` is enabled. If the list grows larger than this maximum size, it is cleaned up by moving the entries in it to the index's main GIN data structure in bulk.

A value specified without units is taken to be kilobytes. The default is four megabytes (4MB).

You can override this setting for individual GIN indexes by changing index storage parameters.

Value Range	Default	Set Classifications
64 - `MAX_KILOBYTES`	4096	coordinator, session, reload

gp_adjust_selectivity_for_outerjoins

Enables the selectivity of NULL tests over outer joins.

Value Range	Default	Set Classifications
Boolean	on	coordinator, session, reload

gp_appendonly_compaction

Enables compacting segment files during `VACUUM` commands. When deactivated, `VACUUM` only truncates the segment files to the EOF value, as is the current behavior. The administrator may want to deactivate compaction in high I/O load situations or low space situations.

Value Range	Default	Set Classifications
Boolean	on	coordinator, session, reload

gp_appendonly_compaction_threshold

Specifies the threshold ratio (as a percentage) of hidden rows to total rows that triggers compaction of the segment file when VACUUM is run without the FULL option (a lazy vacuum). If the ratio of hidden rows in a segment file on a segment is less than this threshold, the segment file is not compacted, and a log message is issued.

Value Range	Default	Set Classifications
integer (%)	10	coordinator, session, reload

gp_autostats_allow_nonowner

The `gp_autostats_allow_nonowner` server configuration parameter determines whether or not to allow WarehousePG to trigger automatic statistics collection when a table is modified by a non-owner.

The default value is `false`; WarehousePG does not trigger automatic statistics collection on a table that is updated by a non-owner.

When set to `true`, WarehousePG will also trigger automatic statistics collection on a table when:

- `gp_autostats_mode=on_change` and the table is modified by a non-owner.
- `gp_autostats_mode=on_no_stats` and the first user to `INSERT` or `COPY` into the table is a non-owner.

The `gp_autostats_allow_nonowner` configuration parameter can be changed only by a superuser.

Value Range	Default	Set Classifications
Boolean	false	coordinator, session, reload, superuser

gp_autostats_lock_wait

The `gp_autostats_lock_wait` server configuration parameter allows you to control whether `ANALYZE` commands triggered by autostats collection will block if they cannot acquire the table lock.

The default value is `off`; `ANALYZE` commands will attempt locks on tables and, if unsuccessful, will proceed without possession of the table lock.

Keeping this parameter turned off will prevent deadlocks and make automatic statistics collection sessions finish in a more timely and predictable fashion.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

When set to `on`, the `ANALYZE` command will block until the table lock is acquired.

Value Range	Default	Set Classifications
Boolean	off	coordinator, session, session, reload

gp_autostats_mode

Specifies the mode for triggering automatic statistics collection with `ANALYZE`. The `on_no_stats` option triggers statistics collection for `CREATE TABLE AS SELECT`, `INSERT`, or `COPY` operations on any table that has no existing statistics.

The `on_change` option triggers statistics collection only when the number of rows affected exceeds the threshold defined by `gp_autostats_on_change_threshold`. Operations that can trigger automatic statistics collection with `on_change` are:

`CREATE TABLE AS SELECT`

`UPDATE`

`DELETE`

`INSERT`

`COPY`

Default is `none`.

> **Note** For partitioned tables, automatic statistics collection is not triggered if data is inserted from the top-level parent table of a partitioned table.

Automatic statistics collection is triggered if data is inserted directly in a leaf table (where the data is stored) of the partitioned table. Statistics are collected only on the leaf table.

Value Range	Default	Set Classifications
none, on_change, none,	on_no_ stats	coordinator, session, reload

gp_autostats_mode_in_functions

Specifies the mode for triggering automatic statistics collection with `ANALYZE` for statements in procedural language functions. The `none` option deactivates statistics collection. The `on_no_stats` option triggers statistics collection for `CREATE TABLE AS SELECT`, `INSERT`, or `COPY` operations that are run in functions on any table that has no existing statistics.

The `on_change` option triggers statistics collection only when the number of rows affected exceeds the threshold defined by `gp_autostats_on_change_threshold`. Operations in functions that can trigger automatic statistics collection with `on_change` are:

`CREATE TABLE AS SELECT`

`UPDATE`

`DELETE`

`INSERT`

`COPY`

Value Range	Default	Set Classifications
none, on_change, on_no_stats,	none	coordinator, session, reload

gp_autostats_on_change_threshold

Specifies the threshold for automatic statistics collection when `gp_autostats_mode` is set to `on_change`. When a triggering table operation affects a number of rows exceeding this threshold, `ANALYZE` is added and statistics are collected for the table.

Value Range	Default	Set Classifications
integer	2147483647	coordinator, session, reload

gp_autovacuum_scope

When `autovacuum=on` (the default), specifies the types of tables that are eligible for automatic vacuuming of dead tuples. WarehousePG supports two `gp_autovacuum_scope` values:

- `catalog` - WarehousePG autovacuums catalog tables only (`pg_catalog` relations).
- `catalog_ao_aux` - WarehousePG autovacuums catalog tables and append-optimized auxiliary tables (`pg_catalog`, `pg_toast`, and `pg_aoseg` relations).

Only superusers can change this setting.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Value Range	Default	Set Classifications
catalog, catalog_ao_aux	catalog	coordinator, system, reload

gp_cached_segworkers_threshold

When a user starts a session with WarehousePG and issues a query, the system creates groups or 'gangs' of worker processes on each segment to do the work. After the work is done, the segment worker processes are destroyed except for a cached number which is set by this parameter. A lower setting conserves system resources on the segment hosts, but a higher setting may improve performance for power-users that want to issue many complex queries in a row.

Value Range	Default	Set Classifications
integer > 0	5	coordinator, session, reload

gp_command_count

Shows how many commands the coordinator has received from the client. Note that a single SQLcommand might actually involve more than one command internally, so the counter may increment by more than one for a single query. This counter also is shared by all of the segment processes working on the command.

Value Range	Default	Set Classifications
integer > 0	1	read only

gp_connection_send_timeout

Timeout for sending data to unresponsive WarehousePG user clients during query processing. A value of 0 deactivates the timeout, WarehousePG waits indefinitely for a client. When the timeout is reached, the query is cancelled with this message:

```
Could not send data to client: Connection timed out.
```

Value Range	Default	Set Classifications
number of seconds	3600 (1 hour)	coordinator, system, reload

gp_content

The local content id if a segment.

Value Range	Default	Set Classifications
integer		read only

gp_create_table_random_default_distribution

Controls table creation when a WarehousePG table is created with a CREATE TABLE or CREATE TABLE AS command that does not contain a DISTRIBUTED BY clause.

For CREATE TABLE, if the value of the parameter is `off` (the default), and the table creation command does not contain a DISTRIBUTED BY clause, WarehousePG chooses the table distribution key based on the command:

- If a `LIKE` or `INHERITS` clause is specified, then WarehousePG copies the distribution key from the source or parent table.
- If a `PRIMARY KEY` or `UNIQUE` constraints are specified, then WarehousePG chooses the largest subset of all the key columns as the distribution key.
- If neither constraints nor a `LIKE` or `INHERITS` clause is specified, then WarehousePG chooses the first suitable column as the distribution key. (Columns with geometric or user-defined data types are not eligible as WarehousePG distribution key columns.)

If the value of the parameter is set to `on`, WarehousePG follows these rules to create a table when the DISTRIBUTED BY clause is not specified:

- If PRIMARY KEY or UNIQUE columns are not specified, the distribution of the table is random (DISTRIBUTED RANDOMLY). Table distribution is random even if the table creation command contains the LIKE or INHERITS clause.
- If PRIMARY KEY or UNIQUE columns are specified, a DISTRIBUTED BY clause must also be specified. If a DISTRIBUTED BY clause is not specified as part of the table creation command, the command fails.

For a CREATE TABLE AS command that does not contain a distribution clause:

- If the Postgres-based planner creates the table, and the value of the parameter is `off`, the table distribution policy is determined based on the command.
- If the Postgres-based planner creates the table, and the value of the parameter is `on`, the table distribution policy is random.
- If GPORCA creates the table, the table distribution policy is random. The parameter value has no affect.

For information about the Postgres-based planner and GPORCA, see "SQL: Querying Data" in the *WarehousePG Administrator Guide*.

Value Range	Default	Set Classifications
boolean	off	coordinator, session, reload

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

gp_dbid

The local content dbid of a segment.

Value Range	Default	Set Classifications
integer		read only

gp_debug_linger

Number of seconds for a WarehousePG process to linger after a fatal internal error.

Value Range	Default	Set Classifications
Any valid time expression (number and unit)	0	coordinator, session, reload

gp_default_storage_options

Set the default values for the following table storage options when a table is created with the `CREATE TABLE` command.

- appendoptimized

  > **Note** You use the `appendoptimized=value` syntax to specify the append-optimized table storage type. `appendoptimized` is a thin alias for the `appendonly` legacy storage option. WarehousePG stores `appendonly` in the catalog, and displays the same when listing the storage options for append-optimized tables.

- blocksize
- checksum
- compresstype
- compresslevel
- orientation

Specify multiple storage option values as a comma separated list.

You can set the storage options with this parameter instead of specifying the table storage options in the `WITH` of the `CREATE TABLE` command. The table storage options that are specified with the `CREATE TABLE` command override the values specified by this parameter.

Not all combinations of storage option values are valid. If the specified storage options are not valid, an error is returned. See the `CREATE TABLE` command for information about table storage options.

The defaults can be set for a database and user. If the server configuration parameter is set at different levels, this the order of precedence, from highest to lowest, of the table storage values when a user logs into a database and creates a table:

1. The values specified in a `CREATE TABLE` command with the `WITH` clause or `ENCODING` clause
2. The value of `gp_default_storage_options` that set for the user with the `ALTER ROLE...SET` command
3. The value of `gp_default_storage_options` that is set for the database with the `ALTER DATABASE...SET` command
4. The value of `gp_default_storage_options` that is set for the WarehousePG cluster with the `gpconfig` utility

The parameter value is not cumulative. For example, if the parameter specifies the `appendoptimized` and `compresstype` options for a database and a user logs in and sets the parameter to specify the value for the `orientation` option, the `appendoptimized`, and `compresstype` values set at the database level are ignored.

This example `ALTER DATABASE` command sets the default `orientation` and `compresstype` table storage options for the database `mytest`.

```
ALTER DATABASE mytest SET gp_default_storage_options = 'orientation=column, compresstype=rle_type'
```

To create an append-optimized table in the `mytest` database with column-oriented table and RLE compression. The user needs to specify only `appendoptimized=TRUE` in the `WITH` clause.

This example `gpconfig` utility command sets the default storage option for a WarehousePG cluster. If you set the defaults for multiple table storage options, the value must be enclosed in single quotes.

```
gpconfig -c 'gp_default_storage_options' -v 'appendoptimized=true, orientation=column'
```

This example `gpconfig` utility command shows the value of the parameter. The parameter value must be consistent across the WarehousePG coordinator and all segments.

```
gpconfig -s 'gp_default_storage_options'
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Value Range	Default	Set Classifications[1]
`appendoptimized` = `TRUE` or `FALSE`	`appendoptimized` = `FALSE`	coordinator, session, reload
`blocksize` = integer between 8192 and 2097152	`blocksize` = `32768`	
`checksum` = `TRUE` or `FALSE`	`checksum` = `TRUE`	
`compresstype` = `ZLIB` or `ZSTD` or `RLE_TYPE` or `NONE`	`compresstype` = `none`	
`compresslevel` = integer between 0 and 19	`compresslevel` = `0`	
`orientation` = `ROW` | `COLUMN`	`orientation` = `ROW`	

Note [1]The set classification when the parameter is set at the system level with the `gpconfig` utility.

gp_dispatch_keepalives_count

Maximum number of TCP keepalive retransmits from a WarehousePG Query Dispatcher to its Query Executors. It controls the number of consecutive keepalive retransmits that can be lost before a connection between a Query Dispatcher and a Query Executor is considered dead.

Value Range	Default	Set Classifications
0 to 127	0 (it uses the system default)	coordinator, system, restart

gp_dispatch_keepalives_idle

Time in seconds between issuing TCP keepalives from a WarehousePG Query Dispatcher to its Query Executors.

Value Range	Default	Set Classifications
0 to 32767	0 (it uses the system default)	coordinator, system, restart

gp_dispatch_keepalives_interval

Time in seconds between TCP keepalive retransmits from a WarehousePG Query Dispatcher to its Query Executors.

Value Range	Default	Set Classifications
0 to 32767	0 (it uses the system default)	coordinator, system, restart

gp_dynamic_partition_pruning

Enables plans that can dynamically eliminate the scanning of partitions.

Value Range	Default	Set Classifications
Boolean	on	coordinator, session, reload

gp_eager_two_phase_agg

Activates or deactivates two-phase aggregation for the Postgres-based planner.

The default value is `off`; the Postgres-based planner chooses the best aggregate path for a query based on the cost. When set to `on`, the Postgres-based planner adds a disable cost to each of the first stage aggregate paths, which in turn forces the Postgres-based planner to generate and choose a multi-stage aggregate path.

Value Range	Default	Set Classifications
Boolean	off	coordinator, session, reload

gp_enable_agg_distinct

Activates or deactivates two-phase aggregation to compute a single distinct-qualified aggregate. This applies only to subqueries that include a single distinct-qualified aggregate function.

Value Range	Default	Set Classifications
Boolean	on	coordinator, session, reload

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

gp_enable_agg_distinct_pruning

Activates or deactivates three-phase aggregation and join to compute distinct-qualified aggregates. This applies only to subqueries that include one or more distinct-qualified aggregate functions.

Value Range	Default	Set Classifications
Boolean	on	coordinator, session, reload

gp_enable_direct_dispatch

Activates or deactivates the dispatching of targeted query plans for queries that access data on a single segment. When on, queries that target rows on a single segment will only have their query plan dispatched to that segment (rather than to all segments). This significantly reduces the response time of qualifying queries as there is no interconnect setup involved. Direct dispatch does require more CPU utilization on the coordinator.

Value Range	Default	Set Classifications
Boolean	on	coordinator, session, reload

gp_enable_fast_sri

When set to `on`, the Postgres-based planner plans single row inserts so that they are sent directly to the correct segment instance (no motion operation required). This significantly improves performance of single-row-insert statements.

Value Range	Default	Set Classifications
Boolean	on	coordinator, session, reload

gp_enable_global_deadlock_detector

Controls whether the WarehousePG Global Deadlock Detector is enabled to manage concurrent `UPDATE` and `DELETE` operations on heap tables to improve performance. See DML: Inserting, Updating and Deleting in the *WarehousePG Administrator Guide*. The default is `off`, the Global Deadlock Detector is deactivated.

If the Global Deadlock Detector is deactivated (the default), WarehousePG runs concurrent update and delete operations on a heap table serially.

If the Global Deadlock Detector is enabled, concurrent updates are permitted and the Global Deadlock Detector determines when a deadlock exists, and breaks the deadlock by cancelling one or more backend processes associated with the youngest transaction(s) involved.

Value Range	Default	Set Classifications
Boolean	off	coordinator, system, restart

gp_enable_groupext_distinct_gather

Activates or deactivates gathering data to a single node to compute distinct-qualified aggregates on grouping extension queries. When this parameter and `gp_enable_groupext_distinct_pruning` are both enabled, the Postgres-based planner uses the cheaper plan.

Value Range	Default	Set Classifications
Boolean	on	coordinator, session, reload

gp_enable_groupext_distinct_pruning

Activates or deactivates three-phase aggregation and join to compute distinct-qualified aggregates on grouping extension queries. Usually, enabling this parameter generates a cheaper query plan that the Postgres-based planner will use in preference to existing plan.

Value Range	Default	Set Classifications
Boolean	on	coordinator, session, reload

gp_enable_multiphase_agg

Activates or deactivates the use of two or three-stage parallel aggregation plans Postgres-based planner. This approach applies to any subquery with aggregation. If `gp_enable_multiphase_agg` is off, then `gp_enable_agg_distinct` and `gp_enable_agg_distinct_pruning` are deactivated.

Value Range	Default	Set Classifications
Boolean	on	coordinator, session, reload

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

gp_enable_predicate_propagation

When enabled, the Postgres-based planner applies query predicates to both table expressions in cases where the tables are joined on their distribution key column(s). Filtering both tables prior to doing the join (when possible) is more efficient.

Value Range	Default	Set Classifications
Boolean	on	coordinator, session, reload

gp_enable_preunique

Enables two-phase duplicate removal for `SELECT DISTINCT` queries (not `SELECT COUNT(DISTINCT)`). When enabled, it adds an extra `SORT DISTINCT` set of plan nodes before motioning. In cases where the distinct operation greatly reduces the number of rows, this extra `SORT DISTINCT` is much cheaper than the cost of sending the rows across the Interconnect.

Value Range	Default	Set Classifications
Boolean	on	coordinator, session, reload

gp_enable_relsize_collection

Enables GPORCA and the Postgres-based planner to use the estimated size of a table (`pg_relation_size` function) if there are no statistics for the table. By default, GPORCA and the planner use a default value to estimate the number of rows if statistics are not available. The default behavior improves query optimization time and reduces resource queue usage in heavy workloads, but can lead to suboptimal plans.

This parameter is ignored for a root partitioned table. When GPORCA is enabled and the root partition does not have statistics, GPORCA always uses the default value. You can use `ANALZYE ROOTPARTITION` to collect statistics on the root partition. See ANALYZE.

Value Range	Default	Set Classifications
Boolean	off	coordinator, session, reload

gp_enable_segment_copy_checking

Controls whether the distribution policy for a table (from the table `DISTRIBUTED` clause) is checked when data is copied into the table with the `COPY FROM...ON SEGMENT` command. If true, an error is returned if a row of data violates the distribution policy for a segment instance. The default is `true` .

If the value is `false` , the distribution policy is not checked. The data added to the table might violate the table distribution policy for the segment instance. Manual redistribution of table data might be required. See the `ALTER TABLE` clause `WITH REORGANIZE` .

The parameter can be set for a database system or a session. The parameter cannot be set for a specific database.

Value Range	Default	Set Classifications
Boolean	true	coordinator, session, reload

gp_enable_sort_limit

Enable `LIMIT` operation to be performed while sorting. Sorts more efficiently when the plan requires the first *limit_number* of rows at most.

Value Range	Default	Set Classifications
Boolean	on	coordinator, session, reload

gp_external_enable_exec

Activates or deactivates the use of external tables that run OS commands or scripts on the segment hosts (`CREATE EXTERNAL TABLE EXECUTE` syntax).

Value Range	Default	Set Classifications
Boolean	on	coordinator, system, restart

gp_explain_jit

Prints summarized JIT information from all query executions when JIT compilation is enabled.

Value Range	Default	Set Classifications
boolean	on	coordinator, session, reload

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

gp_external_max_segs

Sets the number of segments that will scan external table data during an external table operation, the purpose being not to overload the system with scanning data and take away resources from other concurrent operations. This only applies to external tables that use the `gpfdist://` protocol to access external table data.

Value Range	Default	Set Classifications
integer	64	coordinator, session, reload

gp_external_enable_filter_pushdown

Enable filter pushdown when reading data from external tables. If pushdown fails, a query is run without pushing filters to the external data source (instead, WarehousePG applies the same constraints to the result). See Defining External Tables for more information.

Value Range	Default	Set Classifications
Boolean	on	coordinator, session, reload

gp_fts_probe_interval

Specifies the polling interval for the fault detection process (`ftsprobe`). The `ftsprobe` process will take approximately this amount of time to detect a segment failure.

Value Range	Default	Set Classifications
10 - 3600 seconds	1min	coordinator, system, reload

gp_fts_probe_retries

Specifies the number of times the fault detection process (`ftsprobe`) attempts to connect to a segment before reporting segment failure.

Value Range	Default	Set Classifications
integer	5	coordinator, system, reload

gp_fts_probe_timeout

Specifies the allowed timeout for the fault detection process (`ftsprobe`) to establish a connection to a segment before declaring it down.

Value Range	Default	Set Classifications
10 - 3600 seconds	20 secs	coordinator, system, reload

gp_fts_replication_attempt_count

Specifies the maximum number of times that WarehousePG attempts to establish a primary-mirror replication connection. When this count is exceeded, the fault detection process (`ftsprobe`) stops retrying and marks the mirror down.

Value Range	Default	Set Classifications
0 - 100	10	coordinator, system, reload

gp_global_deadlock_detector_period

Specifies the executing interval (in seconds) of the global deadlock detector background worker process.

Value Range	Default	Set Classifications
5 - `INT_MAX` secs	120 secs	coordinator, system, reload

gp_log_endpoints

Controls the amount of parallel retrieve cursor endpoint detail that WarehousePG writes to the server log file.

The default value is `false` , WarehousePG does not log endpoint details to the log file. When set to `true` , WarehousePG writes endpoint detail information to the log file.

Value Range	Default	Set Classifications
Boolean	false	coordinator, session, reload

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

gp_log_fts

Controls the amount of detail the fault detection process (`ftsprobe`) writes to the log file.

Value Range	Default	Set Classifications
OFF, TERSE, VERBOSE, DEBUG	TERSE	coordinator, system, restart

gp_log_interconnect

Controls the amount of information that is written to the log file about communication between WarehousePG segment instance worker processes. The default value is `terse` . The log information is written to both the coordinator and segment instance logs.

Increasing the amount of logging could affect performance and increase disk space usage.

Value Range	Default	Set Classifications
off, terse, verbose, debug	terse	coordinator, session, reload

gp_log_gang

Controls the amount of information that is written to the log file about query worker process creation and query management. The default value is `OFF` , do not log information.

Value Range	Default	Set Classifications
OFF, TERSE, VERBOSE, DEBUG	OFF	coordinator, session, restart

gp_hashjoin_tuples_per_bucket

Sets the target density of the hash table used by HashJoin operations. A smaller value will tend to produce larger hash tables, which can increase join performance.

Value Range	Default	Set Classifications
integer	5	coordinator, session, reload

gp_ignore_error_table

Controls WarehousePG behavior when the deprecated `INTO ERROR TABLE` clause is specified in a `CREATE EXTERNAL TABLE` or `COPY` command.

> **Note** The `INTO ERROR TABLE` clause was deprecated and removed in WarehousePG 5. In WarehousePG 7, this parameter will be removed as well, causing all `INTO ERROR TABLE` invocations be yield a syntax error.

The default value is `false` , WarehousePG returns an error if the `INTO ERROR TABLE` clause is specified in a command.

If the value is `true` , WarehousePG ignores the clause, issues a warning, and runs the command without the `INTO ERROR TABLE` clause. In WarehousePG 6.x and later, you access the error log information with built-in SQL functions. See the CREATE EXTERNAL TABLE or COPY command.

You can set this value to `true` to avoid the WarehousePG error when you run applications that run `CREATE EXTERNAL TABLE` or `COPY` commands that include the unsupoorted `INTO ERROR TABLE` clause.

Value Range	Default	Set Classifications
Boolean	false	coordinator, session, reload

gp_initial_bad_row_limit

For the parameter value *n*, WarehousePG stops processing input rows when you import data with the `COPY` command or from an external table if the first *n* rows processed contain formatting errors. If a valid row is processed within the first *n* rows, WarehousePG continues processing input rows.

Setting the value to 0 deactivates this limit.

The `SEGMENT REJECT LIMIT` clause can also be specified for the `COPY` command or the external table definition to limit the number of rejected rows.

`INT_MAX` is the largest value that can be stored as an integer on your system.

Value Range	Default	Set Classifications
integer 0 - `INT_MAX`	1000	coordinator, session, reload

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

gp_interconnect_address_type

Specifies the type of address binding strategy WarehousePG uses for communication between segment host sockets. There are two types: `unicast` and `wildcard`. The default is `unicast`.

- When this parameter is set to `unicast`, WarehousePG uses the `gp_segment_configuration.address` field to perform address binding. This reduces port usage on segment hosts and prevents interconnect traffic from being routed through unintended (and possibly slower) network interfaces. This is the recommended option.
- When this parameter is set to `wildcard`, WarehousePG uses a wildcard address for binding, enabling the use of any network interface compliant with routing rules.

> **Note** In some cases, inter-segment communication using the unicast strategy may not be possible. One example is if the source segment's address field and the destination segment's address field are on different subnets and/or existing routing rules do not allow for such communication. In these cases, we recommend you use a single subnet for all segment addresses, or fix routing rules to allow communication between subnets. If neither is possible, you will need to configure this parameter to `wildcard` for wildcard address binding.

Value Range	Default	Set Classifications
wildcard,unicast	unicast	local, system, reload

gp_interconnect_debug_retry_interval

Specifies the interval, in seconds, to log WarehousePG interconnect debugging messages when the server configuration parameter gp_log_interconnect is set to `DEBUG`. The default is 10 seconds.

The log messages contain information about the interconnect communication between WarehousePG segment instance worker processes. The information can be helpful when debugging network issues between segment instances.

Value Range	Default	Set Classifications
1 =< Integer < 4096	10	coordinator, session, reload

gp_interconnect_fc_method

Specifies the flow control method used for the default WarehousePG UDPIFC interconnect.

For capacity based flow control, senders do not send packets when receivers do not have the capacity.

Loss based flow control is based on capacity based flow control, and also tunes the sending speed according to packet losses.

Value Range	Default	Set Classifications
CAPACITY, LOSS	LOSS	coordinator, session, reload

gp_interconnect_proxy_addresses

Sets the proxy ports that WarehousePG uses when the server configuration parameter gp_interconnect_type is set to `proxy`. Otherwise, this parameter is ignored. The default value is an empty string ("").

When the `gp_interconnect_type` parameter is set to `proxy`, You must specify a proxy port for the coordinator, standby coordinator, and all primary and mirror segment instances in this format:

```
<db_id>:<cont_id>:<seg_address>:<port>[, ... ]
```

For the coordinator, standby coordinator, and segment instance, the first three fields, db_id, cont_id, and seg_address can be found in thegp_segment_configuration catalog table. The fourth field, port, is the proxy port for the WarehousePG coordinator or a segment instance.

- db_id is the `dbid` column in the catalog table.
- cont_id is the `content` column in the catalog table.
- seg_address is the IP address or hostname corresponding to tge `address` column in the catalog table.
- port is the TCP/IP port for the segment instance proxy that you specify.

> **Important** If a segment instance hostname is bound to a different IP address at runtime, you must run `gpstop -U` to re-load the `gp_interconnect_proxy_addresses` value.

You must specify the value as a single-quoted string. This `gpconfig` command sets the value for `gp_interconnect_proxy_addresses` as a single-quoted string. The WarehousePG cluster consists of a coordinator and a single segment instance.

```
gpconfig --skipvalidation -c gp_interconnect_proxy_addresses -v "'1:-1:192.168.180.50:35432,2:0:192.168.180.54:35000'"
```

For an example of setting `gp_interconnect_proxy_addresses`, see Configuring Proxies for the WarehousePG Interconnect.

Value Range	Default	Set Classifications
string (maximum length - 16384 bytes)		local, system, reload

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

gp_interconnect_queue_depth

Sets the amount of data per-peer to be queued by the WarehousePG interconnect on receivers (when data is received but no space is available to receive it the data will be dropped, and the transmitter will need to resend it) for the default UDPIFC interconnect. Increasing the depth from its default value will cause the system to use more memory, but may increase performance. It is reasonable to set this value between 1 and 10. Queries with data skew potentially perform better with an increased queue depth. Increasing this may radically increase the amount of memory used by the system.

Value Range	Default	Set Classifications
1-2048	4	coordinator, session, reload

gp_interconnect_setup_timeout

Specifies the amount of time, in seconds, that WarehousePG waits for the interconnect to complete setup before it times out.

Value Range	Default	Set Classifications
0 - 7200 seconds	7200 seconds (2 hours)	coordinator, session, reload

gp_interconnect_snd_queue_depth

Sets the amount of data per-peer to be queued by the default UDPIFC interconnect on senders. Increasing the depth from its default value will cause the system to use more memory, but may increase performance. Reasonable values for this parameter are between 1 and 4. Increasing the value might radically increase the amount of memory used by the system.

Value Range	Default	Set Classifications
1 - 4096	2	coordinator, session, reload

gp_interconnect_transmit_timeout

Specifies the amount of time, in seconds, that WarehousePG waits for network transmission of interconnect traffic to complete before it times out.

Value Range	Default	Set Classifications
1 - 7200 seconds	3600 seconds (1 hour)	coordinator, session, reload

gp_interconnect_type

Sets the networking protocol used for WarehousePG interconnect traffic. UDPIFC specifies using UDP with flow control for interconnect traffic, and is the only value supported.

UDPIFC (the default) specifies using UDP with flow control for interconnect traffic. Specify the interconnect flow control method with gp_interconnect_fc_method.

With TCP as the interconnect protocol, WarehousePG has an upper limit of 1000 segment instances - less than that if the query workload involves complex, multi-slice queries.

The `PROXY` value specifies using the TCP protocol, and when running queries, using a proxy for WarehousePG interconnect communication between the coordinator instance and segment instances and between two segment instances. When this parameter is set to `PROXY`, you must specify the proxy ports for the coordinator and segment instances with the server configuration parametergp_interconnect_proxy_addresses. For information about configuring and using proxies with the WarehousePG interconnect, see Configuring Proxies for the WarehousePG Interconnect.

Value Range	Default	Set Classifications
UDPIFC, TCP, PROXY	UDPIFC	local, session, reload

gp_log_format

Specifies the format of the server log files. If using *gp_toolkit* administrative schema, the log files must be in CSV format.

Value Range	Default	Set Classifications
csv, text	csv	local, system, restart

gp_max_local_distributed_cache

Sets the maximum number of distributed transaction log entries to cache in the backend process memory of a segment instance.

The log entries contain information about the state of rows that are being accessed by an SQL statement. The information is used to determine which rows are visible to an SQL transaction when running multiple simultaneous SQL statements in an MVCC environment. Caching distributed transaction log entries locally improves transaction processing speed by improving performance of the row visibility determination process.

The default value is optimal for a wide variety of SQL processing environments.

Value Range	Default	Set Classifications
integer	1024	local, system, restart

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

gp_max_packet_size

Sets the tuple-serialization chunk size for the WarehousePG interconnect.

Value Range	Default	Set Classifications
512-65536	8192	coordinator, system, reload

gp_max_parallel_cursors

Specifies the maximum number of active parallel retrieve cursors allowed on a WarehousePG cluster. A parallel retrieve cursor is considered active after it has been `DECLARE`d, but before it is `CLOSE`d or returns an error.

The default value is `-1`; there is no limit on the number of open parallel retrieve cursors that may be concurrently active in the cluster (up to the maximum value of 1024).

Each parallel retrieve cursor creates upto `N` endpoints, where N is the number of primary segments (including the coordinator) in the cluster. On each primary segment, each endpoint costs a small amount of shared memory and consumes one `retrieve` connection that contributes towards the `max_connections` limit.

This GUC is a way to limit that consumption.

You must be a superuser to change the `gp_max_parallel_cursors` setting.

Value Range	Default	Set Classifications
-1 - 1024	-1	coordinator, superuser, session, reload

gp_max_plan_size

Specifies the total maximum uncompressed size of a query execution plan multiplied by the number of Motion operators (slices) in the plan. If the size of the query plan exceeds the value, the query is cancelled and an error is returned. A value of 0 means that the size of the plan is not monitored.

You can specify a value in `kB`, `MB`, or `GB`. The default unit is `kB`. For example, a value of `200` is 200kB. A value of `1GB` is the same as `1024MB` or `1048576kB`.

Value Range	Default	Set Classifications
integer	0	coordinator, superuser, session, reload

gp_max_slices

Specifies the maximum number of slices (portions of a query plan that are run on segment instances) that can be generated by a query. If the query generates more than the specified number of slices, WarehousePG returns an error and does not run the query. The default value is `0`, no maximum value.

Running a query that generates a large number of slices might affect WarehousePG performance. For example, a query that contains `UNION` or `UNION ALL` operators over several complex views can generate a large number of slices. You can run `EXPLAIN ANALYZE` on the query to view slice statistics for the query.

Value Range	Default	Set Classifications
0 - INT_MAX	0	coordinator, session, reload

gp_max_system_slices

> **NOTE** This parameter is identical in behavior to `gp_max_slices`, except that it requires superuser privileges. In addition, it takes precedence over `gp_max_slices` if `gp_max_slices` is greater than its value.

Specifies the maximum number of slices (portions of a query plan that are run on segment instances) that can be generated by a query. If the query generates more than the specified number of slices, WarehousePG returns an error and does not run the query. The default value is `0`, no maximum value.

Running a query that generates a large number of slices might affect WarehousePG performance. For example, a query that contains `UNION` or `UNION ALL` operators over several complex views can generate a large number of slices. You can run `EXPLAIN ANALYZE` on the query to view slice statistics for the query.

Value Range	Default	Set Classifications
0 - INT_MAX	0	coordinator, session, reload, superuser

gp_motion_cost_per_row

Sets the Postgres-based planner cost estimate for a Motion operator to transfer a row from one segment to another, measured as a fraction of the cost of a sequential page fetch. If 0, then the value used is two times the value of *cpu_tuple_cost*.

Value Range	Default	Set Classifications
floating point	0	coordinator, session, reload

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

gp_postmaster_address_family

When starting a cluster, this server configuration parameter tells a node which type of IP address to use. When set to `auto`, WarehousePG loops through all the ipv4 and ipv6 addresses specified in `listen_addresses`, trying to open a "listening" port on each one.

Value Range	Default	Set Classifications
auto, ipv4, ipv6	auto	local, system, restart, superuser

gp_print_create_gang_time

When a user starts a session with WarehousePG and issues a query, the system creates groups or 'gangs' of worker processes on each segment to do the work. `gp_print_create_gang_time` controls the display of additional information about gang creation, including gang reuse status and the shortest and longest connection establishment time to the segment.

The default value is `false`, WarehousePG does not display the additional gang creation information.

Value Range	Default	Set Classifications
Boolean	false	coordinator, session, reload

gp_quickz_fallback

Determines how WarehousePG handles legacy SQL that specifies a compression type of QuickLZ, which is not supported in WarehousePG 7 and later. When set to `true`, if legacy SQL specifies a compression type of QuickLZ, WarehousePG will apply a compression type of zstd. When set to `false` -- the default -- specifying a compression type of QuickLZ will result in an error.

Value Range	Default	Set Classifications
Boolean	off	coordinator, session, reload

gp_recursive_cte

Controls the availability of the `RECURSIVE` keyword in the `WITH` clause of a `SELECT [INTO]` command, or a `DELETE`, `INSERT` or `UPDATE` command. The keyword allows a subquery in the `WITH` clause of a command to reference itself. The default value is `true`, the `RECURSIVE` keyword is allowed in the `WITH` clause of a command.

For information about the `RECURSIVE` keyword, see the SELECT command and WITH Queries (Common Table Expressions).

The parameter can be set for a database system, an individual database, or a session or query.

> **Note** This parameter was previously named `gp_recursive_cte_prototype`, but has been renamed to reflect the current status of the implementation.

Value Range	Default	Set Classifications
Boolean	true	coordinator, session, restart

gp_reject_percent_threshold

For single row error handling on COPY and external table SELECTs, sets the number of rows processed before SEGMENT REJECT LIMIT *n* PERCENT starts calculating.

Value Range	Default	Set Classifications
1-*n*	300	coordinator, session, reload

gp_reraise_signal

If enabled, will attempt to dump core if a fatal server error occurs.

Value Range	Default	Set Classifications
Boolean	on	coordinator, session, reload

gp_resgroup_memory_policy

> **Note** The `gp_resgroup_memory_policy` server configuration parameter is enforced only when resource group-based resource management is active.

Used by a resource group to manage memory allocation to query operators.

When set to `auto`, WarehousePG uses resource group memory limits to distribute memory across query operators, allocating a fixed size of memory to non-memory-intensive operators and the rest to memory-intensive operators.

When you specify `eager_free`, WarehousePG distributes memory among operators more optimally by re-allocating memory released by operators that have completed their processing to operators in a later query stage.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Value Range	Default	Set Classifications
auto, eager_free	eager_free	local, system, superuser, reload

gp_resgroup_memory_query_fixed_mem

> **Note** The `gp_resgroup_memory_query_fixed_mem` server configuration parameter is enforced only when resource group-based resource management is active.

Specifies a fixed amount of memory, in MB, reserved for all queries in a resource group **for the scope of a session**. When this parameter is set to `0`, the default, the `MEMORY_QUOTA` resource group attribute determines this instead.

While `MEMORY_QUOTA` applies to queries across sessions, `gp_resgroup_memory_query_fixed_mem` overrides that limit at a session level. Thus, you can use this configuration parameter to adjust query memory budget for a particular session, on an ad hoc basis.

The value of `gp_resgroup_memory_query_fixed_mem` must be lower than `max_statement_mem`.

Value Range	Default	Set Classifications
0 < integer < INT_MAX	0	coordinator, session, user

gp_resource_group_bypass

> **Note** The `gp_resource_group_bypass` server configuration parameter is enforced only when resource group-based resource management is active.

Activates or deactivates the enforcement of resource group concurrent transaction limits on WarehousePG resources. The default value is `false`, which enforces resource group transaction limits. Resource groups manage resources such as CPU, memory, and the number of concurrent transactions that are used by queries.

You can set this parameter to `true` to bypass resource group concurrent transaction limitations so that a query can run immediately. If you set this parameter to true, the query no longer enforces the CPU or memory limits assigned to its resource group. Instead, the memory quota assigned to this query is `statement_mem` per query. If there is not enough memory to satisfy the memory allocation request, the query will fail.

This parameter can be set for a session. The parameter cannot be set within a transaction or a function.

Value Range	Default	Set Classifications
Boolean	false	local, session, reload

gp_resource_group_bypass_catalog_query

> **Note** The `gp_resource_group_bypass_catalog_query` server configuration parameter is enforced only when resource group-based resource management is active.

When set to `true` -- the default -- WarehousePG's resource group scheduler bypasses all queries that fulfill both of the following criteria:

- They read exclusively from system catalogs
- They contain in their query text `pg_catalog` schema tables only

> **Note** If a query contains a mix of `pg_catalog` and any other schema tables the scheduler will **not** bypass the query.

When this configuration parameter is set to `false` and the database has reached the maximum amount of concurrent transactions, the scheduler can block queries that exclusively read from system catalogs.

Value Range	Default	Set Classifications
Boolean	true	local, session, reload

gp_resource_group_bypass_direct_dispatch

> **Note** The `gp_resource_group_bypass_direct_dispatch` server configuration parameter is enforced only when resource group-based resource management is active.

When set to `true` (the default) WarehousePG's resource group scheduler bypasses the resource group's limits for a direct dispatch query so it can run immediately. A direct dispatch query is a special type of query that only requires a single segment to participate in the execution. In order to improve efficiency, WarehousePG optimizes this type of query, called Direct Dispatch optimization. The system sends the query plan to the execution of a single segment that needs to execute the plan, instead of sending it to all segments for execution. The query uses resources outside the resource groups to allocate memory. If there is not enough memory to satisfy the memory allocation request, the query will fail. You may only set this parameter for a single session, not within a transaction or a function.

Value Range	Default	Set Classifications
Boolean	true	local, session, reload

gp_resource_group_cgroup_parent

> **Note** The `gp_resource_group_cgroup_parent` server configuration parameter is enforced only when resource group-based resource management is active and cgroup v2 is used.

Identifies the root path of the `gpdb` cgroup hierarchy.

Value Range	Default	Set Classifications

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Value Range	Default	Set Classifications
char	"gpdb.service"	local, system, restart, superuser

gp_resource_group_cpu_limit

> **Note** The `gp_resource_group_cpu_limit` server configuration parameter is enforced only when resource group-based resource management is active.

Identifies the maximum percentage of system CPU resources to allocate to resource groups on each WarehousePG segment node.

Value Range	Default	Set Classifications
0.1 - 1.0	0.9	local, system, restart

gp_resource_group_cpu_priority

Sets the CPU priority for WarehousePG processes relative to non-WarehousePG processes when resource groups are enabled. For example, setting this parameter to `10` sets the ratio of allotted CPU resources for WarehousePG processes to non-WarehousePG processes to 10:1.

> **Note** This ratio calculation applies only when the machine's CPU usage is at 100%.

Value Range	Default	Set Classifications
1 - 50	10	local, system, restart

gp_resource_group_move_timeout

> **Note** The `gp_resource_group_move_timeout` server configuration parameter is enforced only when resource group-based resource management is active.

Cancels the `pg_resgroup_move_query()` function, which moves a running query from one resouce group to another, if it waits longer than the specified number of miliseconds.

Value Range	Default	Set Classifications
10 - `INT_MAX` millisecs	3000 millisecs	coordinator, session, reload

gp_resource_group_queuing_timeout

> **Note** The `gp_resource_group_queuing_timeout` server configuration parameter is enforced only when resource group-based resource management is active.

Cancels a transaction queued in a resource group that waits longer than the specified number of milliseconds. The time limit applies separately to each transaction. The default value is zero; transactions are queued indefinitely and never time out.

Value Range	Default	Set Classifications
0 - `INT_MAX` millisecs	0 millisecs	coordinator, session, reload

gp_resource_manager

Identifies the resource management scheme currently enabled in the WarehousePG cluster. For information about WarehousePG resource management, seeManaging Resources.

- `none` - configures WarehousePG to not use any resource manager. This is the default.
- `group` - configures WarehousePG to use resource groups and base resource group behavior on the cgroup v1 version of Linux cgroup functionality.
- `group-v2` - configures WarehousePG to use resource groups and base resource group behavior on the cgroup v2 version of Linux cgroup functionality.
- `queue` - configures WarehousePG to use resource queues.

Value Range	Default	Set Classifications
none, group, group-v2, queue	none	local, system, restart

gp_resqueue_memory_policy

> **Note** The `gp_resqueue_memory_policy` server configuration parameter is enforced only when resource queue-based resource management is active.

Enables WarehousePG memory management features. The distribution algorithm `eager_free` takes advantage of the fact that not all operators run at the same time(in WarehousePG 4.2 and later). The query plan is divided into stages and WarehousePG eagerly frees memory allocated to a previous stage at the end of that stage's execution, then allocates the eagerly freed memory to the new stage.

When set to `none`, memory management is the same as in WarehousePG releases prior to 4.1.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

When set to `auto`, query memory usage is controlled by statement_mem and resource queue memory limits.

Value Range	Default	Set Classifications
none, auto, eager_free	eager_free	local, system, restart/reload

gp_resqueue_priority

> **Note** The `gp_resqueue_priority` server configuration parameter is enforced only when resource queue-based resource management is active.

Activates or deactivates query prioritization. When this parameter is deactivated, existing priority settings are not evaluated at query run time.

Value Range	Default	Set Classifications
Boolean	on	local, system, restart

gp_resqueue_priority_cpucores_per_segment

> **Note** The `gp_resqueue_priority_cpucores_per_segment` server configuration parameter is enforced only when resource queue-based resource management is active.

Specifies the number of CPU units allocated to each segment instance on a segment host. If the segment is configured with primary-mirror segment instance pairs, use the number of primary segment instances on the host in the calculation. Include any CPU core that is available to the operating system, including virtual CPU cores, in the total number of available cores.

For example, if a WarehousePG cluster has 10-core segment hosts that are configured with four primary segments, set the value to 2.5 on each segment host (10 divided by 4). A coordinator host typically has only a single running coordinator instance, so set the value on the coordinator and standby maaster hosts to reflect the usage of all available CPU cores, in this case 10.

Incorrect settings can result in CPU under-utilization or query prioritization not working as designed.

Value Range	Default	Set Classifications
0.1 - 512.0	4	local, system, restart

gp_resqueue_priority_sweeper_interval

> **Note** The `gp_resqueue_priority_sweeper_interval` server configuration parameter is enforced only when resource queue-based resource management is active.

Specifies the interval at which the sweeper process evaluates current CPU usage. When a new statement becomes active, its priority is evaluated and its CPU share determined when the next interval is reached.

Value Range	Default	Set Classifications
500 - 15000 ms	1000	local, system, restart

gp_retrieve_conn

A session that you initiate with `PGOPTIONS='-c gp_retrieve_conn=true'` is a retrieve session. You use a retrieve session to retrieve query result tuples from a specific endpoint instantiated for a parallel retrieve cursor.

The default value is `false`.

Value Range	Default	Set Classifications
Boolean	false	read only

gp_role

The role of this server process is set to *dispatch* for the coordinator and *execute* for a segment.

Value Range	Default	Set Classifications
dispatchexecute, utility		read only

gp_segment_connect_timeout

Time that the WarehousePG interconnect will try to connect to a segment instance over the network before timing out. Controls the network connection timeout between coordinator and primary segments, and primary to mirror segment replication processes.

Value Range	Default	Set Classifications
Any valid time expression (number and unit)	3min	local, session, reload

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

gp_segments_for_planner

Sets the number of primary segment instances for the Postgres-based planner to assume in its cost and size estimates. If 0, then the value used is the actual number of primary segments. This variable affects the Postgres-based planner's estimates of the number of rows handled by each sending and receiving process in Motion operators.

Value Range	Default	Set Classifications
0-*n*	0	coordinator, session, reload

gp_server_version

Reports the version number of the server as a string. A version modifier argument might be appended to the numeric portion of the version string, example: *5.0.0 beta*.

Value Range	Default	Set Classifications
String. Examples: *5.0.0*	n/a	read only

gp_server_version_num

Reports the version number of the server as an integer. The number is guaranteed to always be increasing for each version and can be used for numeric comparisons. The major version is represented as is, the minor and patch versions are zero-padded to always be double digit wide.

Value Range	Default	Set Classifications
Mmmpp where *M* is the major version, *mm* is the minor version zero-padded and *pp* is the patch version zero-padded. Example: 50000	n/a	read only

gp_session_id

A system assigned ID number for a client session. Starts counting from 1 when the coordinator instance is first started.

Value Range	Default	Set Classifications
1-*n*	14	read only

gp_set_proc_affinity

If enabled, when a WarehousePG server process (postmaster) is started it will bind to a CPU.

Value Range	Default	Set Classifications
Boolean	off	coordinator, system, restart

gp_set_read_only

Set to on to deactivate writes to the database. Any in progress transactions must finish before read-only mode takes affect.

Value Range	Default	Set Classifications
Boolean	off	coordinator, system, restart

gp_statistics_pullup_from_child_partition

This parameter directs the Postgres-based planner on where to obtain statistics when it plans a query on a partitioned table.

The default value is `off`, the Postgres-based planner uses the statistics of the root partitioned table, if it has any, when it plans a query. If the root partitioned table has no statistics, the Postgres-based planner attempts to use the statistics from the largest child partition.

When set to `on`, the Postgres-based planner attempts to use the statistics from the largest child partition when it plans a query on a partitioned table.

Value Range	Default	Set Classifications
Boolean	off	coordinator, session, reload

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

gp_statistics_use_fkeys

When enabled, the Postgres-based planner will use the statistics of the referenced column in the parent table when a column is foreign key reference to another table instead of the statistics of the column itself.

> **Note** This parameter is deprecated and will be removed in a future WarehousePG release.

Value Range	Default	Set Classifications
Boolean	off	coordinator, session, reload

gp_use_legacy_hashops

For a table that is defined with a `DISTRIBUTED BY key\_column` clause, this parameter controls the hash algorithm that is used to distribute table data among segment instances. The default value is `false`, use the jump consistent hash algorithm.

Setting the value to `true` uses the modulo hash algorithm.

Value Range	Default	Set Classifications
Boolean	false	coordinator, session, reload

gp_vmem_idle_resource_timeout

If a database session is idle for longer than the time specified, the session will free system resources (such as shared memory), but remain connected to the database. This allows more concurrent connections to the database at one time.

Value Range	Default	Set Classifications
Any valid time expression (number and unit)	18s	coordinator, session, reload

gp_vmem_protect_limit

When resource queue-based or resource-group based resource management is active, the parameter sets the amount of memory (in number of MBs) that all `postgres` processes of an active segment instance can consume. If a query causes this limit to be exceeded, memory will not be allocated and the query will fail. Note that this is a local parameter and must be set for every segment in the system (primary and mirrors). When setting the parameter value, specify only the numeric value. For example, to specify 4096MB, use the value `4096`. Do not add the units `MB` to the value.

To prevent over-allocation of memory, these calculations can estimate a safe `gp_vmem_protect_limit` value.

First calculate the value of `gp_vmem`. This is the WarehousePG memory available on a host.

- If the total system memory is less than 256 GB, use this formula:

```
gp_vmem = ((SWAP + RAM) – (7.5GB + 0.05 * RAM)) / 1.7
```

- If the total system memory is equal to or greater than 256 GB, use this formula:

```
gp_vmem = ((SWAP + RAM) – (7.5GB + 0.05 * RAM)) / 1.17
```

where SWAP is the host swap space and RAM is the RAM on the host in GB.

Next, calculate the `max_acting_primary_segments`. This is the maximum number of primary segments that can be running on a host when mirror segments are activated due to a failure. With mirrors arranged in a 4-host block with 8 primary segments per host, for example, a single segment host failure would activate two or three mirror segments on each remaining host in the failed host's block. The `max_acting_primary_segments` value for this configuration is 11 (8 primary segments plus 3 mirrors activated on failure).

This is the calculation for `gp_vmem_protect_limit`. The value should be converted to MB.

```
gp_vmem_protect_limit = <gp_vmem> / <acting_primary_segments>
```

For scenarios where a large number of workfiles are generated, this is the calculation for `gp_vmem` that accounts for the workfiles.

- If the total system memory is less than 256 GB:

```
<gp_vmem> = ((<SWAP> + <RAM>) – (7.5GB + 0.05 * <RAM> – (300KB * <total_#_workfiles>))) / 1.7
```

- If the total system memory is equal to or greater than 256 GB:

```
<gp_vmem> = ((<SWAP> + <RAM>) – (7.5GB + 0.05 * <RAM> – (300KB * <total_#_workfiles>))) / 1.17
```

For information about monitoring and managing workfile usage, see the *WarehousePG Administrator Guide*.

Based on the `gp_vmem` value you can calculate the value for the `vm.overcommit_ratio` operating system kernel parameter. This parameter is set when you configure each WarehousePG host.

```
vm.overcommit_ratio = (<RAM> – (0.026 * <gp_vmem>)) / <RAM>
```

> **Note** The default value for the kernel parameter `vm.overcommit_ratio` in Red Hat Enterprise Linux is 50.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

For information about the kernel parameter, see the *WarehousePG Installation Guide*.

Value Range	Default	Set Classifications
integer	8192	local, system, restart

gp_vmem_protect_segworker_cache_limit

If a query executor process consumes more than this configured amount, then the process will not be cached for use in subsequent queries after the process completes. Systems with lots of connections or idle processes may want to reduce this number to free more memory on the segments. Note that this is a local parameter and must be set for every segment.

Value Range	Default	Set Classifications
number of megabytes	500	local, system, restart

gp_workfile_compression

Specifies whether the temporary files created, when a hash aggregation or hash join operation spills to disk, are compressed.

If your WarehousePG installation uses serial ATA (SATA) disk drives, enabling compression might help to avoid overloading the disk subsystem with IO operations.

Value Range	Default	Set Classifications
Boolean	off	coordinator, session, reload

gp_workfile_limit_files_per_query

Sets the maximum number of temporary spill files (also known as workfiles) allowed per query per segment. Spill files are created when running a query that requires more memory than it is allocated. The current query is terminated when the limit is exceeded.

Set the value to 0 (zero) to allow an unlimited number of spill files. coordinator session reload

Value Range	Default	Set Classifications
integer	100000	coordinator, session, reload

gp_workfile_limit_per_query

Sets the maximum disk size an individual query is allowed to use for creating temporary spill files at each segment. The default value is 0, which means a limit is not enforced.

Value Range	Default	Set Classifications
kilobytes	0	coordinator, session, reload

gp_workfile_limit_per_segment

Sets the maximum total disk size that all running queries are allowed to use for creating temporary spill files at each segment. The default value is 0, which means a limit is not enforced.

Value Range	Default	Set Classifications
kilobytes	0	local, system, restart

gpfdist_retry_timeout

Controls the time (in seconds) that WarehousePG waits before returning an error when WarehousePG is attempting to connect or write to a`gpfdist` server and `gpfdist` does not respond. The default value is 300 (5 minutes). A value of 0 deactivates the timeout.

Value Range	Default	Set Classifications
0 - `INT_MAX` (2147483647)	300	local, session, reload

ignore_checksum_failure

Only has effect if data_checksums is enabled.

WarehousePG uses checksums to prevent loading data that has been corrupted in the file system into memory managed by database processes.

By default, when a checksum verify error occurs when reading a heap data page, WarehousePG generates an error and prevents the page from being loaded into managed memory. When `ignore_checksum_failure` is set to on and a checksum verify failure occurs, WarehousePG generates a warning, and allows the page to be read into managed memory. If the page is then updated it is saved to disk and replicated to the mirror. If the page header is corrupt an error is reported even if this option is enabled.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

> **Caution** Setting `ignore_checksum_failure` to on may propagate or hide data corruption or lead to other serious problems. However, if a checksum failure has already been detected and the page header is uncorrupted, setting `ignore_checksum_failure` to on may allow you to bypass the error and recover undamaged tuples that may still be present in the table.

The default setting is off, and it can only be changed by a superuser.

Value Range	Default	Set Classifications
Boolean	off	local, session, reload

integer_datetimes

Reports whether PostgreSQL was built with support for 64-bit-integer dates and times.

Value Range	Default	Set Classifications
Boolean	on	read only

IntervalStyle

Sets the display format for interval values. The value *sql_standard* produces output matching SQL standard interval literals. The value *postgres* produces output matching PostgreSQL releases prior to 8.4 when the DateStyle parameter was set to ISO.

The value *postgres_verbose* produces output matching WarehousePG releases prior to 3.3 when the DateStyle parameter was set to non-ISO output.

The value *iso_8601* will produce output matching the time interval *format with designators* defined in section 4.4.3.2 of ISO 8601. See the PostgreSQL 9.4 documentation for more information.

Value Range	Default	Set Classifications
postgres, postgres_verbose, sql_standard, iso_8601	postgres	coordinator, session, reload

jit

Determines whether JIT compilation may be used by WarehousePG. It enables or disables JIT for both GPORCA and Postgres-based planner.

Value Range	Default	Set Classifications
boolean	off	coordinator, session, reload

jit_above_cost

When using Postgres-based planner, sets the query cost above which JIT compilation is activated when JIT is enabled. Performing JIT compilation costs planning time but can accelerate query execution. Note that setting the JIT cost parameters to '0' forces all queries to be JIT-compiled and, as a result, slows down queries. Setting it to a negative value disables JIT compilation.

Value Range	Default	Set Classifications
floating point	100000	coordinator, session, reload

jit_debugging_support

If LLVM has the required functionality, register generated functions with GDB. This makes debugging easier. The default setting is `off`. This parameter can only be set at server start or when a client connection starts (for example using `PGOPTIONS`).

Value Range	Default	Set Classifications
boolean	off	coordinator, session, reload, superuser

jit_dump_bitcode

Writes the generated LLVM IR out to the file system, inside data_directory. This is only useful for working on the internals of the JIT implementation. The default setting is `off`. Only superusers and users with the appropriate `SET` privilege can change this setting.

Value Range	Default	Set Classifications
boolean	off	coordinator, session, reload

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

jit_expressions

Allows JIT compilation of expressions, when JIT compilation is activated.

Value Range	Default	Set Classifications
boolean	on	coordinator, session, reload

jit_inline_above_cost

When using Postgres-based planner, sets the query cost above which JIT compilation attempts to inline functions and operators. Inlining adds planning time, but can improve execution speed. It is not meaningful to set this to less than `jit_above_cost`. Note that setting the JIT cost parameters to '0' forces all queries to be JIT-compiled and, as a result, slows down queries. Setting it to a negative value disables inlining.

Value Range	Default	Set Classifications
floating point	500000	coordinator, session, reload

jit_optimize_above_cost

When using Postgres-based planner, sets the query cost above which JIT compilation applies expensive optimizations. Such optimization adds planning time, but can improve execution speed. It is not meaningful to set this to less than `jit_above_cost`, and it is unlikely to be beneficial to set it to more than `jit_inline_above_cost`. Note that setting the JIT cost parameters to '0' forces all queries to be JIT-compiled and, as a result, slows down queries. Setting it to a negative value disables expensive optimizations.

Value Range	Default	Set Classifications
floating point	500000	coordinator, session, reload

jit_profiling_support

If LLVM has the required functionality, emit the data needed to allow `perf` command to profile functions generated by JIT. This writes out files to `~/.debug/jit/`. If you have set and loaded the environment variable `JITDUMPDIR`, it will write to `JITDUMPDIR/debug/jit` instead. You are responsible for performing cleanup when desired. The default setting is `off`. This parameter can only be set at server start or when a client connection starts (for example using `PGOPTIONS`).

Value Range	Default	Set Classifications
boolean	off	coordinator, session, reload, superuser

jit_provider

Indicates the name of the JIT provider (library of JIT driver) to load. The default is `llvmjit`, any other value is not officially supported. This parameter can only be set at server start.

Value Range	Default	Set Classifications
string	llvmjit	local, session, restart, superuser

jit_tuple_deforming

Allows JIT compilation of tuple deforming, when JIT compilation is activated.

Value Range	Default	Set Classifications
boolean	on	coordinator, session, reload

join_collapse_limit

The Postgres-based planner will rewrite explicit inner `JOIN` constructs into lists of `FROM` items whenever a list of no more than this many items in total would result. By default, this variable is set the same as *from_collapse_limit*, which is appropriate for most uses. Setting it to 1 prevents any reordering of inner JOINs. Setting this variable to a value between 1 and *from_collapse_limit* might be useful to trade off planning time against the quality of the chosen plan (higher values produce better plans).

Value Range	Default	Set Classifications
1-*n*	20	coordinator, session, reload

krb_caseins_users

Sets whether Kerberos user names should be treated case-insensitively. The default is case sensitive (off).

Value Range	Default	Set Classifications
Boolean	off	coordinator, system, reload

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

krb_server_keyfile

Sets the location of the Kerberos server key file.

Value Range	Default	Set Classifications
path and file name	unset	coordinator, system, restart

lc_collate

Reports the locale in which sorting of textual data is done. The value is determined when the WarehousePG cluster is initialized.

Value Range	Default	Set Classifications
<system dependent>		read only

lc_ctype

Reports the locale that determines character classifications. The value is determined when the WarehousePG cluster is initialized.

Value Range	Default	Set Classifications
<system dependent>		read only

lc_messages

Sets the language in which messages are displayed. The locales available depends on what was installed with your operating system - use *locale -a* to list available locales. The default value is inherited from the execution environment of the server. On some systems, this locale category does not exist. Setting this variable will still work, but there will be no effect. Also, there is a chance that no translated messages for the desired language exist. In that case you will continue to see the English messages.

Value Range	Default	Set Classifications
<system dependent>		local, session, reload

lc_monetary

Sets the locale to use for formatting monetary amounts, for example with the *to_char* family of functions. The locales available depends on what was installed with your operating system - use *locale -a* to list available locales. The default value is inherited from the execution environment of the server.

Value Range	Default	Set Classifications
<system dependent>		local, session, reload

lc_numeric

Sets the locale to use for formatting numbers, for example with the *to_char* family of functions. The locales available depends on what was installed with your operating system - use *locale -a* to list available locales. The default value is inherited from the execution environment of the server.

Value Range	Default	Set Classifications
<system dependent>		local, system, restart

lc_time

This parameter currently does nothing, but may in the future.

Value Range	Default	Set Classifications
<system dependent>		local, system, restart

listen_addresses

Specifies the TCP/IP address(es) on which the server is to listen for connections from client applications - a comma-separated list of host names and/or numeric IP addresses. The special entry * corresponds to all available IP interfaces. If the list is empty, only UNIX-domain sockets can connect.

Value Range	Default	Set Classifications
localhost, host names, IP addresses, * (all available IP interfaces)	*	coordinator, system, restart

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

local_preload_libraries

Comma separated list of shared library files to preload at the start of a client session.

Value Range	Default	Set Classifications
		local, system, restart

lock_timeout

Abort any statement that waits longer than the specified number of milliseconds while attempting to acquire a lock on a table, index, row, or other database object. The time limit applies separately to each lock acquisition attempt. The limit applies both to explicit locking requests (such as `LOCK TABLE`, or `SELECT FOR UPDATE` without `NOWAIT`) and to implicitly-acquired locks. If `log_min_error_statement` is set to `ERROR` or lower, WarehousePG logs the statement that timed out. A value of zero (the default) turns off this lock wait monitoring.

Unlike statement_timeout, this timeout can only occur while waiting for locks. Note that if `statement_timeout` is nonzero, it is rather pointless to set `lock_timeout` to the same or larger value, since the statement timeout would always trigger first.

WarehousePG uses the deadlock_timeout and gp_global_deadlock_detector_period to trigger local and global deadlock detection. Note that if `lock_timeout` is turned on and set to a value smaller than these deadlock detection timeouts, WarehousePG will abort a statement before it would ever trigger a deadlock check in that session.

> **Note** Setting `lock_timeout` in `postgresql.conf` is not recommended because it would affect all sessions

Value Range	Default	Set Classifications
0 - `INT_MAX` millisecs	0 millisecs	coordinator, session, reload

log_autostats

Logs information about automatic `ANALYZE` operations related to gp_autostats_modeand gp_autostats_on_change_threshold.

Value Range	Default	Set Classifications
Boolean	off	coordinator, session, reload, superuser

log_connections

This outputs a line to the server log detailing each successful connection. Some client programs, like psql, attempt to connect twice while determining if a password is required, so duplicate "connection received" messages do not always indicate a problem.

Value Range	Default	Set Classifications
Boolean	off	local, system, reload

log_checkpoints

Causes checkpoints and restartpoints to be logged in the server log. Some statistics are included in the log messages, including the number of buffers written and the time spent writing them.

Value Range	Default	Set Classifications
Boolean	on	local, system, reload

log_directory

Sets the destination directory for log files. You may specify its value as relative to the coordinator and segments data directory or as absolute path. Only superusers and users privilege can change this setting. The default value, `log`, indicates that the logs are located in the `log` directory under the coordinator and segment data directory.

When you specify the value as an absolute path, or as a relative path that is outside the data directory, WarehousePG appends a subdirectory with a unique identifier (DBID) to the directory specified by this parameter. The unique identifier matches the value of `dbid` from `gp_segment_configuration`. For example, if you set `log_directory` as `/tmp/logs`, WarehousePG creates the directories: `/tmp/logs/1` for the coordinator, `/tmp/logs/2` for seg0, `/tmp/logs/3` for seg1, etcetera.

> **Important** Do not remove the default log directories as some WarehousePG utilities will still need them during initialization.

Value Range	Default	Set Classifications
String	log	coordinator, system, reload, superuser

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

log_disconnections

This outputs a line in the server log at termination of a client session, and includes the duration of the session.

Value Range	Default	Set Classifications
Boolean	off	local, system, reload

log_dispatch_stats

When set to "on," this parameter adds a log message with verbose information about the dispatch of the statement.

Value Range	Default	Set Classifications
Boolean	off	local, system, reload

log_duration

Causes the duration of every completed statement which satisfies *log_statement* to be logged.

Value Range	Default	Set Classifications
Boolean	off	coordinator, session, reload, superuser

log_error_verbosity

Controls the amount of detail written in the server log for each message that is logged.

Value Range	Default	Set Classifications
TERSE, DEFAULT, VERBOSE	DEFAULT	coordinator, session, reload, superuser

log_executor_stats

For each query, write performance statistics of the query executor to the server log. This is a crude profiling instrument. Cannot be enabled together with*log_statement_stats*.

Value Range	Default	Set Classifications
Boolean	off	local, system, restart

log_file_mode

On Unix systems this parameter sets the permissions for log files when `logging_collector` is enabled. The parameter value is expected to be a numeric mode specified in the format accepted by the `chmod` and `umask` system calls.

Value Range	Default	Set Classifications
numeric UNIX file permission mode (as accepted by the *chmod* or *umask* commands)	0600	local, system, reload

log_hostname

By default, connection log messages only show the IP address of the connecting host. Turning on this option causes logging of the IP address and host name of the WarehousePG coordinator. Note that depending on your host name resolution setup this might impose a non-negligible performance penalty.

Value Range	Default	Set Classifications
Boolean	off	coordinator, system, reload

log_min_duration_statement

Logs the statement and its duration on a single log line if its duration is greater than or equal to the specified number of milliseconds. Setting this to 0 will print all statements and their durations. -1 deactivates the feature. For example, if you set it to 250 then all SQL statements that run 250ms or longer will be logged. Enabling this option can be useful in tracking down unoptimized queries in your applications.

Value Range	Default	Set Classifications
number of milliseconds, 0, -1	-1	coordinator, session, reload, superuser

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

log_min_error_statement

Controls whether or not the SQL statement that causes an error condition will also be recorded in the server log. All SQL statements that cause an error of the specified level or higher are logged. The default is ERROR. To effectively turn off logging of failing statements, set this parameter to PANIC.

Value Range	Default	Set Classifications
DEBUG5, DEBUG4, DEBUG3, DEBUG2, DEBUG1, INFO, NOTICE, WARNING, ERROR, FATAL, PANIC	ERROR	coordinator, session, reload, superuser

log_min_messages

Controls which message levels are written to the server log. Each level includes all the levels that follow it. The later the level, the fewer messages are sent to the log.

Value Range	Default	Set Classifications
DEBUG5, DEBUG4, DEBUG3, DEBUG2, DEBUG1, INFO, NOTICE, WARNING, LOG, ERROR, FATAL, PANIC	WARNING	coordinator, session, reload, superuser

log_parser_stats

For each query, write performance statistics of the query parser to the server log. This is a crude profiling instrument. Cannot be enabled together with *log_statement_stats*.

Value Range	Default	Set Classifications
Boolean	off	coordinator, session, reload, superuser

log_planner_stats

For each query, write performance statistics of the Postgres-based planner to the server log. This is a crude profiling instrument. Cannot be enabled together with *log_statement_stats*.

Value Range	Default	Set Classifications
Boolean	off	coordinator, session, reload, superuser

log_rotation_age

Determines the amount of time WarehousePG writes messages to the active log file. When this amount of time has elapsed, the file is closed and a new log file is created. Set to zero to deactivate time-based creation of new log files.

Value Range	Default	Set Classifications
Any valid time expression (number and unit)	1d	local, system, restart

log_rotation_size

Determines the size of an individual log file that triggers rotation. When the log file size is equal to or greater than this size, the file is closed and a new log file is created. Set to zero to deactivate size-based creation of new log files.

The maximum value is INT_MAX/1024. If an invalid value is specified, the default value is used. INT_MAX is the largest value that can be stored as an integer on your system.

Value Range	Default	Set Classifications
number of kilobytes	1048576	local, system, restart

log_statement

Controls which SQL statements are logged. DDL logs all data definition commands like CREATE, ALTER, and DROP commands. MOD logs all DDL statements, plus INSERT, UPDATE, DELETE, TRUNCATE, and COPY FROM. PREPARE and EXPLAIN ANALYZE statements are also logged if their contained command is of an appropriate type.

Value Range	Default	Set Classifications
NONE, DDL, MOD, ALL	ALL	coordinator, session, reload, superuser

log_statement_stats

For each query, write total performance statistics of the query parser, planner, and executor to the server log. This is a crude profiling instrument.

Value Range	Default	Set Classifications
Boolean	off	coordinator, session, reload, superuser

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

log_temp_files

Controls logging of temporary file names and sizes. Temporary files can be created for sorts, hashes, temporary query results and spill files. A log entry is made in `log` for each temporary file when it is deleted. Depending on the source of the temporary files, the log entry could be created on either the coordinator and/or segments. A `log_temp_files` value of zero logs all temporary file information, while positive values log only files whose size is greater than or equal to the specified number of kilobytes. The default setting is `-1`, which deactivates logging. Only superusers can change this setting.

Value Range	Default	Set Classifications
Integer	-1	local, session, reload

log_timezone

Sets the time zone used for timestamps written in the log. UnlikeTimeZone, this value is system-wide, so that all sessions will report timestamps consistently. The default is `unknown`, which means to use whatever the system environment specifies as the time zone.

Value Range	Default	Set Classifications
string	unknown	local, system, restart

log_truncate_on_rotation

Truncates (overwrites), rather than appends to, any existing log file of the same name. Truncation will occur only when a new file is being opened due to time-based rotation. For example, using this setting in combination with a log_filename such as `gpseg#-%H.log` would result in generating twenty-four hourly log files and then cyclically overwriting them. When off, pre-existing files will be appended to in all cases.

Value Range	Default	Set Classifications
Boolean	off	local, system, reload

maintenance_work_mem

Specifies the maximum amount of memory to be used in maintenance operations, such as `VACUUM` and `CREATE INDEX`. It defaults to 16 megabytes (16MB). Larger settings might improve performance for vacuuming and for restoring database dumps.

Value Range	Default	Set Classifications
Integer	16	local, system, reload

max_connections

The maximum number of concurrent connections to the database server. In a WarehousePG cluster, user client connections go through the WarehousePG coordinator instance only. Segment instances should allow 3-10 times the amount as the coordinator. When you increase this parameter, max_prepared_transactions must be increased as well. For more information about limiting concurrent connections, see "Configuring Client Authentication" in the *WarehousePG Administrator Guide*.

Increasing this parameter may cause WarehousePG to request more shared memory. See shared_buffers for information about WarehousePG server instance shared memory buffers.

Value Range	Default	Set Classifications
10 - 262143	250 on coordinator750 on segments	

|local, system, restart|

max_files_per_process

Sets the maximum number of simultaneously open files allowed to each server subprocess. If the kernel is enforcing a safe per-process limit, you don't need to worry about this setting. Some platforms such as BSD, the kernel will allow individual processes to open many more files than the system can really support.

Value Range	Default	Set Classifications
integer	1000	local, system, restart

max_function_args

Reports the maximum number of function arguments.

Value Range	Default	Set Classifications
integer	100	read only

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

max_identifier_length

Reports the maximum identifier length.

Value Range	Default	Set Classifications
integer	63	read only

max_index_keys

Reports the maximum number of index keys.

Value Range	Default	Set Classifications
integer	32	read only

max_locks_per_transaction

The shared lock table is created with room to describe locks on *max_locks_per_transaction* * (*max_connections* + *max_prepared_transactions*) objects, so no more than this many distinct objects can be locked at any one time. This is not a hard limit on the number of locks taken by any one transaction, but rather a maximum average value. You might need to raise this value if you have clients that touch many different tables in a single transaction.

Value Range	Default	Set Classifications
integer	128	local, system, restart

max_prepared_transactions

Sets the maximum number of transactions that can be in the prepared state simultaneously. WarehousePG uses prepared transactions internally to ensure data integrity across the segments. This value must be at least as large as the value of max_connections on the coordinator. Segment instances should be set to the same value as the coordinator.

Value Range	Default	Set Classifications
integer	250 on coordinator, 250 on segments	local, system, restart

max_resource_portals_per_transaction

> **Note** The `max_resource_portals_per_transaction` server configuration parameter is enforced only when resource queue-based resource management is active.

Sets the maximum number of simultaneously open user-declared cursors allowed per transaction. Note that an open cursor will hold an active query slot in a resource queue. Used for resource management.

Value Range	Default	Set Classifications
integer	64	coordinator, system, restart

max_resource_queues

> **Note** The `max_resource_queues` server configuration parameter is enforced only when resource queue-based resource management is active.

Sets the maximum number of resource queues that can be created in a WarehousePG cluster. Note that resource queues are system-wide (as are roles) so they apply to all databases in the system.

Value Range	Default	Set Classifications
integer	9	coordinator, system, restart

max_slot_wal_keep_size

Sets the maximum size in megabytes of Write-Ahead Logging (WAL) files on disk per segment instance that can be reserved when WarehousePG streams data to the mirror segment instance or standby coordinator to keep it synchronized with the corresponding primary segment instance or coordinator. The default is -1; when set to the default, WarehousePG can retain an unlimited amount of WAL files on disk.

If the file size exceeds the maximum size, the files are released and are available for deletion. A mirror or standby may no longer be able to continue replication due to removal of required WAL files.

In WarehousePG, replication slots exist internally by default for primary/mirror pairs. Consequently, even if you do not configure this parameter, that functionality is available by default.

> **CAUTION** If `max_slot_wal_keep_size` is set to a non-default value for acting primaries, full and incremental recovery of their mirrors may not be possible. Depending on the workload on the primary running concurrently with a full recovery, the recovery may fail with a missing WAL error. Therefore, you must ensure that `max_slot_wal_keep_size` is set to the default of `-1` or a high enough value before running full recovery. Similarly, depending on how behind the downed mirror is, an incremental recovery of it may fail with a missing WAL error. In this case, full recovery would be the only recourse.

Value Range	Default	Set Classifications
Integer	-1	local, system, reload

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

max_stack_depth

Specifies the maximum safe depth of the server's execution stack. The ideal setting for this parameter is the actual stack size limit enforced by the kernel (as set by *ulimit -s* or local equivalent), less a safety margin of a megabyte or so. Setting the parameter higher than the actual kernel limit will mean that a runaway recursive function can crash an individual backend process.

Value Range	Default	Set Classifications
number of kilobytes	2MB	local, session, reload

max_statement_mem

Sets the maximum memory limit for a query. Helps avoid out-of-memory errors on a segment host during query processing as a result of setting statement_mem too high.

Taking into account the configuration of a single segment host, calculate `max_statement_mem` as follows:

```
(seghost_physical_memory) / (average_number_concurrent_queries)
```

When changing both `max_statement_mem` and `statement_mem`, `max_statement_mem` must be changed first, or listed first in the postgresql.conf file.

Value Range	Default	Set Classifications
number of kilobytes	2000MB	coordinator, session, reload, superuser

max_wal_size

Sets the WAL size at which to trigger a checkpoint. This is the maximum size WarehousePG allows the WAL to grow during automatic checkpoints. This is a soft limit; WAL size can exceed `max_wal_size` under special circumstances, such as heavy load, a failing archive_command, or a high `wal_keep_segments` setting.

If you specify this value without units, it is taken as megabytes. The default is 1 GB.

Increasing this parameter can increase the amount of time needed for crash recovery.

You can set this parameter only in the `postgresql.conf` file or on the server command line.

Value Range	Default	Set Classifications
2 - `MAX_KILOBYTES` (integer)	1024	local, system, reload

min_wal_size

Sets the minimum size to which to shrink the WAL. As long as WAL disk usage stays below this setting, WarehousePG always recycles old WAL files for future use at a checkpoint, rather than remove them. You can use this parameter to ensure that enough WAL space is reserved to handle spikes in WAL usage, for example when running large batch jobs.

If you specify this value without units, it is taken as megabytes. The default is `320` MB.

You can set this parameter only in the `postgresql.conf` file or on the server command line.

Value Range	Default	Set Classifications
2 - `MAX_KILOBYTES` (integer)	320	local, system, reload

optimizer

Activates or deactivates GPORCA when running SQL queries. The default is `on`. If you deactivate GPORCA, WarehousePG uses only the Postgres-based planner.

GPORCA co-exists with the Postgres-based planner. With GPORCA enabled, WarehousePG uses GPORCA to generate an execution plan for a query when possible. If GPORCA cannot be used, then the Postgres-based planner is used.

The optimizer parameter can be set for a database system, an individual database, or a session or query.

For information about the Postgres-based planner and GPORCA, see SQL: Querying Data in the *WarehousePG Administrator Guide*.

Value Range	Default	Set Classifications
Boolean	on	coordinator, session, reload

optimizer_analyze_root_partition

For a partitioned table, controls whether the `ROOTPARTITION` keyword is required to collect root partition statistics when the `ANALYZE` command is run on the table. GPORCA uses the root partition statistics when generating a query plan. The Postgres-based planner does not use these statistics.

The default setting for the parameter is `on`, the `ANALYZE` command can collect root partition statistics without the `ROOTPARTITION` keyword. Root partition statistics are collected when you run `ANALYZE` on the root partition, or when you run `ANALYZE` on a leaf partition of the partitioned table and the other leaf partitions have statistics. When the value is `off`, you must run `ANALZYE ROOTPARTITION` to collect root partition statistics.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

When the value of the server configuration parameter optimizer is `on` (the default), the value of this parameter should also be `on`. For information about collecting table statistics on partitioned tables, see ANALYZE.

For information about the Postgres-based planner and GPORCA, see SQL: Querying Data in the *WarehousePG Administrator Guide*.

Value Range	Default	Set Classifications
Boolean	on	coordinator, session, reload

optimizer_array_expansion_threshold

When GPORCA is enabled (the default) and is processing a query that contains a predicate with a constant array, the `optimizer_array_expansion_threshold` parameter limits the optimization process based on the number of constants in the array. If the array in the query predicate contains more than the number elements specified by parameter, GPORCA deactivates the transformation of the predicate into its disjunctive normal form during query optimization.

The default value is 20.

For example, when GPORCA is running a query that contains an `IN` clause with more than 20 elements, GPORCA does not transform the predicate into its disjunctive normal form during query optimization to reduce optimization time consume less memory. The difference in query processing can be seen in the filter condition for the `IN` clause of the query `EXPLAIN` plan.

Changing the value of this parameter changes the trade-off between a shorter optimization time and lower memory consumption, and the potential benefits from constraint derivation during query optimization, for example conflict detection and partition elimination.

The parameter can be set for a database system, an individual database, or a session or query.

Value Range	Default	Set Classifications
Integer > 0	20	coordinator, session, reload

optimizer_control

Controls whether the server configuration parameter optimizer can be changed with SET, the RESET command, or the WarehousePG utility gpconfig. If the `optimizer_control` parameter value is `on`, users can set the optimizer parameter. If the `optimizer_control` parameter value is `off`, the optimizer parameter cannot be changed.

Value Range	Default	Set Classifications
Boolean	on	coordinator, session, reload, superuser

optimizer_cost_model

When GPORCA is enabled (the default), this parameter controls the cost model that GPORCA chooses for bitmap scans used with bitmap indexes or with btree indexes on AO tables.

- `legacy` - preserves the calibrated cost model used by GPORCA in WarehousePG releases 6.13 and earlier
- `calibrated` - improves cost estimates for indexes
- `experimental` - reserved for future experimental cost models; currently equivalent to the `calibrated` model

The default cost model, `calibrated`, is more likely to choose a faster bitmap index with nested loop joins instead of hash joins.

Value Range	Default	Set Classifications
legacy, calibrated, experimental	calibrated	coordinator, session, reload

optimizer_cte_inlining_bound

When GPORCA is enabled (the default), this parameter controls the amount of inlining performed for common table expression (CTE) queries (queries that contain a `WITH` clause). The default value, 0, deactivates inlining.

The parameter can be set for a database system, an individual database, or a session or query.

Value Range	Default	Set Classifications
Decimal >= 0	0	coordinator, session, reload

optimizer_dpe_stats

When GPORCA is enabled (the default) and this parameter is `true` (the default), GPORCA derives statistics that allow it to more accurately estimate the number of rows to be scanned during dynamic partition elimination.

The parameter can be set for a database system, an individual database, or a session or query.

Value Range	Default	Set Classifications
Boolean	true	coordinator, session, reload

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

optimizer_discard_redistribute_hashjoin

When GPORCA is enabled (the default), this parameter specifies whether the query optimizer should eliminate plans that include a HashJoin operator with a Redistribute Motion child. Eliminating such plans can improve performance in cases where the data being joined exhibits high skewness in the join keys.

The default setting is `off`, GPORCA considers all plan alternatives, including those with a Redistribute Motion child, in the HashJoin operator. If you observe performance issues with queries that use a HashJoin with highly skewed data, you may want to consider setting `optimizer_discard_redistribute_hashjoin` to `on` to instruct GPORCA to discard such plans.

Value Range	Default	Set Classifications
Boolean	off	coordinator, session, reload

optimizer_enable_associativity

When GPORCA is enabled (the default), this parameter controls whether the join associativity transform is enabled during query optimization. The transform analyzes join orders. For the default value `off`, only the GPORCA dynamic programming algorithm for analyzing join orders is enabled. The join associativity transform largely duplicates the functionality of the newer dynamic programming algorithm.

If the value is `on`, GPORCA can use the associativity transform during query optimization.

The parameter can be set for a database system, an individual database, or a session or query.

For information about GPORCA, see About GPORCA in the *WarehousePG Administrator Guide*.

Value Range	Default	Set Classifications
Boolean	off	coordinator, session, reload

optimizer_enable_dml

When GPORCA is enabled (the default) and this parameter is `true` (the default), GPORCA attempts to run DML commands such as `INSERT`, `UPDATE`, and `DELETE`. If GPORCA cannot run the command, WarehousePG falls back to the Postgres-based planner.

When set to `false`, WarehousePG always falls back to the Postgres-based planner when performing DML commands.

The parameter can be set for a database system, an individual database, or a session or query.

For information about GPORCA, see About GPORCA in the *WarehousePG Administrator Guide*.

Value Range	Default	Set Classifications
Boolean	true	coordinator, session, reload

optimizer_enable_dynamicindexonlyscan

When GPORCA is enabled (the default), the `optimizer_enable_dynamicindexonlyscan` parameter controls generation of dynamic index-only scan plan types.

The default value is `on`, GPORCA may generate a dynamic index only scan alternative when planning a query on a partitioned table that does not include single row volatile (SIRV) functions.

When set to `off`, GPORCA does not generate dynamic index-only scan plan alternatives.

The parameter can be set for a database system, an individual database, or a session or query.

Value Range	Default	Set Classifications
Boolean	on	coordinator, session, reload

optimizer_enable_foreign_table

When GPORCA is enabled (the default) and this configuration parameter is `true` (the default), GPORCA generates plans for queries that involve foreign tables. When `false`, queries that include foreign tables fall back to the Postgres-based planner.

Value Range	Default	Set Classifications
Boolean	true	coordinator, session, reload

optimizer_enable_indexonlyscan

When GPORCA is enabled (the default) and this parameter is `true` (the default), GPORCA can generate index-only scan plan types for B-tree indexes and any index type that contains all of the columns used by the query inside the index. (GiST indexes support index-only scans for some operator classes but not others.) GPORCA accesses the index values only, not the data blocks of the relation. This provides a query execution performance improvement, particularly when the table has been vacuumed, has wide columns, and GPORCA does not need to fetch any data blocks (for example, they are visible).

When deactivated (`false`), GPORCA does not generate index-only scan plan types.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

The parameter can be set for a database system, an individual database, or a session or query.

For information about GPORCA, see About GPORCA in the *WarehousePG Administrator Guide*.

Value Range	Default	Set Classifications
Boolean	true	coordinator, session, reload

optimizer_enable_coordinator_only_queries

When GPORCA is enabled (the default), this parameter allows GPORCA to run catalog queries that run only on the WarehousePG coordinator. For the default value `off`, only the Postgres-based planner can run catalog queries that run only on the WarehousePG coordinator.

The parameter can be set for a database system, an individual database, or a session or query.

> **Note** Enabling this parameter decreases performance of short running catalog queries. To avoid this issue, set this parameter only for a session or a query.

For information about GPORCA, see About GPORCA in the *WarehousePG Administrator Guide*.

Value Range	Default	Set Classifications
Boolean	off	coordinator, session, reload

optimizer_enable_multiple_distinct_aggs

When GPORCA is enabled (the default), this parameter allows GPORCA to support Multiple Distinct Qualified Aggregates, such as `SELECT count(DISTINCT a),sum(DISTINCT b) FROM foo`. This parameter is deactivated by default because its plan is generally suboptimal in comparison to the plan generated by the Postgres-based planner.

The parameter can be set for a database system, an individual database, or a session or query.

For information about GPORCA, see About GPORCA in the *WarehousePG Administrator Guide*.

Value Range	Default	Set Classifications
Boolean	off	coordinator, session, reload

optimizer_enable_orderedagg

When GPORCA is enabled (the default), this parameter determines whether or not GPORCA generates a query plan for ordered aggregates.

The default value is `on`, GPORCA generates a plan for a query that includes an ordered aggregate. When `off`, the query falls back to the Postgres-based planner.

You can set this parameter for a database system, an individual database, or a session or query.

Value Range	Default	Set Classifications
Boolean	on	coordinator, session, reload

optimizer_enable_push_join_below_union_all

When GPORCA is enabled (the default), the `optimizer_enable_push_join_below_union_all` parameter controls GPORCA's behaviour when it encounters a query that includes a `JOIN` of a `UNION ALL`.

The default value is `off`, GPORCA performs no transforms when a query includes a `JOIN` of a `UNION ALL`.

When set to `on` and the plan cost makes it eligible, GPORCA transforms a `JOIN` of `UNION ALL` to a `UNION ALL` of `JOIN`s. This transform may improve join performance when the `UNION ALL` children can benefit from join operations for which they are not eligible. Such an example is an indexed nested loop join, which is highly performant when the inner side is large and indexed, and the outer side is small. When the `UNION ALL` of multiple indexed large tables is joined with a small table, this transform pushes the join condition down as the index condition, and generates a more performant query than that utilizing a hash join.

Enabling this transform may increase planning time, so be sure to run and examine `EXPLAIN` output for the query with both parameter settings.

The `optimizer_enable_push_join_below_union_all` parameter can be set for a database system, an individual database, or a session or query.

Value Range	Default	Set Classifications
Boolean	off	coordinator, session, reload

optimizer_enable_replicated_table

When GPORCA is enabled (the default), this parameter controls GPORCA's behavior when it encounters DML operations on a replicated table.

The default value is `on`, GPORCA attempts to plan and execute operations on replicated tables. When `off`, GPORCA immediately falls back to the Postgres-based planner when it detects replicated table operations.

The parameter can be set for a database system, an individual database, or a session or query.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

For information about GPORCA, see About GPORCA in the *WarehousePG Administrator Guide*.

Value Range	Default	Set Classifications
Boolean	on	coordinator, session, reload

optimizer_enable_right_outer_join

When GPORCA is enabled (the default), this parameter allows you to control whether GPORCA generates right outer joins.

When set to the default value of `on`, GPORCA may both generate right outer joins and convert left outer joins to right outer joins if the situation calls for it. By setting this to `off`, you force GPORCA to generate equivalent left outer joins for incoming right outer joins and never generate right outer joins.

In situations in which you are observing poor performance related to right outer joins you may choose to suppress their use by setting this parameter to `off`.

You may set this parameter for a database system, an individual database, or a session or query. However, we recommend that you set this parameter at the query level, as there are a number of use cases where right outer join is the correct query plan alternative to choose.

For information about GPORCA, see the About GPORCA topic.

Value Range	Default	Set Classifications
Boolean	on	coordinator, session, reload

optimizer_force_agg_skew_avoidance

When GPORCA is enabled (the default), this parameter affects the query plan alternatives that GPORCA considers when 3 stage aggregate plans are generated. When the value is `true`, the default, GPORCA considers only 3 stage aggregate plans where the intermediate aggregation uses the `GROUP BY` and `DISTINCT` columns for distribution to reduce the effects of processing skew.

If the value is `false`, GPORCA can also consider a plan that uses `GROUP BY` columns for distribution. These plans might perform poorly when processing skew is present.

For information about GPORCA, see About GPORCA in the *WarehousePG Administrator Guide*.

Value Range	Default	Set Classifications
Boolean	true	coordinator, session, reload

optimizer_force_comprehensive_join_implementation

When GPORCA is enabled (the default), this parameter affects its consideration of nested loop join and hash join alternatives.

The default value is `false`, GPORCA does not consider nested loop join alternatives when a hash join is available, which significantly improves optimization performance for most queries. When set to `true`, GPORCA will explore nested loop join alternatives even when a hash join is possible.

Value Range	Default	Set Classifications
Boolean	false	coordinator, session, reload

optimizer_force_multistage_agg

For the default settings, GPORCA is enabled and this parameter is `false`, GPORCA makes a cost-based choice between a one- or two-stage aggregate plan for a scalar distinct qualified aggregate. When `true`, GPORCA chooses a multi-stage aggregate plan when such a plan alternative is generated.

The parameter can be set for a database system, an individual database, or a session or query.

Value Range	Default	Set Classifications
Boolean	false	coordinator, session, reload

optimizer_force_three_stage_scalar_dqa

For the default settings, GPORCA is enabled and this parameter is `true`, GPORCA chooses a plan with multistage aggregates when such a plan alternative is generated. When the value is `false`, GPORCA makes a cost based choice rather than a heuristic choice.

The parameter can be set for a database system, an individual database, or a session, or query.

Value Range	Default	Set Classifications
Boolean	true	coordinator, session, reload

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

optimizer_jit_above_cost

When using GPORCA, sets the query cost above which JIT compilation is activated when JIT is enabled. Performing JIT compilation costs planning time but can accelerate query execution. Note that setting the JIT cost parameters to '0' forces all queries to be JIT-compiled and, as a result, slows down queries. Setting it to a negative value disables JIT compilation.

Value Range	Default	Set Classifications
Floating point	7500	coordinator, session, reload

optimizer_jit_inline_above_cost

When using GPORCA, sets the query cost above which JIT compilation attempts to inline functions and operators. Inlining adds planning time, but can improve execution speed. It is not meaningful to set this to less than jit_above_cost. Note that setting the JIT cost parameters to '0' forces all queries to be JIT-compiled and, as a result, slows down queries. Setting it to a negative value disables inlining.

Value Range	Default	Set Classifications
Floating point	37500	coordinator, session, reload

optimizer_jit_optimize_above_cost

When using GPORCA, sets the query cost above which JIT compilation applies expensive optimizations. Such optimization adds planning time, but can improve execution speed. It is not meaningful to set this to less than `optimizer_jit_above_cost`, and it is unlikely to be beneficial to set it to more than `optimizer_jit_inline_above_cost`. Note that setting the JIT cost parameters to '0' forces all queries to be JIT-compiled and, as a result, slows down queries. Setting it to a negative value disables expensive optimizations.

Value Range	Default	Set Classifications
Floating point	37500	coordinator, session, reload

optimizer_join_arity_for_associativity_commutativity

The value is an optimization hint to limit the number of join associativity and join commutativity transformations explored during query optimization. The limit controls the alternative plans that GPORCA considers during query optimization. For example, the default value of 18 is an optimization hint for GPORCA to stop exploring join associativity and join commutativity transformations when an n-ary join operator has more than 18 children during optimization.

For a query with a large number of joins, specifying a lower value improves query performance by limiting the number of alternate query plans that GPORCA evaluates. However, setting the value too low might cause GPORCA to generate a query plan that performs sub-optimally.

This parameter has no effect when the `optimizer_join_order` parameter is set to `query` or `greedy`.

This parameter can be set for a database system or a session.

Value Range	Default	Set Classifications
integer > 0	18	local, system, reload

optimizer_join_order

When GPORCA is enabled (the default), this parameter sets the join enumeration algorithm:

- `query` - Uses the join order specified in the query.
- `greedy` - Evaluates the join order specified in the query and alternatives based on minimum cardinalities of the relations in the joins.
- `exhaustive` - Applies transformation rules to find and evaluate up to a configurable threshold number (`optimizer_join_order_threshold`, default 10) of n-way inner joins, and then uses the `greedy` method for the remainder. While planning time drops significantly at that point, plan quality and execution time may get worse.
- `exhaustive2` - Operates with an emphasis on generating join orders that are suitable for dynamic partition elimination. This algorithm applies transformation rules to find and evaluate n-way inner and outer joins. When evaluating very large joins with more than `optimizer_join_order_threshold` (default 10) tables, this algorithm employs a gradual transition to the `greedy` method; planning time goes up smoothly as the query gets more complicated, and plan quality and execution time only gradually degrade. `exhaustive2` provides a good trade-off between planning time and execution time for many queries.

The default value is `exhaustive2`.

Setting this parameter to `query` or `greedy` can generate a suboptimal query plan. However, if the administrator is confident that a satisfactory plan is generated with the `query` or `greedy` setting, query optimization time can be improved by setting the parameter to the lower optimization level.

Setting this parameter to `query` or `greedy` overrides the `optimizer_join_order_threshold` and `optimizer_join_arity_for_associativity_commutativity` parameters.

This parameter can be set for an individual database, a session, or a query.

Value Range	Default	Set Classifications
query, greedy, exhaustive, exhaustive2	exhaustive2	coordinator, session, reload

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

optimizer_join_order_threshold

When GPORCA is enabled (the default), this parameter sets the maximum number of join children for which GPORCA will use the dynamic programming-based join ordering algorithm. You can set this value for a single query or for an entire session.

This parameter has no effect when the `optimizer_join_query` parameter is set to `query` or `greedy`.

Value Range	Default	Set Classifications
0 - 12	10	coordinator, session, reload

optimizer_mdcache_size

Sets the maximum amount of memory on the WarehousePG coordinator that GPORCA uses to cache query metadata (optimization data) during query optimization. The memory limit session based. GPORCA caches query metadata during query optimization with the default settings: GPORCA is enabled and optimizer_metadata_caching is `on`.

The default value is 16384 (16MB). This is an optimal value that has been determined through performance analysis.

You can specify a value in KB, MB, or GB. The default unit is KB. For example, a value of 16384 is 16384KB. A value of 1GB is the same as 1024MB or 1048576KB. If the value is 0, the size of the cache is not limited.

This parameter can be set for a database system, an individual database, or a session or query.

Value Range	Default	Set Classifications
Integer >= 0	16384	coordinator, session, reload

optimizer_metadata_caching

When GPORCA is enabled (the default), this parameter specifies whether GPORCA caches query metadata (optimization data) in memory on the WarehousePG coordinator during query optimization. The default for this parameter is `on`, enable caching. The cache is session based. When a session ends, the cache is released. If the amount of query metadata exceeds the cache size, then old, unused metadata is evicted from the cache.

If the value is `off`, GPORCA does not cache metadata during query optimization.

This parameter can be set for a database system, an individual database, or a session or query.

The server configuration parameter optimizer_mdcache_size controls the size of the query metadata cache.

Value Range	Default	Set Classifications
Boolean	on	coordinator, session, reload

optimizer_minidump

GPORCA generates minidump files to describe the optimization context for a given query. The information in the file is not in a format that can be easily used for debugging or troubleshooting. The minidump file is located under the coordinator data directory and uses the following naming format:

```
Minidump_date_time.mdp
```

The minidump file contains this query related information:

- Catalog objects including data types, tables, operators, and statistics required by GPORCA
- An internal representation (DXL) of the query
- An internal representation (DXL) of the plan produced by GPORCA
- System configuration information passed to GPORCA such as server configuration parameters, cost and statistics configuration, and number of segments
- A stack trace of errors generated while optimizing the query

Setting this parameter to `ALWAYS` generates a minidump for all queries. Set this parameter to `ONERROR` to minimize total optimization time.

For information about GPORCA, see About GPORCA in the *WarehousePG Administrator Guide*.

Value Range	Default	Set Classifications
ONERROR, ALWAYS	ONERROR	coordinator, session, reload

optimizer_nestloop_factor

This parameter adds a costing factor to GPORCA to prioritize hash joins instead of nested loop joins during query optimization. The default value of 1024 was chosen after evaluating numerous workloads with uniformly distributed data. 1024 should be treated as the practical upper bound setting for this parameter. If you find the GPORCA selects hash joins more often than it should, reduce the value to shift the costing factor in favor of nested loop joins.

The parameter can be set for a database system, an individual database, or a session or query.

Value Range	Default	Set Classifications
INT_MAX > 1	1024	coordinator, session, reload

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

optimizer_parallel_union

When GPORCA is enabled (the default), `optimizer_parallel_union` controls the amount of parallelization that occurs for queries that contain a `UNION` or `UNION ALL` clause.

When the value is `off`, the default, GPORCA generates a query plan where each child of an APPEND(UNION) operator is in the same slice as the APPEND operator. During query execution, the children are run in a sequential manner.

When the value is `on`, GPORCA generates a query plan where a redistribution motion node is under an APPEND(UNION) operator. During query execution, the children and the parent APPEND operator are on different slices, allowing the children of the APPEND(UNION) operator to run in parallel on segment instances.

The parameter can be set for a database system, an individual database, or a session or query.

Value Range	Default	Set Classifications
boolean	off	coordinator, session, reload

optimizer_penalize_skew_broadcast_threshold

When GPORCA is enabled (the default), during query optimization GPORCA penalizes the cost of plans that attempt to broadcast more than the value specified by `optimizer_penalize_broadcast_threshold`. For example, if this parameter is set to 100K rows (the default), any broadcast of more than 100K rows is heavily penalized.

When this parameter is set to `0`, GPORCA sets this broadcast threshold to unlimited and never penalizes a broadcast motion.

Value Range	Default	Set Classifications
integer >= 0	100K rows	coordinator, session, reload

optimizer_penalize_skew

When GPORCA is enabled (the default), this parameter allows GPORCA to penalize the local cost of a HashJoin with a skewed Redistribute Motion as child to favor a Broadcast Motion during query optimization. The default value is `true`.

GPORCA determines there is skew for a Redistribute Motion when the NDV (number of distinct values) is less than the number of segments.

The parameter can be set for a database system, an individual database, or a session or query.

For information about GPORCA, see About GPORCA in the *WarehousePG Administrator Guide*.

Value Range	Default	Set Classifications
Boolean	true	coordinator, session, reload

optimizer_print_missing_stats

When GPORCA is enabled (the default), this parameter controls the display of table column information about columns with missing statistics for a query. The default value is `true`, display the column information to the client. When the value is `false`, the information is not sent to the client.

The information is displayed during query execution, or with the `EXPLAIN` or `EXPLAIN ANALYZE` commands.

The parameter can be set for a database system, an individual database, or a session.

Value Range	Default	Set Classifications
Boolean	true	coordinator, session, reload

optimizer_print_optimization_stats

When GPORCA is enabled (the default), this parameter enables logging of GPORCA query optimization statistics for various optimization stages for a query. The default value is off, do not log optimization statistics. To log the optimization statistics, this parameter must be set to on and the parameter client_min_messages must be set to log.

- `set optimizer_print_optimization_stats = on;`
- `set client_min_messages = 'log';`

The information is logged during query execution, or with the `EXPLAIN` or `EXPLAIN ANALYZE` commands.

This parameter can be set for a database system, an individual database, or a session or query.

Value Range	Default	Set Classifications
Boolean	off	coordinator, session, reload

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

optimizer_skew_factor

When GPORCA is enabled (the default), `optimizer_skew_factor` controls skew ratio computation.

The default value is `0`, skew computation is turned off for GPORCA. To enable skew computation, set `optimizer_skew_factor` to a value between `1` and `100`, inclusive.

The larger the `optimizer_skew_factor`, the larger the cost that GPORCA assigns to redistributed hash join, such that GPORCA favors more a broadcast hash join.

The parameter can be set for a database system, an individual database, or a session or query.

Value Range	Default	Set Classifications
integer 0-100	0	coordinator, session, reload

optimizer_sort_factor

When GPORCA is enabled (the default), `optimizer_sort_factor` controls the cost factor to apply to sorting operations during query optimization. The default value `1` specifies the default sort cost factor. The value is a ratio of increase or decrease from the default factor. For example, a value of `2.0` sets the cost factor at twice the default, and a value of `0.5` sets the factor at half the default.

The parameter can be set for a database system, an individual database, or a session or query.

Value Range	Default	Set Classifications
Decimal > 0	1	coordinator, session, reload

optimizer_use_gpdb_allocators

When GPORCA is enabled (the default) and this parameter is `true` (the default), GPORCA uses WarehousePG memory management when running queries. When set to `false`, GPORCA uses GPORCA-specific memory management. WarehousePG memory management allows for faster optimization, reduced memory usage during optimization, and improves GPORCA support of vmem limits when compared to GPORCA-specific memory management.

For information about GPORCA, see About GPORCA in the *WarehousePG Administrator Guide*.

Value Range	Default	Set Classifications
Boolean	true	coordinator, system, restart

optimizer_xform_bind_threshold

When GPORCA is enabled (the default), this parameter controls the maximum number of bindings per transform that GPORCA produces per group expression. Setting this parameter limits the number of alternatives that GPORCA creates, in many cases reducing the optimization time and overall memory usage of queries that include deeply nested expressions.

The default value is `0`, GPORCA produces an unlimited set of bindings.

Value Range	Default	Set Classifications
0 - INT_MAX	0	coordinator, session, reload

password_encryption

When a password is specified in CREATE ROLE or ALTER ROLE, this parameter determines the algorithm to use to encrypt the password. Possible values are scram-sha-256, which will encrypt the password with SCRAM-SHA-256, and md5, which stores the password as an MD5 hash. The default is md5.

Value Range	Default	Set Classifications
md5, scram-sha-256	md5	coordinator, session, reload

plan_cache_mode

Prepared statements (either explicitly prepared or implicitly generated, for example by PL/pgSQL) can be run using *custom* or *generic* plans. Custom plans are created for each execution using its specific set of parameter values, while generic plans do not rely on the parameter values and can be re-used across executions. The use of a generic plan saves planning time, but if the ideal plan depends strongly on the parameter values, then a generic plan might be inefficient. The choice between these options is normally made automatically, but it can be overridden by setting the `plan_cache_mode` parameter. If the prepared statement has no parameters, a generic plan is always used.

The allowed values are `auto` (the default), `force_custom_plan` and `force_generic_plan`. This setting is considered when a cached plan is to be run, not when it is prepared. For more information seePREPARE.

The parameter can be set for a database system, an individual database, a session, or a query.

Value Range	Default	Set Classifications
auto, force_custom_plan, force_generic_plan	auto	coordinator, session, reload

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

pljava_classpath

A colon (`:`) separated list of jar files or directories containing jar files needed for PL/Java functions. The full path to the jar file or directory must be specified, except the path can be omitted for jar files in the `$GPHOME/lib/postgresql/java` directory. The jar files must be installed in the same locations on all WarehousePG hosts and readable by the `gpadmin` user.

The `pljava_classpath` parameter is used to assemble the PL/Java classpath at the beginning of each user session. Jar files added after a session has started are not available to that session.

If the full path to a jar file is specified in `pljava_classpath` it is added to the PL/Java classpath. When a directory is specified, any jar files the directory contains are added to the PL/Java classpath. The search does not descend into subdirectories of the specified directories. If the name of a jar file is included in `pljava_classpath` with no path, the jar file must be in the `$GPHOME/lib/postgresql/java` directory.

> **Note** Performance can be affected if there are many directories to search or a large number of jar files.

If pljava_classpath_insecure is `false` , setting the `pljava_classpath` parameter requires superuser privilege. Setting the classpath in SQL code will fail when the code is run by a user without superuser privilege. The `pljava_classpath` parameter must have been set previously by a superuser or in the `postgresql.conf` file. Changing the classpath in the `postgresql.conf` file requires a reload (`gpstop -u`).

Value Range	Default	Set Classifications
string		coordinator, session, reload, superuser

pljava_classpath_insecure

Controls whether the server configuration parameter pljava_classpath can be set by a user without WarehousePG superuser privileges. When `true` , `pljava_classpath` can be set by a regular user. Otherwise, pljava_classpath can be set only by a database superuser. The default is `false` .

> **Caution** Enabling this parameter exposes a security risk by giving non-administrator database users the ability to run unauthorized Java methods.

Value Range	Default	Set Classifications
Boolean	false	coordinator, session, reload, superuser

pljava_statement_cache_size

Sets the size in KB of the JRE MRU (Most Recently Used) cache for prepared statements.

Value Range	Default	Set Classifications
number of kilobytes	10	coordinator, system, reload, superuser

pljava_release_lingering_savepoints

If true, lingering savepoints used in PL/Java functions will be released on function exit. If false, savepoints will be rolled back.

Value Range	Default	Set Classifications
Boolean	true	coordinator, system, reload, superuser

pljava_vmoptions

Defines the startup options for the Java VM. The default value is an empty string ("").

Value Range	Default	Set Classifications
string		coordinator, system, reload, superuser

port

The database listener port for a WarehousePG instance. The coordinator and each segment has its own port. Port numbers for the WarehousePG cluster must also be changed in the `gp_segment_configuration` catalog. You must shut down your WarehousePG cluster before changing port numbers.

Value Range	Default	Set Classifications
any valid port number	5432	local, system, restart

quote_all_identifiers

Ensures that all identifiers are quoted, even if they are not keywords, when the database generates SQL. See also the `--quote-all-identifiers` option of pg_dump and pg_dumpall.

Value Range	Default	Set Classifications
Boolean	false	local, session, reload

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

random_page_cost

Sets the estimate of the cost of a nonsequentially fetched disk page for the Postgres-based planner. This is measured as a multiple of the cost of a sequential page fetch. A higher value makes it more likely a sequential scan will be used, a lower value makes it more likely an index scan will be used.

Value Range	Default	Set Classifications
floating point	100	coordinator, session, reload

readable_external_table_timeout

When an SQL query reads from an external table, the parameter value specifies the amount of time in seconds that WarehousePG waits before cancelling the query when data stops being returned from the external table.

The default value of 0, specifies no time out. WarehousePG does not cancel the query.

If queries that use gpfdist run a long time and then return the error "intermittent network connectivity issues", you can specify a value for `readable_external_table_timeout`. If no data is returned by gpfdist for the specified length of time, WarehousePG cancels the query.

Value Range	Default	Set Classifications
integer >= 0	0	coordinator, system, reload

repl_catchup_within_range

For WarehousePG coordinator mirroring, controls updates to the active coordinator. If the number of WAL segment files that have not been processed by the `walsender` exceeds this value, WarehousePG updates the active coordinator.

If the number of segment files does not exceed the value, WarehousePG blocks updates to the to allow the `walsender` process the files. If all WAL segments have been processed, the active coordinator is updated.

Value Range	Default	Set Classifications
0 - 64	1	coordinator, system, reload, superuser

wal_buffers

Sets the number of disk-page buffers in shared memory for WAL. This is the amount of shared memory used for WAL data that has not yet been written to disk. The default setting of `-1` selects a size equal to 1/32nd (about 3%) of shared_buffers, but not less than `64kB` nor more than the size of one WAL segment, typically `16MB`. You can set this value manually if the automatic choice is too large or too small, but WarehousePG treats any positive value less than `32kB` as `32kB`. If you specify this value without units, it is taken as WAL blocks, that is `XLOG_BLCKSZ` bytes, typically 32kB.

You can set this parameter only at server start.

The contents of the WAL buffers are written out to disk at every transaction commit, so extremely large values are unlikely to provide a significant benefit. However, setting this value to at least a few megabytes can improve write performance on a busy server where many clients are committing at once. The auto-tuning selected by the default setting of `-1` should give reasonable results in most cases.

Value Range	Default	Set Classifications
-1 - (INT_MAX / XLOG_BLCKSZ) (integer)	-1	local, system, restart

wal_compression

Enables compression of full page writes in a WAL file. This parameter can only be changed by superusers.

> **Note** `wal_compression` can reduce the WAL volume without increasing the risk of unrecoverable data corruption, but at the cost of some extra CPU spent on the compression during WAL logging and on the decompression during WAL replay.

Value Range	Default	Set Classifications
Boolean	on	local, session, reload, superuser

wal_sender_timeout

For WarehousePG coordinator mirroring, sets the maximum time in milliseconds that the `walsender` process on the active coordinator waits for a status message from the `walreceiver` process on the standby coordinator. If a message is not received, the `walsender` logs an error message.

The wal_receiver_status_interval controls the interval between `walreceiver` status messages.

Value Range	Default	Set Classifications
0 - INT_MAX	60000 ms (60 seconds)	coordinator, system, reload, superuser

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

resource_cleanup_gangs_on_wait

> **Note** The `resource_cleanup_gangs_on_wait` server configuration parameter is enforced only when resource queue-based resource management is active.

If a statement is submitted through a resource queue, clean up any idle query executor worker processes before taking a lock on the resource queue.

Value Range	Default	Set Classifications
Boolean	on	coordinator, session, reload

resource_select_only

> **Note** The `resource_select_only` server configuration parameter is enforced only when resource queue-based resource management is active.

Sets the types of queries managed by resource queues. If set to on, then `SELECT`, `SELECT INTO`, `CREATE TABLE AS SELECT`, and `DECLARE CURSOR` commands are evaluated. If set to off `INSERT`, `UPDATE`, and `DELETE` commands will be evaluated as well.

Value Range	Default	Set Classifications
Boolean	off	coordinator, system, restart

row_security

> **Note** This configuration parameter has no effect on roles which bypass every row security policy, for example, superusers and roles configured with the `BYPASSRLS` attribute.

Controls whether to raise an error in lieu of applying a row security policy. When set to `on`, policies apply normally. When set to `off`, queries which would otherwise apply at least one policy fail.

The default is `on`. Change `row_security` to `off` where limited row visibility could cause incorrect results; for example, `pg_dump` makes that change by default.

For more information about row-level security policies, see CREATE POLICY.

Value Range	Default	Set Classifications
Boolean	on	coordinator, system, restart

runaway_detector_activation_percent

For queries that are managed by resource queues or resource groups, this parameter determines when WarehousePG terminates running queries based on the amount of memory the queries are using. A value of 100 deactivates the automatic termination of queries based on the percentage of memory that is utilized.

Either the resource queue or the resource group management scheme can be active in WarehousePG; both schemes cannot be active at the same time. The server configuration parameter gp_resource_manager controls which scheme is active.

This parameter sets the percent of utilized WarehousePG virtual memory that triggers the termination of queries. If the percentage of virtual memory that is utilized for a WarehousePG segment exceeds the specified value, WarehousePG terminates queries managed by resource queues based on memory usage, starting with the query consuming the largest amount of memory. Queries are terminated until the percentage of utilized virtual memory is below the specified percentage.

Specify the maximum virtual memory value for active WarehousePG segment instances with the server configuration parameter gp_vmem_protect_limit.

For example, if `gp_vmem_protect_limit` is set to 10GB, and `runaway_detector_activation_percent` is 90 (90%), WarehousePG starts terminating queries when the utilized virtual memory exceeds 9 GB.

For information about resource groups and resource queues, see [Managing Resources]((../../admin_guide/wlmgmt.html).

Value Range	Default	Set Classifications
percentage (integer)	90	local, system, restart

search_path

Specifies the order in which schemas are searched when an object is referenced by a simple name with no schema component. When there are objects of identical names in different schemas, the one found first in the search path is used. The system catalog schema, *pg_catalog*, is always searched, whether it is mentioned in the path or not. When objects are created without specifying a particular target schema, they will be placed in the first schema listed in the search path. The current effective value of the search path can be examined via the SQL function *current_schema()*. *current_schema()* shows how the requests appearing in *search_path* were resolved.

Value Range	Default	Set Classifications
a comma-separated list of schema names	$user,public	coordinator, session, reload

seq_page_cost

For the Postgres-based planner, sets the estimate of the cost of a disk page fetch that is part of a series of sequential fetches.

Value Range	Default	Set Classifications
floating point	1	coordinator, session, reload

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

server_encoding

Reports the database encoding (character set). It is determined when the WarehousePG cluster is initialized. Ordinarily, clients need only be concerned with the value of *client_encoding*.

Value Range	Default	Set Classifications
<system dependent>	UTF8	read only

server_version

Reports the version of PostgreSQL that this release of WarehousePG is based on.

Value Range	Default	Set Classifications
string	9.4.20	read only

server_version_num

Reports the version of PostgreSQL that this release of WarehousePG is based on as an integer.

Value Range	Default	Set Classifications
integer	90420	read only

shared_buffers

Sets the amount of memory a WarehousePG segment instance uses for shared memory buffers. This setting must be at least 128KB and at least 16KB times max_connections.

Each WarehousePG segment instance calculates and attempts to allocate certain amount of shared memory based on the segment configuration. The value of `shared_buffers` is significant portion of this shared memory calculation, but is not all it. When setting `shared_buffers`, the values for the operating system parameters `SHMMAX` or `SHMALL` might also need to be adjusted.

The operating system parameter `SHMMAX` specifies maximum size of a single shared memory allocation. The value of `SHMMAX` must be greater than this value:

```
`shared_buffers` + <other_seg_shmem>
```

The value of `other_seg_shmem` is the portion the WarehousePG shared memory calculation that is not accounted for by the `shared_buffers` value. The `other_seg_shmem` value will vary based on the segment configuration.

With the default WarehousePG parameter values, the value for `other_seg_shmem` is approximately 111MB for WarehousePG segments and approximately 79MB for the WarehousePG coordinator.

The operating system parameter `SHMALL` specifies the maximum amount of shared memory on the host. The value of `SHMALL` must be greater than this value:

```
(<num_instances_per_host> * ( `shared_buffers` + <other_seg_shmem> )) + <other_app_shared_mem>
```

The value of `other_app_shared_mem` is the amount of shared memory that is used by other applications and processes on the host.

When shared memory allocation errors occur, possible ways to resolve shared memory allocation issues are to increase `SHMMAX` or `SHMALL`, or decrease `shared_buffers` or `max_connections`.

See the *WarehousePG Installation Guide* for information about the WarehousePG values for the parameters `SHMMAX` and `SHMALL`.

Value Range	Default	Set Classifications
integer > 16K * *max_connections*	125MB	local, system, restart

shared_preload_libraries

A comma-separated list of shared libraries that are to be preloaded at server start. PostgreSQL procedural language libraries can be preloaded in this way, typically by using the syntax `$libdir/plXXX'` where XXX is pgsql, perl, tcl, or python. By preloading a shared library, the library startup time is avoided when the library is first used. If a specified library is not found, the server will fail to start.

> **Note** When you add a library to `shared_preload_libraries`, be sure to retain any previous setting of the parameter.

Value Range	Default	Set Classifications
		local, system, restart

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

ssl

Enables SSL connections.

Value Range	Default	Set Classifications
Boolean	off	coordinator, system, restart

ssl_ciphers

Specifies a list of SSL ciphers that are allowed to be used on secure connections. `ssl_ciphers` *overrides* any ciphers string specified in `/etc/openssl.cnf`. The default value `ALL:!ADH:!LOW:!EXP:!MD5:@STRENGTH` enables all ciphers except for ADH, LOW, EXP, and MD5 ciphers, and prioritizes ciphers by their strength.

> **Note** With TLS 1.2 some ciphers in MEDIUM and HIGH strength still use NULL encryption (no encryption for transport), which the default `ssl_ciphers` string allows. To bypass NULL ciphers with TLS 1.2 use a string such as `TLSv1.2:!eNULL:!aNULL`.

See the openssl manual page for a list of supported ciphers.

Value Range	Default	Set Classifications
string	ALL:!ADH:!LOW:!EXP:!MD5:@STRENGTH	coordinator, system, restart

standard_conforming_strings

Determines whether ordinary string literals ('...') treat backslashes literally, as specified in the SQL standard. The default value is on. Turn this parameter off to treat backslashes in string literals as escape characters instead of literal backslashes. Applications may check this parameter to determine how string literals are processed. The presence of this parameter can also be taken as an indication that the escape string syntax (E'...') is supported.

Value Range	Default	Set Classifications
Boolean	on	coordinator, session, reload

statement_mem

Allocates segment host memory per query. The amount of memory allocated with this parameter cannot exceed max_statement_mem or the memory limit on the resource queue or resource group through which the query was submitted. If additional memory is required for a query, temporary spill files on disk are used.

You can use the following calculation to estimate a reasonable `statement_mem` value for a wide variety of situations:

```
( <gp_vmem_protect_limit>GB * .9 ) / <max_expected_concurrent_queries>
```

If you are using resource groups to control resource allocation in your WarehousePG cluster.

- If the server configuration parameter gp_resgroup_memory_query_fixed_mem is set to 0, and the resource group parameter `MEMORY_QUOTA` is set to -1, `statement_mem` sets the amount of memory allocated for a query.
- If you set the configuration parameters gp_resource_group_bypass or gp_resource_group_bypass_catalog_query to bypass the resource group limits, `statement_mem` sets the amount of memory allocated for the query.
- `statement_mem` also sets the amount of memory allocated for a query if its value is greater than `MEMORY_QUOTA` / `CONCURRENCY`.
- Queries whose plan cost is less than the limit `MIN_COST` use `statement_mem` as their memory quota.

If you are using resource queues to control resource allocation in your WarehousePG cluster.

- When gp_resqueue_memory_policy is set to "auto", `statement_mem` and resource queue memory limits control query memory usage.

For information about resource groups and resource queues, see [Managing Resources]((../../admin_guide/wlmgmt.html).

When changing both `max_statement_mem` and `statement_mem`, `max_statement_mem` must be changed first, or listed first in the postgresql.conf file.

Value Range	Default	Set Classifications
number of kilobytes	128MB	coordinator, session, reload

statement_timeout

Abort any statement that takes over the specified number of milliseconds. 0 turns off the limitation.

Value Range	Default	Set Classifications
number of milliseconds	0	coordinator, session, reload

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

stats_queue_level

> **Note** The `stats_queue_level` server configuration parameter is enforced only when resource queue-based resource management is active.

Collects resource queue statistics on database activity.

Value Range	Default	Set Classifications
Boolean	off	coordinator, session, reload

superuser_reserved_connections

Determines the number of connection slots that are reserved for WarehousePG superusers.

Value Range	Default	Set Classifications
integer < *max_connections*	10	local, system, restart

tcp_keepalives_count

How many keepalives may be lost before the connection is considered dead. A value of 0 uses the system default. If TCP_KEEPCNT is not supported, this parameter must be 0.

Use this parameter for all connections that are not between a primary and mirror segment.

Value Range	Default	Set Classifications
number of lost keepalives	0	local, system, restart

tcp_keepalives_idle

Number of seconds between sending keepalives on an otherwise idle connection. A value of 0 uses the system default. If TCP_KEEPIDLE is not supported, this parameter must be 0.

Use this parameter for all connections that are not between a primary and mirror segment.

Value Range	Default	Set Classifications
number of seconds	0	local, system, restart

tcp_keepalives_interval

How many seconds to wait for a response to a keepalive before retransmitting. A value of 0 uses the system default. If TCP_KEEPINTVL is not supported, this parameter must be 0.

Use this parameter for all connections that are not between a primary and mirror segment.

Value Range	Default	Set Classifications
number of seconds	0	local, system, restart

temp_buffers

Sets the maximum memory, in blocks, to allow for temporary buffers by each database session. These are session-local buffers used only for access to temporary tables. The setting can be changed within individual sessions, but only up until the first use of temporary tables within a session. The cost of setting a large value in sessions that do not actually need a lot of temporary buffers is only a buffer descriptor for each block, or about 64 bytes, per increment. However if a buffer is actually used, an additional 32768 bytes will be consumed.

You can set this parameter to the number of 32K blocks (for example, `1024` to allow 32MB for buffers), or specify the maximum amount of memory to allow (for example `'48MB'` for 1536 blocks). The `gpconfig` utility and `SHOW` command report the maximum amount of memory allowed for temporary buffers.

Value Range	Default	Set Classifications
integer	1024 (32MB)	coordinator, session, reload

temp_tablespaces

Specifies tablespaces in which to create temporary objects (temp tables and indexes on temp tables) when a `CREATE` command does not explicitly specify a tablespace. These tablespaces can also include temporary files for purposes such as large data set sorting.

The value is a comma-separated list of tablespace names. When the list contains more than one tablespace name, WarehousePG chooses a random list member each time it creates a temporary object. An exception applies within a transaction, where successively created temporary objects are placed in successive tablespaces from the list. If the selected element of the list is an empty string, WarehousePG automatically uses the default tablespace of the current database instead.

When setting `temp_tablespaces` interactively, avoid specifying a nonexistent tablespace, or a tablespace for which the user does have `CREATE` privileges. For non-superusers, a superuser must `GRANT` them the `CREATE` privilege on the temp tablespace.. When using a previously set value (for example a value in `postgresql.conf`), nonexistent tablespaces are ignored, as are tablespaces for which the user lacks `CREATE` privilege.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

The default value is an empty string, which results in all temporary objects being created in the default tablespace of the current database.

See also default_tablespace.

Value Range	Default	Set Classifications
one or more tablespace names	unset	coordinator, session, reload

TimeZone

Sets the time zone for displaying and interpreting time stamps. The default is to use whatever the system environment specifies as the time zone. SeeDate/Time Keywords in the PostgreSQL documentation.

Value Range	Default	Set Classifications
time zone abbreviation		local, restart

timezone_abbreviations

Sets the collection of time zone abbreviations that will be accepted by the server for date time input. The default is `Default`, which is a collection that works in most of the world. `Australia` and `India`, and other collections can be defined for a particular installation. Possible values are names of configuration files stored in `$GPHOME/share/postgresql/timezonesets/`.

To configure WarehousePG to use a custom collection of timezones, copy the file that contains the timezone definitions to the directory `$GPHOME/share/postgresql/timezonesets/` on the WarehousePG coordinator and segment hosts. Then set value of the server configuration parameter `timezone_abbreviations` to the file. For example, to use a file `custom` that contains the default timezones and the WIB (Waktu Indonesia Barat) timezone.

1. Copy the file `Default` from the directory `$GPHOME/share/postgresql/timezonesets/` the file `custom`. Add the WIB timezone information from the file `Asia.txt` to the `custom`.
2. Copy the file `custom` to the directory `$GPHOME/share/postgresql/timezonesets/` on the WarehousePG coordinator and segment hosts.
3. Set value of the server configuration parameter `timezone_abbreviations` to `custom`.
4. Reload the server configuration file (`gpstop -u`).

Value Range	Default	Set Classifications
string	Default	coordinator, session, reload

track_activities

Enables the collection of information on the currently executing command of each session, along with the time when that command began execution. This parameter is `true` by default. Only superusers can change this setting. See the `pg_stat_activity` view.

> **Note** Even when enabled, this information is not visible to all users, only to superusers and the user owning the session being reported on, so it should not represent a security risk.

Value Range	Default	Set Classifications
Boolean	true	coordinator, session, reload, superuser

track_activity_query_size

Sets the maximum length limit for the query text stored in `query` column of the system catalog view *pg_stat_activity*. The minimum length is 1024 characters.

Value Range	Default	Set Classifications
integer	1024	local, system, restart

track_counts

Collects information about executing commands. Enables the collection of information on the currently executing command of each session, along with the time at which that command began execution.

Value Range	Default	Set Classifications
Boolean	true	coordinator, session, reload, superuser

track_wal_io_timing

Enables timing of WAL I/O calls. This parameter is disabled by default, as it repeatedly queries the operating system for the current time, which may cause significant overhead on some platforms. The viewpg_stat_wal displays WAL I/O timing information. Only superusers and users with the appropriate `SET` privilege can change this setting.

Value Range	Default	Set Classifications
Boolean	false	coordinator, session, reload

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

transaction_isolation

Sets the current transaction's isolation level.

Value Range	Default	Set Classifications
read committed, serializable	read committed	coordinator, session, reload

transaction_read_only

Sets the current transaction's read-only status.

Value Range	Default	Set Classifications
Boolean	off	coordinator, session, reload

transaction_deferrable

For the current read-only serializable transaction, specifies whether to defer until it can be executed with no possible serialization failures.

Value Range	Default	Set Classifications
Boolean	value of `default_transaction_deferrable`	coordinator, session, reload

transform_null_equals

When on, expressions of the form expr = NULL (or NULL = expr) are treated as expr IS NULL, that is, they return true if expr evaluates to the null value, and false otherwise. The correct SQL-spec-compliant behavior of expr = NULL is to always return null (unknown).

Value Range	Default	Set Classifications
Boolean	off	coordinator, session, reload

unix_socket_directories

Specifies the directory of the UNIX-domain socket on which the server is to listen for connections from client applications. Multiple sockets can be created by listing multiple directories separated by commas.

> **Important** Do not change the value of this parameter. The default location is required for WarehousePG utilities.

Value Range	Default	Set Classifications
directory path	0777	local, system, restart

unix_socket_group

Sets the owning group of the UNIX-domain socket. By default this is an empty string, which uses the default group for the current user.

Value Range	Default	Set Classifications
UNIX group name	unset	local, system, restart

unix_socket_permissions

Sets the access permissions of the UNIX-domain socket. UNIX-domain sockets use the usual UNIX file system permission set. Note that for a UNIX-domain socket, only write permission matters.

Value Range	Default	Set Classifications
numeric UNIX file permission mode (as accepted by the *chmod* or *umask* commands)	0777	local, system, restart

update_process_title

Enables updating of the process title every time a new SQL command is received by the server. The process title is typically viewed by the `ps` command.

Value Range	Default	Set Classifications
Boolean	on	local, session, reload

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

vacuum_cleanup_index_scale_factor

Specifies the fraction of the total number of heap tuples counted in the previous statistics collection that can be inserted without incurring an index scan at the `VACUUM` cleanup stage. The purpose of this parameter is to minimize unnecessary vacuum index scans. This setting currently applies to B-tree indexes only. When its value is 0, `VACUUM` cleanup never skips index scans.

If no tuples were deleted from the heap, B-tree indexes are still scanned at the `VACUUM` cleanup stage when at least one of the following conditions is met: the index statistics are stale, or the index contains deleted pages that can be recycled during cleanup. Index statistics are considered to be stale if the number of newly inserted tuples exceeds the `vacuum_cleanup_index_scale_factor` fraction of the total number of heap tuples detected by the previous statistics collection. The total number of heap tuples is stored in the index meta-page. Note that the meta-page does not include this data until `VACUUM` finds no dead tuples, so B-tree index scan at the cleanup stage can only be skipped if the second and subsequent `VACUUM` cycles detect no dead tuples.

Value Range	Default	Set Classifications
floating point 0 to 10000000000	0.1	local, session, reload

vacuum_cost_delay

The length of time that the process will sleep when the cost limit has been exceeded. 0 deactivates the cost-based vacuum delay feature.

Value Range	Default	Set Classifications
milliseconds < 0 (in multiples of 10)	0	local, session, reload

vacuum_cost_limit

The accumulated cost that will cause the vacuuming process to sleep.

Value Range	Default	Set Classifications
integer > 0	200	local, session, reload

vacuum_cost_page_dirty

The estimated cost charged when vacuum modifies a block that was previously clean. It represents the extra I/O required to flush the dirty block out to disk again.

Value Range	Default	Set Classifications
integer > 0	20	local, session, reload

vacuum_cost_page_hit

The estimated cost for vacuuming a buffer found in the shared buffer cache. It represents the cost to lock the buffer pool, lookup the shared hash table and scan the content of the page.

Value Range	Default	Set Classifications
integer > 0	1	local, session, reload

vacuum_cost_page_miss

The estimated cost for vacuuming a buffer that has to be read from disk. This represents the effort to lock the buffer pool, lookup the shared hash table, read the desired block in from the disk and scan its content.

Value Range	Default	Set Classifications
integer > 0	2	local, session, reload

vacuum_freeze_min_age

Specifies the cutoff age (in transactions) that `VACUUM` should use to decide whether to replace transaction IDs with *FrozenXID* while scanning a table.

For information about `VACUUM` and transaction ID management, see "Managing Data" in the *WarehousePG Administrator Guide* and the PostgreSQL documentation.

Value Range	Default	Set Classifications
integer 0-100000000000	50000000	local, session, reload

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

validate_previous_free_tid

Enables a test that validates the free tuple ID (TID) list. The list is maintained and used by WarehousePG. WarehousePG determines the validity of the free TID list by ensuring the previous free TID of the current free tuple is a valid free tuple. The default value is `true`, enable the test.

If WarehousePG detects a corruption in the free TID list, the free TID list is rebuilt, a warning is logged, and a warning is returned by queries for which the check failed. WarehousePG attempts to run the queries.

> **Note** If a warning is returned, please contact Support.

Value Range	Default	Set Classifications
Boolean	true	coordinator, session, reload

verify_gpfdists_cert

When a WarehousePG external table is defined with the `gpfdists` protocol to use SSL security, this parameter controls whether SSL certificate authentication is enabled.

Regardless of the setting of this server configuration parameter, WarehousePG always encrypts data that you read from or write to an external table that specifies the `gpfdists` protocol.

The default is `true`, SSL certificate authentication is enabled when WarehousePG communicates with the `gpfdist` utility to either read data from or write data to an external data source.

The value `false` deactivates SSL certificate authentication. These SSL exceptions are ignored:

- The self-signed SSL certificate that is used by `gpfdist` is not trusted by WarehousePG.
- The host name contained in the SSL certificate does not match the host name that is running `gpfdist`.

When you set `verify_gpfdists_cert` to `false`, the CA certification file is not required for WarehousePG segments.

You can set the value to `false` to deactivate authentication when testing the communication between the WarehousePG external table and the `gpfdist` utility that is serving the external data.

> **Caution** Deactivating SSL certificate authentication exposes a security risk by not validating the `gpfdists` SSL certificate.

For information about the `gpfdists` protocol and how this setting affects the certificate files required on WarehousePG segments, see gpfdists:// Protocol. For information about running the `gpfdist` utility, see gpfdist.

Value Range	Default	Set Classifications
Boolean	true	coordinator, session, reload

vmem_process_interrupt

Enables checking for interrupts before reserving vmem memory for a query during WarehousePG query execution. Before reserving further vmem for a query, check if the current session for the query has a pending query cancellation or other pending interrupts. This ensures more responsive interrupt processing, including query cancellation requests. The default is `off`.

Value Range	Default	Set Classifications
Boolean	off	coordinator, session, reload

wait_for_replication_threshold

When WarehousePG segment mirroring is enabled, specifies the maximum amount of Write-Ahead Logging (WAL)-based records (in KB) written by a transaction on the primary segment instance before the records are written to the mirror segment instance for replication. As the default, WarehousePG writes the records to the mirror segment instance when a checkpoint occurs or the `wait_for_replication_threshold` value is reached.

A value of 0 deactivates the check for the amount of records. The records are written to the mirror segment instance only after a checkpoint occurs.

If you set the value to 0, database performance issues might occur under heavy loads that perform long transactions that do not perform a checkpoint operation.

Value Range	Default	Set Classifications
0 - MAX-INT / 1024	1024	coordinator, system, reload

wal_keep_size

Specifies the minimum size of past log file segments kept in the `pg_wal` directory, in case a standby coordinator or mirror segment instance needs to fetch them for streaming replication. If a standby coordinator or mirror segment instance connected to the sending server falls behind by more than `wal_keep_size` megabytes, the sending server might remove a WAL segment still needed by the standby coordinator or mirror segment instance, in which case the replication connection will be terminated.

This sets only the minimum size of segments retained in `pg_wal`; the system might need to retain more segments for WAL archival or to recover from a checkpoint. If `wal_keep_size` is zero (the default), the number of old WAL segments available to mirror servers is a function of the location of replication slot's `restart_lsn` and `max_slot_wal_keep_size` parameters, as well as the status of WAL archiving.

If this value is specified without units, it is taken as megabytes.

Value Range	Default	Set Classifications
integer	5 times the default size of the write-ahead log file	coordinator, system, reload, superuser

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

wal_receiver_status_interval

For WarehousePG coordinator mirroring, sets the interval in seconds between `walreceiver` process status messages that are sent to the active coordinator. Under heavy loads, the time might be longer.

The value of wal_sender_timeout controls the time that the `walsender` process waits for a `walreceiver` message.

Value Range	Default	Set Classifications
integer 0- INT_MAX/1000	10 sec	coordinator, system, reload, superuser

work_mem

Sets the maximum amount of memory to be used by a query operation (such as a sort or hash table) before writing to temporary disk files. If this value is specified without units, it is taken as kilobytes. The default value is 32 MB. Note that for a complex query, several sort or hash operations might be running in parallel; each operation will be allowed to use as much memory as this value specifies before it starts to write data into temporary files. In addition, several running sessions may be performing such operations concurrently. Therefore, the total memory used could be many times the value of `work_mem`; keep this fact in mind when choosing the value for this parameter. Sort operations are used for `ORDER BY`, `DISTINCT`, and merge joins. Hash tables are used in hash joins, hash-based aggregation, and hash-based processing of `IN` subqueries. Apart from sorting and hashing, bitmap index scans also rely on `work_mem`. Operations relying on tuplestores such as function scans, CTEs, PL/pgSQL and administration UDFs also rely on `work_mem`.

Apart from assigning memory to specific execution operators, setting `work_mem` also influences certain query plans over others, when the Postgres-based planner is used as the optimizer.

`work_mem` is a distinct memory management concept that does not interact with resource queue or resource group memory controls, which are imposed at the query level.

Value Range	Default	Set Classifications
number of kilobytes	32MB	coordinator, session, reload

writable_external_table_bufsize

Size of the buffer that WarehousePG uses for network communication, such as the `gpfdist` utility and external web tables (that use http). Valid units are `KB` (as in `128KB`), `MB`, `GB`, and `TB`. WarehousePG stores data in the buffer before writing the data out. For information about `gpfdist`, see the *WarehousePG Utility Guide*.

Value Range	Default	Set Classifications
integer 32 - 131072 (32KB - 128MB)	64	local, session, reload

xid_stop_limit

The number of transaction IDs prior to the ID where transaction ID wraparound occurs. When this limit is reached, WarehousePG stops creating new transactions to avoid data loss due to transaction ID wraparound.

Value Range	Default	Set Classifications
integer 10000000 - INT_MAX	100000000	local, system, restart

xid_warn_limit

The number of transaction IDs prior to the limit specified by xid_stop_limit. When WarehousePG reaches this limit, it issues a warning to perform a VACUUM operation to avoid data loss due to transaction ID wraparound.

Value Range	Default	Set Classifications
integer 10000000 - INT_MAX	500000000	local, system, restart

xmlbinary

Specifies how binary values are encoded in XML data. For example, when `bytea` values are converted to XML. The binary data can be converted to either base64 encoding or hexadecimal encoding. The default is base64.

The parameter can be set for a database system, an individual database, or a session.

Value Range	Default	Set Classifications
base64, hex	base64	coordinator, session, reload

xmloption

Specifies whether XML data is to be considered as an XML document (`document`) or XML content fragment (`content`) for operations that perform implicit parsing and serialization. The default is `content`.

This parameter affects the validation performed by `xml_is_well_formed()`. If the value is `document`, the function checks for a well-formed XML document. If the value is `content`, the function checks for a well-formed XML content fragment.

> **Note** An XML document that contains a document type declaration (DTD) is not considered a valid XML content fragment. If `xmloption` set to `content`, XML that contains a DTD is not considered valid XML.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

To cast a character string that contains a DTD to the `xml` data type, use the `xmlparse` function with the `document` keyword, or change the `xmloption` value to `document`.

The parameter can be set for a database system, an individual database, or a session. The SQL command to set this option for a session is also available in WarehousePG.

```
SET XML OPTION { DOCUMENT | CONTENT }
```

Value Range	Default	Set Classifications
document, content	content	coordinator, session, reload

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.6.2 Parameter Categories

Configuration parameters affect categories of server behaviors, such as resource consumption, query tuning, and authentication. The following topics describe WarehousePG configuration parameter categories.

- Connection and Authentication Parameters
- System Resource Consumption Parameters
- GPORCA Parameters
- Query Tuning Parameters
- Error Reporting and Logging Parameters
- Runtime Statistics Collection Parameters
- Automatic Vacuum Parameters
- Automatic Statistics Collection Parameters
- Client Connection Default Parameters
- Lock Management Parameters
- Resource Management Parameters (Resource Queues)
- Resource Management Parameters (Resource Groups)
- External Table Parameters
- Database Table Parameters
- Past Version Compatibility Parameters
- WarehousePG cluster Configuration Parameters
- WarehousePG Mirroring Parameters for Coordinator and Segments
- WarehousePG PL/Java Parameters

Connection and Authentication Parameters

These parameters control how clients connect and authenticate to WarehousePG.

Connection Parameters

- client_connection_check_interval
- gp_connection_send_timeout
- gp_dispatch_keepalives_count
- gp_dispatch_keepalives_idle
- gp_dispatch_keepalives_interval
- gp_postmaster_address_family
- gp_vmem_idle_resource_timeout
- listen_addresses
- max_connections
- max_prepared_transactions
- superuser_reserved_connections
- tcp_keepalives_count
- tcp_keepalives_idle
- tcp_keepalives_interval
- unix_socket_directories
- unix_socket_group
- unix_socket_permissions

Security and Authentication Parameters

- authentication_timeout
- db_user_namespace
- krb_caseins_users
- krb_server_keyfile
- password_encryption
- row_security
- ssl
- ssl_ciphers

System Resource Consumption Parameters

These parameters set the limits for system resources consumed by WarehousePG.

Memory Consumption Parameters

These parameters control system memory usage.

- gp_vmem_idle_resource_timeout
- gp_vmem_protect_limit (resource queue-based resource management)
- gp_vmem_protect_segworker_cache_limit
- gp_workfile_limit_files_per_query
- gp_workfile_limit_per_query
- gp_workfile_limit_per_segment
- maintenance_work_mem
- max_stack_depth
- shared_buffers
- temp_buffers
- work_mem

OS Resource Parameters

- max_files_per_process
- shared_preload_libraries

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Cost-Based Vacuum Delay Parameters

> **Caution** Do not use cost-based vacuum delay because it runs asynchronously among the segment instances. The vacuum cost limit and delay is invoked at the segment level without taking into account the state of the entire WarehousePG cluster

You can configure the execution cost of `VACUUM` and `ANALYZE` commands to reduce the I/O impact on concurrent database activity. When the accumulated cost of I/O operations reaches the limit, the process performing the operation sleeps for a while, Then resets the counter and continues execution

- vacuum_cost_delay
- vacuum_cost_limit
- vacuum_cost_page_dirty
- vacuum_cost_page_hit
- vacuum_cost_page_miss

Transaction ID Management Parameters

- xid_stop_limit
- xid_warn_limit

Other Parameters

- gp_max_parallel_cursors

GPORCA Parameters

These parameters control the usage of GPORCA by WarehousePG. For information about GPORCA, seeAbout GPORCA in the *WarehousePG Administrator Guide*.

- gp_enable_relsize_collection
- optimizer
- optimizer_analyze_root_partition
- optimizer_array_expansion_threshold
- optimizer_control
- optimizer_cost_model
- optimizer_cte_inlining_bound
- optimizer_dpe_stats
- optimizer_discard_redistribute_hashjoin
- optimizer_enable_associativity
- optimizer_enable_dml
- optimizer_enable_dynamicindexonlyscan
- optimizer_enable_foreign_table
- optimizer_enable_indexonlyscan
- optimizer_enable_coordinator_only_queries
- optimizer_enable_multiple_distinct_aggs
- optimizer_enable_orderedagg
- optimizer_enable_push_join_below_union_all
- optimizer_enable_replicated_table
- optimizer_enable_right_outer_join
- optimizer_force_agg_skew_avoidance
- optimizer_force_comprehensive_join_implementation
- optimizer_force_multistage_agg
- optimizer_force_three_stage_scalar_dqa
- optimizer_join_arity_for_associativity_commutativity
- optimizer_join_order
- optimizer_join_order_threshold
- optimizer_mdcache_size
- optimizer_metadata_caching
- optimizer_parallel_union
- optimizer_penalize_broadcast_threshold
- optimizer_penalize_skew
- optimizer_print_missing_stats
- optimizer_print_optimization_stats
- optimizer_skew_factor
- optimizer_sort_factor
- optimizer_use_gpdb_allocators
- optimizer_xform_bind_threshold

Query Tuning Parameters

These parameters control aspects of SQL query processing such as query operators and operator settings and statistics sampling.

Postgres-based planner Control Parameters

The following parameters control the types of plan operations the Postgres-based planner can use. Enable or deactivate plan operations to force the Postgres-based planner to choose a different plan. This is useful for testing and comparing query performance using different plan types.

- enable_bitmapscan
- enable_groupagg
- enable_hashagg
- enable_hashjoin
- enable_indexscan
- enable_mergejoin
- enable_nestloop
- enable_partition_pruning
- enable_seqscan
- enable_sort
- enable_tidscan
- gp_eager_two_phase_agg
- gp_enable_agg_distinct

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

- gp_enable_agg_distinct_pruning
- gp_enable_direct_dispatch
- gp_enable_fast_sri
- gp_enable_groupext_distinct_gather
- gp_enable_groupext_distinct_pruning
- gp_enable_multiphase_agg
- gp_enable_predicate_propagation
- gp_enable_preunique
- gp_enable_relsize_collection
- gp_enable_sort_limit

Postgres-based planner Costing Parameters

> **Caution** Do not adjust these query costing parameters. They are tuned to reflect WarehousePG hardware configurations and typical workloads. All of these parameters are related. Changing one without changing the others can have adverse affects on performance.

- cpu_index_tuple_cost
- cpu_operator_cost
- cpu_tuple_cost
- cursor_tuple_fraction
- effective_cache_size
- gp_motion_cost_per_row
- gp_segments_for_planner
- random_page_cost
- seq_page_cost

Database Statistics Sampling Parameters

These parameters adjust the amount of data sampled by an `ANALYZE` operation. Adjusting these parameters affects statistics collection system-wide. You can configure statistics collection on particular tables and columns by using the `ALTER TABLE SET STATISTICS` clause.

- default_statistics_target

Sort Operator Configuration Parameters

- gp_enable_sort_limit

Aggregate Operator Configuration Parameters

- gp_enable_agg_distinct
- gp_enable_agg_distinct_pruning
- gp_enable_multiphase_agg
- gp_enable_preunique
- gp_enable_groupext_distinct_gather
- gp_enable_groupext_distinct_pruning
- gp_workfile_compression

Join Operator Configuration Parameters

- join_collapse_limit
- gp_adjust_selectivity_for_outerjoins
- gp_hashjoin_tuples_per_bucket
- gp_workfile_compression

Other Postgres-based planner Configuration Parameters

- from_collapse_limit
- gp_enable_predicate_propagation
- gp_max_plan_size
- gp_statistics_pullup_from_child_partition
- gp_statistics_use_fkeys

Query Plan Execution

Control the query plan execution.

- gp_max_slices
- gp_max_system_slices
- plan_cache_mode

JIT Configuration Parameters

- gp_explain_jit
- jit
- jit_above_cost
- jit_debugging_support
- jit_dump_bitcode
- jit_expressions
- jit_inline_above_cost
- jit_optimize_above_cost
- jit_profiling_support
- jit_provider
- jit_tuple_deforming
- optimizer_jit_above_cost

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

- optimizer_jit_inline_above_cost
- optimizer_jit_optimize_above_cost

Error Reporting and Logging Parameters

These configuration parameters control WarehousePG logging.

Log Rotation

- log_rotation_age
- log_rotation_size
- log_truncate_on_rotation

When to Log

- client_min_messages
- gp_interconnect_debug_retry_interval
- log_error_verbosity
- log_file_mode
- log_min_duration_statement
- log_min_error_statement
- log_min_messages
- optimizer_minidump

What to Log

- debug_pretty_print
- debug_print_parse
- debug_print_plan
- debug_print_prelim_plan

- log_planner_stats
- log_statement
- log_statement_stats
- log_timezone
- gp_debug_linger
- gp_log_format
- gp_reraise_signal

Automatic Vacuum Parameters

These parameters pertain to auto-vacuuming databases.

- autovacuum
- autovacuum_analyze_scale_factor
- autovacuum_analyze_threshold
- autovacuum_freeze_max_age
- autovacuum_max_workers
- autovacuum_multixact_freeze_max_age
- autovacuum_naptime
- autovacuum_vacuum_cost_delay
- autovacuum_vacuum_cost_limit
- autovacuum_vacuum_scale_factor
- autovacuum_vacuum_threshold
- gp_autovacuum_scope

Runtime Statistics Collection Parameters

These parameters control the server statistics collection feature. When statistics collection is enabled, you can access the statistics data using the*pg_stat* family of system catalog views.

- stats_queue_level
- track_activities
- track_counts
- update_process_title

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Automatic Statistics Collection Parameters

When automatic statistics collection is enabled, you can run `ANALYZE` automatically in the same transaction as an `INSERT`, `UPDATE`, `DELETE`, `COPY` or `CREATE TABLE...AS SELECT` statement when a certain threshold of rows is affected (`on_change`), or when a newly generated table has no statistics (`on_no_stats`). To enable this feature, set the following server configuration parameters in your WarehousePG coordinator `postgresql.conf` file and restart WarehousePG:

- gp_autostats_allow_nonowner
- gp_autostats_lock_wait
- gp_autostats_mode
- gp_autostats_mode_in_functions
- gp_autostats_on_change_threshold
- log_autostats

> **Caution** Depending on the specific nature of your database operations, automatic statistics collection can have a negative performance impact. Carefully evaluate whether the default setting of `on_no_stats` is appropriate for your system.

Client Connection Default Parameters

These configuration parameters set defaults that are used for client connections.

Statement Behavior Parameters

- check_function_bodies
- default_tablespace
- default_transaction_deferrable
- default_transaction_isolation
- default_transaction_read_only
- search_path
- gin_pending_list_limit
- statement_timeout
- temp_tablespaces
- vacuum_cleanup_index_scale_factor
- vacuum_freeze_min_age

Locale and Formatting Parameters

- client_encoding
- DateStyle
- extra_float_digits
- IntervalStyle
- lc_collate
- lc_ctype
- lc_messages
- lc_monetary
- lc_numeric
- lc_time
- TimeZone

Other Client Default Parameters

- dynamic_library_path
- explain_pretty_print
- local_preload_libraries

Lock Management Parameters

These configuration parameters set limits for locks and deadlocks.

- deadlock_timeout
- gp_enable global_deadlock_detector[gp_global_deadlock_detector_period](guc-list.html#gp_enable global_deadlock_detector](guc-list.html)[gp_global_deadlock_detector_period)
- lock_timeout
- max_locks_per_transaction

Resource Management Parameters (Resource Queues)

The following configuration parameters configure the WarehousePG resource management feature (resource queues), query prioritization, memory utilization and concurrency control.

- gp_resqueue_memory_policy
- gp_resqueue_priority
- gp_resqueue_priority_cpucores_per_segment
- gp_resqueue_priority_sweeper_interval
- gp_vmem_idle_resource_timeout
- gp_vmem_protect_limit
- gp_vmem_protect_segworker_cache_limit
- max_resource_queues
- max_resource_portals_per_transaction
- max_statement_mem
- resource_cleanup_gangs_on_wait
- resource_select_only
- runaway_detector_activation_percent
- statement_mem
- stats_queue_level
- vmem_process_interrupt

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Resource Management Parameters (Resource Groups)

The following parameters configure the WarehousePG resource group workload management feature.

- gp_resgroup_memory_policy
- gp_resgroup_memory_query_fixed_mem
- gp_resource_group_bypass
- gp_resource_group_bypass_catalog_query
- gp_resource_group_bypass_direct_dispatch
- gp_resource_group_cgroup_parent
- gp_resource_group_cpu_limit
- gp_resource_group_cpu_priority
- gp_resource_group_move_timeout
- gp_resource_group_queuing_timeout
- gp_resource_manager
- gp_vmem_idle_resource_timeout
- gp_vmem_protect_segworker_cache_limit
- max_statement_mem
- runaway_detector_activation_percent
- statement_mem
- vmem_process_interrupt

External Table Parameters

The following parameters configure the external tables feature of WarehousePG.

- gp_external_enable_exec
- gp_external_enable_filter_pushdown
- gp_external_max_segs
- gp_initial_bad_row_limit
- gp_reject_percent_threshold
- gpfdist_retry_timeout
- readable_external_table_timeout
- writable_external_table_bufsize
- verify_gpfdists_cert

Database Table Parameters

The following parameter configures default option settings for WarehousePG tables.

- default_table_access_method
- gp_create_table_random_default_distribution
- gp_default_storage_options
- gp_enable_segment_copy_checking
- gp_use_legacy_hashops

Append-Optimized Table Parameters

The following parameters configure the append-optimized tables feature of WarehousePG.

- gp_appendonly_compaction
- gp_appendonly_compaction_threshold
- validate_previous_free_tid

Past Version Compatibility Parameters

The following parameters provide compatibility with older PostgreSQL and WarehousePG versions. You do not need to change these parameters in WarehousePG.

PostgreSQL

- array_nulls
- backslash_quote
- escape_string_warning
- gp_quicklz_fallback
- quote_all_identifiers
- standard_conforming_strings
- transform_null_equals

WarehousePG

- gp_ignore_error_table

WarehousePG cluster Configuration Parameters

The parameters in this topic control the configuration of the WarehousePG cluster and its components: segments, coordinator, distributed transaction manager, coordinator mirror, and interconnect.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Interconnect Configuration Parameters

- gp_interconnect_address_type
- gp_interconnect_fc_method
- gp_interconnect_proxy_addresses
- gp_interconnect_queue_depth
- gp_interconnect_setup_timeout
- gp_interconnect_snd_queue_depth
- gp_interconnect_transmit_timeout
- gp_interconnect_type
- gp_max_packet_size

> **Note** WarehousePG supports only the UDPIFC (default) and TCP interconnect types.

Dispatch Configuration Parameters

- gp_cached_segworkers_threshold
- gp_enable_direct_dispatch
- gp_segment_connect_timeout
- gp_set_proc_affinity

Fault Operation Parameters

- gp_set_read_only
- gp_fts_probe_interval
- gp_fts_probe_retries
- gp_fts_probe_timeout
- gp_fts_replication_attempt_count
- gp_log_fts

Distributed Transaction Management Parameters

- gp_max_local_distributed_cache

Read-Only Parameters

- gp_command_count
- gp_content
- gp_dbid
- gp_retrieve_conn
- gp_role
- gp_session_id
- gp_server_version
- gp_server_version_num

WarehousePG Mirroring Parameters for Coordinator and Segments

These parameters control the configuration of the replication between WarehousePG primary coordinator and standby coordinator.

- checkpoint_completion_target
- checkpoint_flush_after
- checkpoint_timeout
- checkpoint_warning
- max_slot_wal_keep_size
- max_wal_size
- min_wal_size
- repl_catchup_within_range
- replication_timeout
- track_wal_io_timing
- wait_for_replication_threshold
- wal_buffers
- wal_compression
- wal_keep_size
- wal_receiver_status_interval

WarehousePG PL/Java Parameters

The parameters in this topic control the configuration of the WarehousePG PL/Java language.

- pljava_classpath
- pljava_classpath_insecure
- pljava_statement_cache_size
- pljava_release_lingering_savepoints
- pljava_vmoptions

XML Data Parameters

The parameters in this topic control the configuration of the WarehousePG XML data type.

- xmlbinary
- xmloption

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.7 WarehousePG cluster utility guide

Reference information for WarehousePG utility programs.

- About the WarehousePG Utilities
  General information about using the WarehousePG utility programs.
- Utility Reference
  The command-line utilities provided with WarehousePG.
- Additional Supplied Utilities
  Additional programs available in the WarehousePG installation.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.7.1 About the WarehousePG Utilities

General information about using the WarehousePG utility programs.

Referencing IP Addresses

When you reference IPv6 addresses in WarehousePG utility programs, or when you use numeric IP addresses instead of hostnames in any management utility, always enclose the IP address in brackets. When specifying an IP address at the command line, the best practice is to escape any brackets or enclose them in single quotes. For example, use either:

```
\[2620:0:170:610::11\]
```

Or:

```
'[2620:0:170:610::11]'
```

Running Backend Server Programs

WarehousePG has modified certain PostgreSQL backend server programs to handle the parallelism and distribution of a WarehousePG cluster. You access these programs only through the WarehousePG management tools and utilities. *Do not run these programs directly.*

The following table identifies certain PostgreSQL backend server programs and the WarehousePG utility command to run instead.

PostgreSQL Program Name	Description	Use Instead
`initdb`	This program is called by `gpinitsystem` when initializing a WarehousePG cluster. It is used internally to create the individual segment instances and the coordinator instance.	gpinitsystem
`ipcclean`	Not used in WarehousePG	N/A
`pg_basebackup`	This program makes a binary copy of a single database instance. WarehousePG uses it for tasks such as creating a standby coordinator instance, or recovering a mirror segment when a full copy is needed. Do not use this utility to back up WarehousePG segment instances because it does not produce MPP-consistent backups.	gpinitstandby, `[gprecoverseg](ref/gprecoverseg.html)`
`pg_controldata`	Not used in WarehousePG	gpstate
`pg_ctl`	This program is called by `gpstart` and `gpstop` when starting or stopping a WarehousePG cluster. It is used internally to stop and start the individual segment instances and the coordinator instance in parallel and with the correct options.	gpstart, gpstop
`pg_resetwal`	DO NOT USE > **Caution** This program might cause data loss or cause data to become unavailable. If this program is used, the WarehousePG cluster is not supported. Thecluster must be reinitialized and restoredby the customer.	N/A
`postgres`	The `postgres` executable is the actual PostgreSQL server process that processes queries.	The main `postgres` process (postmaster) creates other `postgres` subprocesses and `postgres` session as needed to handle client connections.
`postmaster`	`postmaster` starts the `postgres` database server listener process that accepts client connections. In WarehousePG, a `postgres` database listener process runs on the WarehousePG coordinator Instance and on each Segment Instance.	In WarehousePG, you use gpstart and gpstop to start all postmasters (`postgres` processes) in the system at once in the correct order and with the correct options.

7.7.2 Utility Reference

The command-line utilities provided with WarehousePG.

WarehousePG uses the standard PostgreSQL client and server programs and provides additional management utilities for administering a distributed WarehousePG DBMS.

Several utilities are installed when you install the WarehousePG server. These utilities reside in `$GPHOME/bin`.

Other utilities such as clients and backup/restore may be found at Warehouse PG Github Repo

WarehousePG provides the following utility programs. Superscripts identify those utilities that require separate downloads, as well as those utilities that are also installed with the Client and Loader Tools Packages. (See the Note following the table.) All utilities are installed when you install the WarehousePG server, unless specifically identified by a superscript.

- analyzedb
- clusterdb
- createdb[1]
- createuser[1]
- dropdb[1]
- dropuser[1]
- gpactivatestandby
- gpaddmirrors
- gpbackup[2]
- gpcheckcat
- gpcheckperf
- gpconfig
- gpdeletesystem
- gpexpand
- gpfdist[1]
- gpinitstandby
- gpinitsystem
- gpload[1]
- gplogfilter
- gpmovemirrors
- gprecoverseg
- gpreload
- gprestore[2]
- gpssh
- gpssh-exkeys
- gpstart
- gpstate
- gpstop

7.7.2.1 analyzedb

A utility that performs `ANALYZE` operations on tables incrementally and concurrently. For append optimized tables, analyzedb updates statistics only if the statistics are not current.

Synopsis

```
analyzedb -d <dbname>
   { -s <schema>  |
   { -t <schema>.<table>
     [ -i <col1>[,<col2>, ...] |
       -x <col1>[,<col2>, ...] ] } |
     { -f | --file} <config-file> }
   [ -l | --list ]
   [ --gen_profile_only ]
   [ -p <parallel-level> ]
   [ --full ]
   [ --skip_root_stats ]
   [ --skip_orca_root_stats ]
   [ -v | --verbose ]
   [ -a ]
   [ --skip-locked ]

analyzedb { --clean_last | --clean_all }
analyzedb --version
analyzedb { -? | -h | --help }
```

Description

The analyzedb utility updates statistics on table data for the specified tables in a WarehousePG incrementally and concurrently.

While performing ANALYZE operations, analyzedb creates a snapshot of the table metadata and stores it on disk on the coordinator host. An `ANALYZE` operation is performed only if the table has been modified. If a table or partition has not been modified since the last time it was analyzed, analyzedb automatically skips the table or partition because it already contains up-to-date statistics.

- For append optimized tables, analyzedb updates statistics incrementally, if the statistics are not current. For example, if table data is changed after statistics were collected for the table. If there are no statistics for the table, statistics are collected.
- For heap tables, statistics are always updated.

Specify the `--full` option to update append-optimized table statistics even if the table statistics are current.

By default, analyzedb creates a maximum of 5 concurrent sessions to analyze tables in parallel. For each session, analyzedb issues an ANALYZE command to the database and specifies different table names. The `-p` option controls the maximum number of concurrent sessions.

Partitioned Append-Optimized Tables

For a partitioned, append-optimized table, analyzedb checks the root partitioned table and the leaf partitions. If needed, the utility updates statistics for non-current partitions and the root partition. For information about how statistics are collected for partitioned tables, see ANALYZE.

`analyzedb` must sample additional partitions within a partitioned table when it encounters a stale partition, even when statistics are already collected. It is recomended that you run `analyzedb` on the root partition any time that you add a new partition(s) to a partitioned table. This operation both analyzes the leaf partitions in parallel and merges any updated statistics into the root partition.

Notes

The analyzedb utility updates append optimized table statistics if the table has been modified by DML or DDL commands, including INSERT, DELETE, UPDATE, CREATE TABLE, ALTER TABLE and TRUNCATE. The utility determines if a table has been modified by comparing catalog metadata of tables with the previous snapshot of metadata taken during a previous analyzedb operation. The snapshots of table metadata are stored as state files in the directory `db_analyze/<db_name>/<timestamp>` in the WarehousePG coordinator data directory.

The utility preserves old snapshot information from the past 8 days, and the 3 most recent state directories regardless of age, while all other directories are automatically removed. You can also specify the `--clean_last` or `--clean_all` option to remove state files generated by analyzedb.

If you do not specify a table, set of tables, or schema, the analyzedb utility collects the statistics as needed on all system catalog tables and user-defined tables in the database.

External tables are not affected by analyzedb.

Table names that contain spaces are not supported.

Running the `ANALYZE` command on a table, not using the `analyzedb` utility, does not update the table metadata that the `analyzedb` utility uses to determine whether table statistics are up to date.

Options

--clean_last Remove the state files generated by last analyzedb operation. All other options except -d are ignored.

--clean_all Remove all the state files generated by analyzedb. All other options except -d are ignored.

-d dbname Specifies the name of the database that contains the tables to be analyzed. If this option is not specified, the database name is read from the environment variable `PGDATABASE`. If `PGDATABASE` is not set, the user name specified for the connection is used.

-f config-file | --file config-file Text file that contains a list of tables to be analyzed. A relative file path from current directory can be specified.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

The file lists one table per line. Table names must be qualified with a schema name. Optionally, a list of columns can be specified using the -i or -x. No other options are allowed in the file. Other options such as `--full` must be specified on the command line.

Only one of the options can be used to specify the files to be analyzed: `-f` or `--file`, `-t`, or `-s`.

When performing ANALYZE operations on multiple tables, analyzedb creates concurrent sessions to analyze tables in parallel. The `-p` option controls the maximum number of concurrent sessions.

In the following example, the first line performs an ANALYZE operation on the table `public.nation`, the second line performs an ANALYZE operation only on the columns `l_shipdate` and `l_receiptdate` in the table `public.lineitem`.

```
public.nation
public.lineitem -i l_shipdate,l_receiptdate
```

--full Perform an ANALYZE operation on all the specified tables. The operation is performed even if the statistics are up to date.

--gen_profile_only Update the `analyzedb` snapshot of table statistics information without performing any `ANALYZE` operations. If other options specify tables or a schema, the utility updates the snapshot information only for the specified tables.

Specify this option if the `ANALYZE` command was run on database tables and you want to update the `analyzedb` snapshot for the tables.

-i col1,col2, ... Optional. Must be specified with the -t option. For the table specified with the -t option, collect statistics only for the specified columns.

Only -i, or -x can be specified. Both options cannot be specified.

-l | --list Lists the tables that would have been analyzed with the specified options. The ANALYZE operations are not performed.

-p parallel-level The number of tables that are analyzed in parallel. parallel level can be an integer between 1 and 10, inclusive. Default value is 5.

--skip_root_stats This option is no longer used, you may remove it from your scripts.

`--skip_orca_root_stats`

> **Note** Do not use this option if GPORCA is enabled.

Use this option if you find that `ANALYZE ROOTPARTITION` commands take a very long time to complete.

> **Caution** After you run `analyzedb` with this option, subsequent `analyzedb` executions will not update root partition statistics except when changes have been made to the table.

-s schema Specify a schema to analyze. All tables in the schema will be analyzed. Only a single schema name can be specified on the command line.

Only one of the options can be used to specify the files to be analyzed: `-f` or `--file`, `-t`, or `-s`.

-t schema.table Collect statistics only on schema.table. The table name must be qualified with a schema name. Only a single table name can be specified on the command line. You can specify the `-f` option to specify multiple tables in a file or the `-s` option to specify all the tables in a schema.

Only one of these options can be used to specify the files to be analyzed: `-f` or `--file`, `-t`, or `-s`.

-x col1,col2, ... Optional. Must be specified with the -t option. For the table specified with the -t option, exclude statistics collection for the specified columns. Statistics are collected only on the columns that are not listed.

Only -i, or -x can be specified. Both options cannot be specified.

-a Quiet mode. Do not prompt for user confirmation.

--skip-locked Skip relations that cannot be immediately locked.

-h | -? | --help Displays the online help.

-v | --verbose If specified, sets the logging level to verbose to write additional information the log file and to the command line during command execution. The information includes a list of all the tables to be analyzed (including leaf partitions of partitioned tables). Output also includes the duration of each `ANALYZE` operation.

--version Displays the version of this utility.

Examples

An example that collects statistics only on a set of table columns. In the database `mytest`, collect statistics on the columns `shipdate` and `receiptdate` in the table `public.orders`:

```
analyzedb -d mytest -t public.orders -i shipdate,receiptdate
```

An example that collects statistics on a table and exclude a set of columns. In the database `mytest`, collect statistics on the table `public.foo`, and do not collect statistics on the columns `bar` and `test2`.

```
analyzedb -d mytest -t public.foo -x bar,test2
```

An example that specifies a file that contains a list of tables. This command collect statistics on the tables listed in the file `analyze-tables` in the database named `mytest`.

```
analyzedb -d mytest -f analyze-tables
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

If you do not specify a table, set of tables, or schema, the analyzedb utility collects the statistics as needed on all catalog tables and user-defined tables in the specified database. This command refreshes table statistics on the system catalog tables and user-defined tables in the database `mytest`.

```
analyzedb -d mytest
```

You can create a PL/Python function to run the `analyzedb` utility as a WarehousePG function. This example `CREATE FUNCTION` command creates a user defined PL/Python function that runs the `analyzedb` utility and displays output on the command line. Specify `analyzedb` options as the function parameter.

```
CREATE OR REPLACE FUNCTION analyzedb(params TEXT)
  RETURNS VOID AS
$BODY$
    import subprocess
    cmd = ['analyzedb', '-a' ] + params.split()
    p = subprocess.Popen(cmd, stdout=subprocess.PIPE, stderr=subprocess.STDOUT)

    # verbose output of process
    for line in iter(p.stdout.readline, ''):
        plpy.info(line);

    p.wait()
$BODY$
LANGUAGE plpython3u VOLATILE;
```

When this `SELECT` command is run by the gpadmin user, the `analyzedb` utility performs an analyze operation on the table `public.mytable` that is in the database `mytest`.

```
SELECT analyzedb('-d mytest -t public.mytable') ;
```

> **Note** To create a PL/Python function, the PL/Python procedural language must be registered as a language in the database. For example, this `CREATE LANGUAGE` command run as gpadmin registers PL/Python as an untrusted language:

```
CREATE LANGUAGE plpython3u;
```

ANALYZE

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.7.2.2 clusterdb

Reclusters tables that were previously clustered with `CLUSTER`.

Synopsis

```
clusterdb [<connection-option> ...] [--verbose | -v] [--table | -t <table>] [[--dbname | -d] <dbname]

clusterdb [<connection-option> ...] [--verbose | -v] --all | -a

clusterdb -? | --help

clusterdb -V | --version
```

Description

To cluster a table means to physically reorder a table on disk according to an index. Clustering helps improving index seek performance for queries that use that index. Clustering is a one-time operation: when the table is subsequently updated, the changes are not clustered. That is, no attempt is made to store new or updated rows according to their index order.

The `clusterdb` utility will find any tables in a database that have previously been clustered with the `CLUSTER` SQL command, and clusters them again on the same index that was last used. Tables that have never been clustered are not affected.

`clusterdb` is a wrapper around the SQL command CLUSTER. There is no effective difference between clustering databases via this utility and via other methods for accessing the server.

Options

`clusterdb` accepts the following command-line arguments:

-a --all Cluster all databases.

[-d] dbname [--dbname=]dbname Specifies the name of the database to be clustered, when `-a/--all` is not used. If this is not specified, the database name is read from the environment variable `PGDATABASE`. If that is not set, the user name specified for the connection is used. The dbname can be a connection string. If so, connection string parameters will override any conflicting command line options.

-e --echo Echo the commands that `clusterdb` generates and sends to the server.

-q --quiet Do not display progress messages.

-t table --table=table Cluster the named table only. You can cluster multiple tables by specifying multiple `-t` switches.

-v --verbose Print detailed information during processing.

-V --version Print the `clusterdb` version, and exit.

-? --help Show help about `clusterdb` command line arguments, and exit.

Connection Options

`clusterdb` also accepts the following command-line arguments for connection parameters:

-h host --host=host Specifies the host name of the machine on which the WarehousePG coordinator database server is running. If not specified, reads from the environment variable `PGHOST` or defaults to `localhost`.

-p port --port=port Specifies the TCP port on which the WarehousePG coordinator database server is listening for connections. If not specified, reads from the environment variable `PGPORT` or defaults to 5432.

-U username --username=username The database role name to connect as. If not specified, reads from the environment variable `PGUSER` or defaults to the current system role name.

-w --no-password Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

-W --password Force `clusterdb` to prompt for a password before connecting to a database. This option is never essential, since `clusterdb` will automatically prompt for a password if the server demands password authentication. However, `clusterdb` will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-W` to avoid the extra connection attempt.

--maintenance-db=dbname Specifies the name of the database to connect to discover what other databases should be clustered. If not specified, the `postgres` database will be used, and if that does not exist, `template1` will be used. This can be a connection string. If so, connection string parameters will override any conflicting command line options. Also, connection string parameters other than the database name itself will be re-used when connecting to other databases.

Environment

PGDATABASE PGHOST PGPORT PGUSER Default connection parameters.

PG_COLOR Specifies whether to use color in diagnostic messages. Possible values are `always`, `auto`, and `never`.

This utility, like most other WarehousePG utilities, also uses the environment variables supported by `libpq`.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Diagnostics

In case of difficulty, see CLUSTER and psql for discussions of potential problems and error messages. The database server must be running at the targeted host. Also, any default connection settings and environment variables used by the `libpq` front-end library will apply.

Examples

To cluster the database named `test`:

```
clusterdb test
```

To cluster a single table `foo` in a database named `xyzzy`:

```
clusterdb --table=foo xyzzy
```

See Also

CLUSTER

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.7.2.3 createdb

Creates a new database.

Synopsis

```
createdb [<connection-option> ...] [<option> ...] [<dbname> ['<description>']]

createdb -? | --help

createdb -V | --version
```

Description

`createdb` creates a new database in a WarehousePG cluster.

Normally, the database user who runs this command becomes the owner of the new database. However, a different owner can be specified via the `-O` option, if the executing user has appropriate privileges.

`createdb` is a wrapper around the SQL command CREATE DATABASE .

Options

dbname The name of the database to be created. The name must be unique among all other databases in the WarehousePG cluster. If not specified, reads from the environment variable `PGDATABASE`, then `PGUSER` or defaults to the current system user.

description A comment to be associated with the newly created database. Descriptions containing white space must be enclosed in quotes.

-D tablespace | --tablespace=tablespace Specifies the default tablespace for the database. (This name is processed as a double-quoted identifier.)

-e echo Echo the commands that `createdb` generates and sends to the server.

-E encoding | --encoding encoding Character set encoding to use in the new database. Specify a string constant (such as `'UTF8'`), an integer encoding number, or `DEFAULT` to use the default encoding. See the WarehousePG Reference Guide for information about supported character sets.

-l locale | --locale locale Specifies the locale to be used in this database. This is equivalent to specifying both `--lc-collate` and `--lc-ctype`.

--lc-collate locale Specifies the `LC_COLLATE` setting to be used in this database.

--lc-ctype locale Specifies the `LC_CTYPE` setting to be used in this database.

-O owner | --owner=owner The name of the database user who will own the new database. Defaults to the user running this command. (This name is processed as a double-quoted identifier.)

-T template | --template=template The name of the template from which to create the new database. Defaults to `template1`. (This name is processed as a double-quoted identifier.)

-V | --version Print the `createdb` version and exit.

-? | --help Show help about `createdb` command line arguments, and exit.

The options `-D`, `-l`, `-E`, `-O`, and `-T` correspond to options of the underlying SQL command `CREATE DATABASE`; see CREATE DATABASE in the *WarehousePG Reference Guide* for more information about them.

Connection Options

-h host | --host=host The host name of the machine on which the WarehousePG coordinator database server is running. If not specified, reads from the environment variable `PGHOST` or defaults to localhost.

-p port | --port=port The TCP port on which the WarehousePG coordinator database server is listening for connections. If not specified, reads from the environment variable `PGPORT` or defaults to 5432.

-U username | --username=username The database role name to connect as. If not specified, reads from the environment variable `PGUSER` or defaults to the current system role name.

-w | --no-password Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

-W | --password Force a password prompt.

--maintenance-db=dbname Specifies the name of the database to connect to when creating the new database. If not specified, the `postgres` database will be used; if that does not exist (or if it is the name of the new database being created), `template1` will be used.

Examples

To create the database `test` using the default options:

```
createdb test
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

To create the database `demo` using the WarehousePG coordinator on host `gpcoord`, port `54321`, using the `LATIN1` encoding scheme:

```
createdb -p 54321 -h gpcoord -E LATIN1 demo
```

7.7.2.4 createuser

Creates a new database role.

Synopsis

```
createuser [<connection-option> ...] [<role_attribute> ...] [-e] <role_name>

createuser -? | --help

createuser -V | --version
```

Description

`createuser` creates a new WarehousePG role. You must be a superuser or have the `CREATEROLE` privilege to create new roles. You must connect to the database as a superuser to create new superusers.

Superusers can bypass all access permission checks within the database, so superuser privileges should not be granted lightly.

`createuser` is a wrapper around the SQL command `CREATE ROLE`.

Options

role_name The name of the role to be created. This name must be different from all existing roles in this WarehousePG installation.

-c number | --connection-limit=number Set a maximum number of connections for the new role. The default is to set no limit.

-d | --createdb The new role will be allowed to create databases.

-D | --no-createdb The new role will not be allowed to create databases. This is the default.

-e | --echo Echo the commands that `createuser` generates and sends to the server.

-E | --encrypted Encrypts the role's password stored in the database. If not specified, the default password behavior is used.

-i | --inherit The new role will automatically inherit privileges of roles it is a member of. This is the default.

-I | --no-inherit The new role will not automatically inherit privileges of roles it is a member of.

--interactive Prompt for the user name if none is specified on the command line, and also prompt for whichever of the options `-d` / `-D`, `-r` / `-R`, `-s` / `-S` is not specified on the command line.

-l | --login The new role will be allowed to log in to WarehousePG. This is the default.

-L | --no-login The new role will not be allowed to log in (a group-level role).

-N | --unencrypted Does not encrypt the role's password stored in the database. If not specified, the default password behavior is used.

-P | --pwprompt If given, `createuser` will issue a prompt for the password of the new role. This is not necessary if you do not plan on using password authentication.

-r | --createrole The new role will be allowed to create new roles (`CREATEROLE` privilege).

-R | --no-createrole The new role will not be allowed to create new roles. This is the default.

-s | --superuser The new role will be a superuser.

-S | --no-superuser The new role will not be a superuser. This is the default.

-V | --version Print the `createuser` version and exit.

--replication The new user will have the `REPLICATION` privilege, which is described more fully in the documentation for CREATE ROLE.

--no-replication The new user will not have the `REPLICATION` privilege, which is described more fully in the documentation for CREATE ROLE.

-? | --help Show help about `createuser` command line arguments, and exit.

Connection Options

-h host | --host=host The host name of the machine on which the WarehousePG coordinator database server is running. If not specified, reads from the environment variable `PGHOST` or defaults to localhost.

-p port | --port=port The TCP port on which the WarehousePG coordinator database server is listening for connections. If not specified, reads from the environment variable `PGPORT` or defaults to 5432.

-U username | --username=username The database role name to connect as. If not specified, reads from the environment variable `PGUSER` or defaults to the current system role name.

-w | --no-password Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

-W | --password Force a password prompt.

Examples

To create a role `joe` on the default database server:

```
$ createuser joe
```

To create a role `joe` on the default database server with prompting for some additional attributes:

```
$ createuser --interactive joe
Shall the new role be a superuser? (y/n) **n**
Shall the new role be allowed to create databases? (y/n) **n**
Shall the new role be allowed to create more new roles? (y/n) **n**
CREATE ROLE
```

To create the same role `joe` using connection options, with attributes explicitly specified, and taking a look at the underlying command:

```
createuser -h coordinatorhost -p 54321 -S -D -R -e joe
CREATE ROLE joe NOSUPERUSER NOCREATEDB NOCREATEROLE INHERIT
LOGIN;
CREATE ROLE
```

To create the role `joe` as a superuser, and assign password `admin123` immediately:

```
createuser -P -s -e joe
Enter password for new role: admin123
Enter it again: admin123
CREATE ROLE joe PASSWORD 'admin123' SUPERUSER CREATEDB
CREATEROLE INHERIT LOGIN;
CREATE ROLE
```

In the above example, the new password is not actually echoed when typed, but we show what was typed for clarity. However the password will appear in the echoed command, as illustrated if the `-e` option is used.

7.7.2.5 dropdb

Removes a database.

Synopsis

```
dropdb [<connection-option> ...] [-e] [-i] <dbname>

dropdb -? | --help

dropdb -V | --version
```

Description

`dropdb` destroys an existing database. The user who runs this command must be a superuser or the owner of the database being dropped.

`dropdb` is a wrapper around the SQL command `DROP DATABASE`. See the *WarehousePG Reference Guide* for information about `DROP DATABASE.`

Options

dbname The name of the database to be removed.

-e | --echo Echo the commands that `dropdb` generates and sends to the server.

-i | --interactive Issues a verification prompt before doing anything destructive.

-V | --version Print the `dropdb` version and exit.

--if-exists Do not throw an error if the database does not exist. A notice is issued in this case.

-? | --help Show help about `dropdb` command line arguments, and exit.

Connection Options

-h host | --host=host The host name of the machine on which the WarehousePG coordinator database server is running. If not specified, reads from the environment variable `PGHOST` or defaults to localhost.

-p port | --port=port The TCP port on which the WarehousePG coordinator database server is listening for connections. If not specified, reads from the environment variable `PGPORT` or defaults to 5432.

-U username | --username=username The database role name to connect as. If not specified, reads from the environment variable `PGUSER` or defaults to the current system role name.

-w | --no-password Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

-W | --password Force a password prompt.

--maintenance-db=dbname Specifies the name of the database to connect to in order to drop the target database. If not specified, the `postgres` database will be used; if that does not exist (or if it is the name of the database being dropped), `template1` will be used.

Examples

To destroy the database named `demo` using default connection parameters:

```
dropdb demo
```

To destroy the database named `demo` using connection options, with verification, and a peek at the underlying command:

```
dropdb -p 54321 -h coordinatorhost -i -e demo
Database "demo" will be permanently deleted.
Are you sure? (y/n) y
DROP DATABASE "demo"
DROP DATABASE
```

7.7.2.6 dropuser

Removes a database role.

Synopsis

```
dropuser [<connection-option> ...] [-e] [-i] <role_name>

dropuser -? | --help

dropuser -V | --version
```

Description

`dropuser` removes an existing role from WarehousePG. Only superusers and users with the `CREATEROLE` privilege can remove roles. To remove a superuser role, you must yourself be a superuser.

`dropuser` is a wrapper around the SQL command `DROP ROLE`.

Options

role_name The name of the role to be removed. You will be prompted for a name if not specified on the command line and the `-i` / `--interactive` option is used.

-e | --echo Echo the commands that `dropuser` generates and sends to the server.

-i | --interactive Prompt for confirmation before actually removing the role, and prompt for the role name if none is specified on the command line.

--if-exists Do not throw an error if the user does not exist. A notice is issued in this case.

-V | --version Print the `dropuser` version and exit.

-? | --help Show help about `dropuser` command line arguments, and exit.

Connection Options

-h host | --host=host The host name of the machine on which the WarehousePG coordinator database server is running. If not specified, reads from the environment variable `PGHOST` or defaults to localhost.

-p port | --port=port The TCP port on which the WarehousePG coordinator database server is listening for connections. If not specified, reads from the environment variable `PGPORT` or defaults to 5432.

-U username | --username=username The database role name to connect as. If not specified, reads from the environment variable `PGUSER` or defaults to the current system role name.

-w | --no-password Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

-W | --password Force a password prompt.

Examples

To remove the role `joe` using default connection options:

```
dropuser joe
DROP ROLE
```

To remove the role joe using connection options, with verification, and a peek at the underlying command:

```
dropuser -p 54321 -h coordinatorhost -i -e joe
Role "joe" will be permanently removed.
Are you sure? (y/n) y
DROP ROLE "joe"
DROP ROLE
```

7.7.2.7 gpactivatestandby

Activates a standby coordinator host and makes it the active coordinator for the WarehousePG cluster.

Synopsis

```
gpactivatestandby [-d <standby_coordinator_datadir>] [-f] [-a] [-q]
    [-l <logfile_directory>]

gpactivatestandby -v

gpactivatestandby -? | -h | --help
```

Description

The `gpactivatestandby` utility activates a backup, standby coordinator host and brings it into operation as the active coordinator instance for a WarehousePG cluster. The activated standby coordinator effectively becomes the WarehousePG coordinator, accepting client connections on the coordinator port.

> **NOTE** Before running `gpactivatestandby`, be sure to run `gpstate -f` to confirm that the standby coordinator is synchronized with the current coordinator node. If synchronized, the final line of the `gpstate -f` output will look similar to this: `20230607:06:50:06:004205 gpstate:test1-m:gpadmin-[INFO]:--Sync state: sync`

When you initialize a standby coordinator, the default is to use the same port as the active coordinator. For information about the coordinator port for the standby coordinator, see gpinitstandby.

You must run this utility from the coordinator host you are activating, not the failed coordinator host you are deactivating. Running this utility assumes you have a standby coordinator host configured for the system (see gpinitstandby).

The utility will perform the following steps:

- Stops the synchronization process (`walreceiver`) on the standby coordinator
- Updates the system catalog tables of the standby coordinator using the logs
- Activates the standby coordinator to be the new active coordinator for the system
- Restarts the WarehousePG cluster with the new coordinator host

A backup, standby WarehousePG coordinator host serves as a 'warm standby' in the event of the primary WarehousePG coordinator host becoming non-operational. The standby coordinator is kept up to date by transaction log replication processes (the `walsender` and `walreceiver`), which run on the primary coordinator and standby coordinator hosts and keep the data between the primary and standby coordinator hosts synchronized.

If the primary coordinator fails, the log replication process is shutdown, and the standby coordinator can be activated in its place by using the `gpactivatestandby` utility. Upon activation of the standby coordinator, the replicated logs are used to reconstruct the state of the WarehousePG coordinator host at the time of the last successfully committed transaction.

In order to use `gpactivatestandby` to activate a new primary coordinator host, the coordinator host that was previously serving as the primary coordinator cannot be running. The utility checks for a `postmaster.pid` file in the data directory of the deactivated coordinator host, and if it finds it there, it will assume the old coordinator host is still active. In some cases, you may need to remove the `postmaster.pid` file from the deactivated coordinator host data directory before running `gpactivatestandby` (for example, if the deactivated coordinator host process was terminated unexpectedly).

After activating a standby coordinator, run `ANALYZE` to update the database query statistics. For example:

```
psql <dbname> -c 'ANALYZE;'
```

After you activate the standby coordinator as the primary coordinator, the WarehousePG cluster no longer has a standby coordinator configured. You might want to specify another host to be the new standby with the gpinitstandby utility.

Options

-a (do not prompt) Do not prompt the user for confirmation.

-d standby_coordinator_datadir The absolute path of the data directory for the coordinator host you are activating.

If this option is not specified, `gpactivatestandby` uses the value of the `COORDINATOR_DATA_DIRECTORY` environment variable setting on the coordinator host you are activating. If this option is specified, it overrides any setting of `COORDINATOR_DATA_DIRECTORY`.

If a directory cannot be determined, the utility returns an error.

-f (force activation) Use this option to force activation of the backup coordinator host. Use this option only if you are sure that the standby and primary coordinator hosts are consistent.

-l logfile_directory The directory to write the log file. Defaults to `~/gpAdminLogs`.

-q (no screen output) Run in quiet mode. Command output is not displayed on the screen, but is still written to the log file.

-v (show utility version) Displays the version, status, last updated date, and check sum of this utility.

-? | -h | --help (help) Displays the online help.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Example

Activate the standby coordinator host and make it the active coordinator instance for a WarehousePG cluster (run from backup coordinator host you are activating):

```
gpactivatestandby -d /gpdata
```

7.7.2.8 gpaddmirrors

Adds mirror segments to a WarehousePG cluster that was initially configured without mirroring.

Synopsis

```
gpaddmirrors [-p <port_offset>] [-m <datadir_config_file> [-a]] [-s]
   [-d <coordinator_data_directory>] [-b <segment_batch_size>] [-B <batch_size>] [-l <logfile_directory>]
   [-v] [--hba-hostnames <boolean>]

gpaddmirrors -i <mirror_config_file> [-a] [-d <coordinator_data_directory>]
   [-b <segment_batch_size>] [-B <batch_size>] [-l <logfile_directory>] [-v]

gpaddmirrors -o output_sample_mirror_config> [-s] [-m <datadir_config_file>]

gpaddmirrors -?

gpaddmirrors --version
```

Description

The `gpaddmirrors` utility configures mirror segment instances for an existing WarehousePG cluster that was initially configured with primary segment instances only. The utility will create the mirror instances and begin the online replication process between the primary and mirror segment instances. Once all mirrors are synchronized with their primaries, your WarehousePG cluster is fully data redundant.

> **Important**
>
> During the online replication process, WarehousePG should be in a quiescent state, workloads and other queries should not be running.

By default, the utility will prompt you for the file system location(s) where it will create the mirror segment data directories. If you do not want to be prompted, you can pass in a file containing the file system locations using the `-m` option.

The mirror locations and ports must be different than your primary segment data locations and ports.

The utility creates a unique data directory for each mirror segment instance in the specified location using the predefined naming convention. There must be the same number of file system locations declared for mirror segment instances as for primary segment instances. It is OK to specify the same directory name multiple times if you want your mirror data directories created in the same location, or you can enter a different data location for each mirror. Enter the absolute path. For example:

```
Enter mirror segment data directory location 1 of 2 > /gpdb/mirror
Enter mirror segment data directory location 2 of 2 > /gpdb/mirror
```

OR

```
Enter mirror segment data directory location 1 of 2 > /gpdb/m1
Enter mirror segment data directory location 2 of 2 > /gpdb/m2
```

Alternatively, you can run the `gpaddmirrors` utility and supply a detailed configuration file using the `-i` option. This is useful if you want your mirror segments on a completely different set of hosts than your primary segments. The format of the mirror configuration file is:

```
<contentID>|<address>|<port>|<data_dir>
```

Where `<contentID>` is the segment instance content ID, `<address>` is the host name or IP address of the segment host, `<port>` is the communication port, and `<data_dir>` is the segment instance data directory.

For example:

```
0|sdw1-1|60000|/gpdata/m1/gp0
1|sdw1-1|60001|/gpdata/m2/gp1
```

The `gp_segment_configuration` system catalog table can help you determine your current primary segment configuration so that you can plan your mirror segment configuration. For example, run the following query:

```
=# SELECT dbid, content, address as host_address, port, datadir
   FROM gp_segment_configuration
   ORDER BY dbid;
```

If you are creating mirrors on alternate mirror hosts, the new mirror segment hosts must be pre-installed with the WarehousePG software and configured exactly the same as the existing primary segment hosts.

You must make sure that the user who runs `gpaddmirrors` (the `gpadmin` user) has permissions to write to the data directory locations specified. You may want to create these directories on the segment hosts and `chown` them to the appropriate user before running `gpaddmirrors`.

> **Note**
>
> This utility uses secure shell (SSH) connections between systems to perform its tasks. In large WarehousePG deployments, cloud deployments, or deployments with a large number of segments per host, this utility may exceed the host's maximum threshold for unauthenticated connections. Consider updating the SSH `MaxStartups` configuration parameter to increase this threshold. For more information about SSH configuration options, refer to the SSH documentation for your Linux distribution.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Options

-a (do not prompt)

Run in quiet mode - do not prompt for information. Must supply a configuration file with either `-m` or `-i` if this option is used.

-b segment_batch_size

The maximum number of segments per host to operate on in parallel. Valid values are `1` to `128`. If not specified, the utility will start recovering up to 64 segments in parallel on each host.

-B batch_size

The number of hosts to work on in parallel. If not specified, the utility will start working on up to 16 hosts in parallel. Valid values are `1` to `64`.

-d coordinator_data_directory

The coordinator data directory. If not specified, the value set for `$COORDINATOR_DATA_DIRECTORY` will be used.

--hba-hostnames boolean

Optional. Controls whether this utility uses IP addresses or host names in the `pg_hba.conf` file when updating this file with addresses that can connect to WarehousePG. When set to 0 -- the default value -- this utility uses IP addresses when updating this file. When set to 1, this utility uses host names when updating this file. For consistency, use the same value that was specified for `HBA_HOSTNAMES` when the WarehousePG cluster was initialized. For information about how WarehousePG resolves host names in the `pg_hba.conf` file, see Configuring Client Authentication.

-i mirror_config_file

A configuration file containing one line for each mirror segment you want to create. You must have one mirror segment instance listed for each primary segment in the system. The format of this file is as follows (as per attributes in the gp_segment_configuration catalog table):

```
<contentID>|<address>|<port>|<data_dir>
```

Where `<contentID>` is the segment instance content ID, `<address>` is the hostname or IP address of the segment host, `<port>` is the communication port, and `<data_dir>` is the segment instance data directory. For information about using a hostname or IP address, see Specifying Hosts using Hostnames or IP Addresses. Also, see Using Host Systems with Multiple NICs.

-l logfile_directory

The directory to write the log file. Defaults to `~/gpAdminLogs`.

-m datadir_config_file

A configuration file containing a list of file system locations where the mirror data directories will be created. If not supplied, the utility prompts you for locations. Each line in the file specifies a mirror data directory location. For example:

```
/gpdata/m1
/gpdata/m2
/gpdata/m3
/gpdata/m4
```

-o output_sample_mirror_config

If you are not sure how to lay out the mirror configuration file used by the `-i` option, you can run `gpaddmirrors` with this option to generate a sample mirror configuration file based on your primary segment configuration. The utility will prompt you for your mirror segment data directory locations (unless you provide these in a file using `-m`). You can then edit this file to change the host names to alternate mirror hosts if necessary.

-p port_offset

Optional. This number is used to calculate the database ports used for mirror segments. The default offset is 1000. Mirror port assignments are calculated as follows:

```
```
primary_port + offset = mirror_database_port
```
```

For example, if a primary segment has port 50001, then its mirror will use a database port of 51001, by default.

-s (spread mirrors)

Spreads the mirror segments across the available hosts. The default is to group a set of mirror segments together on an alternate host from their primary segment set. Mirror spreading will place each mirror on a different host within the WarehousePG cluster. Spreading is only allowed if there is a sufficient number of hosts in the array (number of hosts is greater than the number of segment instances per host).

-v (verbose)

Sets logging output to verbose.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

--version (show utility version)

Displays the version of this utility.

-? (help)

Displays the online help.

Specifying Hosts using Hostnames or IP Addresses

When specifying a mirroring configuration using the `gpaddmirrors` option `-i`, you can specify either a hostname or an IP address for the <address> value.

- If you specify a hostname, the resolution of the hostname to an IP address should be done locally for security. For example, you should use entries in a local `/etc/hosts` file to map the hostname to an IP address. The resolution of a hostname to an IP address should not be performed by an external service such as a public DNS server. You must stop the WarehousePG cluster before you change the mapping of a hostname to a different IP address.
- If you specify an IP address, the address should not be changed after the initial configuration. When segment mirroring is enabled, replication from the primary to the mirror segment will fail if the IP address changes from the configured value. For this reason, you should use a hostname when enabling mirroring using the `-i` option unless you have a specific requirement to use IP addresses.

When enabling a mirroring configuration that adds hosts to the WarehousePG cluster, `gpaddmirrors` populates the gp_segment_configuration catalog table with the mirror segment instance information. WarehousePG uses the address value of the `gp_segment_configuration` catalog table when looking up host systems for WarehousePG interconnect (internal) communication between the coordinator and segment instances and between segment instances, and for other internal communication.

Using Host Systems with Multiple NICs

If hosts systems are configured with multiple NICs, you can initialize a WarehousePG cluster to use each NIC as a WarehousePG host system. You must ensure that the host systems are configured with sufficient resources to support all the segment instances being added to the host. Also, if you enable segment mirroring, you must ensure that the WarehousePG cluster configuration supports failover if a host system fails. For information about WarehousePG mirroring schemes, see Segment Mirroring Configurations.

For example, this is a segment instance configuration for a simple WarehousePG cluster. The segment host `gp7c` is configured with two NICs, `gp7c-1` and `gp7c-2`, where the WarehousePG cluster uses `gp7c-1` for the coordinator segment and `gp7c-2` for segment instances.

```
select content, role, port, hostname, address from gp_segment_configuration ;

 content | role | port  | hostname | address
---------+------+-------+----------+----------
      -1 | p    |  5432 | gp7c     | gp7c-1
       0 | p    | 40000 | gp7c     | gp7c-2
       0 | m    | 50000 | gp7s     | gp7s
       1 | p    | 40000 | gp7s     | gp7s
       1 | m    | 50000 | gp7c     | gp7c-2
(5 rows)
```

Examples

Add mirroring to an existing WarehousePG cluster using the same set of hosts as your primary data. Calculate the mirror database ports by adding 100 to the current primary segment port numbers:

```
$ gpaddmirrors -p 100
```

Generate a sample mirror configuration file with the `-o` option to use with `gpaddmirrors -i`:

```
$ gpaddmirrors -o /home/gpadmin/sample_mirror_config
```

Add mirroring to an existing WarehousePG cluster using a different set of hosts from your primary data:

```
$ gpaddmirrors -i mirror_config_file
```

Where `mirror_config_file` looks something like this:

```
0|sdw1-1|52001|/gpdata/m1/gp0
1|sdw1-2|52002|/gpdata/m2/gp1
2|sdw2-1|52001|/gpdata/m1/gp2
3|sdw2-2|52002|/gpdata/m2/gp3
```

`gprestore` reference

Description

The `gpbackup` utility backs up the contents of a database into a collection of metadata files and data files that can be used to restore the database at a later time using gprestore. When you back up a database, you can specify table level and schema level filter options to back up specific tables. For example, you can combine schema level and table level options to back up all the tables in a schema except for a single table.

By default, `gpbackup` backs up objects in the specified database as well as global WarehousePG system objects. Use `--without-globals` to omit global objects. gprestore does not restore global objects by default; use `--with-global` s to restore them.

See Objects Included in a Backup or Restore for additional information.

For materialized views, data is not backed up, only the materialized view definition is backed up.

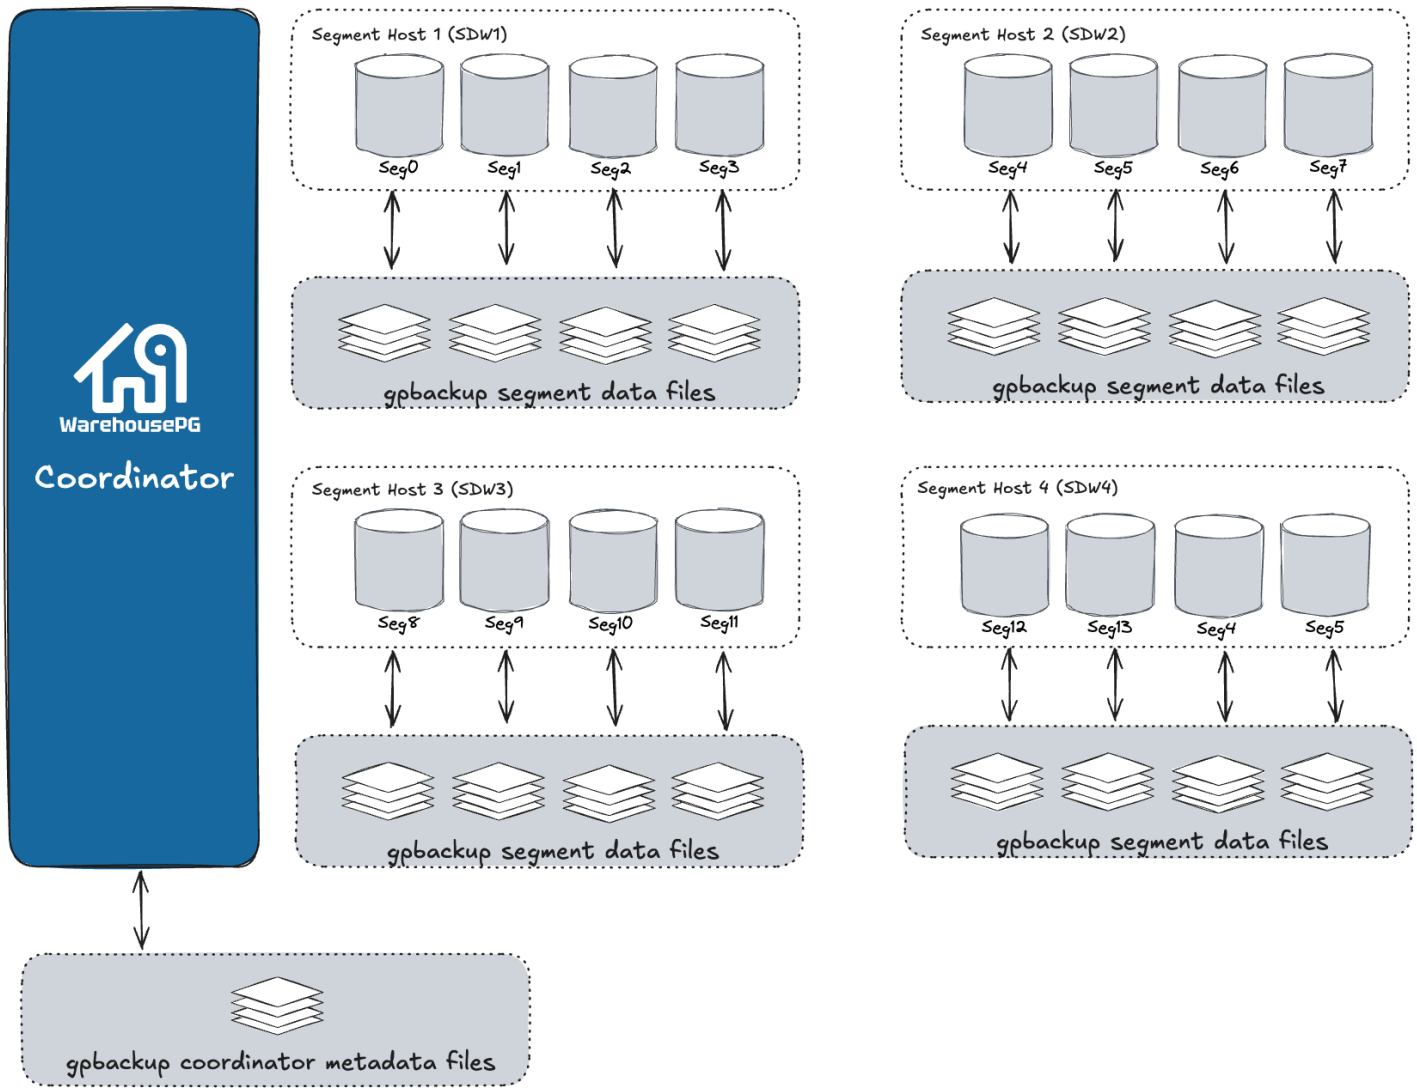
gpbackup stores the object metadata files and DDL files for a backup in the WarehousePG coordinator data directory by default. WarehousePG segments use the `COPY ... ON SEGMENT` command to store their data for backed-up tables in compressed CSV data files, located in each segment's data directory. See Understanding Backup Files for additional information.

You can add the `--backup-dir` option to copy all backup files from the WarehousePG coordinator and segment hosts to an absolute path for later use. Additional options are provided to filter the backup set in order to include or exclude specific tables.

You can create an incremental backup with the `--incremental` option. Incremental backups are efficient when the total amount of data in append-optimized tables or table partitions that changed is small compared to the data has not changed. See Creating and Using Incremental Backups with `gpbackup` and gprestore for information about incremental backups.

With the default `--jobs` option (1 job), each `gpbackup` operation uses a single transaction on the WarehousePG coordinator host. The `COPY ... ON SEGMENT` command performs the backup task in parallel on each segment host. The backup process acquires an `ACCESS SHARE` lock on each table that is backed up. During the table locking process, the database should be in a quiescent state.

When a back up operation completes, `gpbackup` returns a status code. See Return Codes.



The `gpbackup` utility cannot be run while gpexpand is initializing new segments. Backups created before the expansion cannot be restored with gprestore after the cluster expansion is completed.

`gpbackup` can send status email notifications after a back up operation completes. You specify when the utility sends the mail and the email recipients in a configuration file. See Configuring Email Notifications.

> **Note**
>
> This utility uses secure shell (SSH) connections between systems to perform its tasks. In large WarehousePG deployments, cloud deployments, or deployments with a large number of segments per host, this utility may exceed the host's maximum threshold for unauthenticated connections. Consider updating the `SSH MaxStartups` and `MaxSessions` configuration parameters to increase this threshold. For more information about SSH configuration options, refer to the SSH documentation for your Linux distribution.

Parallel Backup with gpbackup and gprestore

Options

`--dbname database_name`
Required. Specifies the database to back up.

`--backup-dir <directory>`
Optional. Copies all required backup files (metadata files and data files) to the specified directory. You must specify directory as an absolute path (not relative). If you do not supply this option, metadata files are created on the WarehousePG coordinator host in the `$MASTER_DATA_DIRECTORY/backups/YYYYMMDD/YYYYMMDDhhmmss/` directory. Segment hosts create CSV data files in the `<seg_dir>/backups/YYYYMMDD/YYYYMMDDhhmmss/` directory. When you specify a custom backup directory, files are copied to these paths in subdirectories of the backup directory.

When invoked together with the `--metadata-only` and `--no-history` options, a backup may have the same timestamp as another backup, provided that each of the two backups has a distinct `--backup-dir` location.

You cannot combine this option with the option `--plugin-config`.

`--compression-level <level>`
Optional. Specifies the compression level (from 1 to 9) used to compress data files. The default is 1.

> **Note**
>
> `gpbackup` uses compression by default.

`--compression-type <type>`
Optional. Specifies the compression type (gzip or zstd) used to compress data files. The default is gzip.

> **Note**
>
> In order to use the zstd compression type, Zstandard must be installed in a `$PATH` accessible by the `gpadmin` user.

`--copy-queue-size int`
Optional. Specifies the number of `COPY` commands `gpbackup` should enqueue when backing up using the `--single-data-file` option. This option optimizes backup performance by reducing the amount of time spent initializing `COP`Y commands. If you do not set this option to 2 or greater, `gpbackup` enqueues 1 `COPY` command at a time.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

> **Note**
>
> This option must be used with the `--single-data-file` option and cannot be used with the `--jobs` option.

`--data-only`
Optional. Backs up only the table data into CSV files, but does not backup metadata files needed to recreate the tables and other database objects.

`--debug`
Optional. Displays verbose debug messages during operation.

`--exclude-schema <schema_name>`
Optional. Specifies a database schema to exclude from the backup. You can specify this option multiple times to exclude multiple schemas. You cannot combine this option with the option `--include-schema`, `--include-schema-file`, or a table filtering option such as `--include-table`.

See Filtering the Contents of a Backup or Restore for more information.

See Requirements and Limitations for limitations when leaf partitions of a partitioned table are in different schemas from the root partition.

`--exclude-schema-file <file_name>`
Optional. Specifies a text file containing a list of schemas to exclude from the backup. Each line in the text file must define a single schema. The file must not include trailing lines. If a schema name uses any character other than a lowercase letter, number, or an underscore character, then you must include that name in double quotes. You cannot combine this option with the option `--include-schema` or `--include-schema-file`, or a table filtering option such as `--include-table`.

See Filtering the Contents of a Backup or Restore for more information.

See Requirements and Limitations for limitations when leaf partitions of a partitioned table are in different schemas from the root partition.

`--exclude-table <schema.table>`
Optional. Specifies a table to exclude from the backup. The table must be in the format `<schema-name>.<table-name>`. If a table or schema name uses any character other than a lowercase letter, number, or an underscore character, then you must include that name in double quotes. You can specify this option multiple times. You cannot combine this option with the option `--exclude-schema`, `--exclude-schema-file`, or another a table filtering option such as `--include-table`.

If you specify a leaf partition name, `gpbackup` ignores the partition names. The leaf partition is not excluded.

See Filtering the Contents of a Backup or Restore for more information.

`--exclude-table-file <file_name>`
Optional. Specifies a text file containing a list of tables to exclude from the backup. Each line in the text file must define a single table using the format `<schema-name>.<table-name>`. The file must not include trailing lines. If a table or schema name uses any character other than a lowercase letter, number, or an underscore character, then you must include that name in double quotes. You cannot combine this option with the option `--exclude-schema`, `--exclude-schema-file`, or another a table filtering option such as `--include-table`.

If you specify leaf partition names in a file that is used with --exclude-table-file, `gpbackup` ignores the partition names. The leaf partitions are not excluded.

See Filtering the Contents of a Backup or Restore for more information.

`--include-schema <schema_name>`
Optional. Specifies a database schema to include in the backup. You can specify this option multiple times to include multiple schemas. If you specify this option, any schemas that are not included in subsequent `--include-schema` options are omitted from the backup set. You cannot combine this option with the options `--exclude-schema`, `--exclude-schema-file`, `--exclude-schema-file`, `--include-table`, or `--include-table-file`. See Filtering the Contents of a Backup or Restore for more information.

`--include-schema-file <file_name>`
Optional. Specifies a text file containing a list of schemas to back up. Each line in the text file must define a single schema. The file must not include trailing lines. If a schema name uses any character other than a lowercase letter, number, or an underscore character, then you must include that name in double quotes.

See Filtering the Contents of a Backup or Restore for more information.

`--include-table <schema.table>`
Optional. Specifies a table to include in the backup. The table must be in the format `<schema-name>.<table-name>`.

You can specify this option multiple times. You cannot combine this option with a schema filtering option such as `--include-schema`, or another table filtering option such as `--exclude-table-file`.

You can also specify the qualified name of a sequence, a view, or a materialized view.

If you specify this option, the utility does not automatically back up dependent objects. You must also explicitly specify dependent objects that are Required. For example if you back up a view or a materialized view, you must also back up the tables that the view or materialized view uses. If you back up a table that uses a sequence, you must also back up the sequence.

You can optionally specify a table leaf partition name in place of the table name, to include only specific leaf partitions in a backup with the `--leaf-partition-dat` a option. When a leaf partition is backed up, the leaf partition data is backed up along with the metadata for the partitioned table.

See Filtering the Contents of a Backup or Restore for more information.

`--include-table-file <file_name>`
Optional. Specifies a text file containing a list of tables to include in the backup. Each line in the text file must define a single table using the format `<schema-name>.<table-name>`. The file must not include trailing lines. For information on specifying special characters in schema and table names, see Schema and Table Names.

Any tables not listed in this file are omitted from the backup set. You cannot combine this option with a schema filtering option such as `--include-schem` a, or another table filtering option such as `--exclude-table-file`.

You can also specify the qualified name of a sequence, a view, or a materialized view.

If you specify this option, the utility does not automatically back up dependent objects. You must also explicitly specify dependent objects that are Required. For example if you back up a view or a materialized view, you must also specify the tables that the view or the materialized view uses. If you specify a table that uses a sequence, you must also specify the sequence.

You can optionally specify a table leaf partition name in place of the table name, to include only specific leaf partitions in a backup with the `--leaf-partition-data` option. When a leaf partition is backed up, the leaf partition data is backed up along with the metadata for the partitioned table.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

See Filtering the Contents of a Backup or Restore for more information.

`--incremental`
Specify this option to add an incremental backup to an incremental backup set. A backup set is a full backup and one or more incremental backups. The backups in the set must be created with a consistent set of backup options to ensure that the backup set can be used in a restore operation.

By default, `gpbackup` attempts to find the most recent existing backup with a consistent set of options. If the backup is a full backup, the utility creates a backup set. If the backup is an incremental backup, the utility adds the backup to the existing backup set. The incremental backup is added as the latest backup in the backup set. You can specify `--from-timestamp` to override the default behavior.

> `--from-timestamp <backup-timestamp>`
> Optional. Specifies the timestamp of a backup. The specified backup must have backup options that are consistent with the incremental backup that is >being created. If the specified backup is a full backup, the utility creates a backup set. If the specified backup is an incremental backup, the >utility adds the incremental backup to the existing backup set.
>
> You must specify `--leaf-partition-dat` a with this option. You cannot combine this option with `--data-only` or `--metadata-only`.
>
> A backup is not created and the utility returns an error if the backup cannot add the backup to an existing incremental backup set or cannot use the >backup to create a backup set.

For information about creating and using incremental backups, see Creating and Using Incremental Backups with gpbackup and gprestore.

`--jobs <int>`
Optional. Specifies the number of jobs to run in parallel when backing up tables. By default, `gpbackup` uses 1 job (database connection). Increasing this number can improve the speed of backing up data. When running multiple jobs, each job backs up tables in separate transactions.

Important: If you specify a value higher than 1, the database should be in a quiescent state while the utility acquires a lock on the tables that are being backed up. If the utility cannot acquire a lock on a table being backed up it will exit.

You cannot use this option in combination with the options `--metadata-only`, `--single-data-file`, or `--plugin-config`.

> **Note**
>
> This option must be used with the `--single-data-file` option and cannot be used with the `--jobs` option. When using the `--jobs` flag, there is a potential deadlock scenario to generate a WARNING message in the log files. During the metadata portion of the backup, the main worker process gathers Access Share locks on all the tables in the backup set. During the data portion of the backup, based on the value of the `--jobs` flag, additional workers are created that attempt to take additional Access Share locks on the tables they back up.
>
> Between the metadata backup and the data backup, if a third party process (operations like `TRUNCATE`, `DROP`, `ALTER`) attempts to access the same tables and obtain an `Exclusive` lock, the worker thread identifies the potential deadlock and hands off the table backup responsibilities to the main worker (that already has an `Access Share` lock on that particular table). A warning message is logged, similar to: `[WARNING]:-Worker 5 could not acquire AccessShareLock for table public.foo.`

`--leaf-partition-data`
Optional. For partitioned tables, creates one data file per leaf partition instead of one data file for the entire table (the default). Using this option also enables you to specify individual leaf partitions to include in or exclude from a backup, with the `--include-table,` --include-table-file`,` --exclude-table`, and` --exclude-table-file` options.

`--metadata-only`
Optional. Creates only the metadata files (DDL) needed to recreate the database objects, but does not back up the actual table data.

`--no-compression`
Optional. Do not compress the table data CSV files.

`--no-history`
Optional. When invoked, `gpbackup` does not write backup run metadata to the history database. This is useful if you prefer not to have an application-maintained SQLite database on your system. However, if you choose not to back up to the history database you lose access to the features of the gpbackup_manager utility.

`--no-inherits`
Optional. Only works when invoked with either the `--include-table` option or the `--include-table-file` option. When invoked, only the metadata of the table itself is backed up, ignoring any inheritance relationships with other tables that would normally cause those tables to also be included in the backup set.

`--plugin-config <config-file_location>`
Specify the location of the `gpbackup` plugin configuration file, a YAML-formatted text file. The file contains configuration information for the plugin application that `gpbackup` uses during the backup operation.

If you specify the `--plugin-config` option when you back up a database, you must specify this option with configuration information for a corresponding plugin application when you restore the database from the backup.

You cannot combine this option with the option `--backup-dir`.

For information about using storage plugin applications, see Using gpbackup Storage Plugins.

`--quiet`
Optional. Suppress all non-warning, non-error log messages.

`--single-backup-dir`
Optional. Store all backup files on a given host in a single directory rather than in distinct per-segment subdirectories under the chosen backup directory. For example, files that were previously created in the `<backup-dir>/gpseg0/backups/<datestamp>/<timestamp>` or `<backup-dir>/gpseg1/backups/<datestamp>/<timestamp>` directories will now be created under `<backup-dir>/backups/<datestamp>/<timestamp>`. You may restore backups taken with this option as normal, but there will be a performance penalty when doing so on some systems. However, this protects you from having to manually reorganize files to the correct segment when you pass the `--resize-cluster` restore option to gprestore. You must use the `--backup-dir` option with this option.

`--single-data-file`
Optional. Create a single data file on each segment host for all tables backed up on that segment. By default, each `gpbackup` creates one compressed CSV file for each table that is backed up on the segment.

> **Note**
>
> If you use the `--single-data-file` option to combine table backups into a single file per segment, you cannot set the gprestore option `--jobs` to a value higher than 1 to perform a parallel restore operation.

`--verbose`
Optional. Print verbose log messages.

`--version`
Optional. Print the version number and exit.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

`--with-stats`
Optional. Include query plan statistics in the backup set.

`--without-globals`
Optional. Omit the global WarehousePG system objects during backup.

`--help`
Displays the online help.

Examples

To create the database `test` using the default options:

```
createdb test
```

To create the database `demo` using the WarehousePG coordinator on host `gpcoord`, port `54321`, using the `LATIN1` encoding scheme:

```
createdb -p 54321 -h gpcoord -E LATIN1 demo
```

7.7.2.10 gpcheckcat

The `gpcheckcat` utility tests WarehousePG catalog tables for inconsistencies.

The utility is in `$GPHOME/bin/lib`.

Synopsis

```
gpcheckcat [ <options<] [ <dbname>]

  Options:
     -g <dir>
     -p <port>
     -s <test_name | 'test_name1, test_name2 [, ...]'>
     -P <password>
     -U <user_name>
     -S {none | only}
     -O
     -R <test_name | 'test_name1, test_name2 [, ...]'>
     -C <catalog_name>
     -B <parallel_processes>
     -v
     -A
     -x "<parameter_name>=<value>"

gpcheckcat  -l

gpcheckcat -? | --help
```

Description

The `gpcheckcat` utility runs multiple tests that check for database catalog inconsistencies. Some of the tests cannot be run concurrently with other workload statements or the results will not be usable. Restart the database in restricted mode when running `gpcheckcat`, otherwise `gpcheckcat` might report inconsistencies due to ongoing database operations rather than the actual number of inconsistencies. If you run `gpcheckcat` without stopping database activity, run it with `-O` option.

> **Note**
>
> Any time you run the utility, it checks for and deletes orphaned, temporary database schemas (temporary schemas without a session ID) in the specified databases. The utility displays the results of the orphaned, temporary schema check on the command line and also logs the results.

Catalog inconsistencies are inconsistencies that occur between WarehousePG cluster tables. In general, there are three types of inconsistencies:

- Inconsistencies in system tables at the segment level. For example, an inconsistency between a system table that contains table data and a system table that contains column data. As another, a system table that contains duplicates in a column that should to be unique.
- Inconsistencies between same system table across segments. For example, a system table is missing row on one segment, but other segments have this row. As another example, the values of specific row column data are different across segments, such as table owner or table access privileges.
- Inconsistency between a catalog table and the filesystem. For example, a file exists in database directory, but there is no entry for it in the pg_class table.

Options

-A

Run `gpcheckcat` on all databases in the WarehousePG installation.

-B <parallel_processes>

The number of processes to run in parallel.

The `gpcheckcat` utility attempts to determine the number of simultaneous processes (the batch size) to use. The utility assumes it can use a buffer with a minimum of 20MB for each process. The maximum number of parallel processes is the number of WarehousePG segment instances. The utility displays the number of parallel processes that it uses when it starts checking the catalog.

> **Note**
>
> The utility might run out of memory if the number of errors returned exceeds the buffer size. If an out of memory error occurs, you can lower the batch size with the `-B` option. For example, if the utility displays a batch size of 936 and runs out of memory, you can specify `-B 468` to run 468 processes in parallel.

-C catalog_table

Run cross consistency, foreign key, and ACL tests for the specified catalog table.

-g data_directory

Generate SQL scripts to fix catalog inconsistencies. The scripts are placed in data_directory.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

-l

List the `gpcheckcat` tests.

-o

Run only the `gpcheckcat` tests that can be run in online (not restricted) mode.

-p port

This option specifies the port that is used by the WarehousePG.

-P password

The password of the user connecting to WarehousePG.

-R test_name | 'test_name1,test_name2 [, ...]'

Specify one or more tests to run. Specify multiple tests as a comma-delimited list of test names enclosed in quotes.

Some tests can be run only when WarehousePG is in restricted mode.

> **These are the tests that can be performed:**
>
> `acl` - Cross consistency check for access control privileges
>
> `aoseg_table` - Check that the vertical partition information (vpinfo) on segment instances is consistent with `pg_attribute` (checks only append-optimized, column storage tables in the database)
>
> `duplicate` - Check for duplicate entries
>
> `foreign_key` - Check foreign keys
>
> `inconsistent` - Cross consistency check for coordinator segment inconsistency
>
> `missing_extraneous` - Cross consistency check for missing or extraneous entries
>
> `mix_distribution_policy` - Check `pg_opclass` and `pg_amproc` to identify tables using a mix of legacy and non-legacy hashops in their distribution policies.
>
> `owner` - Check table ownership that is inconsistent with the coordinator database
>
> `orphaned_toast_tables` - Check for orphaned TOAST tables.
>
> `part_integrity` - Check *pg_partition* branch integrity, partition with OIDs, partition distribution policy
>
> `unique_index_violation` - Check tables that have columns with the unique index constraint for duplicate entries
>
> `dependency` - Check for dependency on non-existent objects (restricted mode only)
>
> `distribution_policy` - Check constraints on randomly distributed tables (restricted mode only)
>
> `namespace` - Check for schemas with a missing schema definition (restricted mode only)
>
> `pgclass` - Check *pg_class* entry that does not have any corresponding *pg_attribute* entry (restricted mode only)

> **Note**
>
> There are several ways a TOAST table can become orphaned where a repair script cannot be generated and a manual catalog change is required. One way is if the `reltoastrelid` entry in *pg_class* points to an incorrect TOAST table (a TOAST table mismatch). Another way is if both the `reltoastrelid` in *pg_class* is missing and the `pg_depend` entry is missing (a double orphan TOAST table). If a manual catalog change is needed, `gpcheckcat` will display detailed steps you can follow to update the catalog. Contact Support if you need help with the catalog change.

-s `test_name | 'test_name1, test_name2 [, ...]'`

Specify one ore more tests to skip. Specify multiple tests as a comma-delimited list of test names enclosed in quotes.

-S {none | only}

Specify this option to control the testing of catalog tables that are shared across all databases in the WarehousePG installation, such as *pg_database*.

The value `none` deactivates testing of shared catalog tables. The value `only` tests only the shared catalog tables.

-U user_name

The user connecting to WarehousePG.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

-? | --help

Displays the online help.

-v (verbose)

Displays detailed information about the tests that are performed.

-x `"<parameter_name>=<value>"`

Set a server configuration parameter, such as `log_min_messages`, at a session level. To set multiple configuration parameters, use the `-x` option multiple times.

Notes

The utility identifies tables with missing attributes and displays them in various locations in the output and in a non-standardized format. The utility also displays a summary list of tables with missing attributes in the format `<database>. <schema>. <table>. <segment_id>` after the output information is displayed.

If `gpcheckcat` detects inconsistent OID (Object ID) information, it generates one or more verification files that contain an SQL query. You can run the SQL query to see details about the OID inconsistencies and investigate the inconsistencies. The files are generated in the directory where `gpcheckcat` is invoked.

This is the format of the file:

```
gpcheckcat.verify.dbname.catalog\_table\_name.test\_name.TIMESTAMP.sql
```

This is an example verification filename created by `gpcheckcat` when it detects inconsistent OID (Object ID) information in the catalog table *pg_type* in the database `mydb`:

```
gpcheckcat.verify.mydb.pg_type.missing_extraneous.20150420102715.sql
```

This is an example query from a verification file:

```
SELECT *
  FROM (
       SELECT relname, oid FROM pg_class WHERE reltype
         IN (1305822,1301043,1301069,1301095)
       UNION ALL
       SELECT relname, oid FROM gp_dist_random('pg_class') WHERE reltype
         IN (1305822,1301043,1301069,1301095)
       ) alltyprelids
  GROUP BY relname, oid ORDER BY count(*) desc ;
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.7.2.11 gpcheckperf

Verifies the baseline hardware performance of the specified hosts.

Synopsis

```
gpcheckperf -d <test_directory> [-d <test_directory> ...]
    {-f <hostfile_gpcheckperf> | - h <hostname> [-h hostname ...]}
    [-r ds] [-B <block_size>] [-S <file_size>] [--buffer-size <buffer_size>] [-D] [-v|-V]

gpcheckperf -d <temp_directory>
    {-f <hostfile_gpchecknet> | - h <hostname> [-h< hostname> ...]}
    [ -r n|N|M [--duration <time>] [--netperf] ] [-D] [-v | -V]

gpcheckperf -?

gpcheckperf --version
```

Description

The `gpcheckperf` utility starts a session on the specified hosts and runs the following performance tests:

- **Disk I/O Test (dd test)** — To test the sequential throughput performance of a logical disk or file system, the utility uses the **dd** command, which is a standard UNIX utility. It times how long it takes to write and read a large file to and from disk and calculates your disk I/O performance in megabytes (MB) per second. By default, the file size that is used for the test is calculated at two times the total random access memory (RAM) on the host. This ensures that the test is truly testing disk I/O and not using the memory cache.
- **Memory Bandwidth Test (stream)** — To test memory bandwidth, the utility uses the STREAM benchmark program to measure sustainable memory bandwidth (in MB/s). This tests that your system is not limited in performance by the memory bandwidth of the system in relation to the computational performance of the CPU. In applications where the data set is large (as in WarehousePG), low memory bandwidth is a major performance issue. If memory bandwidth is significantly lower than the theoretical bandwidth of the CPU, then it can cause the CPU to spend significant amounts of time waiting for data to arrive from system memory.
- **Network Performance Test (gpnetbench*)** — To test network performance (and thereby the performance of the WarehousePG interconnect), the utility runs a network benchmark program that transfers a 5 second stream of data from the current host to each remote host included in the test. The data is transferred in parallel to each remote host and the minimum, maximum, average and median network transfer rates are reported in megabytes (MB) per second. If the summary transfer rate is slower than expected (less than 100 MB/s), you can run the network test serially using the `-r n` option to obtain per-host results. To run a full-matrix bandwidth test, you can specify `-r M` which will cause every host to send and receive data from every other host specified. This test is best used to validate if the switch fabric can tolerate a full-matrix workload.

To specify the hosts to test, use the `-f` option to specify a file containing a list of host names, or use the `-h` option to name single host names on the command-line. If running the network performance test, all entries in the host file must be for network interfaces within the same subnet. If your segment hosts have multiple network interfaces configured on different subnets, run the network test once for each subnet.

You must also specify at least one test directory (with `-d`). The user who runs `gpcheckperf` must have write access to the specified test directories on all remote hosts. For the disk I/O test, the test directories should correspond to your segment data directories (primary and/or mirrors). For the memory bandwidth and network tests, a temporary directory is required for the test program files.

Before using `gpcheckperf`, you must have a trusted host setup between the hosts involved in the performance test. You can use the utility `gpssh-exkeys` to update the known host files and exchange public keys between hosts if you have not done so already. Note that `gpcheckperf` calls to `gpssh` and `gpsync`, so these WarehousePG utilities must also be in your `$PATH`.

Options

-B block_size

Specifies the block size (in KB or MB) to use for disk I/O test. The default is 32KB, which is the same as the WarehousePG page size. The maximum block size is 1 MB.

--buffer-size buffer_size

Specifies the size of the send buffer in kilobytes. The default size is 8 kilobytes.

> **Note** If you want to compare network performance between WarehousePG 6 and WarehousePG 7, set `--buffer-size` to 32KB in WarehousePG 7 to make it consistent with the default WarehousePG 6 buffer size.

-d test_directory

For the disk I/O test, specifies the file system directory locations to test. You must have write access to the test directory on all hosts involved in the performance test. You can use the `-d` option multiple times to specify multiple test directories (for example, to test disk I/O of your primary and mirror data directories).

-d temp_directory

For the network and stream tests, specifies a single directory where the test program files will be copied for the duration of the test. You must have write access to this directory on all hosts involved in the test.

-D (display per-host results)

Reports performance results for each host for the disk I/O tests. The default is to report results for just the hosts with the minimum and maximum performance, as well as the total and average performance of all hosts.

--duration time

Specifies the duration of the network test in seconds (s), minutes (m), hours (h), or days (d). The default is 15 seconds.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

-f hostfile_gpcheckperf

For the disk I/O and stream tests, specifies the name of a file that contains one host name per host that will participate in the performance test. The host name is required, and you can optionally specify an alternate user name and/or SSH port number per host. The syntax of the host file is one host per line as follows:

```
[<username>@]<hostname>[:<ssh_port>]
```

-f hostfile_gpchecknet

For the network performance test, all entries in the host file must be for host addresses within the same subnet. If your segment hosts have multiple network interfaces configured on different subnets, run the network test once for each subnet. For example (a host file containing segment host address names for interconnect subnet 1):

```
sdw1-1
sdw2-1
sdw3-1
```

-h hostname

Specifies a single host name (or host address) that will participate in the performance test. You can use the `-h` option multiple times to specify multiple host names.

--netperf

Specifies that the `netperf` binary should be used to perform the network test instead of the WarehousePG network test. To use this option, you must download `netperf` from https://github.com/HewlettPackard/netperf and install it into `$GPHOME/bin/lib` on all WarehousePG hosts (coordinator and segments).

-r ds{n|N|M}

Specifies which performance tests to run. The default is `dsn`:

- Disk I/O test (`d`)
- Stream test (`s`)
- Network performance test in sequential (`n`), parallel (`N`), or full-matrix (`M`) mode. The optional `--duration` option specifies how long (in seconds) to run the network test. To use the parallel (`N`) mode, you must run the test on an even number of hosts.

  If you would rather use `netperf` (https://github.com/HewlettPackard/netperf) instead of the WarehousePG network test, you can download it and install it into `$GPHOME/bin/lib` on all WarehousePG hosts (coordinator and segments). You would then specify the optional `--netperf` option to use the `netperf` binary instead of the default `gpnetbench*` utilities.

-S file_size

Specifies the total file size to be used for the disk I/O test for all directories specified with `-d`. file_size should equal two times total RAM on the host. If not specified, the default is calculated at two times the total RAM on the host where `gpcheckperf` is run. This ensures that the test is truly testing disk I/O and not using the memory cache. You can specify sizing in KB, MB, or GB.

-v (verbose) | -V (very verbose)

Verbose mode shows progress and status messages of the performance tests as they are run. Very verbose mode shows all output messages generated by this utility.

--version

Displays the version of this utility.

-? (help)

Displays the online help.

Examples

Run the disk I/O and memory bandwidth tests on all the hosts in the file host_file using the test directory of /data1 and /data2:

```
$ gpcheckperf -f hostfile_gpcheckperf -d /data1 -d /data2 -r ds
```

Run only the disk I/O test on the hosts named sdw1 and sdw2using the test directory of /data1. Show individual host results and run in verbose mode:

```
$ gpcheckperf -h sdw1 -h sdw2 -d /data1 -r d -D -v
```

Run the parallel network test using the test directory of /tmp, where hostfile_gpcheck_ic* specifies all network interface host address names within the same interconnect subnet:

```
$ gpcheckperf -f hostfile_gpchecknet_ic1 -r N -d /tmp
$ gpcheckperf -f hostfile_gpchecknet_ic2 -r N -d /tmp
```

Run the same test as above, but use `netperf` instead of the WarehousePG network test (note that `netperf` must be installed in `$GPHOME/bin/lib` on all WarehousePG hosts):

```
$ gpcheckperf -f hostfile_gpchecknet_ic1 -r N --netperf -d /tmp
$ gpcheckperf -f hostfile_gpchecknet_ic2 -r N --netperf -d /tmp
```

7.7.2.12 gpconfig

Sets server configuration parameters on all segments within a WarehousePG cluster.

Synopsis

```
gpconfig -c <param_name> -v <value> [-m <coordinator_value> | --coordinatoronly]
       | -r <param_name> [--coordinatoronly]
       | -l
       [--skipvalidation] [--verbose] [--debug]

gpconfig -s <param_name> [--file | --file-compare] [--verbose] [--debug]

gpconfig --help
```

Description

The `gpconfig` utility allows you to set, unset, or view configuration parameters from the `postgresql.conf` files of all instances (coordinator, segments, and mirrors) in your WarehousePG cluster. When setting a parameter, you can also specify a different value for the coordinator if necessary. For example, parameters such as `max_connections` require a different setting on the coordinator than what is used for the segments. If you want to set or unset a global or coordinator only parameter, use the `--coordinatoronly` option.

> **Note** For configuration parameters of vartype `string`, you may not pass values enclosed in single quotes to `gpconfig -c`.

`gpconfig` can only be used to manage certain parameters. For example, you cannot use it to set parameters such as `port`, which is required to be distinct for every segment instance. Use the `-l` (list) option to see a complete list of configuration parameters supported by `gpconfig`.

When `gpconfig` sets a configuration parameter in a segment `postgresql.conf` file, the new parameter setting always displays at the bottom of the file. When you use `gpconfig` to remove a configuration parameter setting, `gpconfig` comments out the parameter in all segment `postgresql.conf` files, thereby restoring the system default setting. For example, if you use `gpconfig` to remove (comment out) a parameter and later add it back (set a new value), there will be two instances of the parameter; one that is commented out, and one that is enabled and inserted at the bottom of the `postgresql.conf` file.

After setting a parameter, you must restart your WarehousePG cluster or reload the `postgresql.conf` files in order for the change to take effect. Whether you require a restart or a reload depends on the parameter.

For more information about the server configuration parameters, see the *WarehousePG Reference Guide*.

To show the currently set values for a parameter across the system, use the `-s` option.

`gpconfig` uses the following environment variables to connect to the WarehousePG coordinator instance and obtain system configuration information:

- `PGHOST`
- `PGPORT`
- `PGUSER`
- `PGPASSWORD`
- `PGDATABASE`

Options

-c | --change param_name Changes a configuration parameter setting by adding the new setting to the bottom of the `postgresql.conf` files.

-v | --value value The value to use for the configuration parameter you specified with the `-c` option. By default, this value is applied to all segments, their mirrors, the coordinator, and the standby coordinator.

The utility correctly quotes the value when adding the setting to the `postgresql.conf` files.

To set the value to an empty string, enter empty single quotes (`''`).

-m | --coordinatorvalue coordinator_value The coordinator value to use for the configuration parameter you specified with the `-c` option. If specified, this value only applies to the coordinator and standby coordinator. This option can only be used with `-v`.

--coordinatoronly When specified, `gpconfig` will only edit the coordinator `postgresql.conf` file.

-r | --remove param_name Removes a configuration parameter setting by commenting out the entry in the `postgresql.conf` files.

-l | --list Lists all configuration parameters supported by the `gpconfig` utility.

-s | --show param_name Shows the value for a configuration parameter used on all instances (coordinator and segments) in the WarehousePG cluster. If there is a difference in a parameter value among the instances, the utility displays an error message. Running `gpconfig` with the `-s` option reads parameter values directly from the database, and not the `postgresql.conf` file. If you are using `gpconfig` to set configuration parameters across all segments, then running `gpconfig -s` to verify the changes, you might still see the previous (old) values. You must reload the configuration files (`gpstop -u`) or restart the system (`gpstop -r`) for changes to take effect.

--file For a configuration parameter, shows the value from the `postgresql.conf` file on all instances (coordinator and segments) in the WarehousePG cluster. If there is a difference in a parameter value among the instances, the utility displays a message. Must be specified with the `-s` option.

For example, the configuration parameter `statement_mem` is set to 64MB for a user with the `ALTER ROLE` command, and the value in the `postgresql.conf` file is 128MB. Running the command `gpconfig -s statement_mem --file` displays 128MB. The command `gpconfig -s statement_mem` run by the user displays 64MB.

Not valid with the `--file-compare` option.

--file-compare For a configuration parameter, compares the current WarehousePG value with the value in the `postgresql.conf` files on hosts (coordinator and segments). The values in the `postgresql.conf files` represent the value when WarehousePG is restarted.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

If the values are not the same, the utility displays the values from all hosts. If all hosts have the same value, the utility displays a summary report.

Not valid with the `--file` option.

--skipvalidation Overrides the system validation checks of `gpconfig` and allows you to operate on any server configuration parameter, including hidden parameters and restricted parameters that cannot be changed by `gpconfig`. When used with the `-l` option (list), it shows the list of restricted parameters.

```
> **Caution** Use extreme caution when setting configuration parameters with this option.
```

--verbose Displays additional log information during `gpconfig` command execution.

--debug Sets logging output to debug level.

-? | -h | --help Displays the online help.

Examples

Set the `max_connections` setting to 100 on all segments and 10 on the coordinator:

```
gpconfig -c max_connections -v 100 -m 10
```

These examples shows the syntax required due to bash shell string processing.

```
gpconfig -c search_path -v '"\$user",public'
gpconfig -c dynamic_library_path -v '\$libdir'
```

The configuration parameters are added to the `postgresql.conf` file.

```
search_path='"$user",public'
dynamic_library_path='$libdir'
```

Comment out all instances of the `default_statistics_target` configuration parameter, and restore the system default:

```
gpconfig -r default_statistics_target
```

List all configuration parameters supported by `gpconfig`:

```
gpconfig -l
```

Show the values of a particular configuration parameter across the system:

```
gpconfig -s max_connections
```

gpstop

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.7.2.13 gpdeletesystem

Deletes a WarehousePG cluster that was initialized using `gpinitsystem`.

Synopsis

```
gpdeletesystem [-d <coordinator_data_directory>] [-B <parallel_processes>]
   [-f] [-l <logfile_directory>] [-D]

gpdeletesystem -?

gpdeletesystem -v
```

Description

The `gpdeletesystem` utility performs the following actions:

- Stop all `postgres` processes (the segment instances and coordinator instance).
- Deletes all data directories.

Before running `gpdeletesystem`:

- Move any backup files out of the coordinator and segment data directories.
- Make sure that WarehousePG is running.
- If you are currently in a segment data directory, change directory to another location. The utility fails with an error when run from within a segment data directory.

This utility will not uninstall the WarehousePG software.

Options

-d coordinator_data_directory Specifies the coordinator host data directory. If this option is not specified, the setting for the environment variable `COORDINATOR_DATA_DIRECTORY` is used. If this option is specified, it overrides any setting of `COORDINATOR_DATA_DIRECTORY`. If coordinator_data_directory cannot be determined, the utility returns an error.

-B parallel_processes The number of segments to delete in parallel. If not specified, the utility will start up to 60 parallel processes depending on how many segment instances it needs to delete.

-f (force) Force a delete even if backup files are found in the data directories. The default is to not delete WarehousePG instances if backup files are present.

-l logfile_directory The directory to write the log file. Defaults to `~/gpAdminLogs`.

-D (debug) Sets logging level to debug.

-? (help) Displays the online help.

-v (show utility version) Displays the version, status, last updated date, and check sum of this utility.

Examples

Delete a WarehousePG cluster:

```
gpdeletesystem -d /gpdata/gp-1
```

Delete a WarehousePG cluster even if backup files are present:

```
gpdeletesystem -d /gpdata/gp-1 -f
```

7.7.2.14 gpexpand

Expands an existing WarehousePG across new hosts in the system.

Synopsis

```
gpexpand [{-f|--hosts-file} <hosts_file>]
        | {-i|--input} <input_file> [-B <batch_size>]
        | [{-d | --duration} <hh:mm:ss> | {-e|--end} '<YYYY-MM-DD hh:mm:ss>']
          [-a|-analyze]
          [-n  <parallel_processes>]
        | {-r|--rollback}
        | {-c|--clean}
        [-v|--verbose] [-s|--silent]
        [{-t|--tardir} <directory> ]
        [-S|--simple-progress ]

gpexpand -? | -h | --help

gpexpand --version
```

Prerequisites

- You are logged in as the WarehousePG superuser (`gpadmin`).
- The new segment hosts have been installed and configured as per the existing segment hosts. This involves:
  - Configuring the hardware and OS
  - Installing the WarehousePG software
  - Creating the `gpadmin` user account
  - Exchanging SSH keys.

- Enough disk space on your segment hosts to temporarily hold a copy of your largest table.
- When redistributing data, WarehousePG must be running in production mode. WarehousePG cannot be running in restricted mode or in coordinator mode. The `gpstart` options `-R` or `-m` cannot be specified to start WarehousePG.

> **Note** These utilities cannot be run while `gpexpand` is performing segment initialization.

- `gpbackup`
- `gpcheckcat`
- `gpconfig`
- `gprestore`

> **Important** When expanding a WarehousePG cluster, you must deactivate WarehousePG interconnect proxies before adding new hosts and segment instances to the system, and you must update the `gp_interconnect_proxy_addresses` parameter with the newly-added segment instances before you re-enable interconnect proxies. For information about WarehousePG interconnect proxies, see Configuring Proxies for the WarehousePG Interconnect.

For information about preparing a system for expansion, see Expanding a WarehousePG cluster in the *WarehousePG Administrator Guide*.

Description

The `gpexpand` utility performs system expansion in two phases: segment instance initialization and then table data redistribution.

In the initialization phase, `gpexpand` runs with an input file that specifies data directories, dbid values, and other characteristics of the new segment instances. You can create the input file manually, or by following the prompts in an interactive interview.

If you choose to create the input file using the interactive interview, you can optionally specify a file containing a list of expansion system hosts. If your platform or command shell limits the length of the list of hostnames that you can type when prompted in the interview, specifying the hosts with `-f` may be mandatory.

In addition to initializing the segment instances, the initialization phase performs these actions:

- Creates an expansion schema named *gpexpand* in the postgres database to store the status of the expansion operation, including detailed status for tables.

In the table data redistribution phase, `gpexpand` redistributes table data to rebalance the data across the old and new segment instances.

> **Note** Data redistribution should be performed during low-use hours. Redistribution can be divided into batches over an extended period.

To begin the redistribution phase, run `gpexpand` with no options or with the `-d` (duration), `-e` (end time), or `-i` options. If you specify an end time or duration, then the utility redistributes tables in the expansion schema until the specified end time or duration is reached. If you specify `-i` or no options, then the utility redistribution phase continues until all tables in the expansion schema are reorganized. Each table is reorganized using `ALTER TABLE` commands to rebalance the tables across new segments, and to set tables to their original distribution policy. If `gpexpand` completes the reorganization of all tables, it displays a success message and ends.

> **Note** This utility uses secure shell (SSH) connections between systems to perform its tasks. In large WarehousePG deployments, cloud deployments, or deployments with a large number of segments per host, this utility may exceed the host's maximum threshold for unauthenticated connections. Consider updating the SSH `MaxStartups` and `MaxSessions` configuration parameters to increase this threshold. For more information about SSH configuration options, refer to the SSH documentation for your Linux distribution.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Options

-a | --analyze Run `ANALYZE` to update the table statistics after expansion. The default is to not run `ANALYZE`.

-B batch_size Batch size of remote commands to send to a given host before making a one-second pause. Default is `16`. Valid values are 1-128.

The `gpexpand` utility issues a number of setup commands that may exceed the host's maximum threshold for unauthenticated connections as defined by `MaxStartups` in the SSH daemon configuration. The one-second pause allows authentications to be completed before `gpexpand` issues any more commands.

The default value does not normally need to be changed. However, it may be necessary to reduce the maximum number of commands if `gpexpand` fails with connection errors such as `'ssh_exchange_identification: Connection closed by remote host.'`

-c | --clean Remove the expansion schema.

-d | --duration hh:mm:ss Duration of the expansion session from beginning to end.

-e | --end 'YYYY-MM-DD hh:mm:ss' Ending date and time for the expansion session.

-f | --hosts-file filename Specifies the name of a file that contains a list of new hosts for system expansion. Each line of the file must contain a single host name.

This file can contain hostnames with or without network interfaces specified. The `gpexpand` utility handles either case, adding interface numbers to end of the hostname if the original nodes are configured with multiple network interfaces.

```
> **Note** The WarehousePG segment host naming convention is `sdwN` where `sdw` is a prefix and `N` is an integer. For example, `sdw1`, `sdw2` and so on. For hosts with multiple interfaces, the convention is to append a dash \(`-`\) and number to the host name. For example, `sdw1-1` and `sdw1-2` are the two interface names for host `sdw1`.
```

For information about using a hostname or IP address, see Specifying Hosts using Hostnames or IP Addresses. Also, see Using Host Systems with Multiple NICs.

-i | --input input_file Specifies the name of the expansion configuration file, which contains one line for each segment to be added in the format of:

hostname|address|port|datadir|dbid|content|preferred_role

-n parallel_processes The number of tables to redistribute simultaneously. Valid values are 1 - 96.

Each table redistribution process requires two database connections: one to alter the table, and another to update the table's status in the expansion schema. Before increasing `-n`, check the current value of the server configuration parameter `max_connections` and make sure the maximum connection limit is not exceeded.

-r | --rollback Roll back a failed expansion setup operation.

-s | --silent Runs in silent mode. Does not prompt for confirmation to proceed on warnings.

-S | --simple-progress If specified, the `gpexpand` utility records only the minimum progress information in the WarehousePG table *gpexpand.expansion_progress*. The utility does not record the relation size information and status information in the table *gpexpand.status_detail*.

Specifying this option can improve performance by reducing the amount of progress information written to the *gpexpand* tables.

[-t | --tardir] directory The fully qualified path to a directory on segment hosts where the `gpexpand` utility copies a temporary tar file. The file contains WarehousePG files that are used to create segment instances. The default directory is the user home directory.

-v | --verbose Verbose debugging output. With this option, the utility will output all DDL and DML used to expand the database.

--version Display the utility's version number and exit.

-? | -h | --help Displays the online help.

Specifying Hosts using Hostnames or IP Addresses

When expanding a WarehousePG cluster, you can specify either a hostname or an IP address for the value.

- If you specify a hostname, the resolution of the hostname to an IP address should be done locally for security. For example, you should use entries in a local `/etc/hosts` file to map a hostname to an IP address. The resolution of a hostname to an IP address should not be performed by an external service such as a public DNS server. You must stop the WarehousePG cluster before you change the mapping of a hostname to a different IP address.
- If you specify an IP address, the address should not be changed after the initial configuration. When segment mirroring is enabled, replication from the primary to the mirror segment will fail if the IP address changes from the configured value. For this reason, you should use a hostname when expanding a WarehousePG cluster unless you have a specific requirement to use IP addresses.

When expanding a WarehousePG cluster, `gpexpand` populates gp_segment_configuration catalog table with the new segment instance information. WarehousePG uses the `address` value of the `gp_segment_configuration` catalog table when looking up host systems for WarehousePG interconnect (internal) communication between the coordinator and segment instances and between segment instances, and for other internal communication.

Using Host Systems with Multiple NICs

If host systems are configured with multiple NICs, you can expand a WarehousePG cluster to use each NIC as a WarehousePG host system. You must ensure that the host systems are configured with sufficient resources to support all the segment instances being added to the host. Also, if you enable segment mirroring, you must ensure that the expanded WarehousePG cluster configuration supports failover if a host system fails. For information about WarehousePG mirroring schemes, see ../../best_practices/ha.html#topic_ngz_qf4_tt.

For example, this is a `gpexpand` configuration file for a simple WarehousePG cluster. The segment host `gp7s1` and `gp7s2` are configured with two NICs, `-s1` and `-s2`, where the WarehousePG cluster uses each NIC as a host system.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
gp7s1-s2|gp7s1-s2|40001|/data/data1/gpseg2|6|2|p
gp7s2-s1|gp7s2-s1|50000|/data/mirror1/gpseg2|9|2|m
gp7s2-s1|gp7s2-s1|40000|/data/data1/gpseg3|7|3|p
gp7s1-s2|gp7s1-s2|50001|/data/mirror1/gpseg3|8|3|m
```

Examples

Run `gpexpand` with an input file to initialize new segments and create the expansion schema in the postgres database:

```
$ gpexpand -i input_file
```

Run `gpexpand` for sixty hours maximum duration to redistribute tables to new segments:

```
$ gpexpand -d 60:00:00
```

7.7.2.15 gpfdist

Serves data files to or writes data files out from WarehousePG segments.

Synopsis

```
gpfdist [-d <directory>] [-p <http_port>] [-P <last_http_port>] [-l <log_file>]
   [-t <timeout>] [-k <clean_up_timeout>] [-S] [-w <time>] [-v | -V] [-s] [-m <max_length>]
   [--ssl <certificate_path> [--ssl_verify_peer <boolean>] [--sslclean <wait_time>] ]
   [--compress] [--multi_thread <num_threads>]
   [-c <config.yml>]

gpfdist -? | --help

gpfdist --version
```

Description

`gpfdist` is WarehousePG parallel file distribution program. It is used by readable external tables and `gpload` to serve external table files to all WarehousePG segments in parallel. It is used by writable external tables to accept output streams from WarehousePG segments in parallel and write them out to a file.

> **Note** `gpfdist` and `gpload` are compatible only with the WarehousePG major version in which they are shipped. For example, a `gpfdist` utility that is installed with WarehousePG 6.x cannot be used with WarehousePG 7.x.

In order for `gpfdist` to be used by an external table, the `LOCATION` clause of the external table definition must specify the external table data using the `gpfdist://` protocol (see the WarehousePG command `CREATE EXTERNAL TABLE`).

> **Note** If you specify the `--ssl` option to enable SSL security, you must create the external table with the `gpfdists://` protocol.

The benefit of using `gpfdist` is that you are guaranteed maximum parallelism while reading from or writing to external tables, thereby offering the best performance as well as easier administration of external tables.

For readable external tables, `gpfdist` parses and serves data files evenly to all the segment instances in the WarehousePG cluster when users `SELECT` from the external table. For writable external tables, `gpfdist` accepts parallel output streams from the segments when users `INSERT` into the external table, and writes to an output file.

> **Note** When `gpfdist` reads data and encounters a data formatting error, the error message includes a row number indicating the location of the formatting error. `gpfdist` attempts to capture the row that contains the error. However, `gpfdist` might not capture the exact row for some formatting errors.

For readable external tables, if load files are compressed using `gzip` or `bzip2` (have a `.gz` or `.bz2` file extension), `gpfdist` uncompresses the data while loading the data (on the fly). For writable external tables, `gpfdist` compresses the data using `gzip` if the target file has a `.gz` extension.

> **Note** Compression is not supported for readable and writeable external tables when the `gpfdist` utility runs on Windows platforms.

When reading or writing data with the `gpfdist` or `gpfdists` protocol, WarehousePG includes `X-GP-PROTO` in the HTTP request header to indicate that the request is from WarehousePG. The utility rejects HTTP requests that do not include `X-GP-PROTO` in the request header.

Most likely, you will want to run `gpfdist` on your ETL machines rather than the hosts where WarehousePG is installed. To install `gpfdist` on another host, simply copy the utility over to that host and add `gpfdist` to your `$PATH`.

> **Note** When using IPv6, always enclose the numeric IP address in brackets.

Options

-d directory The directory from which `gpfdist` will serve files for readable external tables or create output files for writable external tables. If not specified, defaults to the current directory.

-l log_file The fully qualified path and log file name where standard output messages are to be logged.

-p http_port The HTTP port on which `gpfdist` will serve files. Defaults to 8080.

-P last_http_port The last port number in a range of HTTP port numbers (http_port to last_http_port, inclusive) on which `gpfdist` will attempt to serve files. `gpfdist` serves the files on the first port number in the range to which it successfully binds.

-t timeout Sets the time allowed for WarehousePG to establish a connection to a `gpfdist` process. Default is 5 seconds. Allowed values are 2 to 7200 seconds (2 hours). May need to be increased on systems with a lot of network traffic.

-k clean_up_timeout Sets the number of seconds that `gpfdist` waits before cleaning up the session when there are no `POST` requests from the segments. Default is 300. Allowed values are 300 to 86400. You may increase this value when experiencing heavy network traffic.

-m max_length Sets the maximum allowed data row length in bytes. Default is 32768. Should be used when user data includes very wide rows (or when `line too long` error message occurs). Should not be used otherwise as it increases resource allocation. Valid range is 32K to 256MB. The upper limit is 1MB on Windows systems.

> **Note** Memory issues might occur if you specify a large maximum row length and run a large number of `gpfdist` concurrent connections. For example, setting this value to the maximum of 256MB with 96 concurrent `gpfdist` processes requires approximately 24GB of memory (`(96 + 1) x 246MB`).

-s Enables simplified logging. When this option is specified, only messages with `WARN` level and higher are written to the `gpfdist` log file. `INFO` level messages are not written to the log file. If this option is not specified, all `gpfdist` messages are written to the log file.

You can specify this option to reduce the information written to the log file.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

-S (use O_SYNC) Opens the file for synchronous I/O with the `O_SYNC` flag. Any writes to the resulting file descriptor block `gpfdist` until the data is physically written to the underlying hardware.

-w time Sets the number of seconds that WarehousePG delays before closing a target file such as a named pipe. The default value is 0, no delay. The maximum value is 7200 seconds (2 hours).

For a WarehousePG with multiple segments, there might be a delay between segments when writing data from different segments to the file. You can specify a time to wait before WarehousePG closes the file to ensure all the data is written to the file.

--ssl certificate_path Prompts `gpfdist` to use SSL encryption for the data transfer. After running `gpfdist` with the `--ssl <certificate_path>` option, you must use the `gpfdists://` protocol to load data from this file server. For information on `gpfdists`, refer to gpfdists:// Protocol in the *WarehousePG Administrator Guide*.

The setting of the `--ssl_verify_peer` option determines which of the following files are required in the file system location specified by certificate_path:

```
-   The server certificate file, `server.crt`
-   The server private key file, `server.key`
-   The trusted certificate authorities, `root.crt`
```

The settings of both the verify_gpfdists_cert server configuration parameter and the `--ssl_verify_peer` option also determine which certificate files are required on the WarehousePG segments as described ingpfdists:// Protocol.

You cannot specify the root directory (`/`) as the certificate_path.

--ssl_verify_peer boolean When the `--ssl` option is also provided, specifies whether `gpfdist` enables or disables SSL certificate authentication on the WarehousePG side. The default value is `on` ; `gpfdist` checks the identities of clients, and requires that the `root.crt` , `server.crt` , and `server.key` be present in the certificate_path specified. When set to `off` , `gpfdist` does not check the identities of clients, and requires that only the `server.crt` and `server.key` be present in the `--ssl <certificate_path>` specified. The certificate authority file `root.crt` is not required.

--sslclean wait_time When the utility is run with the `--ssl` option, sets the number of seconds that the utility delays before closing an SSL session and cleaning up the SSL resources after it completes writing data to or from a WarehousePG segment. The default value is 0, no delay. The maximum value is 500 seconds. If the delay is increased, the transfer speed decreases.

In some cases, this error might occur when copying large amounts of data: `gpfdist server closed connection` . To avoid the error, you can add a delay, for example `--sslclean 5` .

--compress Enable compression during data transfer. When specified, `gpfdist` utilizes the Zstandard (`zstd`) compression algorithm. This option is not available on Windows platforms.

--multi_threads num_threads Sets the maximum number of threads that `gpfdist` uses during data transfer, parallelizing the operation. When specified, `gpfdist` automatically compresses the data (also parallelized) before transferring. `gpfdist` supports a maximum of 256 threads. This option is not available on Windows platforms.

-c config.yaml Specifies rules that `gpfdist` uses to select a transform to apply when loading or extracting data. The `gpfdist` configuration file is a YAML 1.1 document.

For information about the file format, see Configuration File Format in the *WarehousePG Administrator Guide*. For information about configuring data transformation with `gpfdist` , see Transforming External Data with gpfdist and gpload in the *WarehousePG Administrator Guide*.

This option is not available on Windows platforms.

-v (verbose) Verbose mode shows progress and status messages.

-V (very verbose) Verbose mode shows all output messages generated by this utility.

-? (help) Displays the online help.

--version Displays the version of this utility.

Notes

You can set the server configuration parameter gpfdist_retry_timeout to control the time that WarehousePG waits before returning an error when a `gpfdist` server does not respond while WarehousePG is attempting to write data to `gpfdist` . The default is 300 seconds (5 minutes).

If the `gpfdist` utility hangs with no read or write activity occurring, you can generate a core dump the next time a hang occurs to help debug the issue. Set the environment variable `GPFDIST_WATCHDOG_TIMER` to the number of seconds of no activity to wait before `gpfdist` is forced to exit. When the environment variable is set and `gpfdist` hangs, the utility is stopped after the specified number of seconds, creates a core dump, and sends relevant information to the log file.

This example sets the environment variable on a Linux system so that `gpfdist` exits after 300 seconds (5 minutes) of no activity.

```
export GPFDIST_WATCHDOG_TIMER=300
```

When you enable compression, `gpfdist` transmits a larger amount of data while maintaining low network usage. Note that compression can be time-intensive, and may potentially reduce transmission speeds. When you utilize multi-threaded execution, the overall time required for compression may decrease, which facilitates faster data transmission while maintaining low network occupancy and high speed.

Examples

To serve files from a specified directory using port 8081 (and start `gpfdist` in the background):

```
gpfdist -d /var/load_files -p 8081 &
```

To start `gpfdist` in the background and redirect output and errors to a log file:

```
gpfdist -d /var/load_files -p 8081 -l /home/gpadmin/log &
```

To enable multi-threaded data transfer (with implicit compression) using four threads, start `gpfdist` as follows:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
gpfdist -d /var/load_files -p 8081 --multi_thread 4
```

To enable SSL certificate authentication without peer verification, start `gpfdist` as follows:

```
gpfdist -d /var/load_files -p 8081 --ssl /path/to/certs --ssl_verify_peer off
```

To stop `gpfdist` when it is running in the background:

--First find its process id:

```
ps ax | grep gpfdist
```

--Then stop the process, for example:

```
kill 3456
```

7.7.2.16 gpinitstandby

Adds and/or initializes a standby coordinator host for a WarehousePG cluster.

Synopsis

```
gpinitstandby { -s <standby_hostname> [-P port] | -r | -n } [-a] [-q]
    [-D] [-S <standby_data_directory>] [-l <logfile_directory>]
    [--hba-hostnames <boolean>]

gpinitstandby -v

gpinitstandby -?
```

Description

The `gpinitstandby` utility adds a backup, standby coordinator instance to your WarehousePG cluster. If your system has an existing standby coordinator instance configured, use the `-r` option to remove it before adding the new standby coordinator instance.

Before running this utility, make sure that the WarehousePG software is installed on the standby coordinator host and that you have exchanged SSH keys between the hosts. It is recommended that the coordinator port is set to the same port number on the coordinator host and the standby coordinator host.

This utility should be run on the currently active *primary* coordinator host. See the *WarehousePG Installation Guide* for instructions.

The utility performs the following steps:

- Updates the WarehousePG cluster catalog to remove the existing standby coordinator information (if the `-r` option is supplied)
- Updates the WarehousePG cluster catalog to add the new standby coordinator instance information
- Edits the `pg_hba.conf` file of the WarehousePG coordinator to allow access from the newly added standby coordinator
- Sets up the standby coordinator instance on the alternate coordinator host
- Starts the synchronization process

A backup, standby coordinator instance serves as a 'warm standby' in the event of the primary coordinator becoming non-operational. The standby coordinator is kept up to date by transaction log replication processes (the `walsender` and `walreceiver`), which run on the primary coordinator and standby coordinator hosts and keep the data between the primary and standby coordinator instances synchronized. If the primary coordinator fails, the log replication process is shut down, and the standby coordinator can be activated in its place by using the `gpactivatestandby` utility. Upon activation of the standby coordinator, the replicated logs are used to reconstruct the state of the coordinator instance at the time of the last successfully committed transaction.

The activated standby coordinator effectively becomes the WarehousePG coordinator, accepting client connections on the coordinator port and performing normal coordinator operations such as SQL command processing and resource management.

> **Important** If the `gpinitstandby` utility previously failed to initialize the standby coordinator, you must delete the files in the standby coordinator data directory before running `gpinitstandby` again. The standby coordinator data directory is not cleaned up after an initialization failure because it contains log files that can help in determining the reason for the failure.

If an initialization failure occurs, a summary report file is generated in the standby host directory `/tmp`. The report file lists the directories on the standby host that require clean up.

Options

-a (do not prompt) Do not prompt the user for confirmation.

-D (debug) Sets logging level to debug.

--hba-hostnames boolean Optional. Controls whether this utility uses IP addresses or host names in the `pg_hba.conf` file when updating this file with addresses that can connect to WarehousePG. When set to 0 -- the default value -- this utility uses IP addresses when updating this file. When set to 1, this utility uses host names when updating this file. For consistency, use the same value that was specified for `HBA_HOSTNAMES` when the WarehousePG cluster was initialized. For information about how WarehousePG resolves host names in the `pg_hba.conf` file, see Configuring Client Authentication.

-l logfile_directory The directory to write the log file. Defaults to `~/gpAdminLogs`.

-n (restart standby coordinator) Specify this option to start a WarehousePG standby coordinator that has been configured but has stopped for some reason.

-P port This option specifies the port that is used by the WarehousePG standby coordinator. The default is the same port used by the active WarehousePG coordinator.

If the WarehousePG standby coordinator is on the same host as the active coordinator, the ports must be different. If the ports are the same for the active and standby coordinator and the host is the same, the utility returns an error.

-q (no screen output) Run in quiet mode. Command output is not displayed on the screen, but is still written to the log file.

-r (remove standby coordinator) Removes the currently configured standby coordinator instance from your WarehousePG cluster.

-s standby_hostname The host name of the standby coordinator host.

-S standby_data_directory The data directory to use for a new standby coordinator. The default is the same directory used by the active coordinator.

If the standby coordinator is on the same host as the active coordinator, a different directory must be specified using this option.

-v (show utility version) Displays the version, status, last updated date, and checksum of this utility.

-? (help) Displays the online help.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Examples

Add a standby coordinator instance to your WarehousePG cluster and start the synchronization process:

```
gpinitstandby -s host09
```

Start an existing standby coordinator instance and synchronize the data with the current primary coordinator instance:

```
gpinitstandby -n
```

> **Note** Do not specify the -n and -s options in the same command.

Add a standby coordinator instance to your WarehousePG cluster specifying a different port:

```
gpinitstandby -s myhost -P 2222
```

If you specify the same host name as the active WarehousePG coordinator, you must also specify a different port number with the `-P` option and a standby data directory with the `-S` option.

Remove the existing standby coordinator from your WarehousePG cluster configuration:

```
gpinitstandby -r
```

7.7.2.17 gpinitsystem

Initializes a WarehousePG cluster using configuration parameters specified in the `gpinitsystem_config` file.

Synopsis

```
gpinitsystem -c <cluster_configuration_file>
            [-h <hostfile_gpinitsystem>]
            [-B <parallel_processes>]
            [-p <postgresql_conf_param_file>]
            [-s <standby_coordinator_host>
                [-P <standby_coordinator_port>]
                [-S <standby_coordinator_datadir> | --standby_datadir=<standby_coordinator_datadir>]]
            [-m <number> | --max_connections=number>]
            [-b <size> | --shared_buffers=<size>]
            [-n <locale> | --locale=<locale>] [--lc-collate=<locale>]
            [--lc-ctype=<locale>] [--lc-messages=<locale>]
            [--lc-monetary=<locale>] [--lc-numeric=<locale>]
            [--lc-time=<locale>] [-e <password> | --su_password=<password>]
            [--mirror-mode={group|spread}] [-a] [-q] [-l <logfile_directory>] [-D]
            [-I <input_configuration_file>]
            [-O <output_configuration_file>]

gpinitsystem -v | --version

gpinitsystem -? | --help
```

Description

The `gpinitsystem` utility creates a WarehousePG instance or writes an input configuration file using the values defined in a cluster configuration file and any command-line options that you provide. SeeInitialization Configuration File Format for more information about the configuration file. Before running this utility, make sure that you have installed the WarehousePG software on all the hosts in the array.

With the `<-O output_configuration_file>` option, `gpinitsystem` writes all provided configuration information to the specified output file. This file can be used with the `-I` option to create a new cluster or re-create a cluster from a backed up configuration. See Initialization Configuration File Format for more information.

In a WarehousePG DBMS, each database instance (the coordinator instance and all segment instances) must be initialized across all of the hosts in the system in such a way that they can all work together as a unified DBMS. The `gpinitsystem` utility takes care of initializing the WarehousePG coordinator and each segment instance, and configuring the system as a whole.

Before running `gpinitsystem`, you must set the `$GPHOME` environment variable to point to the location of your WarehousePG installation on the coordinator host and exchange SSH keys between all host addresses in the array using `gpssh-exkeys`.

This utility performs the following tasks:

- Verifies that the parameters in the configuration file are correct.
- Ensures that a connection can be established to each host address. If a host address cannot be reached, the utility will exit.
- Verifies the locale settings.
- Displays the configuration that will be used and prompts the user for confirmation.
- Initializes the coordinator instance.
- Initializes the standby coordinator instance (if specified).
- Initializes the primary segment instances.
- Initializes the mirror segment instances (if mirroring is configured).
- Configures the WarehousePG cluster and checks for errors.
- Starts the WarehousePG cluster.

> **Note** This utility uses secure shell (SSH) connections between systems to perform its tasks. In large WarehousePG deployments, cloud deployments, or deployments with a large number of segments per host, this utility may exceed the host's maximum threshold for unauthenticated connections. Consider updating the SSH `MaxStartups` and `MaxSessions` configuration parameters to increase this threshold. For more information about SSH configuration options, refer to the SSH documentation for your Linux distribution.

Options

-a Do not prompt the user for confirmation.

-B parallel_processes The number of segments to create in parallel. If not specified, the utility will start up to 4 parallel processes at a time.

-c cluster_configuration_file Required. The full path and filename of the configuration file, which contains all of the defined parameters to configure and initialize a new WarehousePG cluster. See Initialization Configuration File Format for a description of this file. You must provide either the `-c <cluster_configuration_file>` option or the `-I <input_configuration_file>` option to `gpinitsystem`.

-D Sets log output level to debug.

-h hostfile_gpinitsystem Optional. The full path and filename of a file that contains the host addresses of your segment hosts. If not specified on the command line, you can specify the host file using the `MACHINE_LIST_FILE` parameter in the gpinitsystem_config file.

-I input_configuration_file The full path and filename of an input configuration file, which defines the WarehousePG host systems, the coordinator instance and segment instances on the hosts, using the `QD_PRIMARY_ARRAY`, `PRIMARY_ARRAY`, and `MIRROR_ARRAY` parameters. The input configuration file is typically created by using `gpinitsystem` with the `-O output\_configuration\_file` option. Edit those parameters in order to initialize a new cluster or re-create a cluster from a backed up configuration. You must provide either the `-c <cluster_configuration_file>` option or the `-I <input_configuration_file>` option to `gpinitsystem`.

-n locale | --locale=locale Sets the default locale used by WarehousePG. If not specified, the default locale is `en_US.utf8`. A locale identifier consists of a language identifier and a region identifier, and optionally a character set encoding. For example, `sv_SE` is Swedish as spoken in Sweden, `en_US` is U.S. English, and `fr_CA` is French Canadian. If more than one character set can be useful for a locale, then the specifications look like this: `en_US.UTF-8` (locale specification and character set encoding). On most systems, the command `locale` will show the locale environment settings and `locale -a` will show a list of all available locales.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

--lc-collate=locale Similar to `--locale`, but sets the locale used for collation (sorting data). The sort order cannot be changed after WarehousePG is initialized, so it is important to choose a collation locale that is compatible with the character set encodings that you plan to use for your data. There is a special collation name of `C` or `POSIX` (byte-order sorting as opposed to dictionary-order sorting). The `C` collation can be used with any character encoding.

--lc-ctype=locale Similar to `--locale`, but sets the locale used for character classification (what character sequences are valid and how they are interpreted). This cannot be changed after WarehousePG is initialized, so it is important to choose a character classification locale that is compatible with the data you plan to store in WarehousePG.

--lc-messages=locale Similar to `--locale`, but sets the locale used for messages output by WarehousePG. The current version of WarehousePG does not support multiple locales for output messages (all messages are in English), so changing this setting will not have any effect.

--lc-monetary=locale Similar to `--locale`, but sets the locale used for formatting currency amounts.

--lc-numeric=locale Similar to `--locale`, but sets the locale used for formatting numbers.

--lc-time=locale Similar to `--locale`, but sets the locale used for formatting dates and times.

-l logfile_directory The directory to write the log file. Defaults to `~/gpAdminLogs`.

-m number | --max_connections=number Sets the maximum number of client connections allowed to the coordinator. The default is 250.

-O output_configuration_file Optional, used during new cluster initialization. This option writes the `cluster_configuration_file` information (used with -c) to the specified `output_configuration_file`. This file defines the WarehousePG members using the `QD_PRIMARY_ARRAY`, `PRIMARY_ARRAY`, and `MIRROR_ARRAY` parameters. Use this file as a template for the `-I input_configuration_file` option. See Examples for more information.

-p postgresql_conf_param_file Optional. The name of a file that contains `postgresql.conf` parameter settings that you want to set for WarehousePG. These settings will be used when the individual coordinator and segment instances are initialized. You can also set parameters after initialization using the `gpconfig` utility.

-q Run in quiet mode. Command output is not displayed on the screen, but is still written to the log file.

-b size | --shared_buffers=size Sets the amount of memory a WarehousePG server instance uses for shared memory buffers. You can specify sizing in kilobytes (kB), megabytes (MB) or gigabytes (GB). The default is 125MB.

-s standby_coordinator_host Optional. If you wish to configure a backup coordinator instance, specify the host name using this option. The WarehousePG software must already be installed and configured on this host.

-P standby_coordinator_port If you configure a standby coordinator instance with `-s`, specify its port number using this option. The default port is the same as the coordinator port. To run the standby and coordinator on the same host, you must use this option to specify a different port for the standby. The WarehousePG software must already be installed and configured on the standby host.

-S standby_coordinator_datadir | --standby_dir=standby_coordinator_datadir If you configure a standby coordinator host with `-s`, use this option to specify its data directory. If you configure a standby on the same host as the coordinator instance, the coordinator and standby must have separate data directories.

-e superuser_password | --su_password=superuser_password Use this option to specify the password to set for the WarehousePG superuser account (such as `gpadmin`). If this option is not specified, the default password `gparray` is assigned to the superuser account. You can use the `ALTER ROLE` command to change the password at a later time.

```
Recommended security best practices:

-   Do not use the default password option for production environments.
-   Change the password immediately after installation.
```

--mirror-mode={group|spread} Use this option to specify the placement of mirror segment instances on the segment hosts. The default, `group`, groups the mirror segments for all of a host's primary segments on a single alternate host. `spread` spreads mirror segments for the primary segments on a host across different hosts in the WarehousePG cluster. Spreading is only allowed if the number of hosts is greater than the number of segment instances per host. See Overview of Segment Mirroring for information about WarehousePG mirroring strategies.

-v | --version Print the `gpinitsystem` version and exit.

-? | --help Show help about `gpinitsystem` command line arguments, and exit.

Initialization Configuration File Format

`gpinitsystem` requires a cluster configuration file with the following parameters defined. An example initialization configuration file can be found in `$GPHOME/docs/cli_help/gpconfigs/gpinitsystem_config`.

To avoid port conflicts between WarehousePG and other applications, the WarehousePG port numbers should not be in the range specified by the operating system parameter `net.ipv4.ip_local_port_range`. For example, if `net.ipv4.ip_local_port_range = 10000 65535`, you could set WarehousePG base port numbers to these values.

```
PORT_BASE = 6000
MIRROR_PORT_BASE = 7000
```

MACHINE_LIST_FILE

Optional. Can be used in place of the `-h` option. This specifies the file that contains the list of the segment host address names that comprise the WarehousePG cluster. The coordinator host is assumed to be the host from which you are running the utility and should not be included in this file. If your segment hosts have multiple network interfaces, then this file would include all addresses for the host. Give the absolute path to the file.

SEG_PREFIX

Required. This specifies a prefix that will be used to name the data directories on the coordinator and segment instances. The naming convention for data directories in a WarehousePG cluster is SEG_PREFIXnumber where number starts with 0 for segment instances (the coordinator is always -1). So for example, if you choose the prefix `gpseg`, your coordinator instance data directory would be named `gpseg-1`, and the segment instances would be named `gpseg0`, `gpseg1`, `gpseg2`, `gpseg3`, and so on.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

PORT_BASE

Required. This specifies the base number by which primary segment port numbers are calculated. The first primary segment port on a host is set as `PORT_BASE`, and then incremented by one for each additional primary segment on that host. Valid values range from 1 through 65535.

DATA_DIRECTORY

Required. This specifies the data storage location(s) where the utility will create the primary segment data directories. The number of locations in the list dictate the number of primary segments that will get created per physical host (if multiple addresses for a host are listed in the host file, the number of segments will be spread evenly across the specified interface addresses). It is OK to list the same data storage area multiple times if you want your data directories created in the same location. The user who runs `gpinitsystem` (for example, the `gpadmin` user) must have permission to write to these directories. For example, this will create six primary segments per host:

```
declare -a DATA_DIRECTORY=(/data1/primary /data1/primary
/data1/primary /data2/primary /data2/primary /data2/primary)
```

COORDINATOR_HOSTNAME

Required. The host name of the coordinator instance. This host name must exactly match the configured host name of the machine (run the `hostname` command to determine the correct hostname).

COORDINATOR_DIRECTORY

Required. This specifies the location where the data directory will be created on the coordinator host. You must make sure that the user who runs `gpinitsystem` (for example, the `gpadmin` user) has permissions to write to this directory.

COORDINATOR_PORT

Required. The port number for the coordinator instance. This is the port number that users and client connections will use when accessing the WarehousePG cluster.

TRUSTED_SHELL

Required. The shell the `gpinitsystem` utility uses to run commands on remote hosts. Allowed values are `ssh`. You must set up your trusted host environment before running the `gpinitsystem` utility (you can use `gpssh-exkeys` to do this).

ENCODING

Required. The character set encoding to use. This character set must be compatible with the `--locale` settings used, especially `--lc-collate` and `--lc-ctype`. WarehousePG supports the same character sets as PostgreSQL.

DATABASE_NAME

Optional. The name of a WarehousePG database to create after the system is initialized. You can always create a database later using the `CREATE DATABASE` command or the `createdb` utility.

MIRROR_PORT_BASE

Optional. This specifies the base number by which mirror segment port numbers are calculated. The first mirror segment port on a host is set as `MIRROR_PORT_BASE`, and then incremented by one for each additional mirror segment on that host. Valid values range from 1 through 65535 and cannot conflict with the ports calculated by `PORT_BASE`.

MIRROR_DATA_DIRECTORY

Optional. This specifies the data storage location(s) where the utility will create the mirror segment data directories. There must be the same number of data directories declared for mirror segment instances as for primary segment instances (see the `DATA_DIRECTORY` parameter). The user who runs `gpinitsystem` (for example, the `gpadmin` user) must have permission to write to these directories. For example:

```
declare -a MIRROR_DATA_DIRECTORY=(/data1/mirror
/data1/mirror /data1/mirror /data2/mirror /data2/mirror
/data2/mirror)
```

QD_PRIMARY_ARRAY

PRIMARY_ARRAY

MIRROR_ARRAY

Required when using `input_configuration file` with `-I` option. These parameters specify the WarehousePG coordinator host, the primary segment, and the mirror segment hosts respectively. During new cluster initialization, use the `gpinitsystem -O output\_configuration\_file` to populate `QD_PRIMARY_ARRAY`, `PRIMARY_ARRAY`, `MIRROR_ARRAY`.

To initialize a new cluster or re-create a cluster from a backed up configuration, edit these values in the input configuration file used with the `gpinitsystem -I input\_configuration\_file` option. Use one of the following formats to specify the host information:

```
<hostname>~<address>~<port>~<data_directory>/<seg_prefix<segment_id>~<dbid>~<content_id>
```

or

```
<host>~<port>~<data_directory>/<seg_prefix<segment_id>~<dbid>~<content_id>
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

The first format populates the `hostname` and `address` fields in the `gp_segment_configuration` catalog table with the hostname and address values provided in the input configuration file. The second format populates `hostname` and `address` fields with the same value, derived from host.

The WarehousePG coordinator always uses the value -1 for the segment ID and content ID. For example, seg_prefix<segment_id> and dbid values for `QD_PRIMARY_ARRAY` use `-1` to indicate the coordinator instance:

```
QD_PRIMARY_ARRAY=cdw~cdw~5432~/gpdata/coordinator/gpseg-1~1~-1
declare -a PRIMARY_ARRAY=(
sdw1~sdw1~40000~/gpdata/data1/gpseg0~2~0
sdw1~sdw1~40001~/gpdata/data2/gpseg1~3~1
sdw2~sdw2~40000~/gpdata/data1/gpseg2~4~2
sdw2~sdw2~40001~/gpdata/data2/gpseg3~5~3
)
declare -a MIRROR_ARRAY=(
sdw2~sdw2~50000~/gpdata/mirror1/gpseg0~6~0
sdw2~sdw2~50001~/gpdata/mirror2/gpseg1~7~1
sdw1~sdw1~50000~/gpdata/mirror1/gpseg2~8~2
sdw1~sdw1~50001~/gpdata/mirror2/gpseg3~9~3
)
```

To re-create a cluster using a known WarehousePG cluster configuration, you can edit the segment and content IDs to match the values of the system.

HEAP_CHECKSUM

Optional. This parameter specifies if checksums are enabled for heap data. When enabled, checksums are calculated for heap storage in all databases, enabling WarehousePG to detect corruption in the I/O system. This option is set when the system is initialized and cannot be changed later.

The `HEAP_CHECKSUM` option is on by default and turning it off is strongly discouraged. If you set this option to off, data corruption in storage can go undetected and make recovery much more difficult.

To determine if heap checksums are enabled in a WarehousePG cluster, you can query the `data_checksums` server configuration parameter with the `gpconfig` management utility:

```
$ gpconfig -s data_checksums
```

HBA_HOSTNAMES

Optional. This parameter controls whether `gpinitsystem` uses IP addresses or host names in the `pg_hba.conf` file when updating the file with addresses that can connect to WarehousePG. The default value is `0`, the utility uses IP addresses when updating the file. When Initializing WarehousePG, specify `HBA_HOSTNAMES=1` to have the utility use host names in the `pg_hba.conf` file.

For information about how WarehousePG resolves host names in the `pg_hba.conf` file, see Configuring Client Authentication.

Specifying Hosts using Hostnames or IP Addresses

When Initializing WarehousePG with `gpinitsystem`, you can specify segment hosts using either hostnames or IP addresses. For example, you can use hostnames or IP addresses in the file specified with the `-h` option.

- If you specify a hostname, the resolution of the hostname to an IP address should be done locally for security. For example, you should use entries in a local `/etc/hosts` file to map a hostname to an IP address. The resolution of a hostname to an IP address should not be performed by an external service such as a public DNS server. You must stop the WarehousePG cluster before you change the mapping of a hostname to a different IP address.
- If you specify an IP address, the address should not be changed after the initial configuration. When segment mirroring is enabled, replication from the primary to the mirror segment will fail if the IP address changes from the configured value. For this reason, you should use a hostname when Initializing WarehousePG unless you have a specific requirement to use IP addresses.

When initializing the WarehousePG cluster, `gpinitsystem` uses the initialization information to populate the gp_segment_configuration catalog table and adds hosts to the `pg_hba.conf` file. By default, the host IP address is added to the file. Specify the `gpinitsystem` configuration file parameter HBA_HOSTNAMES=1 to add hostnames to the file.

WarehousePG uses the `address` value of the `gp_segment_configuration` catalog table when looking up host systems for WarehousePG interconnect (internal) communication between the coordinator and segment instances and between segment instances, and for other internal communication.

Examples

Initialize a WarehousePG cluster by supplying a cluster configuration file and a segment host address file, and set up a spread mirroring (`--mirror-mode=spread`) configuration:

```
$ gpinitsystem -c gpinitsystem_config -h hostfile_gpinitsystem --mirror-mode=spread
```

Initialize a WarehousePG cluster and set the superuser remote password:

```
$ gpinitsystem -c gpinitsystem_config -h hostfile_gpinitsystem --su-password=mypassword
```

Initialize a WarehousePG cluster with an optional standby coordinator host:

```
$ gpinitsystem -c gpinitsystem_config -h hostfile_gpinitsystem -s host09
```

Initialize a WarehousePG cluster and write the provided configuration to an output file, for example `cluster_init.config`:

```
$ gpinitsystem -c gpinitsystem_config -h hostfile_gpinitsystem -O cluster_init.config
```

The output file uses the `QD_PRIMARY_ARRAY` and `PRIMARY_ARRAY` parameters to define coordinator and segment hosts:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
TRUSTED_SHELL=ssh
CHECK_POINT_SEGMENTS=8
ENCODING=UNICODE
SEG_PREFIX=gpseg
HEAP_CHECKSUM=on
HBA_HOSTNAMES=0
QD_PRIMARY_ARRAY=cdw~cdw.local~5433~/data/coordinator1/gpseg-1~1~-1
declare -a PRIMARY_ARRAY=(
cdw~cdw.local~6001~/data/primary1/gpseg0~2~0
)
declare -a MIRROR_ARRAY=(
cdw~cdw.local~7001~/data/mirror1/gpseg0~3~0
)
```

Initialize a WarehousePG using an input configuration file (a file that defines the WarehousePG cluster) using `QD_PRIMARY_ARRAY` and `PRIMARY_ARRAY` parameters:

```
$ gpinitsystem -I cluster_init.config
```

The following example uses a host system configured with multiple NICs. If host systems are configured with multiple NICs, you can initialize a WarehousePG cluster to use each NIC as a WarehousePG host system. You must ensure that the host systems are configured with sufficient resources to support all the segment instances being added to the host. Also, if high availability is enabled, you must ensure that the WarehousePG cluster configuration supports failover if a host system fails. For information about WarehousePG mirroring schemes, see ../../best_practices/ha.html#topic_ngz_qf4_tt.

For this simple coordinator and segment instance configuration, the host system `gp7c` is configured with two NICs `gp7c-1` and `gp7c-2`. In the configuration, the QD_PRIMARY_ARRAY parameter defines the coordinator segment using `gp7c-1`. The PRIMARY_ARRAY and MIRROR_ARRAY parameters use `gp7c-2` to define a primary and mirror segment instance.

```
QD_PRIMARY_ARRAY=gp7c~gp7c-1~5432~/data/coordinator/gpseg-1~1~-1
declare -a PRIMARY_ARRAY=(
gp7c~gp7c-2~40000~/data/data1/gpseg0~2~0
gp7s~gp7s~40000~/data/data1/gpseg1~3~1
)
declare -a MIRROR_ARRAY=(
gp7s~gp7s~50000~/data/mirror1/gpseg0~4~0
gp7c~gp7c-2~50000~/data/mirror1/gpseg1~5~1
)
```

7.7.2.18 gpload

Runs a load job as defined in a YAML formatted control file.

Synopsis

```
gpload -f <control_file> [-l <log_file>] [-h <hostname>] [-p <port>]
   [-U <username>] [-d <database>] [-W] [--gpfdist_timeout <seconds>]
   [--no_auto_trans] [--max_retries <retry_times>] [[-v | -V] [-q]] [-D]

gpload -?

gpload --version
```

Requirements

The client machine where `gpload` is run must have the following:

- The gpfdist parallel file distribution program installed and in your `$PATH`. This program is located in `$GPHOME/bin` of your WarehousePG server installation.
- Network access to and from all hosts in your WarehousePG cluster (coordinator and segments).
- Network access to and from the hosts where the data to be loaded resides (ETL servers).

Description

`gpload` is a data loading utility that acts as an interface to the WarehousePG external table parallel loading feature. Using a load specification defined in a YAML formatted control file, `gpload` runs a load by invoking the WarehousePG parallel file server (gpfdist), creating an external table definition based on the source data defined, and running an `INSERT`, `UPDATE` or `MERGE` operation to load the source data into the target table in the database.

> **Note** `gpfdist` is compatible only with the WarehousePG major version in which it is shipped. For example, a `gpfdist` utility that is installed with WarehousePG 6.x cannot be used with WarehousePG 7.x.

> **Note** `MERGE` and `UPDATE` operations are not supported if the target table column name is a reserved keyword, has capital letters, or includes any character that requires quotes (" ") to identify the column.

The operation, including any SQL commands specified in the `SQL` collection of the YAML control file (see Control File Format), are performed as a single transaction to prevent inconsistent data when performing multiple, simultaneous load operations on a target table.

Options

-f control_file Required. A YAML file that contains the load specification details. See Control File Format.

--gpfdist_timeout seconds Sets the timeout for the `gpfdist` parallel file distribution program to send a response. Enter a value from `0` to `30` seconds (entering " `0` " to deactivates timeouts). Note that you might need to increase this value when operating on high-traffic networks.

-l log_file Specifies where to write the log file. Defaults to `~/gpAdminLogs/gpload_YYYYMMDD`. For more information about the log file, see Log File Format.

--no_auto_trans Specify `--no_auto_trans` to deactivate processing the load operation as a single transaction if you are performing a single load operation on the target table.

By default, `gpload` processes each load operation as a single transaction to prevent inconsistent data when performing multiple, simultaneous operations on a target table.

-q (no screen output) Run in quiet mode. Command output is not displayed on the screen, but is still written to the log file.

-D (debug mode) Check for error conditions, but do not run the load.

-v (verbose mode) Show verbose output of the load steps as they are run.

-V (very verbose mode) Shows very verbose output.

-? (show help) Show help, then exit.

--version Show the version of this utility, then exit.

Connection Options

-d database The database to load into. If not specified, reads from the load control file, the environment variable `$PGDATABASE` or defaults to the current system user name.

-h hostname Specifies the host name of the machine on which the WarehousePG coordinator database server is running. If not specified, reads from the load control file, the environment variable `$PGHOST` or defaults to `localhost`.

-p port Specifies the TCP port on which the WarehousePG coordinator database server is listening for connections. If not specified, reads from the load control file, the environment variable `$PGPORT` or defaults to 5432.

--max_retries retry_times Specifies the maximum number of times `gpload` attempts to connect to WarehousePG after a connection timeout. The default value is `0`, do not attempt to connect after a connection timeout. A negative integer, such as `-1`, specifies an unlimited number of attempts.

-U username The database role name to connect as. If not specified, reads from the load control file, the environment variable `$PGUSER` or defaults to the current system user name.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

-W (force password prompt) Force a password prompt. If not specified, reads the password from the environment variable `$PGPASSWORD` or from a password file specified by `$PGPASSFILE` or in `~/.pgpass`. If these are not set, then `gpload` will prompt for a password even if `-W` is not supplied.

Control File Format

The `gpload` control file uses the YAML 1.1 document format and then implements its own schema for defining the various steps of a WarehousePG load operation. The control file must be a valid YAML document.

The `gpload` program processes the control file document in order and uses indentation (spaces) to determine the document hierarchy and the relationships of the sections to one another. The use of white space is significant. White space should not be used simply for formatting purposes, and tabs should not be used at all.

The basic structure of a load control file is:

```
---
VERSION: 1.0.0.1
DATABASE: <db_name>
USER: <db_username>
HOST: <coordinator_hostname>
PORT: <coordinator_port>
GPLOAD:
   INPUT:
    - SOURCE:

    - FAST_MATCH: true | false
   SQL:
    - BEFORE: "<sql_command>"
    - AFTER: "<sql_command>"
```

VERSION Optional. The version of the `gpload` control file schema. The current version is 1.0.0.1.

DATABASE Optional. Specifies which database in the WarehousePG cluster to connect to. If not specified, defaults to `$PGDATABASE` if set or the current system user name. You can also specify the database on the command line using the `-d` option.

USER Optional. Specifies which database role to use to connect. If not specified, defaults to the current user or `$PGUSER` if set. You can also specify the database role on the command line using the `-U` option.

If the user running `gpload` is not a WarehousePG superuser, then the appropriate rights must be granted to the user for the load to be processed. See the *WarehousePG Reference Guide* for more information.

HOST Optional. Specifies WarehousePG coordinator host name. If not specified, defaults to localhost or `$PGHOST` if set. You can also specify the coordinator host name on the command line using the `-h` option.

PORT Optional. Specifies WarehousePG coordinator port. If not specified, defaults to 5432 or `$PGPORT` if set. You can also specify the coordinator port on the command line using the `-p` option.

GPLOAD Required. Begins the load specification section. A `GPLOAD` specification must have an `INPUT` and an `OUTPUT` section defined.

```
INPUT
Required. Defines the location and the format of the input data to be loaded. `gpload` will start one or more instances of the [gpfdist](gpfdist.html) file
distribution program on the current host and create the required external table definition\(s\) in WarehousePG that point to the source data. Note that the host
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

from which you run `gpload` must be accessible over the network by all WarehousePG hosts \(coordinator and segments\).

SOURCE
Required. The `SOURCE` block of an `INPUT` specification defines the location of a source file. An `INPUT` section can have more than one `SOURCE` block defined. Each `SOURCE` block defined corresponds to one instance of the [gpfdist](gpfdist.html) file distribution program that will be started on the local machine. Each `SOURCE` block defined must have a `FILE` specification.

For more information about using the `gpfdist` parallel file server and single and multiple `gpfdist` instances, see [Loading and Unloading Data](../../admin_guide/load/topics/g-loading-and-unloading-data.html).

LOCAL_HOSTNAME
Optional. Specifies the host name or IP address of the local machine on which `gpload` is running. If this machine is configured with multiple network interface cards \(NICs\), you can specify the host name or IP of each individual NIC to allow network traffic to use all NICs simultaneously. The default is to use the local machine's primary host name or IP only.

PORT
Optional. Specifies the specific port number that the [gpfdist](gpfdist.html) file distribution program should use. You can also supply a `PORT_RANGE` to select an available port from the specified range. If both `PORT` and `PORT_RANGE` are defined, then `PORT` takes precedence. If neither `PORT` or `PORT_RANGE` are defined, the default is to select an available port between 8000 and 9000.

If multiple host names are declared in `LOCAL_HOSTNAME`, this port number is used for all hosts. This configuration is desired if you want to use all NICs to load the same file or set of files in a given directory location.

PORT_RANGE
Optional. Can be used instead of `PORT` to supply a range of port numbers from which `gpload` can choose an available port for this instance of the [gpfdist](gpfdist.html) file distribution program.

FILE
Required. Specifies the location of a file, named pipe, or directory location on the local file system that contains data to be loaded. You can declare more than one file so long as the data is of the same format in all files specified.

If the files are compressed using `gzip` or `bzip2` \(have a `.gz` or `.bz2` file extension\), the files will be uncompressed automatically \(provided that `gunzip` or `bunzip2` is in your path\).

When specifying which source files to load, you can use the wildcard character \(`*`\) or other C-style pattern matching to denote multiple files. The files specified are assumed to be relative to the current directory from which `gpload` is run \(or you can declare an absolute path\).

SSL
Optional. Specifies usage of SSL encryption. If `SSL` is set to true, `gpload` starts the `gpfdist` server with the `--ssl` option and uses the `gpfdists://` protocol.

CERTIFICATES_PATH
Required when SSL is `true`; cannot be specified when SSL is `false` or unspecified. The location specified in `CERTIFICATES_PATH` must contain the following files:

- The server certificate file, `server.crt`
- The server private key file, `server.key`
- The trusted certificate authorities, `root.crt`

The root directory \(`/`\) cannot be specified as `CERTIFICATES_PATH`.

FULLY_QUALIFIED_DOMAIN_NAME
Optional. Specifies whether `gpload` resolve hostnames to the fully qualified domain name \(FQDN\) or the local hostname. If the value is set to `true`, names are resolved to the FQDN. If the value is set to `false`, resolution is to the local hostname. The default is `false`.

A fully qualified domain name might be required in some situations. For example, if the WarehousePG cluster is in a different domain than an ETL application that is being accessed by `gpload`.

COLUMNS
Optional. Specifies the schema of the source data file\(s\) in the format of `field\_name:data\_type`. The `DELIMITER` character in the source file is what separates two data value fields \(columns\). A row is determined by a line feed character \(`0x0a`\).

If the input `COLUMNS` are not specified, then the schema of the output `TABLE` is implied, meaning that the source data must have the same column order, number of columns, and data format as the target table.

The default source-to-target mapping is based on a match of column names as defined in this section and the column names in the target `TABLE`. This default mapping can be overridden using the `MAPPING` section.

TRANSFORM
Optional. Specifies the name of the input transformation passed to `gpload`. For information about XML transformations, see "Loading and Unloading Data" in the *WarehousePG Administrator Guide*.

TRANSFORM_CONFIG
Required when `TRANSFORM` is specified. Specifies the location of the transformation configuration file that is specified in the `TRANSFORM` parameter, above.

MAX_LINE_LENGTH
Optional. Sets the maximum allowed data row length in bytes. Default is 32768. Should be used when user data includes very wide rows (or when `line too long` error message occurs). Should not be used otherwise as it increases resource allocation. Valid range is 32K to 256MB. The upper limit is 1MB on Windows systems.

FORMAT
Optional. Specifies the format of the source data file\(s\) - either plain text \(`TEXT`\) or comma separated values \(`CSV`\) format. Defaults to `TEXT` if not specified. For more information about the format of the source data, see [Loading and Unloading Data](../../admin_guide/load/topics/g-loading-and-unloading-data.html).

DELIMITER
Optional. Specifies a single ASCII character that separates columns within each row \(line\) of data. The default is a tab character in TEXT mode, a comma in CSV mode. You can also specify a non- printable ASCII character or a non-printable unicode character, for example: `"\x1B"` or `"\u001B"`. The escape string syntax, `E'<character-code>'`, is also supported for non-printable characters. The ASCII or unicode character must be enclosed in single quotes. For example: `E'\x1B'` or `E'\u001B'`.

ESCAPE
Specifies the single character that is used for C escape sequences \(such as `\n`, `\t`, `\100`, and so on\) and for escaping data characters that might otherwise be taken as row or column delimiters. Make sure to choose an escape character that is not used anywhere in your actual column data. The default escape character

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

is a \\ \(backslash\) for text-formatted files and a `"` \(double quote\) for csv-formatted files, however it is possible to specify another character to represent an escape. It is also possible to deactivate escaping in text-formatted files by specifying the value `'OFF'` as the escape value. This is very useful for data such as text-formatted web log data that has many embedded backslashes that are not intended to be escapes.

NEWLINE
Specifies the type of newline used in your data files, one of:

- LF \(Line feed, 0x0A\)
- CR \(Carriage return, 0x0D\)
- CRLF \(Carriage return plus line feed, 0x0D 0x0A\).

If not specified, WarehousePG detects the newline type by examining the first row of data that it receives, and uses the first newline type that it encounters.

NULL_AS
Optional. Specifies the string that represents a null value. The default is `\N` \(backslash-N\) in `TEXT` mode, and an empty value with no quotations in `CSV` mode. You might prefer an empty string even in `TEXT` mode for cases where you do not want to distinguish nulls from empty strings. Any source data item that matches this string will be considered a null value.

FILL_MISSING_FIELDS
Optional. The default value is `false`. When reading a row of data that has missing trailing field values \(the row of data has missing data fields at the end of a line or row\), WarehousePG returns an error.

If the value is `true`, when reading a row of data that has missing trailing field values, the values are set to `NULL`. Blank rows, fields with a `NOT NULL` constraint, and trailing delimiters on a line will still report an error.

See the `FILL MISSING FIELDS` clause of the [CREATE EXTERNAL TABLE](../../ref_guide/sql_commands/CREATE_EXTERNAL_TABLE.html) command.

FORCE_NOT_NULL
Optional. In CSV mode, processes each specified column as though it were quoted and hence not a NULL value. For the default null string in CSV mode \(nothing between two delimiters\), this causes missing values to be evaluated as zero-length strings.

QUOTE
Required when `FORMAT` is `CSV`. Specifies the quotation character for `CSV` mode. The default is double-quote \(`"`\).

HEADER
Optional. Specifies that the first line in the data file\(s\) is a header row \(contains the names of the columns\) and should not be included as data to be loaded. If using multiple data source files, all files must have a header row. The default is to assume that the input files do not have a header row.

ENCODING
Optional. Character set encoding of the source data. Specify a string constant \(such as `'SQL_ASCII'`\), an integer encoding number, or `'DEFAULT'` to use the default client encoding. If not specified, the default client encoding is used. For information about supported character sets, see the *WarehousePG Reference Guide*.

> **Note** If you *change* the `ENCODING` value in an existing `gpload` control file, you must manually drop any external tables that were creating using the previous `ENCODING` configuration. `gpload` does not drop and recreate external tables to use the new `ENCODING` if `REUSE_TABLES` is set to `true`.

ERROR_LIMIT
Optional. Enables single row error isolation mode for this load operation. When enabled, input rows that have format errors will be discarded provided that the error limit count is not reached on any WarehousePG segment instance during input processing. If the error limit is not reached, all good rows will be loaded and any error rows will either be discarded or captured as part of error log information. The default is to cancel the load operation on the first error encountered. Note that single row error isolation only applies to data rows with format errors; for example, extra or missing attributes, attributes of a wrong data type, or invalid client encoding sequences. Constraint errors, such as primary key violations, will still cause the load operation to be cancelled if encountered. For information about handling load errors, see [Loading and Unloading Data](../../admin_guide/load/topics/g-loading-and-unloading-data.html).

LOG_ERRORS
Optional when `ERROR_LIMIT` is declared. Value is either `true` or `false`. The default value is `false`. If the value is `true`, rows with formatting errors are logged internally when running in single row error isolation mode. You can examine formatting errors with the WarehousePG built-in SQL function `gp_read_error_log('<table_name>')`. If formatting errors are detected when loading data, `gpload` generates a warning message with the name of the table that contains the error information similar to this message.

```
<timestamp>|WARN|1 bad row, please use GPDB built-in function gp_read_error_log('table-name')
   to access the detailed error row
```

If `LOG_ERRORS: true` is specified, `REUSE_TABLES: true` must be specified to retain the formatting errors in WarehousePG error logs. If `REUSE_TABLES: true` is not specified, the error information is deleted after the `gpload` operation. Only summary information about formatting errors is returned. You can delete the formatting errors from the error logs with the WarehousePG function `gp_truncate_error_log()`.

> **Note** When `gpfdist` reads data and encounters a data formatting error, the error message includes a row number indicating the location of the formatting error. `gpfdist` attempts to capture the row that contains the error. However, `gpfdist` might not capture the exact row for some formatting errors.

For more information about handling load errors, see "Loading and Unloading Data" in the *WarehousePG Administrator Guide*. For information about the `gp_read_error_log()` function, see the [CREATE EXTERNAL TABLE](../../ref_guide/sql_commands/CREATE_EXTERNAL_TABLE.html) command.

EXTERNAL
Optional. Defines the schema of the external table database objects created by `gpload`.

The default is to use the WarehousePG `search_path`.

SCHEMA

Required when `EXTERNAL` is declared. The name of the schema of the external table. If the schema does not exist, an error is returned.

If `%` (percent character) is specified, the schema of the table name specified by `TABLE` in the `OUTPUT` section is used. If the table name does not specify a schema, the default schema is used.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
OUTPUT
Required. Defines the target table and final data column values that are to be loaded into the database.

TABLE
Required. The name of the target table to load into.

MODE
Optional. Defaults to `INSERT` if not specified. There are three available load modes:

INSERT - Loads data into the target table using the following method:

```
INSERT INTO <target_table> SELECT * FROM <input_data>;
```

UPDATE - Updates the `UPDATE_COLUMNS` of the target table where the rows have `MATCH_COLUMNS` attribute values equal to those of the input data, and the optional `UPDATE_CONDITION` is true. `UPDATE` is not supported if the target table column name is a reserved keyword, has capital letters, or includes any character that requires quotes \(" "\) to identify the column.

MERGE - Inserts new rows and updates the `UPDATE_COLUMNS` of existing rows where attribute values are equal to those of the input data, and the optional `MATCH_COLUMNS` is true. New rows are identified when the `MATCH_COLUMNS` value in the source data does not have a corresponding value in the existing data of the target table. In those cases, the **entire row** from the source file is inserted, not only the `MATCH` and `UPDATE` columns. If there are multiple new `MATCH_COLUMNS` values that are the same, only one new row for that value will be inserted. Use `UPDATE_CONDITION` to filter out the rows to discard. `MERGE` is not supported if the target table column name is a reserved keyword, has capital letters, or includes any character that requires quotes \(" "\) to identify the column.

MATCH_COLUMNS
Required if `MODE` is `UPDATE` or `MERGE`. Specifies the column\(s\) to use as the join condition for the update. The attribute value in the specified target column\(s\) must be equal to that of the corresponding source data column\(s\) in order for the row to be updated in the target table.

UPDATE_COLUMNS
Required if `MODE` is `UPDATE` or `MERGE`. Specifies the column\(s\) to update for the rows that meet the `MATCH_COLUMNS` criteria and the optional `UPDATE_CONDITION`.

UPDATE_CONDITION
Optional. Specifies a Boolean condition \(similar to what you would declare in a `WHERE` clause\) that must be met in order for a row in the target table to be updated.

MAPPING
Optional. If a mapping is specified, it overrides the default source-to-target column mapping. The default source-to-target mapping is based on a match of column names as defined in the source `COLUMNS` section and the column names of the target `TABLE`. A mapping is specified as either:

`<target_column_name>: <source_column_name>`

or

`<target_column_name>: '<expression>'`

Where <expression\> is any expression that you would specify in the `SELECT` list of a query, such as a constant value, a column reference, an operator invocation, a function call, and so on.
```

PRELOAD Optional. Specifies operations to run prior to the load operation. Right now the only preload operation is `TRUNCATE`.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
TRUNCATE
Optional. If set to true, `gpload` will remove all rows in the target table prior to loading it. Default is false.

REUSE\_TABLES
Optional. If set to true, `gpload` will not drop the external table objects and staging table objects it creates. These objects will be reused for future load
operations that use the same load specifications. This improves performance of trickle loads \(ongoing small loads to the same target table\).

If `LOG_ERRORS: true` is specified, `REUSE_TABLES: true` must be specified to retain the formatting errors in WarehousePG error logs. If `REUSE_TABLES: true` is
not specified, formatting error information is deleted after the `gpload` operation.

If the <external\_table\_name\> exists, the utility uses the existing table. The utility returns an error if the table schema does not match the `OUTPUT` table
schema.

STAGING\_TABLE
Optional. Specify the name of the temporary external table that is created during a `gpload` operation. The external table is used by `gpfdist`. `REUSE_TABLES:
true` must also specified. If `REUSE_TABLES` is false or not specified, `STAGING_TABLE` is ignored. By default, `gpload` creates a temporary external table with a
randomly generated name.

If external\_table\_name contains a period \(.\), `gpload` returns an error. If the table exists, the utility uses the table. The utility returns an error if the
existing table schema does not match the `OUTPUT` table schema.

The utility uses the value of [SCHEMA](#cfschema) in the `EXTERNAL` section as the schema for <external\_table\_name\>. If the `SCHEMA` value is `%`, the schema
for <external\_table\_name\> is the same as the schema of the target table, the schema of [TABLE](#cftable) in the `OUTPUT` section.

If `SCHEMA` is not set, the utility searches for the table \(using the schemas in the database `search_path`\). If the table is not found, external\_table\_name
is created in the default `PUBLIC` schema.

`gpload` creates the staging table using the distribution key\(s\) of the target table as the distribution key\(s\) for the staging table. If the target table was
created `DISTRIBUTED RANDOMLY`, `gpload` uses `MATCH_COLUMNS` as the staging table's distribution key\(s\).

FAST\_MATCH
Optional. If set to true, `gpload` only searches the database for matching external table objects when reusing external tables. The utility does not check the
external table column names and column types in the catalog table `pg_attribute` to ensure that the table can be used for a `gpload` operation. Set the value to
true to improve `gpload` performance when reusing external table objects and the database catalog table `pg_attribute` contains a large number of rows. The
utility returns an error and quits if the column definitions are not compatible.

The default value is false, the utility checks the external table definition column names and column types.

`REUSE_TABLES: true` must also specified. If `REUSE_TABLES` is false or not specified and `FAST_MATCH: true` is specified, `gpload` returns a warning message.
```

SQL Optional. Defines SQL commands to run before and/or after the load operation. You can specify multiple `BEFORE` and/or `AFTER` commands. List commands in the order of desired execution.

```
BEFORE
Optional. An SQL command to run before the load operation starts. Enclose commands in quotes.

AFTER
Optional. An SQL command to run after the load operation completes. Enclose commands in quotes.
```

Log File Format

Log files output by `gpload` have the following format:

```
<timestamp>|<level>|<message>
```

Where <timestamp> takes the form: `YYYY-MM-DD HH:MM:SS`, level is one of `DEBUG`, `LOG`, `INFO`, `ERROR`, and message is a normal text message.

Some `INFO` messages that may be of interest in the log files are (where # corresponds to the actual number of seconds, units of data, or failed rows):

```
INFO|running time: <#.##> seconds
INFO|transferred <#.#> kB of <#.#> kB.
INFO|gpload succeeded
INFO|gpload succeeded with warnings
INFO|gpload failed
INFO|1 bad row
INFO|<#> bad rows
```

Notes

If your database object names were created using a double-quoted identifier (delimited identifier), you must specify the delimited name within single quotes in the `gpload` control file. For example, if you create a table as follows:

```
CREATE TABLE "MyTable" ("MyColumn" text);
```

Your YAML-formatted `gpload` control file would refer to the above table and column names as follows:

```
- COLUMNS:
   - '"MyColumn"': text
OUTPUT:
   - TABLE: public.'"MyTable"'
```

If the YAML control file contains the unsupported `ERROR_TABLE` element, `gpload` logs a warning stating that `ERROR_TABLE` is not supported, and load errors are handled as if the `LOG_ERRORS` and `REUSE_TABLE` elements were set to `true`. Rows with formatting errors are logged internally when running in single row error isolation mode.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Examples

Run a load job as defined in `my_load.yml`:

```
gpload -f my_load.yml
```

Example load control file:

```
---
VERSION: 1.0.0.1
DATABASE: ops
USER: gpadmin
HOST: cdw-1
PORT: 5432
GPLOAD:
   INPUT:
    - SOURCE:
         LOCAL_HOSTNAME:
           - etl1-1
           - etl1-2
           - etl1-3
           - etl1-4
         PORT: 8081
         FILE:
           - /var/load/data/*
    - COLUMNS:
           - name: text
           - amount: float4
           - category: text
           - descr: text
           - date: date
    - FORMAT: text
    - DELIMITER: '|'
    - ERROR_LIMIT: 25
    - LOG_ERRORS: true
   OUTPUT:
    - TABLE: payables.expenses
    - MODE: INSERT
   PRELOAD:
    - REUSE_TABLES: true
   SQL:
   - BEFORE: "INSERT INTO audit VALUES('start', current_timestamp)"
   - AFTER: "INSERT INTO audit VALUES('end', current_timestamp)"
```

7.7.2.19 gplogfilter

Searches through WarehousePG log files for specified entries.

Synopsis

```
gplogfilter [<timestamp_options>] [<pattern_options>]
     [<output_options>] [<input_options>] [<input_file>]

gplogfilter --help

gplogfilter --version
```

Description

The `gplogfilter` utility can be used to search through a WarehousePG log file for entries matching the specified criteria. If an input file is not supplied, then `gplogfilter` will use the `$COORDINATOR_DATA_DIRECTORY` environment variable to locate the WarehousePG coordinator log file in the standard logging location. To read from standard input, use a dash (`-`) as the input file name. Input files may be compressed using `gzip` . In an input file, a log entry is identified by its timestamp in `YYYY-MM-DD [hh:mm[:ss]]` format.

You can also use `gplogfilter` to search through all segment log files at once by running it through the `gpssh` utility. For example, to display the last three lines of each segment log file:

```
gpssh -f seg_host_file
=> source /usr/edb/whpg7/greenplum_path.sh
=> gplogfilter -n 3 /gpdata/*/log/gpdb*.csv
```

By default, the output of `gplogfilter` is sent to standard output. Use the `-o` option to send the output to a file or a directory. If you supply an output file name ending in `.gz` , the output file will be compressed by default using maximum compression. If the output destination is a directory, the output file is given the same name as the input file.

Options

Timestamp Options

`-b datetime | --begin=datetime` Specifies a starting date and time to begin searching for log entries in the format of `YYYY-MM-DD [hh:mm[:ss]]` .

If a time is specified, the date and time must be enclosed in either single or double quotes. This example encloses the date and time in single quotes:

```
gplogfilter -b '2013-05-23 14:33'
```

`-e datetime | --end=datetime` Specifies an ending date and time to stop searching for log entries in the format of `YYYY-MM-DD [hh:mm[:ss]]` .

If a time is specified, the date and time must be enclosed in either single or double quotes. This example encloses the date and time in single quotes:

```
gplogfilter -e '2013-05-23 14:33'
```

`-d<time> | --duration=<time>` Specifies a time duration to search for log entries in the format of `[hh][:mm[:ss]]` . If used without either the `-b` or `-e` option, will use the current time as a basis.

Pattern Matching Options

`-c i \[gnore] | r \[espect] | --case=i \[gnore] | r \[espect]` Matching of alphabetic characters is case sensitive by default unless proceeded by the `--case=ignore` option.

`-C 'string' | --columns='string'` Selects specific columns from the log file. Specify the desired columns as a comma-delimited string of column numbers beginning with 1, where the second column from left is 2, the third is 3, and so on. See "Viewing the Database Server Log Files" in the *WarehousePG Administrator Guide* for details about the log file format and for a list of the available columns and their associated number.

`-f 'string' | --find='string'` Finds the log entries containing the specified string.

`-F 'string' | --nofind='string'` Rejects the log entries containing the specified string.

`-m regex | --match=regex` Finds log entries that match the specified Python regular expression. See https://docs.python.org/library/re.html for Python regular expression syntax.

`-M regex | --nomatch=regex` Rejects log entries that match the specified Python regular expression. See https://docs.python.org/library/re.html for Python regular expression syntax.

`-t | --trouble` Finds only the log entries that have `ERROR:` , `FATAL:` , or `PANIC:` in the first line.

Output Options

`-n <integer> | --tail=<integer>` Limits the output to the last <integer> of qualifying log entries found.

`-s <offset> </offset>\[limit] | --slice=<offset> </offset>\[limit]` From the list of qualifying log entries, returns the <limit> number of entries starting at the <offset> entry number, where an <offset> of zero (`0`) denotes the first entry in the result set and an <offset> of any number greater than zero counts back from the end of the result set.

`-o <output_file> | --out=<output_file>` Writes the output to the specified file or directory location instead of `STDOUT` .

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

`-z 0-9 | --zip=0-9` Compresses the output file to the specified compression level using `gzip`, where `0` is no compression and `9` is maximum compression. If you supply an output file name ending in `.gz`, the output file will be compressed by default using maximum compression.

`-a | --append` If the output file already exists, appends to the file instead of overwriting it.

Input Options

`input_file` The name of the input log file(s) to search through. If an input file is not supplied, `gplogfilter` will use the `$COORDINATOR_DATA_DIRECTORY` environment variable to locate the WarehousePG coordinator log file. To read from standard input, use a dash (`-`) as the input file name.

`-u | --unzip` Uncompress the input file using `gunzip`. If the input file name ends in `.gz`, it will be uncompressed by default.

`--help` Displays the online help.

`--version` Displays the version of this utility.

Examples

Display the last three error messages in the coordinator log file:

```
gplogfilter -t -n 3
```

Display all log messages in the coordinator log file timestamped in the last 10 minutes:

```
gplogfilter -d :10
```

Display log messages in the coordinator log file containing the string `|con6 cmd11|`:

```
gplogfilter -f '|con6 cmd11|'
```

Using gpssh, run `gplogfilter` on the segment hosts and search for log messages in the segment log files containing the string `con6` and save output to a file.

```
gpssh -f seg_hosts_file -e 'source
/usr/edb/whpg7/greenplum_path.sh ; gplogfilter -f
con6 /gpdata/*/log/gpdb*.csv' > seglog.out
```

7.7.2.20 gpmemreport

Interprets the output created by the gpmemwatcher utility and generates output files in a readable format.

Synopsis

```
gpmemreport [<GZIP_FILE>] [[-s <START>] | [--start= <START>]] [[-e <END>] | [--end= <END>]]

gpmemreport --version

gpmemreport -h | --help
```

Description

The `gpmemreport` utility helps interpret the output file created by the gpmemwatcher utility.

When running `gpmemreport` against the `.gz` files generated by `gpmemwatcher`, it generates a series of files, where each file corresponds to a 60 second period of data collected by `gpmemwatcher` converted into a readable format.

Options

-s | --start start_time Indicates the start of the reporting period. Timestamp format must be `'%Y-%m-%d %H:%M:%S'`.

-e | --end end_time Indicates the end of the reporting period. Timestamp format must be `'%Y-%m-%d %H:%M:%S'`.

--version Displays the version of this utility.

-h | --help Displays the online help.

Examples

Example 1: Extract all the files generated by `gpmemwatcher` for the WarehousePG coordinator

Locate the output `.gz` file from `gpmemwatcher` and run `gpmemreport` against it:

```
$ gpmemreport cdw.ps.out.gz
>>>21:11:19:15:37:18<<<

>>>21:11:19:15:38:18<<<

>>>21:11:19:15:39:18<<<
```

Check that the generated files are listed under the current directory:

```
$ ls -thrl
-rw-rw-r--. 1 gpadmin gpadmin 1.2K Nov 19 15:50 20211119-153718
-rw-rw-r--. 1 gpadmin gpadmin 1.2K Nov 19 15:50 20211119-153818
-rw-rw-r--. 1 gpadmin gpadmin 1.2K Nov 19 15:50 20211119-153918
```

Example 2: Extract the files generated by `gpmemwatcher` for the WarehousePG coordinator starting after a certain timestamp

Locate the output `.gz` file from `gpmemwatcher` and run `gpmemreport` against it, indicating the start time as `2021-11-19 15:38:00`:

```
$ gpmemreport cdw.ps.out.gz --start='2021-11-19 15:38:00'
>>>21:11:19:15:37:18<<<

>>>21:11:19:15:38:18<<<

>>>21:11:19:15:39:18<<<
```

Check under the current directory that only the selected timestamp files are listed:

```
$ ls -thrl
-rw-rw-r--. 1 gpadmin gpadmin 1.2K Nov 19 15:50 20211119-153818
-rw-rw-r--. 1 gpadmin gpadmin 1.2K Nov 19 15:50 20211119-153918
```

7.7.2.21 gpmemwatcher

Tracks the memory usage of each process in a WarehousePG cluster.

Synopsis

```
gpmemwatcher [-f | --host_file <hostfile>]

gpmemwatcher --stop [-f | --host_file <hostfile>]

gpmemwatcher --version

gpmemwatcher -h | --help
```

Description

The `gpmemwatcher` utility is a daemon that runs on all servers of a WarehousePG cluster. It tracks the memory usage of each process by collecting the output of the `ps` command every 60 seconds. It is a low impact process that only consumes 4 MB of memory. It will generate approximately 30 MB of data over a 24-hour period.

You may use this utility if WarehousePG is reporting `Out of memory` errors and causing segments to go down or queries to fail. You collect the memory usage information of one or multiple servers within the WarehousePG cluster with `gpmemwatcher` and then use gpmemreport to analyze the files collected.

Options

-f | --host_file hostfile Indicates the hostfile input file that lists the hosts from which the utility should collect memory usage information. The file must include the hostnames and a working directory that exists on each one of the hosts. For example:

```
```
cdw:/home/gpadmin/gpmemwatcher_dir/working
sdw1:/home/gpadmin/gpmemwatcher_dir/working
sdw2:/home/gpadmin/gpmemwatcher_dir/working
sdw3:/home/gpadmin/gpmemwatcher_dir/working
sdw4:/home/gpadmin/gpmemwatcher_dir/working
```
```

--stop Stops all the `gpmemwatcher` processes, generates `.gz` data files in the current directory, and removes all the work files from all the hosts.

--version Displays the version of this utility.

-h | --help Displays the online help.

Examples

Example 1: Start the utility specifying the list of hosts from which to collect the information

Create the file `/home/gpadmin/hostmap.txt` that contains the following:

```
cdw:/home/gpadmin/gpmemwatcher_dir/working
sdw1:/home/gpadmin/gpmemwatcher_dir/working
sdw2:/home/gpadmin/gpmemwatcher_dir/working
sdw3:/home/gpadmin/gpmemwatcher_dir/working
sdw4:/home/gpadmin/gpmemwatcher_dir/working
```

Make sure that the path `/home/gpadmin/gpmemwatcher_dir/working` exists on all hosts.

Start the utility:

```
$ gpmemwatcher -f /home/gpadmin/hostmap.txt
```

Example 2: Stop utility and dump the resulting into a `.gz` file

Stop the utility you started in Example 1:

```
$ gpmemwatcher -f /home/gpadmin/hostmap.txt --stop
```

The results `.gz` files will be dumped into the directory where you are running the command:

```
$ [gpadmin@gpdb-m]$ ls -thrl
-rw-rw-r--. 1 gpadmin gpadmin 2.8K Nov 19 15:17 cdw.ps.out.gz
-rw-rw-r--. 1 gpadmin gpadmin 2.8K Nov 19 15:17 sdw1.ps.out.gz
-rw-rw-r--. 1 gpadmin gpadmin 2.8K Nov 19 15:17 sdw2.ps.out.gz
-rw-rw-r--. 1 gpadmin gpadmin 2.8K Nov 19 15:17 sdw3.ps.out.gz
-rw-rw-r--. 1 gpadmin gpadmin 2.8K Nov 19 15:17 sdw4.ps.out.gz
```

7.7.2.22 gpmovemirrors

Moves mirror segment instances to new locations.

Synopsis

```
gpmovemirrors -i <move_config_file> [-d <coordinator_data_directory>]
          [-l <logfile_directory>] [-b <segment_batch_size>]
          [-B <batch_size>] [-v] [--hba-hostnames <boolean>] [-a]

gpmovemirrors -?

gpmovemirrors --version
```

Description

The `gpmovemirrors` utility moves mirror segment instances to new locations. You may want to move mirrors to new locations to optimize distribution or data storage.

By default, the utility will prompt you for the file system location(s) where it will move the mirror segment data directories.

You must make sure that the user who runs `gpmovemirrors` (the `gpadmin` user) has permissions to write to the data directory locations specified. You may want to create these directories on the segment hosts and `chown` them to the appropriate user before running `gpmovemirrors`.

Options

-a (do not prompt)

Do not prompt the user for confirmation.

-b segment_batch_size

The maximum number of segments per host to operate on in parallel. Valid values are `1` to `128`. If not specified, the utility will start recovering up to 64 segments in parallel on each host.

-B batch_size

The number of hosts to work on in parallel. If not specified, the utility will start working on up to 16 hosts in parallel. Valid values are `1` to `64`.

-d coordinator_data_directory

The coordinator data directory. If not specified, the value set for `$COORDINATOR_DATA_DIRECTORY` will be used.

--hba-hostnames boolean

Optional. Controls whether this utility uses IP addresses or host names in the `pg_hba.conf` file when updating this file with addresses that can connect to WarehousePG. When set to 0 -- the default value -- this utility uses IP addresses when updating this file. When set to 1, this utility uses host names when updating this file. For consistency, use the same value that was specified for `HBA_HOSTNAMES` when the WarehousePG cluster was initialized. For information about how WarehousePG resolves host names in the `pg_hba.conf` file, see Configuring Client Authentication.

-i move_config_file

A configuration file containing information about which mirror segments to move, and where to move them.

You must have one mirror segment listed for each primary segment in the system. Each line inside the configuration file has the following format (as per attributes in the `gp_segment_configuration` catalog table):

```
<old_address>|<port>|<data_dir> <new_address>|<port>|<data_dir>
```

Where `<old_address>` and `<new_address>` are the host names or IP addresses of the segment hosts, `<port>` is the communication port, and `<data_dir>` is the segment instance data directory.

-l logfile_directory

The directory to write the log file. Defaults to `~/gpAdminLogs`.

-v (verbose)

Sets logging output to verbose.

--version (show utility version)

Displays the version of this utility.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

-? (help)

Displays the online help.

Examples

Moves mirrors from an existing WarehousePG cluster to a different set of hosts:

```
$ gpmovemirrors -i move_config_file
```

Where the `move_config_file` looks something like this:

```
sdw2|50000|/data2/mirror/gpseg0 sdw3|50000|/data/mirror/gpseg0
sdw2|50001|/data2/mirror/gpseg1 sdw4|50001|/data/mirror/gpseg1
sdw3|50002|/data2/mirror/gpseg2 sdw1|50002|/data/mirror/gpseg2
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.7.2.23 gprecoverseg

Recovers a primary or mirror segment instance that has been marked as down (if mirroring is enabled).

Synopsis

```
gprecoverseg [[-p <new_recover_host>[,...]] | -i <recover_config_file>] [-d <coordinator_data_directory>]
             [-b <segment_batch_size>] [-B <batch_size>] [-F [-s]] [-a] [-q] [--differential]
               [--hba-hostnames <boolean>]
             [--no-progress] [-l <logfile_directory>] [--max-rate <max_rate>]

gprecoverseg -r [--replay-lag <replay_lag>] [--disable-replay-lag]

gprecoverseg -o <output_recover_config_file>
             [-p <new_recover_host>[,...]]

gprecoverseg -? | -h | --help

gprecoverseg -v | --verbose

gprecoverseg --version
```

Description

In a system with mirrors enabled, the `gprecoverseg` utility reactivates a failed segment instance and identifies the changed database files that require resynchronization. Once `gprecoverseg` completes this process, the system goes into `Not in Sync` mode until the recovered segment is brought up to date. The system is online and fully operational during resynchronization.

During an incremental recovery (the `-F` option is not specified), if `gprecoverseg` detects a segment instance with mirroring deactivated in a system with mirrors activated, the utility reports that mirroring is deactivated for the segment, does not attempt to recover that segment instance, and continues the recovery process.

A segment instance can fail for several reasons, such as a host failure, network failure, or disk failure. When a segment instance fails, its status is marked as `d` (down) in the WarehousePG cluster catalog, and its mirror is activated in `Not in Sync` mode. In order to bring the failed segment instance back into operation again, you must first correct the problem that made it fail in the first place, and then recover the segment instance in WarehousePG using `gprecoverseg`.

> **Note** If incremental recovery was not successful and the down segment instance data is not corrupted, contact Support.

Segment recovery using `gprecoverseg` requires that you have an active mirror to recover from. For systems that do not have mirroring enabled, or in the event of a double fault (a primary and mirror pair both down at the same time) — you must take manual steps to recover the failed segment instances and then perform a system restart to bring the segments back online. For example, this command restarts a system.

```
gpstop -r
```

By default, a failed segment is recovered in place, meaning that the system brings the segment back online on the same host and data directory location on which it was originally configured. In this case, use the following format for the recovery configuration file (using `-i`). Note that `failed_host_name` is an optional parameter.

```
<failed_host_name>|<failed_host_address>|<port>|<data_directory>
```

In some cases, this may not be possible (for example, if a host was physically damaged and cannot be recovered). In this situation, `gprecoverseg` allows you to recover failed segments to a completely new host (using `-p`), on an alternative data directory location on your remaining live segment hosts (using `-s`), or by supplying a recovery configuration file (using `-i`) in the following format. The word <SPACE> indicates the location of a required space. Do not add additional spaces. The parameter `failed_host_name` is optional.

```
<failed_host_name>|<failed_host_address>|<port>|<data_directory><SPACE><recovery_host_name>|<recovery_host_address>|<port>|<data_directory>
```

See the `-i` option below for details and examples of a recovery configuration file.

The `gp_segment_configuration` system catalog table can help you determine your current segment configuration so that you can plan your mirror recovery configuration. For example, run the following query:

```
=# SELECT dbid, content, address, port, datadir
   FROM gp_segment_configuration
   ORDER BY dbid;
```

The new recovery segment host must be pre-installed with the WarehousePG software and configured exactly the same as the existing segment hosts. A spare data directory location must exist on all currently configured segment hosts and have enough disk space to accommodate the failed segments.

The recovery process marks the segment as up again in the WarehousePG cluster catalog, and then initiates the resynchronization process to bring the transactional state of the segment up-to-date with the latest changes. The system is online and available during `Not in Sync` mode.

Options

-a (do not prompt) : Do not prompt the user for confirmation.

-b segment_batch_size : The maximum number of segments per host to operate on in parallel. Valid values are `1` to `128`. If not specified, the utility will start recovering up to 64 segments in parallel on each host.

-B batch_size : The number of hosts to work on in parallel. If not specified, the utility will start working on up to 16 hosts in parallel. Valid values are `1` to `64`.

-d coordinator_data_directory : Optional. The coordinator host data directory. If not specified, the value set for `$COORDINATOR_DATA_DIRECTORY` will be used.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

-F (full recovery) : Optional. Perform a full copy of the active segment instance in order to recover the failed segment, rather than the default behavior of copying only the changes that occurred while the segment was down.

```
>**Caution**
>A full recovery deletes the data directory of the down segment instance before copying the data from the active (current primary) segment instance. Before performing a full recovery, ensure that the segment failure did not cause data corruption and that any host segment disk issues have been fixed.

Also, for a full recovery, the utility does not restore custom files that are stored in the segment instance data directory even if the custom files are also in the active segment instance. You must restore the custom files manually. For example, when using the `gpfdists` protocol (`gpfdist` with SSL encryption) to manage external data, client certificate files are required in the segment instance `$PGDATA/gpfdists` directory. These files are not restored. For information about configuring `gpfdists`, see [Encrypting gpfdist Connections](../../security_guide/encryption.html).

Use the `-s` option to output a new line once per second for each segment. Alternatively, use the `--no-progress` option to completely deactivate progress reports. To avoid copying the entire contents of the data directory during a full recovery after a previous full recovery failed, use `gprecoverseg`s

speed up the amount of time full recovery takes, use the `--differential` option to skip recovery of files and directories that have not changed since the last time `gprecoverseg` ran.
```

--differential (Differential recovery) : Optional. Perform a differential copy of the active segment instance in order to recover the failed segment. The default is to only copy over the incremental changes that occurred while the segment was down.

--hba-hostnames boolean : Optional. Controls whether this utility uses IP addresses or host names in the `pg_hba.conf` file when updating this file with addresses that can connect to WarehousePG. When set to 0 -- the default value -- this utility uses IP addresses when updating this file. When set to 1, this utility uses host names when updating this file. For consistency, use the same value that was specified for `HBA_HOSTNAMES` when the WarehousePG cluster was initialized. For information about how WarehousePG resolves host names in the `pg_hba.conf` file, see Configuring Client Authentication.

-i recover_config_file : Specifies the name of a file with the details about failed segments to recover.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Each line in the config file specifies a segment to recover. This line can have one of three formats. In the event of in-place \(incremental\) recovery, enter one group of pipe-delimited fields in the line. For example:

```
failedAddress|failedPort|failedDataDirectory
```

or

```
failedHostname|failedAddress|failedPort|failedDataDirectory
```

For recovery to a new location, enter two groups of fields separated by a space in the line. The required space is indicated by <SPACE\>. Do not add additional spaces.

```
failedAddress|failedPort|failedDataDirectory<SPACE>newAddress|newPort|newDataDirectory
```

or

```
failedHostname|failedAddress|failedPort|failedDataDirectory<SPACE>newHostname|newAddress|newPort|newDataDirectory
```

To do mix recovery, include a field with values I/D/F/i/d/f on each line. Default is incremental recovery if recovery_type field is not provided.

```
recoveryType|failedAddress|failedPort|failedDataDirectory
```

recoveryType field supports below values:
    I/i for incremental recovery
    D/d for differential recovery
    F/f for full recovery

> **Note** Lines beginning with `#` are treated as comments and ignored.

Examples

In-place \(incremental\) recovery of a single mirror

```
sdw1-1|50001|/data1/mirror/gpseg16
```

Recovery of a single mirror to a new host

```
sdw1-1|50001|/data1/mirror/gpseg16<SPACE>sdw4-1|50001|/data1/recover1/gpseg16
```

In-place recovery of down mirrors with recovery type:

```
sdw1-1|50001|/data1/mirror/gpseg1   // Does incremental recovery (By default)
I|sdw1-1|50001|/data1/mirror/gpseg1   // Does incremental recovery
i|sdw1-1|50001|/data1/mirror/gpseg1   // Does incremental recovery
D|sdw2-1|50002|/data1/mirror/gpseg2   // Does Differential recovery
d|sdw2-1|50002|/data1/mirror/gpseg2   // Does Differential recovery
F|sdw3-1|50003|/data1/mirror/gpseg3   // Does Full recovery
f|sdw3-1|50003|/data1/mirror/gpseg3   // Does Full recovery
```

Obtaining a Sample File

You can use the `-o` option to output a sample recovery configuration file to use as a starting point. The output file lists the currently invalid segments and their default recovery location. This file format can be used with the `-i` option for in-place \(incremental\) recovery.

-l logfile_directory : The directory to write the log file. Defaults to `~/gpAdminLogs`.

--max-rate <max_rate>

: Optional. Specifies the maximum bandwidth rate for a full recovery of failed segments. The rate is specified in kB/s. You may use the suffix `k` or `M` to signify kB/s or MB/s. The valid values ranges from 32kB/s to 1048576kB/s (1024MB/s). The default value is to use the entire available network bandwidth to perform the full recovery. Note that incremental and differential recoveries do not support this option, they use the entire available network bandwidth.

-o output_recover_config_file : Specifies a file name and location to output a sample recovery configuration file. This file can be edited to supply alternate recovery locations if needed. The following example outputs the default recovery configuration file:

```
$ gprecoverseg -o /home/gpadmin/recover_config_file
```

-p new_recover_host[,...] : Specifies a new host outside of the currently configured WarehousePG cluster on which to recover invalid segments.

: The new host must have the WarehousePG software installed and configured, and have the same hardware and OS configuration as the current segment hosts (same OS version, locales, `gpadmin` user account, data directory locations created, ssh keys exchanged, number of network interfaces, network interface naming convention, and so on). Specifically, the WarehousePG binaries must be installed, the new host must be able to connect password-less with all segments including the WarehousePG coordinator, and any other WarehousePG specific OS configuration parameters must be applied.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

: > **Note** In the case of multiple failed segment hosts, you can specify the hosts to recover with a comma-separated list. However, it is strongly recommended to recover one host at a time. If you must recover more than one host at a time, then it is critical to ensure that a double fault scenario does not occur, in which both the segment primary and corresponding mirror are offline.

-q (no screen output) : Run in quiet mode. Command output is not displayed on the screen, but is still written to the log file.

-r (rebalance segments) : After a segment recovery, segment instances may not be returned to the preferred role that they were given at system initialization time. This can leave the system in a potentially unbalanced state, as some segment hosts may have more active segments than is optimal for top system performance. This option rebalances primary and mirror segments by returning them to their preferred roles. All segments must be valid and resynchronized before running `gprecoverseg -r`. If there are any in progress queries, they will be cancelled and rolled back.

--replay-lag : Replay lag(in GBs) allowed on mirror when rebalancing the segments. Default is 10 GB. If the replay_lag (flush_lsn-replay_lsn) is more than the value provided with this option then rebalance will be aborted.

--disable-replay-lag : Disable replay lag check when rebalancing segments

-s (sequential progress) : Show `pg_basebackup` or `pg_rewind` progress sequentially instead of in-place. Useful when writing to a file, or if a tty does not support escape sequences. The default is to show progress in-place.

--no-progress : Suppresses progress reports from the `pg_basebackup`, `pg_rewind`, or `rsync` utility. The default is to display progress.

--differential : Optional. During a full recovery, copy from the primary segment to the mirror segment only the files and directories that changed since the segment failed. You may use the `--differential` option for in-place full recovery only. See Recovery Scenarios for more information on in-place recovery versus recovery to a different host.

```
>**Note**
>The `--differential` option cannot be combined with any of the following `gprecoverseg` options: `-i`, `-o`, `-F`, or `-p`.
```

-v | --verbose : Sets logging output to verbose.

--version : Displays the version of this utility.

-? | -h | --help : Displays the online help.

Examples

Example 1: Recover Failed Segments in Place

Recover any failed segment instances in place:

```
$ gprecoverseg
```

Example 2: Rebalance Failed Segments If Not in Preferred Roles

First, verify that all segments are up and running, reysynchronization has completed, and there are segments **not** in preferred roles:

```
$ gpstate -e
```

Then, if necessary, rebalance the segments:

```
$ gprecoverseg -r
```

Example 3: Recover Failed Segments to a Separate Host

Recover any failed segment instances to a newly configured new segment host:

```
$ gprecoverseg -i <recover_config_file>
```

7.7.2.24 gpreload

Reloads WarehousePG table data sorting the data based on specified columns.

> **Note** The `gpreload` utility is deprecated and will be removed in the next major release of WarehousePG. UseALTER TABLE REPACK BY COLUMNS to physically reorder a table based on one or more columns.

Synopsis

```
gpreload -d <database> [-p <port>] {-t | --table-file} <path_to_file> [-a]

gpreload -h

gpreload --version
```

Description

The `gpreload` utility reloads table data with column data sorted. For tables that were created with the table storage option `appendoptimized=TRUE` and compression enabled, reloading the data with sorted data can improve table compression. You specify a list of tables to be reloaded and the table columns to be sorted in a text file.

Compression is improved by sorting data when the data in the column has a relatively low number of distinct values when compared to the total number of rows.

For a table being reloaded, the order of the columns to be sorted might affect compression. The columns with the fewest distinct values should be listed first. For example, listing state then city would generally result in better compression than listing city then state.

```
public.cust_table: state, city
public.cust_table: city, state
```

For information about the format of the file used with `gpreload`, see the `--table-file` option.

Notes

To improve reload performance, indexes on tables being reloaded should be removed before reloading the data.

Running the `ANALYZE` command after reloading table data might query performance because of a change in the data distribution of the reloaded data.

For each table, the utility copies table data to a temporary table, truncates the existing table data, and inserts data from the temporary table to the table in the specified sort order. Each table reload is performed in a single transaction.

For a partitioned table, you can reload the data of a leaf partition. However, data is inserted from the root partitioned table, which acquires a `ROW EXCLUSIVE` lock on the entire table.

Options

-a (do not prompt) Optional. If specified, the `gpreload` utility does not prompt the user for confirmation.

-d database The database that contains the tables to be reloaded. The `gpreload` utility connects to the database as the user running the utility.

-p port The WarehousePG coordinator port. If not specified, the value of the `PGPORT` environment variable is used. If the value is not available, an error is returned.

{-t | --table-file } path_to_file The location and name of file containing list of schema qualified table names to reload and the column names to reorder from the WarehousePG. Only user defined tables are supported. Views or system catalog tables are not supported.

If indexes are defined on table listed in the file, `gpreload` prompts to continue.

Each line specifies a table name and the list of columns to sort. This is the format of each line in the file:

`schema.table_name: column [desc] [, column2 [desc] ... ]`

The table name is followed by a colon (:) and then at least one column name. If you specify more than one column, separate the column names with a comma. The columns are sorted in ascending order. Specify the keyword `desc` after the column name to sort the column in descending order.

Wildcard characters are not supported.

If there are errors in the file, `gpreload` reports the first error and exits. No data is reloaded.

The following example reloads three tables:

```
public.clients: region, state, rep_id desc
public.merchants: region, state
test.lineitem: group, assy, whse
```

In the first table `public.clients`, the data in the `rep_id` column is sorted in descending order. The data in the other columns are sorted in ascending order.

--version (show utility version) Displays the version of this utility.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

-? (help) Displays the online help.

Example

This example command reloads the tables in the database `mytest` that are listed in the file `data-tables.txt`.

```
gpreload -d mytest --table-file data-tables.txt
```

7.7.2.25 gprestore

Restore a WarehousePG backup set that was created using the `gpbackup` utility. By default `gprestore` will read the metadata and DDL files located in the Coordinator host data directory, and will load the CSV formatted table data stored locally on each segment hosts.

Synopsis

```
gprestore --timestamp <YYYYMMDDHHMMSS>
   [--backup-dir <directory>]
   [--copy-queue-size <int>]
   [--create-db]
   [--data-only]
   [--debug]
   [--exclude-schema <schema_name> [--exclude-schema <schema_name> ...]]
   [--exclude-schema-file <file_name>]
   [--exclude-table <schema.table> [--exclude-table <schema.table> ...]]
   [--exclude-table-file <file_name>]
   [--help]
   [--include-schema <schema_name> [--include-schema <schema_name> ...]]
   [--include-schema-file <file_name>]
   [--include-table <schema.table> [--include-table <schema.table> ...]]
   [--include-table-file <file_name>]
   [--incremental]
   [--jobs <int>]
   [--metadata-only]
   [--on-error-continue]
   [--plugin-config <config_file_location>]
   [--quiet]
   [--redirect-db <database_name>]
   [--redirect-schema <schema_name>]
   [--report-dir]
   [--resize-cluster]
   [--run-analyze]
   [--timestamp <YYYYMMDDHHMMSS>]
   [--truncate-table]
   [--verbose]
   [--version]
   [--with-globals]
   [--with-stats]

gprestore --help
```

`gpbackup` reference

Description

To use `gprestore` to restore from a backup set, you must include the `--timestamp` option to specify the exact timestamp value (`YYYYMMDDHHMMSS`) of the backup set to restore. If you specified a custom `--backup-dir` to consolidate the backup files, include the same `--backup-dir` option with `gprestore` to locate the backup files.

If the backup you specify is an incremental backup, you need a complete set of backup files (a full backup and any required incremental backups). `gprestore` ensures that the complete backup set is available before attempting to restore a backup.

Important: For incremental backup sets, the backups must be on a single device. For example, a backup set must all be on a Data Domain system.

When restoring from a backup set, `gprestore` restores to a database with the same name as the name specified when creating the backup set. If the target database exists and a table being restored exists in the database, the restore operation fails. Include the `--create-db` option if the target database does not exist in the cluster. You can optionally restore a backup set to a different database by using the `--redirect-db` option.

When restoring a backup set that contains data from some leaf partitions of a partitioned tables, the partitioned table is restored along with the data for the leaf partitions. For example, you create a backup with the `gpbackup` option `--include-table-file` and the text file lists some leaf partitions of a partitioned table. Restoring the backup creates the partitioned table and restores the data only for the leaf partitions listed in the file.

By default, only database objects in the backup set are restored. WarehousePG system objects are automatically included in a `gpbackup` backup set, but these objects are only restored if you include the `--with-globals` option to `gprestore` .

During a restore operation, automatic updating of table statistics is deactivated for the tables being restored. If you backed up query plan statistics using the `--with-stats` option, you can restore those statistics by providing `--with-stats` to `gprestore` . If you did not use `--with-stats` during a backup, or you want to collect current statistics during the restore operation, you can use the `--run-analyze` option to run `ANALYZE` on the restored tables.

When a materialized view is restored, the data is not restored. To populate the materialized view with data, use `REFRESH MATERIALIZED VIEW` . The tables that are referenced by the materialized view definition must be available. The `gprestore` log file lists the materialized views that were restored and the `REFRESH MATERIALIZED VIEW` commands that are used to populate the materialized views with data.

Performance of restore operations can be improved by creating multiple parallel connections to restore table data and metadata. By default `gprestore` uses 1 connection, but you can increase this number with the `--jobs` option for large restore operations.

When a restore operation completes, `gprestore` returns a status code.

`gprestore` can send status email notifications after a back up operation completes. You specify when the utility sends the mail and the email recipients in a configuration file.

Note: This utility uses secure shell (SSH) connections between systems to perform its tasks. In large WarehousePG deployments, cloud deployments, or deployments with a large number of segments per host, this utility may exceed the host's maximum threshold for unauthenticated connections. Consider updating the SSH `MaxStartups` and `MaxSessions` configuration parameters to increase this threshold. For more information about SSH configuration options, refer to the SSH documentation for your Linux distribution.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Options

--timestamp YYYYMMDDHHMMSS

Required. Specifies the timestamp of the `gpbackup` backup set to restore. By default `gprestore` tries to locate metadata files for the timestamp on the WarehousePG Coordinator host in the $COORDINATOR_DATA_DIRECTORY/backups/YYYYMMDD/YYYYMMDDhhmmss/ directory, and CSV data files in the `<seg_dir>/backups/YYYYMMDD/YYYYMMDDhhmmss/` directory of each segment host.

--backup-dir directory

Optional. Sources all backup files (metadata files and data files) from the specified directory. You must specify directory as an absolute path (not relative). If you do not supply this option, `gprestore` tries to locate metadata files for the timestamp on the WarehousePG Coordinator host in the $COORDINATOR_DATA_DIRECTORY/backups/YYYYMMDD/YYYYMMDDhhmmss/ directory. CSV data files must be available on each segment in the `<seg_dir>/backups/YYYYMMDD/YYYYMMDDhhmmss/` directory. Include this option when you specify a custom backup directory with `gpbackup`.

You cannot combine this option with the option `--plugin-config`.

--copy-queue-size int

Optional. Specifies the number of `COPY` commands `gprestore` should enqueue when restoring a backup set. This option optimizes restore performance by reducing the amount of time spent initializing `COPY` commands. If you do not set this option to 2 or greater, `gprestore` enqueues 1 `COPY` command at a time.

--create-db

Optional. Creates the database before restoring the database object metadata.

The database is created by cloning the empty standard system database `template0`.

--data-only

Optional. Restores table data from a backup created with the `gpbackup` utility, without creating the database tables. This option assumes the tables exist in the target database. To restore data for a specific set of tables from a backup set, you can specify an option to include tables or schemas or exclude tables or schemas. Specify the `--with-stats` option to restore table statistics from the backup.

The backup set must contain the table data to be restored. For example, a backup created with the `gpbackup` option `--metadata-only` does not contain table data.

`SEQUENCE` values are updated to match the values taken at the time of the backup.

To restore only database tables, without restoring the table data, see the option `--metadata-only`.

--debug

Optional. Displays verbose and debug log messages during a restore operation.

--exclude-schema schema_name

Optional. Specifies a database schema to exclude from the restore operation. You can specify this option multiple times. You cannot combine this option with the option `--include-schema`, `--include-schema-file`, or a table filtering option such as `--include-table`.

--exclude-schema-file file_name

Optional. Specifies a text file containing a list of schemas to exclude from the backup. Each line in the text file must define a single schema. The file must not include trailing lines. If a schema name uses any character other than a lowercase letter, number, or an underscore character, then you must include that name in double quotes. You cannot combine this option with the option `--include-schema` or `--include-schema-file`, or a table filtering option such as `--include-table`.

--exclude-table schema.table

Optional. Specifies a table to exclude from the restore operation. You can specify this option multiple times. The table must be in the format `<schema-name>.<table-name>`. If a table or schema name uses any character other than a lowercase letter, number, or an underscore character, then you must include that name in double quotes. You can specify this option multiple times. If the table is not in the backup set, the restore operation fails. You cannot specify a leaf partition of a partitioned table.

You cannot combine this option with the option `--exclude-schema`, `--exclude-schema-file`, or another a table filtering option such as `--include-table`.

--exclude-table-file file_name

Optional. Specifies a text file containing a list of tables to exclude from the restore operation. Each line in the text file must define a single table using the format `<schema-name>.<table-name>`. The file must not include trailing lines. If a table or schema name uses any character other than a lowercase letter, number, or an underscore character, then you must include that name in double quotes. If a table is not in the backup set, the restore operation fails. You cannot specify a leaf partition of a partitioned table.

You cannot combine this option with the option `--exclude-schema`, `--exclude-schema-file`, or another a table filtering option such as `--include-table`.

--help

Displays the online help.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

--include-schema schema_name

Optional. Specifies a database schema to restore. You can specify this option multiple times. If you specify this option, any schemas that you specify must be available in the backup set. Any schemas that are not included in subsequent `--include-schema` options are omitted from the restore operation.

If a schema that you specify for inclusion exists in the database, the utility issues an error and continues the operation. The utility fails if a table being restored exists in the database.

You cannot use this option if objects in the backup set have dependencies on multiple schemas.

--include-schema-file file_name

Optional. Specifies a text file containing a list of schemas to restore. Each line in the text file must define a single schema. The file must not include trailing lines. If a schema name uses any character other than a lowercase letter, number, or an underscore character, then you must include that name in double quotes.

The schemas must exist in the backup set. Any schemas not listed in this file are omitted from the restore operation.

You cannot use this option if objects in the backup set have dependencies on multiple schemas.

--include-table schema.table

Optional. Specifies a table to restore. The table must be in the format `<schema-name>.<table-name>`. You can specify this option multiple times. You cannot specify a leaf partition of a partitioned table.

You can also specify the qualified name of a sequence, a view, or a materialized view.

If you specify this option, the utility does not automatically restore dependent objects. You must also explicitly specify the dependent objects that are required. For example if you restore a view or a materialized view, you must also restore the tables that the view or the materialized view uses. If you restore a table that uses a sequence, you must also restore the sequence. The dependent objects must exist in the backup set.

You cannot combine this option with a schema filtering option such as `--include-schema`, or another table filtering option such as `--exclude-table-file`.

--include-table-file file_name

Optional. Specifies a text file containing a list of tables to restore. Each line in the text file must define a single table using the format `<schema-name>.<table-name>`. The file must not include trailing lines. Any tables not listed in this file are omitted from the restore operation. You cannot specify a leaf partition of a partitioned table.

You can also specify the qualified name of a sequence, a view, or a materialized view.

If you specify this option, the utility does not automatically restore dependent objects. You must also explicitly specify dependent objects that are required. For example, if you restore a view or a materialized view, you must also specify the tables that the view or the materialized uses. If you specify a table that uses a sequence, you must also specify the sequence. The dependent objects must exist in the backup set.

For a materialized view, the data is not restored. To populate the materialized view with data, you must use `REFRESH MATERIALIZED VIEW` and the tables that are referenced by the materialized view definition must be available.

If you use the `--include-table-file` option, `gprestore` does not create roles or set the owner of the tables. The utility restores table indexes and rules. Triggers are also restored but are not supported in WarehousePG.

--incremental

Optional. Requires the `--data-only option`. Restores only the table data in the incremental backup specified by the `--timestamp` option. Table data is not restored from previous incremental backups in the backup set. **Warning:** This is a Beta feature and is not supported in a production environment.

An incremental backup contains the following table data that can be restored.

- Data from all heap tables.
- Data from append-optimized tables that have been modified since the previous backup.
- Data from leaf partitions that have been modified from the previous backup.

When this option is specified, `gprestore` restores table data by truncating the table and reloading data into the table. `SEQUENCE` values are then updated to match the values taken at the time of the backup.

Before performing the restore operation, `gprestore` ensures that the tables being restored exist. If a table does not exist, `gprestore` returns an error and exits. If the `--on-error-continue` option is specified, `gprestore` logs missing tables and attempts to complete the restore operation.

> **Warning**
>
> When this option is specified, `gpbackup` assumes that no changes have been made to the table definitions of the tables being restored, such as adding or removing columns.--truncate-table

Optional. Truncate data from a set of tables before restoring the table data from a backup. This option lets you replace table data with data from a backup. Otherwise, table data might be duplicated.

You must specify the set of tables with either the option `--include-table` or `--include-table-file`. You must also specify `--data-only` to restore table data without creating the tables.

You can use this option with the `--redirect-db` option. You cannot use this option with `--redirect-schema`.

--jobs int

Optional. Specifies the number of parallel connections to use when restoring table data and metadata. By default, `gprestore` uses 1 connection. Increasing this number can improve the speed of restoring data. **Note:** If you used the `gpbackup --single-data-file` option to combine table backups into a single file per segment, you cannot set `--jobs` to a value higher than 1 to perform a parallel restore operation.

--metadata-only

Optional. Creates database tables from a backup created with the `gpbackup` utility, but does not restore the table data. This option assumes the tables do not exist in the target database. To create a specific set of tables from a backup set, you can specify an option to include tables or schemas or exclude tables or schemas. Specify the option `--with-globals` to restore the WarehousePG system objects.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

The backup set must contain the DDL for tables to be restored. For example, a backup created with the `gpbackup` option `--data-only` does not contain the DDL for tables.

--on-error-continue

Optional. Specify this option to continue the restore operation if an SQL error occurs when creating database metadata (such as tables, roles, or functions) or restoring data. If another type of error occurs, the utility exits. The default is to exit on the first error.

When this option is included, the utility displays an error summary and writes error information to the `gprestore` log file and continues the restore operation. The utility also creates text files in the backup directory that contain the list of tables that generated SQL errors.

- Tables with metadata errors - `gprestore_<backup-timestamp>_<restore-time>_error_tables_metadata`
- Tables with data errors - `gprestore_<backup-timestamp>_<restore-time>_error_tables_data`

--plugin-config config-file_location

Specify the location of the `gpbackup` plugin configuration file, a YAML-formatted text file. The file contains configuration information for the plugin application that `gprestore` uses during the restore operation.

If you specify the `--plugin-config` option when you back up a database, you must specify this option with configuration information for a corresponding plugin application when you restore the database from the backup.

You cannot combine this option with the option `--backup-dir`.

--quiet

Optional. Suppress all non-warning, non-error log messages.

--redirect-db database_name

Optional. Restore to the specified database_name instead of to the database that was backed up.

--redirect-schema schema_name

Optional. Restore data in the specified schema instead of the original schemas. The specified schema must already exist. If the data being restored is in multiple schemas, all the data is redirected into the specified schema.

This option must be used with an option that includes tables or schemas: `--include-table`, `--include-table-file`, `--include-schema`, or `--include-schema-file`.

You cannot use this option with an option that excludes schemas or tables such as `--exclude-schema` or `--exclude-table`.

You can use this option with the `--metadata-only` or `--data-only` options.

--report-dir /path/to/report

Optional. The absolute path of the directory to which restore report and error tables will be written.

--resize-cluster

Optional. Invoke this option to enable restoring data to a cluster that has a different number of segments than the cluster from which the data was backed up.

Warning: This is a Beta feature and is not supported in a production environment.

> **Note**
>
> In order to enable the `--resize-cluster` feature for `gprestore`, the backup set must have been taking using using `gpbackup` 1.26 or later.

--run-analyze

Optional. Run `ANALYZE` on the tables that are restored. For a partitioned table, `ANALYZE` is run on the root partitioned table. If `--with-stats` was specified for the backup, those statistics are ignored. You cannot use this option with `--with-stats`.

If the backup being restored used the `gpbackup` option `--leaf-partition-data`, `gprestore` runs `ANALYZE` only on the individual leaf partitions that are restored, not the root partitioned table.

Depending the tables being restored, running `ANALYZE` on restored tables might increase the duration of the restore operation.

--timestamp YYYYMMDDHHMMSS

Required. Specifies the timestamp of the `gpbackup` backup set to restore. By default `gprestore` tries to locate metadata files for the timestamp on the WarehousePG Coordinator host in the $COORDINATOR_DATA_DIRECTORY/backups/YYYYMMDD/YYYYMMDDhhmmss/ directory, and CSV data files in the `<seg_dir>/backups/YYYYMMDD/YYYYMMDDhhmmss/` directory of each segment host.

--truncate-table

Optional. Removes existing data from the tables being restored, to eliminate the chance of duplicate data.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

--verbose

Optional. Displays verbose log messages during a restore operation.--versionOptional. Print the version number and exit.

--version

Optional. Displays the verison of the gprestore utility.

--with-globals

Optional. Restores WarehousePG system objects in the backup set, in addition to database objects.

--with-stats

Optional. Restore query plan statistics from the backup set. If the backup set was not created with the `--with-stats` option, an error is returned. Restored tables will only have statistics from the backup. You cannot use this option with `--run-analyze`.

To collect current statistics for the restored tables during the restore operation, use the `--run-analyze` option. As an alternative, you can run the `ANALYZE` command on the tables after the tables are restored.

Return Codes

One of these codes is returned after `gprestore` completes.

- 0 -- Restore completed with no problems.
- 1 -- Restore completed with non-fatal errors. See log file for more information.
- 2 -- Restore failed with a fatal error. See log file for more information.

Examples

Create the ww_customer database and restore all schemas and tables in the backup set for the indicated timestamp:

```
$ dropdb ww_customer
$ gprestore --timestamp 20250515182209 --create-db
```

Restore the backup set to the "customer" database instead of the "demo" database that was backed up:

```
$ createdb customer
$ gprestore --timestamp 20250515182209 --redirect-db customer
```

Restore global WarehousePG metadata and query plan statistics in addition to the database objects:

```
$ gprestore --timestamp 20250515182209 --create-db --with-globals --with-stats
```

Restore, using backup files that were created in the /mnt/nfs/wwhpg_backups directory, creating 8 parallel connections:

```
$ gprestore --backup-dir /mnt/nfs/whpg_backups/ --timestamp 20250515182209 --create-db --jobs 8
```

Restore only the `emea_customer` schema included in the backup set:

```
$ dropdb ww_customer
$ gprestore --include-schema emea_customer --backup-dir /mnt/nfs/whpg_backups/ --timestamp 20250515182209 --create-db
```

If you restore from an incremental backup set, all the required files in the backup set must be available to `gprestore`. For example, the following timestamp keys specify an incremental backup set. 20250518010000 is the full backup and the others are incremental backups.

```
20250518010000 (full backup, Sunday 1am)
20250519020000 (incremental backup, Monday 2am)
20250520030000 (incremental backup, Tuesday 3am)
20250521040000 (incremental backup, Wedndesday 4am)
20250522050000 (incremental backup, Thursday 5am)
20250523060000 (incremental backup, Friday 6am)
20250524070000 (incremental backup, Saturday 7am)
```

The following `gprestore` command specifies the timestamp `20250521040000` (Wednesday). The incremental backup with the timestamps `20250520030000` (Tuesday), `20250519020000` (Monday) and the full backup `20250518010000` (Sunday) must be available to perform a restore.

```
$ gprestore --timestamp 20250521040000 --redirect-db customer_incra --create-db
```

Provides SSH access to multiple hosts at once.

Synopsis

```
gpssh { -f <hostfile_gpssh> | - h <hostname> [-h <hostname> ...] } \[-s\] [-e]
      [-d <seconds>] [-t <multiplier>] [-v]
      [<bash_command>]

gpssh -?

gpssh --version
```

Description

The `gpssh` utility allows you to run bash shell commands on multiple hosts at once using SSH (secure shell). You can run a single command by specifying it on the command-line, or omit the command to enter into an interactive command-line session.

To specify the hosts involved in the SSH session, use the `-f` option to specify a file containing a list of host names, or use the `-h` option to name single host names on the command-line. At least one host name (`-h`) or a host file (`-f`) is required. Note that the current host is ***not*** included in the session by default — to include the local host, you must explicitly declare it in the list of hosts involved in the session.

Before using `gpssh` , you must have a trusted host setup between the hosts involved in the SSH session. You can use the utility `gpssh-exkeys` to update the known host files and exchange public keys between hosts if you have not done so already.

If you do not specify a command on the command-line, `gpssh` will go into interactive mode. At the `gpssh` command prompt (`=>`), you can enter a command as you would in a regular bash terminal command-line, and the command will be run on all hosts involved in the session. To end an interactive session, press `CTRL` + `D` on the keyboard or type `exit` or `quit` .

If a user name is not specified in the host file, `gpssh` will run commands as the currently logged in user. To determine the currently logged in user, do a `whoami` command. By default, `gpssh` goes to `$HOME` of the session user on the remote hosts after login. To ensure commands are run correctly on all remote hosts, you should always enter absolute paths.

If you encounter network timeout problems when using `gpssh` , you can use `-d` and `-t` options or set parameters in the `gpssh.conf` file to control the timing that `gpssh` uses when validating the initial `ssh` connection. For information about the configuration file, see gpssh Configuration File.

Options

bash_command A bash shell command to run on all hosts involved in this session (optionally enclosed in quotes). If not specified, `gpssh` starts an interactive session.

-d (delay) seconds Optional. Specifies the time, in seconds, to wait at the start of a `gpssh` interaction with `ssh` . Default is `0.05` . This option overrides the `delaybeforesend` value that is specified in the `gpssh.conf` configuration file.

Increasing this value can cause a long wait time during `gpssh` startup.

-e (echo) Optional. Echoes the commands passed to each host and their resulting output while running in non-interactive mode.

-f hostfile_gpssh Specifies the name of a file that contains a list of hosts that will participate in this SSH session. The syntax of the host file is one host per line.

-h hostname Specifies a single host name that will participate in this SSH session. You can use the `-h` option multiple times to specify multiple host names.

-s Optional. If specified, before running any commands on the target host, `gpssh` sources the file `greenplum_path.sh` in the directory specified by the `$GPHOME` environment variable.

This option is valid for both interactive mode and single command mode.

-t multiplier Optional. A decimal number greater than 0 (zero) that is the multiplier for the timeout that `gpssh` uses when validating the `ssh` prompt. Default is `1` . This option overrides the `prompt_validation_timeout` value that is specified in the `gpssh.conf` configuration file.

Increasing this value has a small impact during `gpssh` startup.

-v (verbose mode) Optional. Reports additional messages in addition to the command output when running in non-interactive mode.

--version Displays the version of this utility.

-? (help) Displays the online help.

gpssh Configuration File

The `gpssh.conf` file contains parameters that let you adjust the timing that `gpssh` uses when validating the initial `ssh` connection. These parameters affect the network connection before the `gpssh` session runs commands with `ssh` . The location of the file is specified by the environment variable `COORDINATOR_DATA_DIRECTORY` . If the environment variable is not defined or the `gpssh.conf` file does not exist, `gpssh` uses the default values or the values set with the `-d` and `-t` options. For information about the environment variable, see the *WarehousePG Reference Guide*.

The `gpssh.conf` file is a text file that consists of a `[gpssh]` section and parameters. On a line, the `#` (pound sign) indicates the start of a comment. This is an example `gpssh.conf` file.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
[gpssh]
delaybeforesend = 0.05
prompt_validation_timeout = 1.0
sync_retries = 5
```

These are the `gpssh.conf` parameters.

delaybeforesend = seconds Specifies the time, in seconds, to wait at the start of a `gpssh` interaction with `ssh`. Default is 0.05. Increasing this value can cause a long wait time during `gpssh` startup. The `-d` option overrides this parameter.

prompt_validation_timeout = multiplier A decimal number greater than 0 (zero) that is the multiplier for the timeout that `gpssh` uses when validating the `ssh` prompt. Increasing this value has a small impact during `gpssh` startup. Default is `1`. The `-t` option overrides this parameter.

sync_retries = attempts A non-negative integer that specifies the maximum number of times that `gpssh` attempts to connect to a remote WarehousePG host. The default is 3. If the value is 0, `gpssh` returns an error if the initial connection attempt fails. Increasing the number of attempts also increases the time between retry attempts. This parameter cannot be configured with a command-line option.

The `-t` option also affects the time between retry attempts.

Increasing this value can compensate for slow network performance or segment host performance issues such as heavy CPU or I/O load. However, when a connection cannot be established, an increased value also increases the delay when an error is returned.

Examples

Start an interactive group SSH session with all hosts listed in the file `hostfile_gpssh`:

```
$ gpssh -f hostfile_gpssh
```

At the `gpssh` interactive command prompt, run a shell command on all the hosts involved in this session.

```
=> ls -a /data/primary/*
```

Exit an interactive session:

```
=> exit
=> quit
```

Start a non-interactive group SSH session with the hosts named `sdw1` and `sdw2` and pass a file containing several commands named `command_file` to `gpssh`:

```
$ gpssh -h sdw1 -h sdw2 -v -e < command_file
```

Run single commands in non-interactive mode on hosts `sdw2` and `localhost`:

```
$ gpssh -h sdw2 -h localhost -v -e 'ls -a /data/primary/*'
$ gpssh -h sdw2 -h localhost -v -e 'echo $GPHOME'
$ gpssh -h sdw2 -h localhost -v -e 'ls -1 | wc -l'
```

7.7.2.27 gpssh-exkeys

Exchanges SSH public keys between hosts.

Synopsis

```
gpssh-exkeys -f <hostfile_exkeys> | -h <hostname> [-h <hostname> ...]

gpssh-exkeys -e <hostfile_exkeys> -x <hostfile_gpexpand>

gpssh-exkeys -?

gpssh-exkeys --version
```

Description

The `gpssh-exkeys` utility exchanges SSH keys between the specified host names (or host addresses). This allows SSH connections between WarehousePG hosts and network interfaces without a password prompt. The utility is used to initially prepare a WarehousePG cluster for passwordless SSH access, and also to prepare additional hosts for passwordless SSH access when expanding a WarehousePG cluster.

Keys are exchanged as the currently logged in user. You run the utility on the coordinator host as the `gpadmin` user (the user designated to own your WarehousePG installation). WarehousePG management utilities require that the `gpadmin` user be created on all hosts in the WarehousePG cluster, and the utilities must be able to connect as that user to all hosts without a password prompt.

You can also use `gpssh-exkeys` to enable passwordless SSH for additional users, `root`, for example.

The `gpssh-exkeys` utility has the following prerequisites:

- The user must have an account on the coordinator, standby, and every segment host in the WarehousePG cluster.
- The user must have an `id_rsa` SSH key pair installed on the coordinator host.
- The user must be able to connect with SSH from the coordinator host to every other host machine without entering a password. (This is called "1-*n* passwordless SSH.")

You can enable 1-*n* passwordless SSH using the `ssh-copy-id` command to add the user's public key to each host's `authorized_keys` file. The `gpssh-exkeys` utility enables "*n*-*n* passwordless SSH," which allows the user to connect with SSH from any host to any other host in the cluster without a password.

To specify the hosts involved in an SSH key exchange, use the `-f` option to specify a file containing a list of host names (recommended), or use the `-h` option to name single host names on the command-line. At least one host name (`-h`) or a host file (`-f`) is required. Note that the local host is included in the key exchange by default.

To specify new expansion hosts to be added to an existing WarehousePG cluster, use the `-e` and `-x` options. The `-e` option specifies a file containing a list of existing hosts in the system that have already exchanged SSH keys. The `-x` option specifies a file containing a list of new hosts that need to participate in the SSH key exchange.

The `gpssh-exkeys` utility performs key exchange using the following steps:

- Adds the user's public key to the user's own `authorized_keys` file on the current host.
- Updates the `known_hosts` file of the current user with the host key of each host specified using the `-h`, `-f`, `-e`, and `-x` options.
- Connects to each host using `ssh` and obtains the user's `authorized_keys`, `known_hosts`, and `id_rsa.pub` files.
- Adds keys from the `id_rsa.pub` files obtained from each host to the `authorized_keys` file of the current user.
- Updates the `authorized_keys`, `known_hosts`, and `id_rsa.pub` files on all hosts with new host information (if any).

Options

-e hostfile_exkeys When doing a system expansion, this is the name and location of a file containing all configured host names and host addresses (interface names) for each host in your current WarehousePG cluster (coordinator, standby coordinator, and segments), one name per line without blank lines or extra spaces. Hosts specified in this file cannot be specified in the host file used with `-x`.

-f hostfile_exkeys Specifies the name and location of a file containing all configured host names and host addresses (interface names) for each host in your WarehousePG cluster (coordinator, standby coordinator and segments), one name per line without blank lines or extra spaces.

-h hostname Specifies a single host name (or host address) that will participate in the SSH key exchange. You can use the `-h` option multiple times to specify multiple host names and host addresses.

--version Displays the version of this utility.

-x hostfile_gpexpand When doing a system expansion, this is the name and location of a file containing all configured host names and host addresses (interface names) for each new segment host you are adding to your WarehousePG cluster, one name per line without blank lines or extra spaces. Hosts specified in this file cannot be specified in the host file used with `-e`.

-? (help) Displays the online help.

Examples

Exchange SSH keys between all host names and addresses listed in the file `hostfile_exkeys`:

```
$ gpssh-exkeys -f hostfile_exkeys
```

Exchange SSH keys between the hosts `sdw1`, `sdw2`, and `sdw3`:

```
$ gpssh-exkeys -h sdw1 -h sdw2 -h sdw3
```

Exchange SSH keys between existing hosts `sdw1`, `sdw2`, and `sdw3`, and new hosts `sdw4` and `sdw5` as part of a system expansion operation:

7.7.2.28 gpstart

Starts a WarehousePG cluster.

Synopsis

```
gpstart [-d <coordinator_data_directory>] [-B <parallel_processes>] [-R]
        [-m] [-y] [-a] [-t <timeout_seconds>] [-l <logfile_directory>]
        [--skip-heap-checksum-validation]
        [-v | -q]

gpstart -? | -h | --help

gpstart --version
```

Description

The `gpstart` utility is used to start the WarehousePG server processes. When you start a WarehousePG cluster, you are actually starting several `postgres` database server listener processes at once (the coordinator and all of the segment instances). The `gpstart` utility handles the startup of the individual instances. Each instance is started in parallel.

As part of the startup process, the utility checks the consistency of heap checksum setting among the WarehousePG coordinator and segment instances, either enabled or deactivated on all instances. If the heap checksum setting is different among the instances, an error is returned and WarehousePG does not start. The validation can be deactivated by specifying the option `--skip-heap-checksum-validation`. For more information about heap checksums, see Enabling High Availability and Data Consistency Features in the *WarehousePG Administrator Guide*.

> **Note** Before you can start a WarehousePG cluster, you must have initialized the system using `gpinitsystem`. Enabling or deactivating heap checksums is set when you initialize the system and cannot be changed after initialization.

If the WarehousePG cluster is configured with a standby coordinator, and `gpstart` does not detect it during startup, `gpstart` displays a warning and lets you cancel the startup operation.

- If the `-a` option (deactivate interactive mode prompts) is not specified, `gpstart` displays and logs these messages:

  ```
  Standby host is unreachable, cannot determine whether the standby is currently acting as the coordinator. Received error: <error>
  Continue only if you are certain that the standby is not acting as the coordinator.
  ```

  It also displays this prompt to continue startup:

  ```
  Continue with startup Yy|Nn (default=N):
  ```

- If the `-a` option is specified, the utility does not start the system. The messages are only logged, and `gpstart` adds this log message:

  ```
  Non interactive mode detected. Not starting the cluster. Start the cluster in interactive mode.
  ```

If the standby coordinator is not accessible, you can start the system and troubleshoot standby coordinator issues while the system is available.

Options

-a Do not prompt the user for confirmation. Deactivates interactive mode.

-B parallel_processes The number of segments to start in parallel. If not specified, the utility will start up to 64 parallel processes depending on how many segment instances it needs to start.

-d coordinator_data_directory Optional. The coordinator host data directory. If not specified, the value set for `$COORDINATOR_DATA_DIRECTORY` will be used.

-l logfile_directory The directory to write the log file. Defaults to `~/gpAdminLogs`.

-m Optional. Starts the coordinator instance only, which may be useful for maintenance tasks. This mode only allows connections to the coordinator in utility mode. For example:

`PGOPTIONS='-c gp_role=utility' psql`

The consistency of the heap checksum setting on coordinator and segment instances is not checked.

-q Run in quiet mode. Command output is not displayed on the screen, but is still written to the log file.

-R Starts WarehousePG in restricted mode (only database superusers are allowed to connect).

--skip-heap-checksum-validation During startup, the utility does not validate the consistency of the heap checksum setting among the WarehousePG coordinator and segment instances. The default is to ensure that the heap checksum setting is the same on all instances, either enabled or deactivated.

```
> **Caution** Starting WarehousePG without this validation could lead to data loss. Use this option to start WarehousePG only when it is necessary to ignore the heap checksum verification errors to recover data or to troubleshoot the errors.
```

-t timeout_seconds Specifies a timeout in seconds to wait for a segment instance to start up. If a segment instance was shutdown abnormally (due to power failure or killing its `postgres` database listener process, for example), it may take longer to start up due to the database recovery and validation process. If not specified, the default timeout is 600 seconds.

-v Displays detailed status, progress and error messages output by the utility.

-y Optional. Do not start the standby coordinator host. The default is to start the standby coordinator host and synchronization process.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

-? | -h | --help Displays the online help.

--version Displays the version of this utility.

Examples

Start a WarehousePG cluster:

```
gpstart
```

Start a WarehousePG cluster in restricted mode (only allow superuser connections):

```
gpstart -R
```

Start the WarehousePG coordinator instance only and connect in utility mode:

```
gpstart -m
PGOPTIONS='-c gp_role=utility' psql
```

7.7.2.29 gpstate

Shows the status of a running WarehousePG cluster.

Synopsis

```
gpstate [-d <coordinator_data_directory>] [-B <parallel_processes>]
          [-s | -b | -Q \| -e\] \[-m \| -c] [-p] [-i] [-f] [-v | -q] | -x
          [-l <log_directory>]

gpstate -? | -h | --help
```

Description

The `gpstate` utility displays information about a running WarehousePG instance. There is additional information you may want to know about a WarehousePG cluster, since it is comprised of multiple PostgreSQL database instances (segments) spanning multiple machines. The `gpstate` utility provides additional status information for a WarehousePG cluster, such as:

- Which segments are down.
- Coordinator and segment configuration information (hosts, data directories, etc.).
- The ports used by the system.
- A mapping of primary segments to their corresponding mirror segments.

Options

-b (brief status) Optional. Display a brief summary of the state of the WarehousePG cluster. This is the default option.

-B parallel_processes The number of segments to check in parallel. If not specified, the utility will start up to 60 parallel processes depending on how many segment instances it needs to check.

-c (show primary to mirror mappings) Optional. Display mapping of primary segments to their corresponding mirror segments.

-d coordinator_data_directory Optional. The coordinator data directory. If not specified, the value set for `$COORDINATOR_DATA_DIRECTORY` will be used.

-e (show segments with mirror status issues) Show details on primary/mirror segment pairs that have potential issues. These issues include:

```
-   Whether any segments are down.
-   Whether any primary-mirror segment pairs are out of sync - including information on how many bytes are remaining to sync \(as displayed in the `WAL sync
remaining bytes` output field\).

    > **Note** `gpstate -e` does not display segment pairs that are in sync.

    > **Note** You must have `rsync` version 3.1.x or higher installed in order to view the tracking information for segments undergoing a differential recovery.

-   Whether any primary-mirror segment pairs are not in their preferred roles.
```

-f (show standby coordinator details) Display details of the standby coordinator host if configured.

-i (show WarehousePG version) Display the WarehousePG software version information for each instance.

-l logfile_directory The directory to write the log file. Defaults to `~/gpAdminLogs`.

-m (list mirrors) Optional. List the mirror segment instances in the system and their current role.

-p (show ports) List the port numbers used throughout the WarehousePG cluster.

-q (no screen output) Optional. Run in quiet mode. Except for warning messages, command output is not displayed on the screen. However, this information is still written to the log file.

-Q (quick status) Optional. Checks segment status in the system catalog on the coordinator host. Does not poll the segments for status.

-s (detailed status) Optional. Displays detailed status information about the WarehousePG cluster.

-v (verbose output) Optional. Displays error messages and outputs detailed status and progress information.

-x (expand) Optional. Displays detailed information about the progress and state of a WarehousePG cluster expansion.

-? | -h | --help (help) Displays the online help.

Output Field Definitions

The following output fields are reported by `gpstate -s` for the coordinator:

Output Data	Description
Coordinator host	host name of the coordinator
Coordinator postgres process ID	PID of the coordinator database listener process

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Output Data	Description
Coordinator data directory	file system location of the coordinator data directory
Coordinator port	port of the coordinator `postgres` database listener process
Coordinator current role	dispatch = regular operating mode utility = maintenance mode
WarehousePG cluster configuration type	Standard = one NIC per host Multi-Home = multiple NICs per host
WarehousePG initsystem version	version of WarehousePG when system was first initialized
WarehousePG current version	current version of WarehousePG
Postgres version	version of PostgreSQL that WarehousePG is based on
WarehousePG mirroring status	physical mirroring or none
Coordinator standby	host name of the standby coordinator
Standby coordinator state	status of the standby coordinator: active or passive

The following output fields are reported by `gpstate -s` for each primary segment:

Output Data	Description
Hostname	system-configured host name
Address	network address host name (NIC name)
Datadir	file system location of segment data directory
Port	port number of segment `postgres` database listener process
Current Role	current role of a segment: Mirror or Primary
Preferred Role	role at system initialization time: Mirror or Primary
Mirror Status	status of a primary/mirror segment pair: Synchronized = data is up to date on both Not in Sync = the mirror segment has not caught up to the primary segment
Current write location	Location where primary segment is writing new logs as they come in
Bytes remaining to send to mirror	Bytes remaining to be sent from primary to mirror
Active PID	active process ID of a segment
Coordinator reports status as	segment status as reported in the system catalog: Up or Down
Database status	status of WarehousePG to incoming requests: Up, Down, or Suspended. A Suspended state means database activity is temporarily paused while a segment transitions from one state to another.

The following output fields are reported by `gpstate -s` for each mirror segment:

Output Data	Description
Hostname	system-configured host name
Address	network address host name (NIC name)
Datadir	file system location of segment data directory
Port	port number of segment `postgres` database listener process
Current Role	current role of a segment: Mirror or Primary
Preferred Role	role at system initialization time: Mirror or Primary
Mirror Status	status of a primary/mirror segment pair: Synchronized = data is up to date on both Not in Sync = the mirror segment has not caught up to the primary segment
WAL Sent Location	Log location up to which the primary segment has sent log data to the mirror
WAL Flush Location	Log location up to which the mirror segment has flushed the log data to disk
WAL Replay Location	Log location up to which the mirror segment has replayed logs locally
Bytes received but remain to flush	Difference between flush log location and sent log location
Bytes received but remain to replay	Difference between replay log location and sent log location
Active PID	active process ID of a segment
Coordinator reports status as	segment status as reported in the system catalog: Up or Down
Database status	status of WarehousePG to incoming requests: Up, Down, or Suspended. A Suspended state means database activity is temporarily paused while a segment transitions from one state to another.

> **Note** When there is no connection between a primary segment and its mirror, `gpstate -s` displays `Unknown` in the following fields:

- `Bytes remaining to send to mirror`
- `WAL Sent Location`
- `WAL Flush Location`
- `WAL Replay Location`
- `Bytes received but remain to flush`
- `Bytes received but remain to replay`

The following output fields are reported by `gpstate -f` for standby coordinator replication status:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Output Data	Description
Standby address	hostname of the standby coordinator
Standby data dir	file system location of the standby coordinator data directory
Standby port	port of the standby coordinator `postgres` database listener process
Standby PID	process ID of the standby coordinator
Standby status	status of the standby coordinator: Standby host passive
WAL Sender State	write-ahead log (WAL) streaming state: streaming, startup,backup, catchup
Sync state	WAL sender synchronization state: sync
Sent Location	WAL sender transaction log (xlog) record sent location
Flush Location	WAL receiver xlog record flush location
Replay Location	standby xlog record replay location

Examples

Show detailed status information of a WarehousePG cluster:

```
gpstate -s
```

Do a quick check for down segments in the coordinator host system catalog:

```
gpstate -Q
```

Show information about mirror segment instances:

```
gpstate -m
```

Show information about the standby coordinator configuration:

```
gpstate -f
```

Display the WarehousePG software version information:

```
gpstate -i
```

7.7.2.30 gpstop

Stops or restarts a WarehousePG cluster.

Synopsis

```
gpstop [-d <coordinator_data_directory>] [-B parallel_processes>]
       [-M smart | fast | immediate] [-t <timeout_seconds>] [-r] [-y] [-a]
       [-l <logfile_directory>] [-v | -q]

gpstop -m [-d <coordinator_data_directory>] [-y] [-l <logfile_directory>] [-v | -q]

gpstop -u [-d <coordinator_data_directory>] [-l <logfile_directory>] [-v | -q]

gpstop --host <host_namea> [-d <coordinator_data_directory>] [-l <logfile_directory>]
       [-t <timeout_seconds>] [-a] [-v | -q]

gpstop --version

gpstop -? | -h | --help
```

Description

The `gpstop` utility is used to stop the database servers that comprise a WarehousePG cluster. When you stop a WarehousePG cluster, you are actually stopping several `postgres` database server processes at once (the coordinator and all of the segment instances). The `gpstop` utility handles the shutdown of the individual instances. Each instance is shutdown in parallel.

The default shutdown mode (`-M smart`) waits for current client connections to finish before completing the shutdown. If any connections remain open after the timeout period, or if you interrupt with CTRL-C `gpstop` lists the open connections and prompts whether to continue waiting for connections to finish, or to perform a fast or immediate shutdown. The default timeout period is 120 seconds and can be changed with the `-t timeout\_seconds` option.

Specify the `-M fast` shutdown mode to roll back all in-progress transactions and terminate any connections before shutting down.

With the `-u` option, the utility uploads changes made to the coordinator `pg_hba.conf` file or to *runtime* configuration parameters in the coordinator `postgresql.conf` file without interruption of service. Note that any active sessions will not pick up the changes until they reconnect to the database.

Options

-a Do not prompt the user for confirmation.

-B parallel_processes The number of segments to stop in parallel. If not specified, the utility will start up to 64 parallel processes depending on how many segment instances it needs to stop.

-d coordinator_data_directory Optional. The coordinator host data directory. If not specified, the value set for `$COORDINATOR_DATA_DIRECTORY` will be used.

--host host_name The utility shuts down the WarehousePG segment instances on the specified host to allow maintenance on the host. Each primary segment instance on the host is shut down and the associated mirror segment instance is promoted to a primary segment if the mirror segment is on another host. Mirror segment instances on the host are shut down.

The segment instances are not shut down and the utility returns an error in these cases:

```
-   Segment mirroring is not enabled for the system.
-   The coordinator or standby coordinator is on the host.
-   Both a primary segment instance and its mirror are on the host.
```

This option cannot be specified with the `-m` , `-r` , `-u` , or `-y` options.

```
> **Note** The `gprecoverseg` utility restores segment instances. Run `gprecoverseg` commands to start the segments as mirrors and then to return the segments to
their preferred role \(primary segments\).
```

-l logfile_directory The directory to write the log file. Defaults to `~/gpAdminLogs` .

-m Optional. Shuts down a WarehousePG coordinator instance that was started in maintenance mode.

-M fast Fast shut down. Any transactions in progress are interrupted and rolled back.

-M immediate Immediate shut down. Any transactions in progress are cancelled.

This mode kills all `postgres` processes without allowing the database server to complete transaction processing or clean up any temporary or in-process work files.

-M smart Smart shut down. This is the default shutdown mode. `gpstop` waits for active user connections to disconnect and then proceeds with the shutdown. If any user connections remain open after the timeout period (or if you interrupt by pressing CTRL-C) `gpstop` lists the open user connections and prompts whether to continue waiting for connections to finish, or to perform a fast or immediate shutdown.

-q Run in quiet mode. Command output is not displayed on the screen, but is still written to the log file.

-r Restart after shutdown is complete.

-t timeout_seconds Specifies a timeout threshold (in seconds) to wait for a segment instance to shutdown. If a segment instance does not shutdown in the specified number of seconds, `gpstop` displays a message indicating that one or more segments are still in the process of shutting down and that you cannot restart WarehousePG until the segment instance(s) are stopped. This option is useful in situations where `gpstop` is run and there are very large transactions that need to rollback. These large transactions can take over a minute to rollback and surpass the default timeout period of 120 seconds.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

-u This option reloads the `pg_hba.conf` files of the coordinator and segments and the runtime parameters of the `postgresql.conf` files but does not shutdown the WarehousePG cluster. Use this option to make new configuration settings active after editing `postgresql.conf` or `pg_hba.conf`. Note that this only applies to configuration parameters that are designated as *runtime* parameters.

-v Displays detailed status, progress and error messages output by the utility.

-y Do not stop the standby coordinator process. The default is to stop the standby coordinator.

-? | -h | --help Displays the online help.

--version Displays the version of this utility.

Examples

Stop a WarehousePG cluster in smart mode:

```
gpstop
```

Stop a WarehousePG cluster in fast mode:

```
gpstop -M fast
```

Stop all segment instances and then restart the system:

```
gpstop -r
```

Stop a coordinator instance that was started in maintenance mode:

```
gpstop -m
```

Reload the `postgresql.conf` and `pg_hba.conf` files after making configuration changes but do not shutdown the WarehousePG cluster:

```
gpstop -u
```

7.7.2.31 gpsync

Copies files between multiple hosts at once.

Synopsis

```
gpsync { -f <hostfile_gpssh> | -h <hostname> [-h <hostname> ...] }
      [-a][-J <character>] [-v] [[<user>@]<hostname>:]<file_to_copy> [...]
      [[<user>@]<hostname>:]<copy_to_path>

gpsync -?

gpsync --version
```

Description

The `gpsync` utility allows you to copy one or more files from the specified hosts to other specified hosts in one command using remote sync. For example, you can copy a file from the WarehousePG coordinator host to all of the segment hosts at the same time.

To specify the hosts involved in the remote sync session, use the `-f` option to specify a file containing a list of host names, or use the `-h` option to name single host names on the command-line. At least one host name (`-h`) or a host file (`-f`) is required. The `-J` option allows you to specify a single character to substitute for the hostname in the `copy from` and `copy to` destination strings. If `-J` is not specified, the default substitution character is an equal sign (`=`). For example, the following command will copy `.bashrc` from the local host to `/home/gpadmin` on all hosts named in `hostfile_gpssh` :

```
gpsync -f hostfile_gpssh .bashrc =:/home/gpadmin
```

If a user name is not specified in the host list or with user `@` in the file path, `gpsync` will copy files as the currently logged in user. To determine the currently logged in user, do a `whoami` command. By default, `gpsync` goes to `$HOME` of the session user on the remote hosts after login. To ensure the file is copied to the correct location on the remote hosts, it is recommended that you use absolute paths.

Before using `gpsync` , you must have a trusted host setup between the hosts involved in the remote sync session. You can use the utility `gpssh-exkeys` to update the known host files and exchange public keys between hosts if you have not done so already.

Options

-f hostfile_gpssh Specifies the name of a file that contains a list of hosts that will participate in this remote sync session. The syntax of the host file is one host per line as follows:

```
<hostname>
```

-h hostname

Specifies a single host name that will participate in this remote sync session. You can use the `-h` option multiple times to specify multiple host names.

-a

Sync source and target directories in archival mode.

-J character

The `-J` option allows you to specify a single character to substitute for the hostname in the `copy from` and `copy to` destination strings. If `-J` is not specified, the default substitution character is an equal sign (`=`).

-v (verbose mode)

Optional. Reports additional messages in addition to the remote sync command output.

file_to_copy

Required. The file name (or absolute path) of a file that you want to copy to other hosts (or file locations). This can be either a file on the local host or on another named host.

copy_to_path

Required. The path where you want the file(s) to be copied on the named hosts. If an absolute path is not used, the file will be copied relative to `$HOME` of the session user. You can also use the equal sign ' `=` ' (or another character that you specify with the `-J` option) in place of a hostname. This will then substitute in each host name as specified in the supplied host file (`-f`) or with the `-h` option.

-? (help)

Displays the online help.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

--version

Displays the version of this utility.

Examples

Copy the file named `installer.tar` to `/` on all the hosts in the file `hostfile_gpssh`.

```
gpsync -f hostfile_gpssh installer.tar =:/
```

Copy the file named myfuncs.so to the specified location on the hosts named `sdw1` and `sdw2`:

```
gpsync -h sdw1 -h sdw2 myfuncs.so =:/usr/edb/whpg7/lib
```

7.7.2.32 pg_config

Retrieves information about the installed version of WarehousePG.

Synopsis

```
pg_config [<option> ...]

pg_config -? | --help

pg_config --gp_version
```

Description

The `pg_config` utility prints configuration parameters of the currently installed version of WarehousePG. It is intended, for example, to be used by software packages that want to interface to WarehousePG to facilitate finding the required header files and libraries. Note that information printed out by `pg_config` is for the WarehousePG coordinator only.

If more than one option is given, the information is printed in that order, one item per line. If no options are given, all available information is printed, with labels.

Options

--bindir Print the location of user executables. Use this, for example, to find the `psql` program. This is normally also the location where the `pg_config` program resides.

--docdir Print the location of documentation files.

--includedir Print the location of C header files of the client interfaces.

--pkgincludedir Print the location of other C header files.

--includedir-server Print the location of C header files for server programming.

--libdir Print the location of object code libraries.

--pkglibdir Print the location of dynamically loadable modules, or where the server would search for them. (Other architecture-dependent data files may also be installed in this directory.)

--localedir Print the location of locale support files.

--mandir Print the location of manual pages.

--sharedir Print the location of architecture-independent support files.

--sysconfdir Print the location of system-wide configuration files.

--pgxs Print the location of extension makefiles.

--configure Print the options that were given to the configure script when WarehousePG was configured for building.

--cc Print the value of the CC variable that was used for building WarehousePG. This shows the C compiler used.

--cppflags Print the value of the `CPPFLAGS` variable that was used for building WarehousePG. This shows C compiler switches needed at preprocessing time.

--cflags Print the value of the `CFLAGS` variable that was used for building WarehousePG. This shows C compiler switches.

--cflags_sl Print the value of the `CFLAGS_SL` variable that was used for building WarehousePG. This shows extra C compiler switches used for building shared libraries.

--ldflags Print the value of the `LDFLAGS` variable that was used for building WarehousePG. This shows linker switches.

--ldflags_ex Print the value of the `LDFLAGS_EX` variable that was used for building WarehousePG. This shows linker switches that were used for building executables only.

--ldflags_sl Print the value of the `LDFLAGS_SL` variable that was used for building WarehousePG. This shows linker switches used for building shared libraries only.

--libs Print the value of the `LIBS` variable that was used for building WarehousePG. This normally contains `-l` switches for external libraries linked into WarehousePG.

--version Print the version of PostgreSQL backend server.

--gp_version Print the version of WarehousePG.

Examples

To reproduce the build configuration of the current WarehousePG installation, run the following command:

```
eval ./configure 'pg_config --configure'
```

The output of `pg_config --configure` contains shell quotation marks so arguments with spaces are represented correctly. Therefore, using `eval` is required for proper results.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.7.2.33 pg_dump

Extracts a database into a single script file or other archive file.

Synopsis

```
pg_dump [<connection-option> ...] [<dump_option> ...] [<dbname>]

pg_dump -? | --help

pg_dump -V | --version
```

Description

`pg_dump` is a standard PostgreSQL utility for backing up a database, and is also supported in WarehousePG. It creates a single (non-parallel) dump file. For routine backups of WarehousePG, it is better to use the WarehousePG backup utility, `gpbackup`, for the best performance.

Use `pg_dump` if you are migrating your data to another database vendor's system, or to another WarehousePG cluster with a different segment configuration (for example, if the system you are migrating to has greater or fewer segment instances). To restore, you must use the corresponding pg_restore utility (if the dump file is in archive format), or you can use a client program such aspsql (if the dump file is in plain text format).

Since `pg_dump` is compatible with regular PostgreSQL, it can be used to migrate data into WarehousePG. The `pg_dump` utility in WarehousePG is very similar to the PostgreSQL `pg_dump` utility, with the following exceptions and limitations:

- If using `pg_dump` to backup a WarehousePG database, keep in mind that the dump operation can take a long time (several hours) for very large databases. Also, you must make sure you have sufficient disk space to create the dump file.
- If you are migrating data from one WarehousePG cluster to another, use the `--gp-syntax` command-line option to include the `DISTRIBUTED BY` clause in `CREATE TABLE` statements. This ensures that WarehousePG table data is distributed with the correct distribution key columns upon restore.

`pg_dump` makes consistent backups even if the database is being used concurrently. `pg_dump` does not block other users accessing the database (readers or writers).

When used with one of the archive file formats and combined with `pg_restore`, `pg_dump` provides a flexible archival and transfer mechanism. `pg_dump` can be used to backup an entire database, then `pg_restore` can be used to examine the archive and/or select which parts of the database are to be restored. The most flexible output file formats are the custom format (`-Fc`) and the directory format (`-Fd`). They allow for selection and reordering of all archived items, support parallel restoration, and are compressed by default. The directory format is the only format that supports parallel dumps.

Options

\<dbname> Specifies the name of the database to be dumped. If this is not specified, the environment variable `PGDATABASE` is used. If that is not set, the user name specified for the connection is used.

Dump Options

-a | --data-only Dump only the data, not the schema (data definitions). Table data and sequence values are dumped.

This option is similar to, but for historical reasons not identical to, specifying `--section=data`.

-b | --blobs Include large objects in the dump. This is the default behavior except when `--schema`, `--table`, or `--schema-only` is specified. The `-b` switch is only useful add large objects to dumps where a specific schema or table has been requested. Note that blobs are considered data and therefore will be included when `--data-only` is used, but not when `--schema-only` is.

```
> **Note** WarehousePG does not support the PostgreSQL [large object facility](https://www.postgresql.org/docs/12/largeobjects.html) for streaming user data that is stored in large-object structures.
```

-B | --no-blobs Exclude large objects in the dump.

When both `-b` and `-B` are specified, `pg_dump` outputs large objects, when data is being dumped, see the `-b` documentation.

```
> **Note** WarehousePG does not support the PostgreSQL [large object facility](https://www.postgresql.org/docs/12/largeobjects.html) for streaming user data that is stored in large-object structures.
```

-c | --clean Adds commands to the text output file to clean (drop) database objects prior to outputting the commands for creating them. (Restore might generate some harmless error messages, if any objects were not present in the destination database.) Note that objects are not dropped before the dump operation begins, but `DROP` commands are added to the DDL dump output files so that when you use those files to do a restore, the `DROP` commands are run prior to the `CREATE` commands. This option is only meaningful for the plain-text format. For the archive formats, you may specify the option when you callpg_restore.

-C | --create Begin the output with a command to create the database itself and reconnect to the created database. (With a script of this form, it doesn't matter which database in the destination installation you connect to before running the script.) If `--clean` is also specified, the script drops and recreates the target database before reconnecting to it. This option is only meaningful for the plain-text format. For the archive formats, you may specify the option when you call pg_restore. With `--create`, the output also includes the database's comment if any, and any configuration variable settings that are specific to this database, that is, any `ALTER DATABASE ... SET ...` and `ALTER ROLE ... IN DATABASE ... SET ...` commands that mention this database. Access privileges for the database itself are also dumped, unless `--no-acl` is specified.

-E \<encoding> | --encoding=\<encoding> Create the dump in the specified character set encoding. By default, the dump is created in the database encoding. (Another way to get the same result is to set the `PGCLIENTENCODING` environment variable to the desired dump encoding.)

-f \<file> | --file=\<file> Send output to the specified file. This parameter can be omitted for file-based output formats, in which case the standard output is used. It must be given for the directory output format however, where it specifies the target directory instead of a file. In this case the directory is created by `pg_dump` and must not exist before.

-F p|c|d|t | --format=plain|custom|directory|tar Selects the format of the output. format can be one of the following:

- p | plain — Output a plain-text SQL script file (the default).
- c | custom — Output a custom archive suitable for input into pg_restore. Together with the directory output format, this is the most flexible output format in that it allows manual selection and reordering of archived items during restore. This format is compressed by default.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

- d | directory — Output a directory-format archive suitable for input into `pg_restore`. This will create a directory with one file for each table and blob being dumped, plus a so-called Table of Contents file describing the dumped objects in a machine-readable format that `pg_restore` can read. A directory format archive can be manipulated with standard Unix tools; for example, files in an uncompressed archive can be compressed with the `gzip` tool. This format is compressed by default and also supports parallel dumps.
- t | tar — Output a tar-format archive suitable for input into pg_restore. The tar format is compatible with the directory format; extracting a tar-format archive produces a valid directory-format archive. However, the tar format does not support compression. Also, when using tar format the relative order of table data items cannot be changed during restore.

-j \<njobs> | --jobs=\<njobs> Run the dump in parallel by dumping \<njobs> tables simultaneously. This option reduces the time of the dump but it also increases the load on the database server. You can only use this option with the directory output format because this is the only output format where multiple processes can write their data at the same time.

> **Note** Parallel dumps using `pg_dump` are parallelized only on the query dispatcher (coordinator) node, not across the query executor (segment) nodes as is the case when you use `gpbackup`.

`pg_dump` will open \<njobs> + 1 connections to the database, so make sure your max_connections setting is high enough to accommodate all connections.

Requesting exclusive locks on database objects while running a parallel dump could cause the dump to fail. The reason is that the `pg_dump` coordinator process requests shared locks on the objects that the worker processes are going to dump later in order to make sure that nobody deletes them and makes them go away while the dump is running. If another client then requests an exclusive lock on a table, that lock will not be granted but will be queued waiting for the shared lock of the coordinator process to be released. Consequently, any other access to the table will not be granted either and will queue after the exclusive lock request. This includes the worker process trying to dump the table. Without any precautions this would be a classic deadlock situation. To detect this conflict, the `pg_dump` worker process requests another shared lock using the `NOWAIT` option. If the worker process is not granted this shared lock, somebody else must have requested an exclusive lock in the meantime and there is no way to continue with the dump, so `pg_dump` has no choice but to cancel the dump.

For a consistent backup, the database server needs to support synchronized snapshots, a feature that was introduced in WarehousePG 6.0. With this feature, database clients can ensure they see the same data set even though they use different connections. `pg_dump -j` uses multiple database connections; it connects to the database once with the coordinator process and once again for each worker job. Without the synchronized snapshot feature, the different worker jobs wouldn't be guaranteed to see the same data in each connection, which could lead to an inconsistent backup.

If you want to run a parallel dump of a pre-6.0 server, you need to make sure that the database content doesn't change from between the time the coordinator connects to the database until the last worker job has connected to the database. The easiest way to do this is to halt any data modifying processes (DDL and DML) accessing the database before starting the backup. You also need to specify the `--no-synchronized-snapshots` parameter when running `pg_dump -j` against a pre-6.0 WarehousePG server.

-n \<pattern> | --schema=\<pattern> Dump only schemas matching the schema pattern; this selects both the schema itself, and all its contained objects. When this option is not specified, all non-system schemas in the target database will be dumped. Multiple schemas can be selected by writing multiple `-n` switches. Also, the pattern parameter is interpreted as a pattern according to the same rules used by `psql`'s `\d` commands, so multiple schemas can also be selected by writing wildcard characters in the pattern. When using wildcards, be careful to quote the pattern if needed to prevent the shell from expanding the wildcards.

When `-n` is specified, `pg_dump` makes no attempt to dump any other database objects that the selected schema(s) may depend upon. Therefore, there is no guarantee that the results of a specific-schema dump can be successfully restored by themselves into a clean database.

```
> **Note** Non-schema objects such as blobs are not dumped when `-n` is specified. You can add blobs back to the dump with the `--blobs` switch.
```

-N \<pattern> | --exclude-schema=\<pattern> Do not dump any schemas matching the pattern. The pattern is interpreted according to the same rules as for `-n`. `-N` can be specified more than once to exclude schemas matching any of several patterns. When both `-n` and `-N` are specified, the behavior is to dump just the schemas that match at least one `-n` switch but no `-N` switches. If `-N` appears without `-n`, then schemas matching `-N` are excluded from what is otherwise a normal dump.

-O | --no-owner Do not output commands to set ownership of objects to match the original database. By default, `pg_dump` issues `ALTER OWNER` or `SET SESSION AUTHORIZATION` statements to set ownership of created database objects. These statements will fail when the script is run unless it is started by a superuser (or the same user that owns all of the objects in the script). To make a script that can be restored by any user, but will give that user ownership of all the objects, specify `-O`. This option is only meaningful for the plain-text format. For the archive formats, you may specify the option when you call pg_restore.

-s | --schema-only Dump only the object definitions (schema), not data.

This option is the inverse of `--data-only`. It is similar to, but for historical reasons not identical to, specifying `--section=pre-data --section=post-data`.

(Do not confuse this with the `--schema` option, which uses the word "schema" in a different meaning.)

To exclude table data for only a subset of tables in the database, see `--exclude-table-data`.

-S \<username> | --superuser=\<username> Specify the superuser user name to use when deactivating triggers. This is relevant only if `--disable-triggers` is used. It is better to leave this out, and instead start the resulting script as a superuser.

```
> **Note** WarehousePG does not support user-defined triggers.
```

-t \<pattern> | --table=\<pattern> Dump only tables (or views or materialized views or sequences or foreign tables) matching the pattern. Specify the table in the format `schema.table`.

Multiple tables can be selected by writing multiple `-t` switches. Also, the pattern parameter is interpreted as a pattern according to the same rules used by `psql`'s `\d` commands, so multiple tables can also be selected by writing wildcard characters in the pattern. When using wildcards, be careful to quote the pattern if needed to prevent the shell from expanding the wildcards. The `-n` and `-N` switches have no effect when `-t` is used, because tables selected by `-t` will be dumped regardless of those switches, and non-table objects will not be dumped.

```
> **Note** When `-t` is specified, `pg_dump` makes no attempt to dump any other database objects that the selected table\(s\) may depend upon. Therefore, there is
no guarantee that the results of a specific-table dump can be successfully restored by themselves into a clean database.

Also, `-t` cannot be used to specify a child table of a partitioned table. To dump a partitioned table, you must specify the root partitioned table name.
```

-T \<pattern> | --exclude-table=\<pattern> Do not dump any tables matching the table pattern. The pattern is interpreted according to the same rules as for `-t`. `-T` can be specified more than once to exclude tables matching any of several patterns. When both `-t` and `-T` are given, the behavior is to dump just the tables that match at least one `-t` switch but no `-T` switches. If `-T` appears without `-t`, then tables matching `-T` are excluded from what is otherwise a normal dump.

-v | --verbose Specifies verbose mode. This will cause `pg_dump` to output detailed object comments and start/stop times to the dump file, and progress messages to standard error.

-V | --version Print the `pg_dump` version and exit.

-x | --no-privileges | --no-acl Prevent dumping of access privileges (`GRANT/REVOKE` commands).

-Z 0..9 | --compress=0..9 Specify the compression level to use. Zero means no compression. For the custom archive format, this specifies compression of individual table-data segments, and the default is to compress at a moderate level.

For plain text output, setting a non-zero compression level causes the entire output file to be compressed, as though it had been fed through `gzip`; but the default is not to compress. The tar archive format currently does not support compression at all.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

--binary-upgrade This option is for use by in-place upgrade utilities. Its use for other purposes is not recommended or supported. The behavior of the option may change in future releases without notice.

--column-inserts | --attribute-inserts Dump data as `INSERT` commands with explicit column names `(INSERT INTO <table> (<column>, ...) VALUES ...)`. This will make restoration very slow; it is mainly useful for making dumps that can be loaded into non-PostgreSQL-based databases. However, since this option generates a separate command for each row, an error in reloading a row causes only that row to be lost rather than the entire table contents.

--disable-dollar-quoting This option deactivates the use of dollar quoting for function bodies, and forces them to be quoted using SQL standard string syntax.

--disable-triggers This option is relevant only when creating a data-only dump. It instructs `pg_dump` to include commands to temporarily deactivate triggers on the target tables while the data is reloaded. Use this if you have triggers on the tables that you do not want to invoke during data reload. The commands emitted for `--disable-triggers` must be done as superuser. So, you should also specify a superuser name with `-S`, or preferably be careful to start the resulting script as a superuser. This option is only meaningful for the plain-text format. For the archive formats, you may specify the option when you call pg_restore.

```
> **Note** WarehousePG does not support user-defined triggers.
```

--enable-row-security This option is relevant only when dumping the contents of a table which has row security. By default, `pg_dump` sets `row_security` to off, to ensure that all data is dumped from the table. If the user does not have sufficient privileges to bypass row security, then an error is thrown. This parameter instructs `pg_dump` to set `row_security` to on instead, allowing the user to dump the parts of the contents of the table that they have access to.

If you use this option, you likely also want the dump be in `INSERT` format, as the `COPY FROM` during restore does not support row security.

--exclude-table-and-children=\<pattern> This option is equivalent to `-T` or `--exclude-table`, except that it also excludes any partitions of child tables that inherit from the table(s) matching the \<table> name.

--exclude-table-data=\<pattern> Do not dump data for any tables matching the pattern. The pattern is interpreted according to the same rules as for `-t`. `--exclude-table-data` can be specified more than once to exclude tables matching any of several patterns. This option is useful when you need the definition of a particular table even though you do not need the data in it.

To exclude data for all tables in the database, see `--schema-only`.

--exclude-table-data-and-children=\<pattern> This option is equivalent to `--exclude-table-data`, except that it also excludes any partitions of child tables that inherit from the table(s) matching the \<table> name.

--extra-float-digits=ndigits Use the specified value of `extra_float_digits` when dumping floating-point data, instead of the maximum available precision. Routine dumps made for backup purposes should not use this option.

--if-exists Use conditional commands (for example, add an `IF EXISTS` clause) when cleaning database objects. This option is not valid unless `--clean` is also specified.

--inserts Dump data as `INSERT` commands (rather than `COPY`). This will make restoration very slow; it is mainly useful for making dumps that can be loaded into non-PostgreSQL-based databases. However, since this option generates a separate command for each row, an error in reloading a row causes only that row to be lost rather than the entire table contents. Note that the restore may fail altogether if you have rearranged column order. The `--column-inserts` option is safe against column order changes, though even slower.

--load-via-partition-root When dumping data for a table partition, make the `COPY` or `INSERT` statements target the root of the partitioning hierarchy that contains it, rather than the partition itself. This causes the appropriate partition to be re-determined for each row when the data is loaded. This may be useful when restoring data on a server where rows do not always fall into the same partitions as they did on the original server. That could happen, for example, if the partitioning column is of type `text` and the two systems have different definitions of the collation used to sort the partitioning column.

--lock-wait-timeout=\<timeout> Do not wait forever to acquire shared table locks at the beginning of the dump. Instead, fail if unable to lock a table within the specified timeout. The timeout may be specified in any of the formats accepted by `SET statement_timeout`. Specify timeout as a number of milliseconds.

--no-comments Do not dump comments.

--no-security-labels Do not dump security labels.

--no-sync By default, `pg_dump` waits for all files to be written safely to disk. This option causes `pg_dump` to return without waiting, which is faster, but could leave the dump corrupt if there is a subsequent operating system crash. This option is generally useful for testing but should not be used when dumping data from a production installation.

--no-synchronized-snapshots This option allows running `pg_dump -j` against a pre-6.0 WarehousePG server; see the documentation of the `-j` parameter for more details.

--no-tablespaces Do not output commands to select tablespaces. With this option, all objects will be created in whichever tablespace is the default during restore.

This option is only meaningful for the plain-text format. For the archive formats, you can specify the option when you call `pg_restore`.

--no-unlogged-table-data Do not dump the contents of unlogged tables. This option has no effect on whether or not the table definitions (schema) are dumped; it only suppresses dumping the table data. Data in unlogged tables is always excluded when dumping from a standby server.

--on-conflict-do-nothing Add `ON CONFLICT DO NOTHING` to `INSERT` commands. This option is not valid unless `--inserts`, `--column-inserts`, or `--rows-per-insert` is also specified.

--quote-all-identifiers Force quoting of all identifiers. This option is recommended when dumping a database from a server whose WarehousePG major version is different from `pg_dump`'s, or when the output is intended to be loaded into a server of a different major version. By default, `pg_dump` quotes only identifiers that are reserved words in its own major version. This sometimes results in compatibility issues when dealing with servers of other versions that may have slightly different sets of reserved words. Using `--quote-all-identifiers` prevents such issues, at the price of a harder-to-read dump script.

--rows-per-insert=\<nrows> Dump data as `INSERT` commands (rather than `COPY`). Controls the maximum number of rows per `INSERT` command. The value specified must be a number greater than zero. Any error during restoring will cause only rows that are part of the problematic `INSERT` to be lost, rather than the entire table contents.

--section=\<sectionname> Only dump the named section. The section name can be `pre-data`, `data`, or `post-data`. This option can be specified more than once to select multiple sections. The default is to dump all sections.

The `data` section contains actual table data and sequence values. `post-data` items include definitions of indexes, triggers, rules, and constraints other than validated check constraints. `pre-data` items include all other data definition items.

--serializable-deferrable Use a serializable transaction for the dump, to ensure that the snapshot used is consistent with later database states; but do this by waiting for a point in the transaction stream at which no anomalies can be present, so that there isn't a risk of the dump failing or causing other transactions to roll back with a `serialization_failure`.

This option is not beneficial for a dump which is intended only for disaster recovery. It could be useful for a dump used to load a copy of the database for reporting or other read-only load sharing while the original database continues to be updated. Without it the dump may reflect a state which is not consistent with any serial execution of the transactions eventually committed. For example, if batch processing techniques are used, a batch may show as closed in the dump without all of the items which are in the batch appearing.

This option will make no difference if there are no read-write transactions active when `pg_dump` is started. If read-write transactions are active, the start of the dump may be delayed for an indeterminate length of time. Once running, performance with or without the switch is the same.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

> **Note** Because WarehousePG does not support serializable transactions, the `--serializable-deferrable` option has no effect in WarehousePG.

--snapshot=\<snapshotname> Use the specified synchronized snapshot when making a dump of the database.

This option is useful when you need to synchronize the dump with a concurrent session.

In the case of a parallel dump, the snapshot name defined by this option is used rather than taking a new snapshot.

--strict-names Require that each schema (`-n` / `--schema`) and table (`-t` / `--table`) qualifier match at least one schema/table in the database to be dumped. Note that if none of the schema/table qualifiers find matches, `pg_dump` generates an error even without `--strict-names` .

This option has no effect on `-N` / `--exclude-schema` , `-T` / `--exclude-table` , or `--exclude-table-data` . An exclude pattern failing to match any objects is not considered an error.

--table-and-children=\<table> This option is equivalent to `-t` or `--table` , except that it also includes any partitions of child tables that inherit from the table(s) matching the \<table> name.

--use-set-session-authorization Output SQL-standard `SET SESSION AUTHORIZATION` commands instead of `ALTER OWNER` commands to determine object ownership. This makes the dump more standards-compatible, but depending on the history of the objects in the dump, may not restore properly. A dump using `SET SESSION AUTHORIZATION` requires superuser privileges to restore correctly, whereas `ALTER OWNER` requires lesser privileges.

--gp-syntax | --no-gp-syntax Use `--gp-syntax` to dump WarehousePG syntax in the `CREATE TABLE` statements. This allows the distribution policy (`DISTRIBUTED BY` or `DISTRIBUTED RANDOMLY` clauses) of a WarehousePG table to be dumped, which is useful for restoring into other WarehousePG clusters. The default is to include WarehousePG syntax when connected to a WarehousePG cluster, and to exclude it when connected to a regular PostgreSQL system.

--function-oids \<oids> Dump the function(s) specified in the oids list of object identifiers.

```
> **Note** This option is provided solely for use by other administration utilities; its use for any other purpose is not recommended or supported. The behavior
of the option may change in future releases without notice.
```

--relation-oids \<oids> Dump the relation(s) specified in the oids list of object identifiers.

```
> **Note** This option is provided solely for use by other administration utilities; its use for any other purpose is not recommended or supported. The behavior
of the option may change in future releases without notice.
```

-? | --help Show help about `pg_dump` command line arguments, and exit.

Connection Options

-d \<dbname> | --dbname=\<dbname> Specifies the name of the database to connect to. This is equivalent to specifying dbname as the first non-option argument on the command line.

If this parameter contains an `=` sign or starts with a valid URI prefix (`postgresql://` or `postgres://`), it is treated as a conninfo string. See Connection Strings in the PostgreSQL documentation for more information. Connection strings parameters override any conflicting command line option.

-h \<host> | --host=\<host> The host name of the machine on which the WarehousePG coordinator database server is running. If not specified, reads from the environment variable `PGHOST` or defaults to `localhost` .

-p \<port> | --port=\<port> The TCP port on which the WarehousePG coordinator database server is listening for connections. If not specified, reads from the environment variable `PGPORT` or defaults to `5432` . `

-U \<username> | --username=\<username> The database role name to connect as. If not specified, reads from the environment variable `PGUSER` or defaults to the current system role name.

-W | --password Force a password prompt.

This option is never required; `pg_dump` automatically prompts for a password if the server demands password authentication. However, `pg_dump` will waste a connection attempt determining that the server wants a password. In some cases it is worth typing `-W` to avoid the extra connection attempt.

-w | --no-password Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

--role=\<rolename> Specifies a role name to be used to create the dump. This option causes `pg_dump` to issue a `SET ROLE <rolename>` command after connecting to the database. It is useful when the authenticated user (specified by `-U`) lacks privileges needed by `pg_dump` , but can switch to a role with the required rights. Some installations have a policy against logging in directly as a superuser, and use of this option allows dumps to be made without violating the policy.

Environment

PGDATABASE PGHOST PGOPTIONS PGPORT PGUSER Default connection parameters.

PG_COLOR Specifies whether to use color in diagnostic messages. Possible values are `always` , `auto` , and `never` .

This utility also uses the environment variables supported by libpq.

Notes

If your database cluster has any local additions to the `template1` database, be careful to restore the output of `pg_dump` into a truly empty database; otherwise you are likely to get errors due to duplicate definitions of the added objects. To make an empty database without any local additions, copy from `template0` not `template1` , for example:

```
CREATE DATABASE foo WITH TEMPLATE template0;
```

When a data-only dump is chosen and the option `--disable-triggers` is used, `pg_dump` emits commands to deactivate triggers on user tables before inserting the data and commands to re-enable them after the data has been inserted. If the restore is stopped in the middle, the system catalogs may be left in the wrong state.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

The dump file produced by `pg_dump` does not contain the statistics used by the optimizer to make query planning decisions. Therefore, it is wise to run `ANALYZE` after restoring from a dump file to ensure optimal performance.

The database activity of `pg_dump` is normally collected by the statistics collector. If this is undesirable, you can set parameter `track_counts` to false via `PGOPTIONS` or the `ALTER USER` command.

Because `pg_dump` may be used to transfer data to newer versions of WarehousePG, the output of `pg_dump` can be expected to load into WarehousePG versions newer than `pg_dump` 's version. `pg_dump` can also dump from WarehousePG versions older than its own version. However, `pg_dump` cannot dump from WarehousePG versions newer than its own major version; it will refuse to even try, rather than risk making an invalid dump. Also, it is not guaranteed that `pg_dump` 's output can be loaded into a server of an older major version — not even if the dump was taken from a server of that version. Loading a dump file into an older server may require manual editing of the dump file to remove syntax not understood by the older server. Use of the `--quote-all-identifiers` option is recommended in cross-version cases, as it can prevent problems arising from varying reserved-word lists in different WarehousePG versions.

Examples

Dump a database called `mydb` into a SQL-script file:

```
pg_dump mydb > db.sql
```

To reload such a script into a (freshly created) database named `newdb` :

```
psql -d newdb -f db.sql
```

Dump a WarehousePG in tar file format and include distribution policy information:

```
pg_dump -Ft --gp-syntax mydb > db.tar
```

To dump a database into a custom-format archive file:

```
pg_dump -Fc mydb > db.dump
```

To dump a database into a directory-format archive:

```
pg_dump -Fd mydb -f dumpdir
```

To dump a database into a directory-format archive in parallel with 5 worker jobs:

```
pg_dump -Fd mydb -j 5 -f dumpdir
```

To reload an archive file into a (freshly created) database named `newdb` :

```
pg_restore -d newdb db.dump
```

To reload an archive file into the same database it was dumped from, discarding the current contents of that database:

```
pg_restore -d postgres --clean --create db.dump
```

To dump a single table named `mytab` :

```
pg_dump -t mytab mydb > db.sql
```

To dump all tables whose names start with `emp` in the `detroit` schema, except for the table named `employee_log` :

```
pg_dump -t 'detroit.emp*' -T detroit.employee_log mydb > db.sql
```

To dump all schemas whose names start with `east` or `west` and end in `gsm` , excluding any schemas whose names contain the word `test` :

```
pg_dump -n 'east*gsm' -n 'west*gsm' -N '*test*' mydb > db.sql
```

The same dump as above, using regular expression notation to consolidate the switches:

```
pg_dump -n '(east|west)*gsm' -N '*test*' mydb > db.sql
```

To dump all database objects except for tables whose names begin with `ts_` :

```
pg_dump -T 'ts_*' mydb > db.sql
```

To specify an upper-case or mixed-case name in `-t` and related switches, you need to double-quote the name; else it will be folded to lower case. But double quotes are special to the shell, so they in turn must be quoted. To dump a single table with a mixed-case name, you must specify something like:

```
pg_dump -t "\"MixedCaseName\"" mydb > mytab.sql
```

7.7.2.34 pg_dumpall

Extracts all databases in a WarehousePG cluster to a single script file or other archive file.

Synopsis

```
pg_dumpall [<connection-option> ...] [<dump_option> ...]

pg_dumpall -? | --help

pg_dumpall -V | --version
```

Description

`pg_dumpall` is a standard PostgreSQL utility for backing up all databases in a WarehousePG (or PostgreSQL) instance, and is also supported in WarehousePG. It creates a single (non-parallel) dump file. For routine backups of WarehousePG it is better to use the WarehousePG backup utility, `gpbackup`, for the best performance.

`pg_dumpall` creates a single script file that contains SQL commands that can be used as input to psql to restore the databases. It does this by calling pg_dump for each database. `pg_dumpall` also dumps global objects that are common to all databases. (`pg_dump` does not save these objects.) This currently includes information about database users and groups, and access permissions that apply to databases as a whole.

Since `pg_dumpall` reads tables from all databases you will most likely have to connect as a database superuser in order to produce a complete dump. Also you will need superuser privileges to run the saved script in order to be allowed to add users and groups, and to create databases.

The SQL script will be written to the standard output. Use the `[-f | --file]` option or shell operators to redirect it into a file.

`pg_dumpall` needs to connect several times to the WarehousePG coordinator server (once per database). If you use password authentication it is likely to ask for a password each time. It is convenient to have a `~/.pgpass` file in such cases.

Options

Dump Options

-a | --data-only Dump only the data, not the schema (data definitions). This option is only meaningful for the plain-text format. For the archive formats, you may specify the option when you call pg_restore.

-c | --clean Output commands to clean (drop) database objects prior to (the commands for) creating them. This option is only meaningful for the plain-text format. For the archive formats, you may specify the option when you call pg_restore.

-E encoding | --encoding=encoding Create the dump in the specified character set encoding. By default, the dump is created in the database encoding. (An alternate method to achieve the same result is to set the `PGCLIENTENCODING` environment variable to the desired dump encoding.)

-f filename | --file=filename Send output to the specified file. If this is omitted, `pg_dump` sends the output to standard out.

-g | --globals-only Dump only global objects (roles and tablespaces), no databases.

-O | --no-owner Do not output commands to set ownership of objects to match the original database. By default, pg_dump issues `ALTER OWNER` or `SET SESSION AUTHORIZATION` statements to set ownership of created database objects. These statements will fail when the script is run unless it is started by a superuser (or the same user that owns all of the objects in the script). To make a script that can be restored by any user, but will give that user ownership of all the objects, specify `-O`. This option is only meaningful for the plain-text format. For the archive formats, you may specify the option when you call pg_restore.

-r | --roles-only Dump only roles, not databases or tablespaces.

-s | --schema-only Dump only the object definitions (schema), not data.

-S username | --superuser=username Specify the superuser user name to use when deactivating triggers. This is relevant only if `--disable-triggers` is used. It is better to leave this out, and instead start the resulting script as a superuser.

```
> **Note** WarehousePG does not support user-defined triggers.
```

-t | --tablespaces-only Dump only tablespaces, not databases or roles.

-v | --verbose Specifies verbose mode. This will cause `[pg\_dump](pg_dump.html)` to output detailed object comments and start/stop times to the dump file, and progress messages to standard error.

-V | --version Print the `pg_dumpall` version and exit.

-x | --no-privileges | --no-acl Prevent dumping of access privileges (`GRANT/REVOKE` commands).

--binary-upgrade This option is for use by in-place upgrade utilities. Its use for other purposes is not recommended or supported. The behavior of the option may change in future releases without notice.

--column-inserts | --attribute-inserts Dump data as `INSERT` commands with explicit column names (`INSERT INTO <table> (<column>, ...) VALUES ...`). This will make restoration very slow; it is mainly useful for making dumps that can be loaded into non-PostgreSQL-based databases. Also, since this option generates a separate command for each row, an error in reloading a row causes only that row to be lost rather than the entire table contents.

--disable-dollar-quoting This option deactivates the use of dollar quoting for function bodies, and forces them to be quoted using SQL standard string syntax.

--disable-triggers This option is relevant only when creating a data-only dump. It instructs `pg_dumpall` to include commands to temporarily deactivate triggers on the target tables while the data is reloaded. Use this if you have triggers on the tables that you do not want to invoke during data reload. The commands emitted for `--disable-triggers` must be done as superuser. So, you should also specify a superuser name with `-S`, or preferably be careful to start the resulting script as a superuser.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
> **Note** WarehousePG does not support user-defined triggers.
```

--extra-float-digits=ndigits Use the specified value of `extra_float_digits` when dumping floating-point data, instead of the maximum available precision. Routine dumps made for backup purposes should not use this option.

--exclude-database=pattern Do not dump databases whose name matches pattern. Multiple patterns can be excluded by writing multiple `--exclude-database` switches. The pattern parameter is interpreted as a pattern according to the same rules used by `psql`'s `\d` commands, so multiple databases can also be excluded by writing wildcard characters in the pattern. When using wildcards, be careful to quote the pattern if needed to prevent shell wildcard expansion.

--if-exists Use conditional commands (for example, add an `IF EXISTS` clause) to drop databases and other objects. This option is not valid unless `--clean` is also specified.

--inserts Dump data as `INSERT` commands (rather than `COPY`). This will make restoration very slow; it is mainly useful for making dumps that can be loaded into non-PostgreSQL-based databases. Also, since this option generates a separate command for each row, an error in reloading a row causes only that row to be lost rather than the entire table contents. Note that the restore may fail altogether if you have rearranged column order. The `--column-inserts` option is safe against column order changes, though even slower.

--load-via-partition-root When dumping data for a table partition, make the `COPY` or `INSERT` statements target the root of the partitioning hierarchy that contains it, rather than the partition itself. This causes the appropriate partition to be re-determined for each row when the data is loaded. This may be useful when restoring data on a server where rows do not always fall into the same partitions as they did on the original server. That could happen, for example, if the partitioning column is of type `text` and the two systems have different definitions of the collation used to sort the partitioning column.

--lock-wait-timeout=timeout Do not wait forever to acquire shared table locks at the beginning of the dump. Instead, fail if unable to lock a table within the specified timeout. The timeout may be specified in any of the formats accepted by `SET statement_timeout`. Allowed values vary depending on the server version you are dumping from, but an integer number of milliseconds is accepted by all WarehousePG versions.

--no-comments Do not dump comments.

--no-role-passwords Do not dump passwords for roles. When restored, roles will have a null password, and password authentication will always fail until the password is set. Since password values are not required when this option is specified, the role information is read from the catalog view `pg_roles` instead of `pg_authid`. Consequently, this option also helps if access to `pg_authid` is restricted by some security policy.

--no-security-labels Do not dump security labels.

--no-sync By default, `pg_dumpall` waits for all files to be written safely to disk. Specifying this option causes `pg_dumpall` to return without waiting, which is faster, but implies that a subsequent operating system crash can leave the dump corrupt. This option is generally useful for testing, and should not be used when dumping data from a production installation.

--no-tablespaces Do not output commands to create tablespaces nor select tablespaces for objects. With this option, all objects will be created in whichever tablespace is the default during restore.

--no-unlogged-table-data Do not dump the contents of unlogged tables. This option has no effect on whether or not the table definitions (schema) are dumped; it only suppresses dumping the table data.

--on-conflict-do-nothing Add `ON CONFLICT DO NOTHING` to `INSERT` commands. This option is not valid unless `--inserts` or `--column-inserts` is also specified.

--quote-all-identifiers Force quoting of all identifiers. This option is recommended when dumping a database from a server whose WarehousePG major version is different from `pg_dumpall`'s, or when the output is intended to be loaded into a server of a different major version. By default, `pg_dumpall` quotes only identifiers that are reserved words in its own major version. This sometimes results in compatibility issues when dealing with servers of other versions that may have slightly different sets of reserved words. Using `--quote-all-identifiers` prevents such issues, at the price of a harder-to-read dump script.

--resource-queues Dump resource queue definitions.

--resource-groups Dump resource group definitions.

--rows-per-insert=nrows Dump data as `INSERT` commands (rather than `COPY)`. Controls the maximum number of rows per `INSERT` command. The value specified must be a number greater than zero. Any error during restoring will cause only rows that are part of the problematic `INSERT` to be lost, rather than the entire table contents.

--use-set-session-authorization Output SQL-standard `SET SESSION AUTHORIZATION` commands instead of `ALTER OWNER` commands to determine object ownership. This makes the dump more standards compatible, but depending on the history of the objects in the dump, may not restore properly. A dump using `SET SESSION AUTHORIZATION` requires superuser privileges to restore correctly, whereas `ALTER OWNER` requires lesser privileges.

--gp-syntax Output WarehousePG syntax in the `CREATE TABLE` statements. This allows the distribution policy (`DISTRIBUTED BY` or `DISTRIBUTED RANDOMLY` clauses) of a WarehousePG table to be dumped, which is useful for restoring into other WarehousePG clusters.

--no-gp-syntax Do not output the table distribution clauses in the `CREATE TABLE` statements.

-? | --help Show help about `pg_dumpall` command line arguments, and exit.

Connection Options

-d connstr | --dbname=connstr Specifies parameters used to connect to the server, as a connection string. See Connection Strings in the PostgreSQL documentation for more information.

The option is called `--dbname` for consistency with other client applications, but because `pg_dumpall` needs to connect to many databases, the database name in the connection string will be ignored. Use the `-l` option to specify the name of the database used to dump global objects and to discover what other databases should be dumped.

-h host | --host=host The host name of the machine on which the WarehousePG coordinator database server is running. If not specified, reads from the environment variable `PGHOST` or defaults to `localhost`.

-l dbname | --database=dbname Specifies the name of the database in which to connect to dump global objects. If not specified, the `postgres` database is used. If the `postgres` database does not exist, the `template1` database is used.

-p port | --port=port The TCP port on which the WarehousePG coordinator database server is listening for connections. If not specified, reads from the environment variable `PGPORT` or defaults to `5432`.

-U username | --username= username The database role name to connect as. If not specified, reads from the environment variable `PGUSER` or defaults to the current system role name.

-w | --no-password Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

-W | --password Force a password prompt. This option is never essential, since `pg_dumpall` will automatically prompt for a password if the server demands password authentication. However, `pg_dumpall` will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-W` to avoid the extra connection attempt. Note that the password prompt will occur again for each database to be dumped. It may be preferable to set up a `~/.pgpass` file rather than to rely on manual password entry.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

--role=rolename Specifies a role name to be used to create the dump. This option causes `pg_dumpall` to issue a `SET ROLE <rolename>` command after connecting to the database. It is useful when the authenticated user (specified by `-U`) lacks privileges needed by `pg_dumpall`, but can switch to a role with the required rights. Some installations have a policy against logging in directly as a superuser, and use of this option allows dumps to be made without violating the policy.

Environment

PGHOST PGOPTIONS PGPORT PGUSER Default connection parameters.

PG_COLOR Specifies whether to use color in diagnostic messages. Possible values are `always`, `auto`, and `never`.

This utility also uses the environment variables supported by libpq.

Notes

Since `pg_dumpall` calls pg_dump internally, some diagnostic messages will refer to `pg_dump`.

The `--clean` option can be useful even when your intention is to restore the dump script into a fresh cluster. Use of `--clean` authorizes the script to drop and re-create the built-in `postgres` and `template1` databases, ensuring that those databases will retain the same properties (for instance, locale and encoding) that they had in the source cluster. Without the option, those databases will retain their existing database-level properties, as well as any pre-existing contents.

Once restored, it is wise to run `ANALYZE` on each database so the query planner has useful statistics. You can also run `vacuumdb -a -z` to vacuum and analyze all databases.

Do no expect the dump script to run completely without errors. In particular, because the script issues `CREATE ROLE` for every role existing in the source cluster, it is certain to generate a "role already exists" error for the bootstrap superuser, unless the destination cluster was initialized with a different bootstrap superuser name. This error is harmless and can be ignored. Use of the `--clean` option is likely to produce additional harmless error messages about non-existent objects; minimize those by adding `--if-exists`.

`pg_dumpall` requires all needed tablespace directories to exist before the restore; otherwise, database creation will fail for databases in non-default locations.

Examples

To dump all databases:

```
pg_dumpall > db.out
```

To reload database(s) from this file, you can use:

```
psql template1 -f db.out
```

To dump only global objects (including resource queues):

```
pg_dumpall -g --resource-queues
```

7.7.2.35 pg_restore

Restores a database from an archive file created by `pg_dump`.

Synopsis

```
pg_restore [<connection-option> ...] [<restore_option> ...] [<filename>]

pg_restore -? | --help

pg_restore -V | --version
```

Description

`pg_restore` is a utility for restoring a database from an archive created by pg_dump in one of the non-plain-text formats. It will issue the commands necessary to reconstruct the database to the state it was in at the time it was saved. The archive files also allow `pg_restore` to be selective about what is restored, or even to reorder the items prior to being restored.

`pg_restore` can operate in two modes. If a database name is specified, the archive is restored directly into the database. Otherwise, a script containing the SQL commands necessary to rebuild the database is created and written to a file or standard output. The script output is equivalent to the plain text output format of `pg_dump`. Some of the options controlling the output are therefore analogous to `pg_dump` options.

`pg_restore` cannot restore information that is not present in the archive file. For instance, if the archive was made using the "dump data as `INSERT` commands" option, `pg_restore` will not be able to load the data using `COPY` statements.

Options

filename Specifies the location of the archive file (or directory, for a directory-format archive) to be restored. If not specified, the standard input is used.

Restore Options

-a | --data-only Restore only the data, not the schema (data definitions). Table data and sequence values are restored, if present in the archive.

```
This option is similar to, but for historical reasons not identical to, specifying `--section=data`.
```

-c | --clean Clean (drop) database objects before recreating them. (If you do not also specify `--if-exists`, this may generate some harmless error messages if any objects were not present in the destination database.)

-C | --create Create the database before restoring into it. If `--clean` is also specified, drop and recreate the target database before connecting to it.

With `--create`, `pg_restore` also restores the database's comment if any, and any configuration variable settings that are specific to this database, that is, any `ALTER DATABASE ... SET ...` and `ALTER ROLE ... IN DATABASE ... SET ...` commands that mention this database. Access privileges for the database itself are also restored, unless `--no-acl` is specified.

When this option is used, the database named with `-d` is used only to issue the initial `DROP DATABASE` and `CREATE DATABASE` commands. All data is restored into the database name that appears in the archive.

-d dbname | --dbname=dbname Connect to this database and restore directly into this database. The dbname can be aConnection Strings. If so, connection string parameters override any conflicting command line options.

-e | --exit-on-error Exit if an error is encountered while sending SQL commands to the database. The default is to continue and to display a count of errors at the end of the restoration.

-f outfilename | --file=outfilename Specify output file for generated script, or for the listing when used with `-l`. Use `-` for `stdout`.

-F c|d|t | --format={custom | directory | tar} The format of the archive produced by pg_dump. It is not necessary to specify the format, since `pg_restore` will determine the format automatically. Format can be `custom`, `directory`, or `tar`.

-I index | --index=index Restore definition of named index only. You can specify multiple indexes with multiple `-I` switches.

-j | --number-of-jobs | --jobs=number-of-jobs Run the most time-consuming parts of `pg_restore` — those which load data, create indexes, or create constraints — using multiple concurrent jobs. This option can dramatically reduce the time to restore a large database to a server running on a multiprocessor machine. This option is ignored when emitting a script rather than connecting directly to a database server.

Each job is one process or one thread, depending on the operating system, and uses a separate connection to the server.

The optimal value for this option depends on the hardware setup of the server, of the client, and of the network. Factors include the number of CPU cores and the disk setup. A good place to start is the number of CPU cores on the server, but values larger than that can also lead to faster restore times in many cases. Of course, values that are too high will lead to decreased performance because of thrashing.

Only the custom and directory archive formats ase supported with this option. The input file must be a regular file or directory (not, for example, a pipe or standard input). Also, multiple jobs cannot be used together with the option `--single-transaction`.

-l | --list List the table contents of the archive. The output of this operation can be used as input to the `-L` option. Note that if filtering switches such as `-n` or `-t` are used with `-l`, they restrict the items listed.

-L list-file | --use-list=list-file Restore only those archive elements that are listed in list-file, and restore them in the order they appear in the file. Note that if filtering switches such as `-n` or `-t` are used with `-L`, they further restrict the items restored.

list-file is normally created by editing the output of a previous `-l` operation. Lines can be moved or removed, and can also be commented out by placing a semicolon `;`) at the start of the line. See below for examples.

-n schema | --schema=schema Restore only objects that are in the named schema. You can specify multiple schemas with multiple `-n` switches. Combine with the `-t` option to restore just a specific table.

-N schema | --exclude-schema=schema Do not restore objects that are in the named schema. You can specify multiple schemas to exclude with multiple `-N` switches.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

When both `-n` and `-N` are specified for the same schema name, the `-N` switch takes precedence and the schema is excluded.

-O | --no-owner Do not output commands to set ownership of objects to match the original database. By default, `pg_restore` issues `ALTER OWNER` or `SET SESSION AUTHORIZATION` statements to set ownership of created schema elements. These statements will fail unless the initial connection to the database is made by a superuser (or the same user that owns all of the objects in the script). With `-O`, any user name can be used for the initial connection, and this user will own all the created objects.

-P function-name(argtype [, ...]) | --function=function-name(argtype [, ...]) Restore the named function only. The function name must be enclosed in quotes. Be careful to spell the function name and arguments exactly as they appear in the dump file's table of contents (as shown by the `--list` option). You can specify multiple functions with multiple `-P` switches.

-s | --schema-only Restore only the schema (data definitions), not data, to the extent that schema entries are present in the archive.

This option is the inverse of `--data-only`. It is similar to, but for historical reasons not identical to, specifying `--section=pre-data --section=post-data`.

(Do not confuse this with the `--schema` option, which uses the word *schema* in a different meaning.)

-S username | --superuser=username Specify the superuser user name to use when deactivating triggers. This is only relevant if `--disable-triggers` is used.

```
> **Note** WarehousePG does not support user-defined triggers.
```

-t table | --table=table Restore definition and/or data of the named table only. "table" includes views, materialized views, sequences, and foreign tables. You can specify multiple tables with multiple `-t` switches. Combine this option with the `-n` option to specify table(s) in a particular schema. When you specify `-t`, `pg_restore` makes no attempt to restore any other database objects that the selected table(s) might depend upon. Therefore, there is no guarantee that a specific-table restore into a clean database will succeed. This option does not behave identically to the `-t` option of `pg_dump`. `pg_restore` does not currently support wild-card matching, nor can you include a schema name within its `-t`. And, while `pg_dump`'s `-t` flag will also dump subsidiary objects (such as indexes) of the selected table(s), `pg_restore`'s `-t` flag does not include such subsidiary objects.

```
> **Note** In versions prior to WarehousePG 7, this flag matched only tables, not any other type of relation.
```

-T trigger | --trigger=trigger Restore named trigger only.

```
> **Note** WarehousePG does not support user-defined triggers.
```

-v | --verbose Specifies verbose mode.

-V | --version Print the `pg_restore` version and exit.

-x | --no-privileges | --no-acl Prevent restoration of access privileges (`GRANT/REVOKE` commands).

-1 | --single-transaction Run the restore as a single transaction (that is, wrap the emitted commands in `BEGIN`/`COMMIT1). This ensures that either all of the commands complete successfully, or no changes are applied. This option implies` --exit-on-error`.

--disable-triggers This option is relevant only when performing a data-only restore. It instructs `pg_restore` to run commands to temporarily deactivate triggers on the target tables while the data is reloaded. Use this if you have triggers on the tables that you do not want to invoke during data reload. The commands emitted for `--disable-triggers` must be invoked as superuser. So you should also specify a superuser name with `-S` or, preferably, run `pg_restore` as a superuser.

```
> **Note** WarehousePG does not support user-defined triggers.
```

--enable-row-security This option is relevant only when restoring the contents of a table which has row security. By default, `pg_restore` sets `row_security` to off, to ensure that all data is restored in to the table. If the user does not have sufficient privileges to bypass row security, then an error is thrown. This parameter instructs `pg_restore` to set `row_security` to on instead, allowing the user to attempt to restore the contents of the table with row security enabled. This might still fail if the user does not have the right to insert the rows from the dump into the table.

This option currently also requires the dump be in `INSERT` format, as `COPY FROM` does not support row security.

--if-exists Use conditional commands (for example, add an `IF EXISTS` clause) to drop database objects. This option is not valid unless `--clean` is also specified.

--no-comments Do not output commands to restore comments, even if the archive contains them.

--no-data-for-failed-tables By default, table data is restored even if the creation command for the table failed (for example, because it already exists). With this option, data for such a table is skipped. This behavior is useful when the target database may already contain the desired table contents. Specifying this option prevents duplicate or obsolete data from being loaded. This option is effective only when restoring directly into a database, not when producing SQL script output.

--no-security-labels Do not output commands to restore security labels, even if the archive contains them.

--no-tablespaces Do not output commands to select tablespaces. With this option, all objects will be created in whichever tablespace is the default during restore.

--section=sectionname Only restore the named section. The section name can be `pre-data`, `data`, or `post-data`. This option can be specified more than once to select multiple sections. The data section contains actual table data. Post-data items consist of definitions of indexes, triggers, rules, and constraints other than validated check constraints. Pre-data items consist of all other data definition items. The default is to restore all sections.

--strict-names Require that each schema (`-n`/`--schema`) and table (`-t`/`--table`) qualifier match at least one schema/table in the backup file.

--use-set-session-authorization Output SQL-standard `SET SESSION AUTHORIZATION` commands instead of `ALTER OWNER` commands to determine object ownership. This makes the dump more standards-compatible, but depending on the history of the objects in the dump, it might not restore properly.

-? | --help Show help about `pg_restore` command line arguments, and exit.

Connection Options

-h host | --host host The host name of the machine on which the WarehousePG coordinator database server is running. If not specified, reads from the environment variable `PGHOST` or defaults to `localhost`.

-p port | --port port The TCP port on which the WarehousePG coordinator database server is listening for connections. If not specified, reads from the environment variable `PGPORT` or defaults to `5432`.

-U username | --username username The database role name to connect as. If not specified, reads from the environment variable `PGUSER` or defaults to the current system role name.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

-w | --no-password Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

-W | --password Force a password prompt.

This option is never required, since `pg_restore` automatically prompts for a password if the server demands password authentication. However, `pg_restore` will waste a connection attempt determinig that the server wants a password. In some cases it is worth typing `-W` to avoid the extra connection attempt.

--role=rolename Specifies a role name to be used to perform the restore. This option causes `pg_restore` to issue a `SET ROLE <rolename>` command after connecting to the database. It is useful when the authenticated user (specified by `-U`) lacks privileges needed by `pg_restore`, but can switch to a role with the required rights. Some installations have a policy against logging in directly as a superuser, and use of this option allows restores to be performed without violating the policy.

Environment

PGHOST PGOPTIONS PGPORT PGUSER Default connection parameters.

PG_COLOR Specifies whether to use color in diagnostic messages. Possible values are `always`, `auto`, and `never`.

This utility also uses the environment variables supported by libpq.

Diagnostics

When you specify a direct database connection using the `-d` option, `pg_restore` internally executes SQL statements. If you have problems running `pg_restore`, make sure you are able to select information from the database using, for example, `psql`. Also, any default connection settings and environment variables used by the `libpq` front-end library will apply.

Notes

If your installation has any local additions to the `template1` database, be careful to load the output of `pg_restore` into a truly empty database; otherwise you are likely to get errors due to duplicate definitions of the added objects. To make an empty database without any local additions, copy from `template0` not `template1`, for example:

```
CREATE DATABASE foo WITH TEMPLATE template0;
```

When restoring data to a pre-existing table and the option `--disable-triggers` is used, `pg_restore` emits commands to deactivate triggers on user tables before inserting the data, then emits commands to re-enable them after the data has been inserted. If the restore is stopped in the middle, the system catalogs may be left in the wrong state.

See also the pg_dump documentation for details on limitations of `pg_dump`.

Once restored, it is wise to run `ANALYZE` on each restored table so the query planner has useful statistics.

Examples

Assume we have dumped a database called `mydb` into a custom-format dump file:

```
pg_dump -Fc mydb > db.dump
```

To drop the database and recreate it from the dump:

```
dropdb mydb
pg_restore -C -d template1 db.dump
```

Run the following commands to reload the dump into a new database called `newdb`. Notice there is no `-C` option provided. Instead, connect directly to the database to which to restore to. Also note that the new database is cloned from `template0` not `template1`, to ensure that it is initially empty:

```
createdb -T template0 newdb
pg_restore -d newdb db.dump
```

To reorder database items, you must first dump the table of contents of the archive:

```
pg_restore -l db.dump > db.list
```

The listing file consists of a header and one line for each item, for example,

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
; Archive created at Mon Sep 14 13:55:39 2019
;     dbname: DBDEMOS
;     TOC Entries: 81
;     Compression: 9
;     Dump Version: 1.10-0
;     Format: CUSTOM
;     Integer: 4 bytes
;     Offset: 8 bytes
;     Dumped from database version: 9.4.24
;     Dumped by pg_dump version: 9.4.24
;
; Selected TOC Entries:
;
3; 2615 2200 SCHEMA - public pasha
1861; 0 0 COMMENT - SCHEMA public pasha
1862; 0 0 ACL - public pasha
317; 1247 17715 TYPE public composite pasha
319; 1247 25899 DOMAIN public domain0 pasha2
```

Semicolons start a comment, and the numbers at the start of lines refer to the internal archive ID assigned to each item. You can comment out, delete, and reorder lines in the file. For example:

```
10; 145433 TABLE map_resolutions postgres
;2; 145344 TABLE species postgres
;4; 145359 TABLE nt_header postgres
6; 145402 TABLE species_records postgres
;8; 145416 TABLE ss_old postgres
```

You can use this file as input to `pg_restore`, to restore only items 10 and 6, in that order:

```
pg_restore -L db.list db.dump
```

7.7.2.36 psql

Interactive command-line interface for WarehousePG

Synopsis

```
psql [<option> ...] [<dbname> [<username>]]
```

Description

`psql` is a terminal-based front-end to WarehousePG. It enables you to type in queries interactively, issue them to WarehousePG, and see the query results. Alternatively, input can be from a file. In addition, it provides a number of meta-commands and various shell-like features to facilitate writing scripts and automating a wide variety of tasks.

Options

-a | --echo-all Print all nonempty input lines to standard output as they are read. (This does not apply to lines read interactively.) This is equivalent to setting the variable ECHO to `all`.

-A | --no-align Switches to unaligned output mode. (The default output mode is aligned.)

-c 'command' | --command='command' Specifies that `psql` is to run the specified command string, and then exit. This is useful in shell scripts. command must be either a command string that is completely parseable by the server, or a single backslash command. Thus you cannot mix SQL and `psql` meta-commands with this option. To achieve that, you could pipe the string into `psql`, like this:

```
```
echo '\x \\ SELECT * FROM foo;' | psql
```
```

(`\\` is the separator meta-command.)

If the command string contains multiple SQL commands, they are processed in a single transaction, unless there are explicit `BEGIN/COMMIT` commands included in the string to divide it into multiple transactions. This is different from the behavior when the same string is fed to `psql`'s standard input. Also, only the result of the last SQL command is returned.

-d dbname | --dbname=dbname Specifies the name of the database to connect to. This is equivalent to specifying dbname as the first non-option argument on the command line.

If this parameter contains an `=` sign or starts with a valid URI prefix (`postgresql://` or `postgres://`), it is treated as a `conninfo` string. See Connection Strings in the PostgreSQL documentation for more information.

-e | --echo-queries Copy all SQL commands sent to the server to standard output as well.

-E | --echo-hidden Echo the actual queries generated by `\d` and other backslash commands. You can use this to study `psql`'s internal operations. This is equivalent to setting the variable ECHO_HIDDEN to `on`.

-f filename | --file=filename Use the file filename as the source of commands instead of reading commands interactively. After the file is processed, `psql` terminates. This is in many ways equivalent to the meta-command `\i`.

If filename is `-` (hyphen), then standard input is read until an EOF indication or `\q` meta-command. Note however that Readline is not used in this case (much as if `-n` had been specified).

Using this option is subtly different from writing `psql < <filename>`. In general, both will do what you expect, but using `-f` enables some nice features such as error messages with line numbers. There is also a slight chance that using this option will reduce the start-up overhead. On the other hand, the variant using the shell's input redirection is (in theory) guaranteed to yield exactly the same output you would have received had you entered everything by hand.

-F separator | --field-separator=separator Use the specified separator as the field separator for unaligned output.

-H | --html Turn on HTML tabular output.

-l | --list List all available databases, then exit. Other non-connection options are ignored.

-L filename | --log-file=filename Write all query output into the specified log file, in addition to the normal output destination.

-n | --no-readline Do not use Readline for line editing and do not use the command history. This can be useful to turn off tab expansion when cutting and pasting.

-o filename | --output=filename Put all query output into the specified file.

-P assignment | --pset=assignment Allows you to specify printing options in the style of `\pset` on the command line. Note that here you have to separate name and value with an equal sign instead of a space. Thus to set the output format to `LaTeX`, you could write `-P format=latex`.

-q | --quiet Specifies that `psql` should do its work quietly. By default, it prints welcome messages and various informational output. If this option is used, none of this happens. This is useful with the `-c` option. This is equivalent to setting the variable QUIET to `on`.

-R separator | --record-separator=separator Use separator as the record separator for unaligned output.

-s | --single-step Run in single-step mode. That means the user is prompted before each command is sent to the server, with the option to cancel execution as well. Use this to debug scripts.

-S | --single-line Runs in single-line mode where a new line terminates an SQL command, as a semicolon does.

-t | --tuples-only Turn off printing of column names and result row count footers, etc. This command is equivalent to `\pset tuples_only` and is provided for convenience.

-T table_options | --table-attr= table_options Allows you to specify options to be placed within the HTML table tag. See `\pset` for details.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

-v assignment | --set=assignment | --variable= assignment Perform a variable assignment, like the `\set` meta command. Note that you must separate name and value, if any, by an equal sign on the command line. To unset a variable, leave off the equal sign. To set a variable with an empty value, use the equal sign but leave off the value. These assignments are done during a very early stage of start-up, so variables reserved for internal purposes might get overwritten later.

-V | --version Print the `psql` version and exit.

-x | --expanded Turn on the expanded table formatting mode.

-X | --no-psqlrc Do not read the start-up file (neither the system-wide `psqlrc` file nor the user's `~/.psqlrc` file).

-z | --field-separator-zero Set the field separator for unaligned output to a zero byte.

-0 | --record-separator-zero Set the record separator for unaligned output to a zero byte. This is useful for interfacing, for example, with `xargs -0`.

-1 | --single-transaction When `psql` runs a script, adding this option wraps `BEGIN`/`COMMIT` around the script to run it as a single transaction. This ensures that either all the commands complete successfully, or no changes are applied.

If the script itself uses `BEGIN`, `COMMIT`, or `ROLLBACK`, this option will not have the desired effects. Also, if the script contains any command that cannot be run inside a transaction block, specifying this option will cause that command (and hence the whole transaction) to fail.

-? | --help Show help about `psql` command line arguments, and exit.

Connection Options

-h host | --host=host The host name of the machine on which the WarehousePG coordinator database server is running. If not specified, reads from the environment variable `PGHOST` or defaults to localhost.

When starting `psql` on the coordinator host, if the host value begins with a slash, it is used as the directory for the UNIX-domain socket.

-p port | --port=port The TCP port on which the WarehousePG coordinator database server is listening for connections. If not specified, reads from the environment variable `PGPORT` or defaults to 5432.

-U username | --username=username The database role name to connect as. If not specified, reads from the environment variable `PGUSER` or defaults to the current system role name.

-W | --password Force a password prompt. `psql` should automatically prompt for a password whenever the server requests password authentication. However, currently password request detection is not totally reliable, hence this option to force a prompt. If no password prompt is issued and the server requires password authentication, the connection attempt will fail.

-w --no-password Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a .pgpass file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

> **Note** This option remains set for the entire session, and so it affects uses of the meta-command `\connect` as well as the initial connection attempt.

Exit Status

`psql` returns 0 to the shell if it finished normally, 1 if a fatal error of its own (out of memory, file not found) occurs, 2 if the connection to the server went bad and the session was not interactive, and 3 if an error occurred in a script and the variable `ON_ERROR_STOP` was set.

Usage

Connecting to a Database

`psql` is a client application for WarehousePG. In order to connect to a database you need to know the name of your target database, the host name and port number of the WarehousePG coordinator server and what database user name you want to connect as. `psql` can be told about those parameters via command line options, namely `-d`, `-h`, `-p`, and `-U` respectively. If an argument is found that does not belong to any option it will be interpreted as the database name (or the user name, if the database name is already given). Not all of these options are required; there are useful defaults. If you omit the host name, `psql` will connect via a UNIX-domain socket to a coordinator server on the local host, or via TCP/IP to `localhost` on machines that do not have UNIX-domain sockets. The default coordinator port number is 5432. If you use a different port for the coordinator, you must specify the port. The default database user name is your operating-system user name, as is the default database name. Note that you cannot just connect to any database under any user name. Your database administrator should have informed you about your access rights.

When the defaults are not right, you can save yourself some typing by setting any or all of the environment variables `PGAPPNAME`, `PGDATABASE`, `PGHOST`, `PGPORT`, and `PGUSER` to appropriate values.

It is also convenient to have a `~/.pgpass` file to avoid regularly having to type in passwords. This file should reside in your home directory and contain lines of the following format:

```
<hostname>:<port>:<database>:<username>:<password>
```

The permissions on `.pgpass` must disallow any access to world or group (for example: `chmod 0600 ~/.pgpass`). If the permissions are less strict than this, the file will be ignored. (The file permissions are not currently checked on Microsoft Windows clients, however.)

An alternative way to specify connection parameters is in a `conninfo` string or a URI, which is used instead of a database name. This mechanism gives you very wide control over the connection. For example:

```
$ psql "service=myservice sslmode=require"
$ psql postgresql://gpcoordinator:5433/mydb?sslmode=require
```

This way you can also use LDAP for connection parameter lookup as described in LDAP Lookup of Connection Parameters in the PostgreSQL documentation. See Parameter Keywords in the PostgreSQL documentation for more information on all the available connection options.

If the connection could not be made for any reason (insufficient privileges, server is not running, etc.), `psql` will return an error and terminate.

If at least one of standard input or standard output are a terminal, then `psql` sets the client encoding to `auto`, which will detect the appropriate client encoding from the locale settings (`LC_CTYPE` environment variable on Unix systems). If this doesn't work out as expected, the client encoding can be overridden using the environment variable `PGCLIENTENCODING`.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Entering SQL Commands

In normal operation, `psql` provides a prompt with the name of the database to which `psql` is currently connected, followed by the string **=>** for a regular user or **=#** for a superuser. For example:

```
testdb=>
testdb=#
```

At the prompt, the user may type in SQL commands. Ordinarily, input lines are sent to the server when a command-terminating semicolon is reached. An end of line does not terminate a command. Thus commands can be spread over several lines for clarity. If the command was sent and run without error, the results of the command are displayed on the screen.

If untrusted users have access to a database that has not adopted a secure schema usage pattern, begin your session by removing publicly-writable schemas from search_path. You can add `options=-csearch_path=` to the connection string or issue `SELECT pg_catalog.set_config('search_path', '', false)` before other SQL commands. This consideration is not specific to `psql`; it applies to every interface for running arbitrary SQL commands.

Meta-Commands

Anything you enter in `psql` that begins with an unquoted backslash is a `psql` meta-command that is processed by `psql` itself. These commands help make `psql` more useful for administration or scripting. Meta-commands are more commonly called slash or backslash commands.

The format of a `psql` command is the backslash, followed immediately by a command verb, then any arguments. The arguments are separated from the command verb and each other by any number of whitespace characters.

To include whitespace into an argument you may quote it with single quotes. To include a single quote into such an argument, write two single quotes within single-quoted text. Anything contained in single quotes is furthermore subject to C-like substitutions for `\n` (new line), `\t` (tab), `\b` (backspace), `\r` (carriage return), `\f` (form feed), `\digits` (octal), and `\xdigits` (hexadecimal). A backslash preceding any other character within single-quoted text quotes that single character, whatever it is.

Within an argument, text that is enclosed in backquotes (```) is taken as a command line that is passed to the shell. The output of the command (with any trailing newline removed) replaces the backquoted text.

If an unquoted colon (`:`) followed by a `psql` variable name appears within an argument, it is replaced by the variable's value, as described in SQL Interpolation.

Some commands take an SQL identifier (such as a table name) as argument. These arguments follow the syntax rules of SQL: Unquoted letters are forced to lowercase, while double quotes (`"`) protect letters from case conversion and allow incorporation of whitespace into the identifier. Within double quotes, paired double quotes reduce to a single double quote in the resulting name. For example, `FOO"BAR"BAZ` is interpreted as `fooBARbaz`, and `"A weird"" name"` becomes `A weird" name`.

Parsing for arguments stops when another unquoted backslash occurs. This is taken as the beginning of a new meta-command. The special sequence `\\` (two backslashes) marks the end of arguments and continues parsing SQL commands, if any. That way SQL and `psql` commands can be freely mixed on a line. But in any case, the arguments of a meta-command cannot continue beyond the end of the line.

The following meta-commands are defined:

\a If the current table output format is unaligned, it is switched to aligned. If it is not unaligned, it is set to unaligned. This command is kept for backwards compatibility. See `\pset` for a more general solution.

\c | \connect [dbname [username] [host] [port]] | conninfo Establishes a new WarehousePG connection. The connection parameters to use can be specified either using a positional syntax, or using `conninfo` connection strings as detailed in libpq Connection Strings.

Where the command omits database name, user, host, or port, the new connection can reuse values from the previous connection. By default, values from the previous connection are reused except when processing a `conninfo` string. Passing a first argument of `-reuse-previous=on` or `-reuse-previous=off` overrides that default. When the command neither specifies nor reuses a particular parameter, the `libpq` default is used. Specifying any of dbname, username, host or port as `-` is equivalent to omitting that parameter.

If the new connection is successfully made, the previous connection is closed. If the connection attempt failed, the previous connection will only be kept if `psql` is in interactive mode. When running a non-interactive script, processing will immediately stop with an error. This distinction was chosen as a user convenience against typos, and a safety mechanism that scripts are not accidentally acting on the wrong database.

Examples:

```
```
=> \c mydb myuser host.dom 6432
=> \c service=foo
=> \c "host=localhost port=5432 dbname=mydb connect_timeout=10 sslmode=disable"
=> \c postgresql://tom@localhost/mydb?application_name=myapp
```
```

\C [title] Sets the title of any tables being printed as the result of a query or unset any such title. This command is equivalent to `\pset title`.

\cd [directory] Changes the current working directory. Without argument, changes to the current user's home directory. To print your current working directory, use `\!pwd`.

\conninfo Displays information about the current connection including the database name, the user name, the type of connection (UNIX domain socket, `TCP/IP`, etc.), the host, and the port.

\copy {table [(column_list)] | (query)} {from | to} {'filename' | program 'command' | stdin | stdout | pstdin | pstdout} [with] (option [, ...])] Performs a frontend (client) copy. This is an operation that runs an SQL `[COPY](../../ref_guide/sql_commands/COPY.html)` command, but instead of the server reading or writing the specified file, `psql` reads or writes the file and routes the data between the server and the local file system. This means that file accessibility and privileges are those of the local user, not the server, and no SQL superuser privileges are required.

When `program` is specified, command is run by `psql` and the data from or to command is routed between the server and the client. This means that the execution privileges are those of the local user, not the server, and no SQL superuser privileges are required.

`\copy ... from stdin | to stdout` reads/writes based on the command input and output respectively. All rows are read from the same source that issued the command, continuing until `\.` is read or the stream reaches `EOF`. Output is sent to the same place as command output. To read/write from `psql`'s standard input or output, use `pstdin` or `pstdout`. This option is useful for populating tables in-line within a SQL script file.

The syntax of the command is similar to that of the SQL COPY command, and option must indicate one of the options of the SQL `COPY` command. Note that, because of this, special parsing rules apply to the `\copy` command. In particular, the variable substitution rules and backslash escapes do not apply.

This operation is not as efficient as the SQL `COPY` command because all data must pass through the client/server connection.

\copyright Shows the copyright and distribution terms of PostgreSQL on which WarehousePG is based.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

\d [relation_pattern] | \d+ [relation_pattern] | \dS [relation_pattern] For each relation (table, external table, view, materialized view, index, sequence, or foreign table) or composite type matching the relation pattern, show all columns, their types, the tablespace (if not the default) and any special attributes such as `NOT NULL` or defaults. Associated indexes, constraints, rules, and triggers are also shown. For foreign tables, the associated foreign server is shown as well.

```
-   For some types of relation, `\d` shows additional information for each column: column values for sequences, indexed expressions for indexes, and foreign data
wrapper options for foreign tables.
-   The command form `\d+` is identical, except that more information is displayed: any comments associated with the columns of the table are shown, as is the
presence of OIDs in the table, the view definition if the relation is a view.
    <br/><br/>For partitioned tables, the command `\d` or `\d+` specified with the root partitioned table or a child table displays information about the table
including partition keys on the current level of the partitioned table. The command `\d+` also displays the immediate child partitions of the table and whether
the partition is an external table or regular table.
    <br/><br/>For append-optimized tables and column-oriented tables, `\d+` displays the storage options for a table. For append-optimized tables, the options are
displayed for the table. For column-oriented tables, storage options are displayed for each column.

-   By default, only user-created objects are shown; supply a pattern or the `S` modifier to include system objects.
    <br/><br/>> **Note** If `\d` is used without a pattern argument, it is equivalent to `\dtvmsE` which will show a list of all visible tables, views,
materialized views, sequences, and foreign tables.
```

\da[S] [aggregate_pattern] Lists aggregate functions, together with the data types they operate on. If a pattern is specified, only aggregates whose names match the pattern are shown. By default, only user-created objects are shown; supply a pattern or the `S` modifier to include system objects.

\db[+] [tablespace_pattern] Lists all available tablespaces and their corresponding paths. If pattern is specified, only tablespaces whose names match the pattern are shown. If + is appended to the command name, each object is listed with its associated permissions.

\dc[S+] [conversion_pattern] Lists conversions between character-set encodings. If a pattern is specified, only conversions whose names match the pattern are listed. By default, only user-created objects are shown; supply a pattern or the `S` modifier to include system objects. If `+` is appended to the command name, each object is listed with its associated description.

\dC[+] [pattern] Lists type casts. If a pattern is specified, only casts whose source or target types match the pattern are listed. If `+` is appended to the command name, each object is listed with its associated description.

\dd[S] [pattern] Shows the descriptions of objects of type `constraint`, `operator class`, `operator family`, `rule`, and `trigger`. All other comments may be viewed by the respective backslash commands for those object types.

`\dd` displays descriptions for objects matching the pattern, or of visible objects of the appropriate type if no argument is given. But in either case, only objects that have a description are listed. By default, only user-created objects are shown; supply a pattern or the `S` modifier to include system objects.

Descriptions for objects can be created with the `COMMENT` SQL command.

\ddp [pattern] Lists default access privilege settings. An entry is shown for each role (and schema, if applicable) for which the default privilege settings have been changed from the built-in defaults. If pattern is specified, only entries whose role name or schema name matches the pattern are listed.

The ALTER DEFAULT PRIVILEGES command is used to set default access privileges. The meaning of the privilege display is explained under GRANT.

\dD[S+] [domain_pattern] Lists domains. If a pattern is specified, only domains whose names match the pattern are shown. By default, only user-created objects are shown; supply a pattern or the `S` modifier to include system objects. If `+` is appended to the command name, each object is listed with its associated permissions and description.

\dEimstPv[S+] [external_table | index | materialized_view | sequence | table | parent table | view] This is not the actual command name: the letters `E`, `i`, `m`, `s`, `t`, `P`, and `v` stand for external table, index, materialized view, sequence, table, parent table, and view, respectively. You can specify any or all of these letters, in any order, to obtain a listing of objects of these types. For example, `\dit` lists indexes and tables. If `+` is appended to the command name, each object is listed with its physical size on disk and its associated description, if any. If a pattern is specified, only objects whose names match the pattern are listed. By default, only user-created objects are shown; supply a pattern or the `S` modifier to include system objects.

\des[+] [foreign_server_pattern] Lists foreign servers. If a pattern is specified, only those servers whose name matches the pattern are listed. If the form `\des+` is used, a full description of each server is shown, including the server's ACL, type, version, options, and description.

\det[+] [foreign_table_pattern] Lists all foreign tables. If a pattern is specified, only entries whose table name or schema name matches the pattern are listed. If the form `\det+` is used, generic options and the foreign table description are also displayed.

\deu[+] [user_mapping_pattern] Lists user mappings. If a pattern is specified, only those mappings whose user names match the pattern are listed. If the form `\deu+` is used, additional information about each mapping is shown.

```
> **Caution** `\deu+` might also display the user name and password of the remote user, so care should be taken not to disclose them.
```

\dew[+] [foreign_data_wrapper_pattern] Lists foreign-data wrappers. If a pattern is specified, only those foriegn-data wrappers whose name matches the pattern are listed. If the form `\dew+` is used, the ACL, options, and description of the foreign-data wrapper are also shown.

\df[antwS+] [function_pattern] Lists functions, together with their arguments, return types, and function types, which are classified as "agg" (aggregate), "normal", "trigger", or "window". To display only functions of a specific type(s), add the corresponding letters `a`, `n`, `t`, or `w`, to the command. If a pattern is specified, only functions whose names match the pattern are shown. If the form `\df+` is used, additional information about each function, including security, volatility, language, source code, and description, is shown. By default, only user-created objects are shown; supply a pattern or the `S` modifier to include system objects.

\dF[+] [pattern] Lists text search configurations. If a pattern is specified, only configurations whose names match the pattern are shown. If the form `\dF+` is used, a full description of each configuration is shown, including the underlying text search parser and the dictionary list for each parser token type.

\dFd[+] [pattern] Lists text search dictionaries. If a pattern is specified, only dictionaries whose names match the pattern are shown. If the form `\dFd+` is used, additional information is shown about each selected dictionary, including the underlying text search template and the option values.

\dFp[+] [pattern] Lists text search parsers. If a pattern is specified, only parsers whose names match the pattern are shown. If the form `\dFp+` is used, a full description of each parser is shown, including the underlying functions and the list of recognized token types.

\dFt[+] [pattern] Lists text search templates. If a pattern is specified, only templates whose names match the pattern are shown. If the form `\dFt+` is used, additional information is shown about each template, including the underlying function names.

\dg[+] [role_pattern] Lists database roles. (Since the concepts of "users" and "groups" have been unified into "roles", this command is now equivalent to `\du`.) If a pattern is specified, only those roles whose names match the pattern are listed. If the form `\dg+` is used, additional information is shown about each role; currently this adds the comment for each role.

\dl This is an alias for `\lo_list`, which shows a list of large objects.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

> **Note** WarehousePG does not support the PostgreSQL [large object facility](https://www.postgresql.org/docs/12/largeobjects.html) for streaming user data that is stored in large-object structures.

\dL[S+] [pattern] Lists procedural languages. If a pattern is specified, only languages whose names match the pattern are listed. By default, only user-created languages are shown; supply the `S` modifier to include system objects. If `+` is appended to the command name, each language is listed with its call handler, validator, access privileges, and whether it is a system object.

\dn[S+] [schema_pattern] Lists all available schemas (namespaces). If a pattern is specified, only schemas whose names match the pattern are listed. By default, only user- create objects are show; supply a pattern or the `S` modifier to include system objects. If `+` is appended to the command name, each object is listed with its associated permissions and description, if any.

\do[S] [operator_pattern] Lists available operators with their operand and return types. If a pattern is specified, only operators whose names match the pattern are listed. By default, only user-created objects are shown; supply a pattern or the `S` modifier to include system objects.

\dO[S+] [pattern] Lists collations. If a pattern is specified, only collations whose names match the pattern are listed. By default, only user-created objects are shown; supply a pattern or the `S` modifier to include system objects. If `+` is appended to the command name, each collation is listed with its associated description, if any. Note that only collations usable with the current database's encoding are shown, so the results may vary in different databases of the same installation.

\dp [relation_pattern_to_show_privileges] Lists tables, views, and sequences with their associated access privileges. If a pattern is specified, only tables, views, and sequences whose names match the pattern are listed. TheGRANT and REVOKE commands are used to set access privileges. The meaning of the privilege display is explained under GRANT.

\drds [role-pattern [database-pattern]] Lists defined configuration settings. These settings can be role-specific, database-specific, or both. role-pattern and database-pattern are used to select specific roles and database to list, respectively. If omitted, or if `*` is specified, all settings are listed, including those not role-specific or database-specific, respectively.

The ALTER ROLE and ALTER DATABASE commands are used to define per-role and per-database role configuration settings.

\dT[S+] [datatype_pattern] Lists data types. If a pattern is specified, only types whose names match the pattern are listed. If `+` is appended to the command name, each type is listed with its internal name and size, its allowed values if it is an `enum` type, and its associated permissions. By default, only user-created objects are shown; supply a pattern or the `S` modifier to include system objects.

\du[+] [role_pattern] Lists database roles. (Since the concepts of "users" and "groups" have been unified into "roles", this command is now equivalent to `\dg`.) If a pattern is specified, only those roles whose names match the pattern are listed. If the form `\du+` is used, additional information is shown about each role; currently this adds the comment for each role.

\dx[+] [extension_pattern] Lists installed extensions. If a pattern is specified, only those extensions whose names match the pattern are listed. If the form `\dx+` is used, all of the objects belonging to each matching extension are listed.

\dy[+] [pattern] Lists event triggers. If a pattern is specified, only those triggers whose names match the pattern are listed. If `+` is appended to the command name, each object is listed with its associated description.

\dy[+] [pattern] Lists event triggers. If a pattern is specified, only those triggers whose names match the pattern are listed. If `+` is appended to the command name, each object is listed with its associated description.

> **Note** WarehousePG does not support user-defined triggers.

\e | \edit [filename] [line_number] If filename is specified, the file is edited; after the editor exits, its content is copied back to the query buffer. If no filename is given, the current query buffer is copied to a temporary file which is then edited in the same fashion.

The new query buffer is then re-parsed according to the normal rules of `psql`, where the whole buffer is treated as a single line. (Thus you cannot make scripts this way. Use `\i` for that.) This means also that if the query ends with (or rather contains) a semicolon, it is immediately run. In other cases it will merely wait in the query buffer; type semicolon or `\g` to send it, or `\r` to cancel.

If a line number is specified, `psql` will position the cursor on the specified line of the file or query buffer. Note that if a single all-digits argument is given, `psql` assumes it is a line number, not a file name.

See Environment for information about configuring and customizing your editor.

\echo text [...] Prints the arguments to the standard output, separated by one space and followed by a newline. This can be useful to intersperse information in the output of scripts. If the first argument is an unquoted `-n`, the trailing newline is not written.

> **Note** If you use the `\o` command to redirect your query output you might wish to use `\qecho` instead of this command.

\ef [function_description [line_number]] This command fetches and edits the definition of the named function, in the form of a `CREATE OR REPLACE FUNCTION` command. Editing is done in the same way as for `\edit`. After the editor exits, the updated command waits in the query buffer; type semicolon or `\g` to send it, or `\r` to cancel.

The target function can be specified by name alone, or by name and arguments, for example `foo(integer, text)`. The argument types must be given if there is more than one function with the same name.

If no function is specified, a blank `CREATE FUNCTION` template is presented for editing.

If a line number is specified, `psql` will position the cursor on the specified line of the function body. (Note that the function body typically does not begin on the first line of the file.)

See Environment for information about configuring and customizing your editor.

\encoding [encoding] Sets the client character set encoding. Without an argument, this command shows the current encoding.

\f [field_separator_string] Sets the field separator for unaligned query output. The default is the vertical bar (`|`). See also `\pset` for a generic way of setting output options.

\g [filename] \g [| command] Sends the current query input buffer to the server, and optionally stores the query's output in filename or pipes the output to the shell command command. The file or command is written to only if the query successfully returns zero or more tuples, not if the query fails or is a non-data-returning SQL command.

A bare `\g` is essentially equivalent to a semi-colon. A `\g` with argument is a one-shot alternative to the `\o` command.

\gset [prefix] Sends the current query input buffer to the server and stores the query's output into `psql` variables. The query to be run must return exactly one row. Each column of the row is stored into a separate variable, named the same as the column. For example:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
=> SELECT 'hello' AS var1, 10 AS var2;
-> \gset
=> \echo :var1 :var2
hello 10

```

If you specify a prefix, that string is prepended to the query's column names to create the variable names to use:

```
=> SELECT 'hello' AS var1, 10 AS var2;
-> \gset result_
=> \echo :result_var1 :result_var2
hello 10
```

If a column result is NULL, the corresponding variable is unset rather than being set.

If the query fails or does not return one row, no variables are changed.

\h | \help [sql_command] Gives syntax help on the specified SQL command. If a command is not specified, then `psql` will list all the commands for which syntax help is available. If command is an asterisk (`*`) then syntax help on all SQL commands is shown. To simplify typing, commands that consist of several words do not have to be quoted.

\H | \html Turns on HTML query output format. If the HTML format is already on, it is switched back to the default aligned text format. This command is for compatibility and convenience, but see `\pset` about setting other output options.

\i | \include filename Reads input from the file filename and runs it as though it had been typed on the keyboard.

If filename is `-` (hyphen), then standard input is read until an EOF indication or `\q` meta-command. This can be used to intersperse interactive input with input from files. Note that Readline behavior will be used only if it is active at the outermost level.

If you want to see the lines on the screen as they are read you must set the variable `ECHO` to `all`.

\ir | \include_relative filename The `\ir` command is similar to `\i`, but resolves relative file names differently. When running in interactive mode, the two commands behave identically. However, when invoked from a script, `\ir` interprets file names relative to the directory in which the script is located, rather than the current working directory.

\l[+] | \list[+] [pattern] List the databases in the server and show their names, owners, character set encodings, and access privileges. If a pattern is specified, only databases whose names match the pattern are listed. If `+` is appended to the command name, database sizes, default tablespaces, and descriptions are also displayed. (Size information is only available for databases that the current user can connect to.)

\lo_export loid filename Reads the large object with OID loid from the database and writes it to filename. Note that this is subtly different from the server function `lo_export`, which acts with the permissions of the user that the database server runs as and on the server's file system. Use `\lo_list` to find out the large object's OID.

```
> **Note** WarehousePG does not support the PostgreSQL [large object facility](https://www.postgresql.org/docs/12/largeobjects.html) for streaming user data that
is stored in large-object structures.
```

\lo_import large_object_filename [comment] Stores the file into a large object. Optionally, it associates the given comment with the object. Example:

```
mydb=> \lo_import '/home/gpadmin/pictures/photo.xcf' 'a
picture of me'
lo_import 152801
```

The response indicates that the large object received object ID 152801 which one ought to remember if one wants to access the object ever again. For that reason it is recommended to always associate a human-readable comment with every object. Those can then be seen with the `\lo_list` command. Note that this command is subtly different from the server-side `lo_import` because it acts as the local user on the local file system, rather than the server's user and file system.

> **Note** WarehousePG does not support the PostgreSQL large object facility for streaming user data that is stored in large-object structures.

\lo_list Shows a list of all large objects currently stored in the database, along with any comments provided for them.

```
> **Note** WarehousePG does not support the PostgreSQL [large object facility](https://www.postgresql.org/docs/12/largeobjects.html) for streaming user data that
is stored in large-object structures.
```

\lo_unlink largeobject_oid Deletes the large object of the specified OID from the database. Use `\lo_list` to find out the large object's OID.

```
> **Note** WarehousePG does not support the PostgreSQL [large object facility](https://www.postgresql.org/docs/12/largeobjects.html) for streaming user data that
is stored in large-object structures.
```

\o | \out [filename] \o | \out [`|` command] Saves future query results to the file filename or pipes future results to the shell command command. If no argument is specified, the query output is reset to the standard output. Query results include all tables, command responses, and notices obtained from the database server, as well as output of various backslash commands that query the database (such as `\d`), but not error messages. To intersperse text output in between query results, use `\qecho`.

\p Print the current query buffer to the standard output.

\password [username] Changes the password of the specified user (by default, the current user). This command prompts for the new password, encrypts it, and sends it to the server as an `ALTER ROLE` command. This makes sure that the new password does not appear in cleartext in the command history, the server log, or elsewhere.

\prompt [text] name Prompts the user to supply text, which is assigned to the variable name. An optional prompt string, text, can be specified. (For multiword prompts, surround the text with single quotes.)

By default, `\prompt` uses the terminal for input and output. However, if the `-f` command line switch was used, `\prompt` uses standard input and standard output.

\pset [print_option [value]] This command sets options affecting the output of query result tables. print_option describes which option is to be set. The semantics of value vary depending on the selected option. For some options, omitting value causes the option to be toggled or unset, as described under the particular option. If no such behavior is mentioned, then omitting value just results in the current setting being displayed.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

`\pset` without any arguments displays the current status of all printing options.

Adjustable printing options are:

```
-   **`border`** - The value must be a number. In general, the higher the number the more borders and lines the tables will have, but this depends on the
particular format. In HTML format, this will translate directly into the `border=...` attribute; in the other formats only values `0` \(no border\), `1` \
(internal dividing lines\), and `2` \(table frame\) make sense. `latex` and `latex-longtable` also support a `border` value of 3 which adds a dividing line
between each row.
-   **`columns`** - Sets the target width for the `wrapped` format, and also the width limit for determining whether output is wide enough to require the pager or
switch to the vertical display in expanded auto mode. The default is zero. Zero causes the target width to be controlled by the environment variable `COLUMNS`, or
the detected screen width if `COLUMNS` is not set. In addition, if `columns` is zero then the wrapped format affects screen output only. If columns is nonzero
then file and pipe output is wrapped to that width as well.
    <br/><br/>After setting the target width, use the command `\pset format wrapped` to enable the wrapped format.

-   **`expanded`** \| **`x`** - If value is specified it must be either `on` or `off`, which will activate or deactivate expanded mode, or `auto`. If value is
omitted the command toggles between the `on` and `off` settings. When expanded mode is enabled, query results are displayed in two columns, with the column name
on the left and the data on the right. This mode is useful if the data wouldn't fit on the screen in the normal "horizontal" mode. In the `auto` setting, the
expanded mode is used whenever the query output is wider than the screen, otherwise the regular mode is used. The `auto` setting is only effective in the aligned
and wrapped formats. In other formats, it always behaves as if the expanded mode is `off`.
-   **`fieldsep`** - Specifies the field separator to be used in unaligned output mode. That way one can create, for example, tab- or comma-separated output,
which other programs might prefer. To set a tab as field separator, type `\pset fieldsep '\t'`. The default field separator is `'|'` \(a vertical bar\).
-   **`fieldsep_zero`** - Sets the field separator to use in unaligned output format to a zero byte.
-   **`footer`** - If value is specified it must be either `on` or `off` which will activate or deactivate display of the table footer \(the \(n rows\) count\).
If value is omitted the command toggles footer display on or off.
-   **`format`** - Sets the output format to one of `unaligned`, `aligned`, `html`, `latex` \(uses `tabular`\), `latex-longtable`, `troff-ms`, or `wrapped`.
Unique abbreviations are allowed.
    **`unaligned`** format writes all columns of a row on one line, separated by the currently active field separator. This is useful for creating output that
might be intended to be read in by other programs \(for example, tab-separated or comma-separated format\).
    <br/><br/>**`aligned`** format is the standard, human-readable, nicely formatted text output; this is the default.
    <br/><br/>The **`html`**, **`latex`**, **`latex-longtable`**, and **`troff-ms`** formats put out tables that are intended to be included in documents using
the respective mark-up language. They are not complete documents! \(This might not be so dramatic in HTML, but in LaTeX you must have a complete document wrapper.
`latex-longtable` also requires the LaTeX `longtable` and `booktabs` packages.\)
    <br/><br/>The **`wrapped`** format is like `aligned`, but wraps wide data values across lines to make the output fit in the target column width. The target
width is determined as described under the `columns` option. Note that `psql` does not attempt to wrap column header titles; the `wrapped` format behaves the same
as `aligned` if the total width needed for column headers exceeds the target.

-   **`linestyle`** \[**`unicode`** \| **`ascii`** \| **`old-ascii`**\] - Sets the border line drawing style to one of unicode, ascii, or old-ascii. Unique
abbreviations, including one letter, are allowed for the three styles. The default setting is `ascii`. This option only affects the `aligned` and `wrapped` output
formats.
    <br/><br/>**`ascii`** - uses plain ASCII characters. Newlines in data are shown using a `+` symbol in the right-hand margin. When the wrapped format wraps
data from one line to the next without a newline character, a dot \(`.`\) is shown in the right-hand margin of the first line, and again in the left-hand margin
of the following line.
    <br/><br/>**`old-ascii`** - style uses plain ASCII characters, using the formatting style used in PostgreSQL 8.4 and earlier. Newlines in data are shown using
a `:` symbol in place of the left-hand column separator. When the data is wrapped from one line to the next without a newline character, a `;` symbol is used in
place of the left-hand column separator.
    <br/><br/>**`unicode`** - style uses Unicode box-drawing characters. Newlines in data are shown using a carriage return symbol in the right-hand margin. When
the data is wrapped from one line to the next without a newline character, an ellipsis symbol is shown in the right-hand margin of the first line, and again in
the left-hand margin of the following line.
    <br/><br/>When the `border` setting is greater than zero, this option also determines the characters with which the border lines are drawn. Plain ASCII
characters work everywhere, but Unicode characters look nicer on displays that recognize them.

-   **`null 'string'`** - The second argument is a string to print whenever a column is null. The default is to print nothing, which can easily be mistaken for an
empty string. For example, one might prefer `\pset null '(null)'`.
-   **`numericlocale`** - If value is specified it must be either `on` or `off` which will activate or deactivate display of a locale-specific character to
separate groups of digits to the left of the decimal marker. If value is omitted the command toggles between regular and locale-specific numeric output.
-   **`pager`** - Controls the use of a pager for query and `psql` help output. If the environment variable `PAGER` is set, the output is piped to the specified
program. Otherwise a platform-dependent default \(such as `more`\) is used. When `off`, the pager program is not used. When `on`, the pager is used only when
appropriate, i.e. when the output is to a terminal and will not fit on the screen. Pager can also be set to `always`, which causes the pager to be used for all
terminal output regardless of whether it fits on the screen. `\pset pager` without a value toggles pager use on and off.
-   **`recordsep`** - Specifies the record \(line\) separator to use in unaligned output mode. The default is a newline character.
-   **`recordsep_zero`** - Sets the record separator to use in unaligned output format to a zero byte.
-   **`tableattr`** \| **`T`** \[text\] - In HTML format, this specifies attributes to be placed inside the HTML `table` tag. This could for example be
`cellpadding` or `bgcolor`. Note that you probably don't want to specify `border` here, as that is already taken care of by `\pset border`. If no value is given,
the table attributes are unset.
    <br/><br/>In `latex-longtable` format, this controls the proportional width of each column containing a left-aligned data type. It is specified as a
whitespace-separated list of values, e.g. `'0.2 0.2 0.6'`. Unspecified output columns use the last specified value.

-   **`title`** \[text\] - Sets the table title for any subsequently printed tables. This can be used to give your output descriptive tags. If no value is given,
the title is unset.
-   **`tuples_only`** \| **`t`** \[novalue \| on \| off\] - If value is specified, it must be either `on` or `off` which will activate or deactivate tuples-only
mode. If value is omitted the command toggles between regular and tuples-only output. Regular output includes extra information such as column headers, titles,
and various footers. In tuples-only mode, only actual table data is shown. The `\t` command is equivalent to `\pset``tuples_only` and is provided for convenience.

**Tip:**

There are various shortcut commands for `\pset`. See `\a`, `\C`, `\f`, `\H`, `\t`, `\T`, and `\x`.
```

\q | \quit Quits the `psql` program. In a script file, only execution of that script is terminated.

\qecho text [...] This command is identical to `\echo` except that the output will be written to the query output channel, as set by `\o`.

\r | \reset Resets (clears) the query buffer.

\s [filename] Print `psql`'s command line history to `filename`. If `filename` is omitted, the history is written to the standard output (using the pager if appropriate). This command is not available if `psql` was built without `Readline` support.

\set [name [value [...]]] Sets the `psql` variable name to value, or if more than one value is given, to the concatenation of all of them. If only one argument is given, the variable is just set with an empty value. To unset a variable, use the `\unset` command.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

`\set` without any arguments displays the names and values of all currently-set `psql` variables.

Valid variable names can contain characters, digits, and underscores. See "Variables" in Advanced Features. Variable names are case-sensitive.

Although you are welcome to set any variable to anything you want, `psql` treats several variables as special. They are documented in the topic about variables.

This command is unrelated to the SQL command SET.

\setenv name [value] Sets the environment variable name to value, or if the value is not supplied, unsets the environment variable. Example:

```
testdb=> \setenv PAGER less
testdb=> \setenv LESS -imx4F
```

\sf[+] function_description This command fetches and shows the definition of the named function, in the form of a `CREATE OR REPLACE FUNCTION` command. The definition is printed to the current query output channel, as set by `\o`.

The target function can be specified by name alone, or by name and arguments, for example `foo(integer, text)`. The argument types must be given if there is more than one function of the same name.

If `+` is appended to the command name, then the output lines are numbered, with the first line of the function body being line 1.

\t [novalue | on | off] The `\t` command by itself toggles a display of output column name headings and row count footer. The values `on` and `off` set the tuples display, regardless of the current setting. This command is equivalent to `\pset tuples_only` and is provided for convenience.

\T table_options Specifies attributes to be placed within the `table` tag in HTML output format. This command is equivalent to `\pset tableattr table_options`

\timing [novalue | on | off] Without a parameter, toggles a display of how long each SQL statement takes, in milliseconds. The values `on` and `off` set the time display, regardless of the current setting.

\unset name Unsets (deletes) the `psql` variable name.

\w | \write filename \w | \write `|` command Outputs the current query buffer to the file filename or pipes it to the shell command command.

\watch [seconds] Repeatedly runs the current query buffer (like `\g`) until interrupted or the query fails. Wait the specified number of seconds (default 2) between executions.

\x [on | off | auto] Sets or toggles expanded table formatting mode. As such it is equivalent to `\pset expanded`.

\z [pattern] Lists tables, views, and sequences with their associated access privileges. If a pattern is specified, only tables, views and sequences whose names match the pattern are listed. This is an alias for `\dp`.

\! [command] Escapes to a separate shell or runs the shell command command. The arguments are not further interpreted; the shell will see them as-is. In particular, the variable substitution rules and backslash escapes do not apply.

\? Shows help information about the `psql` backslash commands.

Patterns

The various `\d` commands accept a pattern parameter to specify the object name(s) to be displayed. In the simplest case, a pattern is just the exact name of the object. The characters within a pattern are normally folded to lower case, just as in SQL names; for example, `\dt FOO` will display the table named `foo`. As in SQL names, placing double quotes around a pattern stops folding to lower case. Should you need to include an actual double quote character in a pattern, write it as a pair of double quotes within a double-quote sequence; again this is in accord with the rules for SQL quoted identifiers. For example, `\dt "FOO""BAR"` will display the table named `FOO"BAR` (not `foo"bar`). Unlike the normal rules for SQL names, you can put double quotes around just part of a pattern, for instance `\dt FOO"FOO"BAR` will display the table named `fooFOObar`.

Within a pattern, `*` matches any sequence of characters (including no characters) and `?` matches any single character. (This notation is comparable to UNIX shell file name patterns.) For example, `\dt int*` displays all tables whose names begin with `int`. But within double quotes, `*` and `?` lose these special meanings and are just matched literally.

A pattern that contains a dot (`.`) is interpreted as a schema name pattern followed by an object name pattern. For example, `\dt foo*.bar*` displays all tables whose table name starts with `bar` that are in schemas whose schema name starts with `foo`. When no dot appears, then the pattern matches only objects that are visible in the current schema search path. Again, a dot within double quotes loses its special meaning and is matched literally.

Advanced users can use regular-expression notations. All regular expression special characters work as specified in thePostgreSQL documentation on regular expressions, except for `.` which is taken as a separator as mentioned above, `*` which is translated to the regular-expression notation `.*`, and `?` which is translated to `.`. You can emulate these pattern characters at need by writing `?` for `.`, `(R+|)` for `R*`, or `(R|)` for `R?`. Remember that the pattern must match the whole name, unlike the usual interpretation of regular expressions; write `*` at the beginning and/or end if you don't wish the pattern to be anchored. Note that within double quotes, all regular expression special characters lose their special meanings and are matched literally. Also, the regular expression special characters are matched literally in operator name patterns (such as the argument of `\do`).

Whenever the pattern parameter is omitted completely, the `\d` commands display all objects that are visible in the current schema search path – this is equivalent to using the pattern `*.`. To see all objects in the database, use the pattern `*.*.`

Advanced Features

Variables

`psql` provides variable substitution features similar to common UNIX command shells. Variables are simply name/value pairs, where the value can be any string of any length. The name must consist of letters (including non-Latin letters), digits, and underscores.

To set a variable, use the psql meta-command `\set`. For example,

```
testdb=> \set foo bar
```

sets the variable `foo` to the value `bar`. To retrieve the content of the variable, precede the name with a colon, for example:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
testdb=> \echo :foo
bar
```

This works in both regular SQL commands and meta-commands; there is more detail in SQL Interpolation.

If you call `\set` without a second argument, the variable is set, with an empty string as value. To unset (i.e., delete) a variable, use the command `\unset`. To show the values of all variables, call `\set` without any argument.

> **Note** The arguments of `\set` are subject to the same substitution rules as with other commands. Thus you can construct interesting references such as `\set :foo 'something'` and get 'soft links' or 'variable variables' of Perl or PHP fame, respectively. Unfortunately, there is no way to do anything useful with these constructs. On the other hand, `\set bar :foo` is a perfectly valid way to copy a variable.

A number of these variables are treated specially by `psql`. They represent certain option settings that can be changed at run time by altering the value of the variable, or in some cases represent changeable state of `psql`. Although you can use these variables for other purposes, this is not recommended, as the program behavior might grow really strange really quickly. By convention, all specially treated variables' names consist of all upper-case ASCII letters (and possibly digits and underscores). To ensure maximum compatibility in the future, avoid using such variable names for your own purposes. A list of all specially treated variables follows.

AUTOCOMMIT When on (the default), each SQL command is automatically committed upon successful completion. To postpone commit in this mode, you must enter a `BEGIN` or `START TRANSACTION` SQL command. When off or unset, SQL commands are not committed until you explicitly issue `COMMIT` or `END`. The autocommit-on mode works by issuing an implicit `BEGIN` for you, just before any command that is not already in a transaction block and is not itself a `BEGIN` or other transaction-control command, nor a command that cannot be run inside a transaction block (such as `VACUUM`).

In autocommit-off mode, you must explicitly abandon any failed transaction by entering `ABORT` or `ROLLBACK`. Also keep in mind that if you exit the session without committing, your work will be lost.

The autocommit-on mode is PostgreSQL's traditional behavior, but autocommit-off is closer to the SQL spec. If you prefer autocommit-off, you may wish to set it in your `~/.psqlrc` file.

COMP_KEYWORD_CASE Determines which letter case to use when completing an SQL key word. If set to `lower` or `upper`, the completed word will be in lower or upper case, respectively. If set to `preserve-lower` or `preserve-upper` (the default), the completed word will be in the case of the word already entered, but words being completed without anything entered will be in lower or upper case, respectively.

DBNAME The name of the database you are currently connected to. This is set every time you connect to a database (including program start-up), but can be unset.

ECHO If set to `all`, all nonempty input lines are printed to standard output as they are read. (This does not apply to lines read interactively.) To select this behavior on program start-up, use the switch `-a`. If set to queries, `psql` prints each query to standard output as it is sent to the server. The switch for this is `-e`.

ECHO_HIDDEN When this variable is set to `on` and a backslash command queries the database, the query is first shown. This feature helps you to study WarehousePG internals and provide similar functionality in your own programs. (To select this behavior on program start-up, use the switch `-E`.) If you set the variable to the value `noexec`, the queries are just shown but are not actually sent to the server and run.

ENCODING The current client character set encoding.

FETCH_COUNT If this variable is set to an integer value > 0, the results of `SELECT` queries are fetched and displayed in groups of that many rows, rather than the default behavior of collecting the entire result set before display. Therefore only a limited amount of memory is used, regardless of the size of the result set. Settings of 100 to 1000 are commonly used when enabling this feature. Keep in mind that when using this feature, a query may fail after having already displayed some rows.

Although you can use any output format with this feature, the default aligned format tends to look bad because each group of `FETCH_COUNT` rows will be formatted separately, leading to varying column widths across the row groups. The other output formats work better.

HISTCONTROL If this variable is set to `ignorespace`, lines which begin with a space are not entered into the history list. If set to a value of `ignoredups`, lines matching the previous history line are not entered. A value of `ignoreboth` combines the two options. If unset, or if set to any other value than those above, all lines read in interactive mode are saved on the history list.

HISTFILE The file name that will be used to store the history list. The default value is `~/.psql_history`. For example, putting

```
```
\set HISTFILE ~/.psql_history- :DBNAME
```
```

in `~/.psqlrc` will cause `psql` to maintain a separate history for each database.

HISTSIZE The number of commands to store in the command history. The default value is 500.

HOST The database server host you are currently connected to. This is set every time you connect to a database (including program start-up), but can be unset.

IGNOREEOF If unset, sending an `EOF` character (usually `CTRL+D`) to an interactive session of `psql` will terminate the application. If set to a numeric value, that many `EOF` characters are ignored before the application terminates. If the variable is set but has no numeric value, the default is `10`.

LASTOID The value of the last affected OID, as returned from an `INSERT` or `lo_import` command. This variable is only guaranteed to be valid until after the result of the next SQL command has been displayed.

ON_ERROR_ROLLBACK When set to `on`, if a statement in a transaction block generates an error, the error is ignored and the transaction continues. When set to `interactive`, such errors are only ignored in interactive sessions, and not when reading script files. When unset or set to `off`, a statement in a transaction block that generates an error cancels the entire transaction. The error rollback mode works by issuing an implicit `SAVEPOINT` for you, just before each command that is in a transaction block, and rolls back to the savepoint on error.

ON_ERROR_STOP By default, command processing continues after an error. When this variable is set to `on`, processing will instead stop immediately. In interactive mode, `psql` will return to the command prompt; otherwise, `psql` will exit, returning error code 3 to distinguish this case from fatal error conditions, which are reported using error code 1. In either case, any currently running scripts (the top-level script, if any, and any other scripts which it may have in invoked) will be terminated immediately. If the top-level command string contained multiple SQL commands, processing will stop with the current command.

PORT The database server port to which you are currently connected. This is set every time you connect to a database (including program start-up), but can be unset.

PROMPT1 PROMPT2 PROMPT3 These specify what the prompts `psql` issues should look like. See "Prompting".

QUIET Setting this variable to `on` is equivalent to the command line option `-q`. It is not very useful in interactive mode.

SINGLELINE This variable is equivalent to the command line option `-S`.

SINGLESTEP Setting this variable to `on` is equivalent to the command line option `-s`.

USER The database user you are currently connected as. This is set every time you connect to a database (including program start-up), but can be unset.

VERBOSITY This variable can be set to the values `default`, `verbose`, or `terse` to control the verbosity of error reports.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

SQL Interpolation

A key feature of `psql` variables is that you can substitute ("interpolate") them into regular SQL statements, as well as the arguments of meta-commands. Furthermore, `psql` provides facilities for ensuring that variable values used as SQL literals and identifiers are properly quoted. The syntax for interpolating a value without any quoting is to prepend the variable name with a colon (`:`). For example,

```
testdb=> \set foo 'my_table'
testdb=> SELECT * FROM :foo;
```

would query the table `my_table`. Note that this may be unsafe: the value of the variable is copied literally, so it can contain unbalanced quotes, or even backslash commands. You must make sure that it makes sense where you put it.

When a value is to be used as an SQL literal or identifier, it is safest to arrange for it to be quoted. To quote the value of a variable as an SQL literal, write a colon followed by the variable name in single quotes. To quote the value as an SQL identifier, write a colon followed by the variable name in double quotes. These constructs deal correctly with quotes and other special characters embedded within the variable value. The previous example would be more safely written this way:

```
testdb=> \set foo 'my_table'
testdb=> SELECT * FROM :"foo";
```

Variable interpolation will not be performed within quoted SQL literals and identifiers. Therefore, a construction such as `':foo'` doesn't work to produce a quoted literal from a variable's value (and it would be unsafe if it did work, since it wouldn't correctly handle quotes embedded in the value).

One example use of this mechanism is to copy the contents of a file into a table column. First load the file into a variable and then interpolate the variable's value as a quoted string:

```
testdb=> \set content `cat my_file.txt`
testdb=> INSERT INTO my_table VALUES (:'content');
```

(Note that this still won't work if `my_file.txt` contains `NUL` bytes. `psql` does not support embedded `NUL` bytes in variable values.)

Since colons can legally appear in SQL commands, an apparent attempt at interpolation (that is, `:name`, `:'name'`, or `:"name"`) is not replaced unless the named variable is currently set. In any case, you can escape a colon with a backslash to protect it from substitution.

The colon syntax for variables is standard SQL for embedded query languages, such as ECPG. The colon syntaxes for array slices and type casts are WarehousePG extensions, which can sometimes conflict with the standard usage. The colon-quote syntax for escaping a variable's value as an SQL literal or identifier is a `psql` extension.

Prompting

The prompts `psql` issues can be customized to your preference. The three variables `PROMPT1`, `PROMPT2`, and `PROMPT3` contain strings and special escape sequences that describe the appearance of the prompt. Prompt 1 is the normal prompt that is issued when `psql` requests a new command. Prompt 2 is issued when more input is expected during command entry, for example because the command was not terminated with a semicolon or a quote was not closed. Prompt 3 is issued when you are running an SQL `COPY FROM STDIN` command and you need to type in a row value on the terminal.

The value of the selected prompt variable is printed literally, except where a percent sign (`%`) is encountered. Depending on the next character, certain other text is substituted instead. Defined substitutions are:

%M The full host name (with domain name) of the database server, or `[local]` if the connection is over a UNIX domain socket, or `[local:/dir/name]`, if the UNIX domain socket is not at the compiled in default location.

%m The host name of the database server, truncated at the first dot, or `[local]` if the connection is over a UNIX domain socket.

%> The port number at which the database server is listening.

%n The database session user name. (The expansion of this value might change during a database session as the result of the command `SET SESSION AUTHORIZATION`.)

%/ The name of the current database.

%~ Like `%/`, but the output is `~` (tilde) if the database is your default database.

%# If the session user is a database superuser, then a **#**, otherwise a **>**. (The expansion of this value might change during a database session as the result of the command `SET SESSION AUTHORIZATION`.)

%R In prompt 1 normally `=`, but `^` if in single-line mode, or `!` if the session is disconnected from the database (which can happen if `\connect` fails). In prompt 2 `%R` is replaced by a character that depends on why `psql` expects more input: `-` if the command simply wasn't terminated yet, but `*` if there is an unfinished `/* ... */` comment, a single quote if there is an unfinished quoted string, a double quote if there is an unfinished quoted identifier, a dollar sign if there is an unfinished dollar-quoted string, or `(` if there is an unmatched left parenthesis. In prompt 3 `%R` doesn't produce anything.

%x Transaction status: an empty string when not in a transaction block, or***** when in a transaction block, or**!** when in a failed transaction block, or**?** when the transaction state is indeterminate (for example, because there is no connection).

%digits The character with the indicated octal code is substituted.

%:name: The value of the `psql` variable name. See "Variables" in Advanced Features for details.

%`command` The output of command, similar to ordinary back-tick substitution.

%[... %] Prompts may contain terminal control characters which, for example, change the color, background, or style of the prompt text, or change the title of the terminal window. In order for line editing to work properly, these non-printing control characters must be designated as invisible by surrounding them with `%[` and `%]`. Multiple pairs of these may occur within the prompt. For example,

```
testdb=> \set PROMPT1 '%[%033[1;33;40m%]%n@%/%R%[%033[0m%]%#'
```

results in a boldfaced (`1;`) yellow-on-black (`33;40`) prompt on VT100-compatible, color-capable terminals. To insert a percent sign into your prompt, write `%%`. The default prompts are `'%/%R%# '` for prompts 1 and 2, and `'>> '` for prompt 3.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Command-Line Editing

`psql` uses the `readline` library for convenient line editing and retrieval. The command history is automatically saved when `psql` exits and is reloaded when `psql` starts up. Tab-completion is also supported, although the completion logic makes no claim to be an SQL parser. The queries generated by tab-completion can also interfere with other SQL commands, e.g. `SET TRANSACTION ISOLATION LEVEL`. If for some reason you do not like the tab completion, you can turn it off by putting this in a file named `.inputrc` in your home directory:

```
$if psql
set disable-completion on
$endif
```

Environment

COLUMNS If `\pset columns` is zero, controls the width for the wrapped format and width for determining if wide output requires the pager or should be switched to the vertical format in expanded auto mode.

PAGER If the query results do not fit on the screen, they are piped through this command. Typical values are `more` or `less`. The default is platform-dependent. The use of the pager can be deactivated by setting PAGER to empty, or by using pager-related options of the `\pset` command.

PGDATABASE PGHOST PGPORT PGUSER Default connection parameters.

PSQL_EDITOR EDITOR VISUAL Editor used by the `\e` and `\ef` commands. The variables are examined in the order listed; the first that is set is used.

The built-in default editors are `vi` on Unix systems and `notepad.exe` on Windows systems.

PSQL_EDITOR_LINENUMBER_ARG When `\e` or `\ef` is used with a line number argument, this variable specifies the command-line argument used to pass the starting line number to the user's editor. For editors such as Emacs or `vi`, this is a plus sign. Include a trailing space in the value of the variable if there needs to be space between the option name and the line number. Examples:

```
```
PSQL_EDITOR_LINENUMBER_ARG='+'
PSQL_EDITOR_LINENUMBER_ARG='--line '
```
```

The default is `+` on Unix systems (corresponding to the default editor `vi`, and useful for many other common editors); but there is no default on Windows systems.

PSQL_HISTORY Alternative location for the command history file. Tilde (`~`) expansion is performed.

PSQLRC Alternative location of the user's `.psqlrc` file. Tilde (`~`) expansion is performed.

SHELL Command run by the `\!` command.

TMPDIR Directory for storing temporary files. The default is `/tmp`.

Files

psqlrc and ~/.psqlrc Unless it is passed an `-X` or `-c` option, `psql` attempts to read and run commands from the system-wide startup file (`psqlrc`) and then the user's personal startup file (`~/.psqlrc`), after connecting to the database but before accepting normal commands. These files can be used to set up the client and/or the server to taste, typically with `\set` and `SET` commands.

The system-wide startup file is named `psqlrc` and is sought in the installation's "system configuration" directory, which is most reliably identified by running `pg_config --sysconfdir`. By default this directory will be `../etc/` relative to the directory containing the WarehousePG executables. The name of this directory can be set explicitly via the `PGSYSCONFDIR` environment variable.

The user's personal startup file is named `.psqlrc` and is sought in the invoking user's home directory. On Windows, which lacks such a concept, the personal startup file is named `%APPDATA%\postgresql\psqlrc.conf`. The location of the user's startup file can be set explicitly via the `PSQLRC` environment variable.

Both the system-wide startup file and the user's personal startup file can be made psql-version-specific by appending a dash and the underlying PostgreSQL major or minor release number to the file name, for example `~/.psqlrc-9.4`. The most specific version-matching file will be read in preference to a non-version-specific file.

.psql_history The command-line history is stored in the file `~/.psql_history`, or `%APPDATA%\postgresql\psql_history` on Windows.

The location of the history file can be set explicitly via the `PSQL_HISTORY` environment variable.

Notes

`psql` works best with servers of the same or an older major version. Backslash commands are particularly likely to fail if the server is of a newer version than `psql` itself. However, backslash commands of the `\d` family should work with older server versions, though not necessarily with servers newer than `psql` itself. The general functionality of running SQL commands and displaying query results should also work with servers of a newer major version, but this cannot be guaranteed in all cases.

If you want to use `psql` to connect to several servers of different major versions, it is recommended that you use the newest version of `psql`. Alternatively, you can keep a copy of `psql` from each major version around and be sure to use the version that matches the respective server. But in practice, this additional complication should not be necessary.

Notes for Windows Users

`psql` is built as a console application. Since the Windows console windows use a different encoding than the rest of the system, you must take special care when using 8-bit characters within `psql`. If `psql` detects a problematic console code page, it will warn you at startup. To change the console code page, two things are necessary:

Set the code page by entering:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
cmd.exe /c chcp 1252
```

`1252` is a character encoding of the Latin alphabet, used by Microsoft Windows for English and some other Western languages. If you are using Cygwin, you can put this command in `/etc/profile`.

Set the console font to Lucida Console, because the raster font does not work with the ANSI code page.

Examples

Start `psql` in interactive mode:

```
psql -p 54321 -U sally mydatabase
```

In `psql` interactive mode, spread a command over several lines of input. Notice the changing prompt:

```
testdb=> CREATE TABLE my_table (
testdb(>  first integer not null default 0,
testdb(>  second text)
testdb-> ;
CREATE TABLE
```

Look at the table definition:

```
testdb=> \d my_table
            Table "public.my_table"
 Column    |  Type   |      Modifiers
-----------+---------+--------------------
 first     | integer | not null default 0
 second    | text    |
Distributed by: (first)
```

Run `psql` in non-interactive mode by passing in a file containing SQL commands:

```
psql -f /home/gpadmin/test/myscript.sql
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.7.2.37 reindexdb

Rebuilds indexes in a database.

Synopsis

```
reindexdb [<connection-option> ...] [<option> ...] [-S | --schema <schema>] ...
        [-t | --table <table>]
        [-i | --index <index>] ... [<dbname>]

reindexdb [<connection-option> ...] [<option> ...] -a | --all

reindexdb [<connection-option> ...] [<option> ...] -s | --system [<dbname>]

reindexdb -? | --help

reindexdb -V | --version
```

Description

`reindexdb` is a utility for rebuilding indexes in WarehousePG.

`reindexdb` is a wrapper around the SQL command REINDEX. There is no effective difference between reindexing databases via this utility and via other methods for accessing the server.

Options

`reindexdb` accepts the following command-line arguments:

-a --all Reindex all databases.

[-d] dbname [--dbname=]dbname Specifies the name of the database to be reindexed, when `-a` or `--all` is not used. If this is not specified, WarehousePG reads the database name from the environment variable `PGDATABASE`. If that is not set, the user name specified for the connection is used. The dbname can be a connection string. If so, connection string parameters will override any conflicting command line options.

-e --echo Echo the commands that `reindexdb` generates and sends to the server.

-i index --index=index Recreate index only. You can recreate multiple indexes by specifying multiple `-i` switches.

-q --quiet Do not display progress messages.

-s --system Reindex system catalogs only.

-S schema --schema=schema Reindex schema only. You can reindex multiple schemas by specifying multiple `-S` switches.

-t table --table=table Reindex table only. You can reindex multiple tables by specifying multiple `-t` switches.

-v --verbose Print detailed information during processing.

-V --version Print the `reindexdb` version and exit.

-? --help Show help about `reindexdb` command line arguments, and exit.

Connection Options

`reindexdb` also accepts the following command-line arguments for connection parameters:

-h host --host=host Specifies the host name of the machine on which the WarehousePG coordinator database server is running. If not specified, reads from the environment variable `PGHOST` or defaults to localhost.

-p port --port=port Specifies the TCP port on which the WarehousePG coordinator database server is listening for connections. If not specified, reads from the environment variable `PGPORT` or defaults to 5432.

-U username --username=username The database user name to connect as. If not specified, reads from the environment variable `PGUSER` or defaults to the current system user name.

-w --no-password Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

-W --password Force `reindexdb` to prompt for a password before connecting to a database. This option is never essential, since `reindexdb` automatically prompts for a password if the server demands password authentication. However, `reindexdb` will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-W` to avoid the extra connection attempt.

--maintenance-db=dbname Specifies the name of the database to connect to discover what other databases should be reindexed, when `-a` or `--all` is used. If not specified, the `postgres` database will be used, and if that does not exist, `template1` will be used. This can be a connection. If so, connection string parameters will override any conflicting command line options. Also, connection string parameters other than the database name itself will be re-used when connecting to other databases.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Notes

`reindexdb` causes locking of system catalog tables, which could affect currently running queries. To avoid disrupting ongoing business operations, schedule the `reindexb` operation during a period of low activity.

`reindexdb` might need to connect several times to the coordinator server, asking for a password each time. It is convenient to have a `~/.pgpass` file in such cases.

Environment

PGDATABASE PGHOST PGPORT PGUSER Default connection parameters.

PG_COLOR Specifies whether to use color in diagnostic messages. Possible values are `always`, `auto`, and `never`.

This utility, like most other WarehousePG utilities, also uses the environment variables supported by `libpq`.

Diagnostics

In case of difficulty, see REINDEX and psql for discussions of potential problems and error messages. The database server must be running at the targeted host. Also, any default connection settings and environment variables used by the `libpq` front-end library will apply.

Notes

`reindexdb` might need to connect several times to the WarehousePG server, asking for a password each time. It is convenient to have a `~/.pgpass` file in such cases.

Examples

To reindex the database named `mydb`:

```
reindexdb mydb
```

To reindex the table `foo` and the index `bar` in a database named `abcd`:

```
reindexdb --table=foo --index=bar abcd
```

7.7.2.38 vacuumdb

Garbage-collects and analyzes a database.

Synopsis

```
vacuumdb [<connection-option>...] [--full | -f] [--freeze | -F] [--verbose | -v]
    [--analyze | -z] [--analyze-only | -Z] [--disable-page-skipping] [--skip-locked] [--table | -t <table> [( <column> [,...] )] ] [<dbname>]

vacuumdb [<connection-option>...] [--all | -a] [--full | -f] [-F]
    [--verbose | -v] [--analyze | -z]
    [--analyze-only | -Z]
    [--disable-page-skipping]
    [--skip-locked]

vacuumdb -? | --help

vacuumdb -V | --version
```

Description

`vacuumdb` is a utility for cleaning a WarehousePG database. `vacuumdb` will also generate internal statistics used by the WarehousePG query optimizer.

`vacuumdb` is a wrapper around the SQL command `VACUUM`. There is no effective difference between vacuuming databases via this utility and via other methods for accessing the server.

Options

-a | --all Vacuums all databases.

[-d] dbname | [--dbname=]dbname The name of the database to vacuum. If this is not specified and `-a` (or `--all`) is not used, the database name is read from the environment variable `PGDATABASE`. If that is not set, the user name specified for the connection is used.

-e | --echo Echo the commands that `reindexdb` generates and sends to the server.

-f | --full Selects a full vacuum, which may reclaim more space, but takes much longer and exclusively locks the table.

```
> **Caution** A `VACUUM FULL` is not recommended in WarehousePG.
```

-F | --freeze Freeze row transaction information.

-q | --quiet Do not display a response.

-t table [(column)] | --table= table [(column)] Clean or analyze this table only. Column names may be specified only in conjunction with the `--analyze` or `--analyze-all` options. Multiple tables can be vacuumed by writing multiple `-t` switches. If you specify columns, you probably have to escape the parentheses from the shell.

-v | --verbose Print detailed information during processing.

-z | --analyze Collect statistics for use by the query planner.

-Z | --analyze-only Only calculate statistics for use by the query planner (no vacuum).

--disable-page-skipping Disable all page-skipping behavior.

--skip-locked Skip relations that cannot be immediately locked.

-V | --version Print the `vacuumdb` version and exit.

-? | --help Show help about `vacuumdb` command line arguments, and exit.

Connection Options

-h host | --host=host Specifies the host name of the machine on which the WarehousePG coordinator database server is running. If not specified, reads from the environment variable `PGHOST` or defaults to localhost.

-p port | --port=port Specifies the TCP port on which the WarehousePG coordinator database server is listening for connections. If not specified, reads from the environment variable `PGPORT` or defaults to 5432.

-U username | --username=username The database role name to connect as. If not specified, reads from the environment variable `PGUSER` or defaults to the current system user name.

-w | --no-password Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

-W | --password Force a password prompt.

--maintenance-db=dbname Specifies the name of the database to connect to discover what other databases should be vacuumed. If not specified, the `postgres` database will be used, and if that does not exist, `template1` will be used.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Notes

`vacuumdb` might need to connect several times to the coordinator server, asking for a password each time. It is convenient to have a `~/.pgpass` file in such cases.

Examples

To clean the database `test`:

```
vacuumdb test
```

To clean and analyze a database named `bigdb`:

```
vacuumdb --analyze bigdb
```

To clean a single table `foo` in a database named `mydb`, and analyze a single column `bar` of the table. Note the quotes around the table and column names to escape the parentheses from the shell:

```
vacuumdb --analyze --verbose --table 'foo(bar)' mydb
```

7.7.2.39 pgbouncer

Manages database connection pools.

Synopsis

```
pgbouncer [OPTION ...] <pgbouncer.ini>

  OPTION
    [ -d | --daemon ]
    [ -R | --reboot ]
    [ -q | --quiet ]
    [ -v | --verbose ]
    [ {-u | --user}=username ]

pgbouncer [ -V | --version ] | [ -h | --help ]
```

Description

PgBouncer is a light-weight connection pool manager for WarehousePG and PostgreSQL databases. PgBouncer maintains a pool of connections for each database user and database combination. PgBouncer either creates a new database connection for the client or reuses an existing pooled connection for the same user and database. When the client disconnects, PgBouncer returns the connection to the pool for re-use.

PgBouncer supports the standard connection interface shared by PostgreSQL and WarehousePG. The WarehousePG client application (for example, `psql`) should connect to the host and port on which PgBouncer is running rather than directly to the WarehousePG coordinator host and port.

You configure PgBouncer and its access to WarehousePG via a configuration file. You provide the configuration file name, usually `<pgbouncer.ini>`, when you run the `pgbouncer` command. This file provides location information for WarehousePGs. The `pgbouncer.ini` file also specifies process, connection pool, authorized users, and authentication configuration for PgBouncer, among other configuration options.

By default, the `pgbouncer` process runs as a foreground process. You can optionally start `pgbouncer` as a background (daemon) process with the `-d` option.

The `pgbouncer` process is owned by the operating system user that starts the process. You can optionally specify a different user name under which to start `pgbouncer`.

PgBouncer includes a `psql`-like administration console. Authorized users can connect to a virtual database to monitor and manage PgBouncer. You can manage a PgBouncer daemon process via the admin console. You can also use the console to update and reload the PgBouncer configuration at runtime without stopping and restarting the process.

For additional information about PgBouncer, refer to the PgBouncer FAQ.

Options

-d | --daemon Run PgBouncer as a daemon (a background process). The default start-up mode is to run as a foreground process.

In daemon mode, setting `pidfile` as well as `logfile` or `syslog` is required. No log messages will be written to `stderr` after going into the background.

To stop a PgBouncer process that was started as a daemon, issue the `SHUTDOWN` command from the PgBouncer administration console.

-R | --reboot Restart PgBouncer using the specified command line arguments. That means connecting to the running process, loading the open sockets from it, and then using them. If there is no active process, boot normally. Non-TLS connections to databases are maintained during restart; TLS connections are dropped.

To restart PgBouncer as a daemon, specify the options `-Rd`.

```
>  **Note** This option is deprecated. Instead, use a rolling restart with multiple Pgbouncer processes listening on the same port using `so_reuseport` instead.

> **Note** Restart is available only if the operating system supports Unix sockets and the PgBouncer `unix_socket_dir` configuration is not deactivated.
```

-q | --quiet Run quietly. Do not log to `stderr`. This does not affect logging verbosity, only that `stderr` is not to be used. For use in `init.d` scripts.

-v | --verbose Increase message verbosity. Can be specified multiple times.

{-u | --user=} \<username> Assume the identity of username on PgBouncer process start-up.

-V | --version Show the version and exit.

-h | --help Show the command help message and exit.

7.7.2.40 pgbouncer-admin

PgBouncer Administration Console.

Synopsis

```
psql -p <port> pgbouncer
```

Description

The PgBouncer Administration Console is available via `psql`. Connect to the PgBouncer `<port>` and the virtual database named `pgbouncer` to log in to the console.

Users listed in the `pgbouncer.ini` configuration parameters `admin_users` and `stats_users` have privileges to log in to the PgBouncer Administration Console. When `auth_type=any`, then any user is allowed in as a stats_user.

Additionally, the user name `pgbouncer` is allowed to log in without password when the login comes via the Unix socket and the client has same Unix user UID as the running process.

The admin console currently only supports the simple query protocol. Some drivers use the extended query protocol for all commands; these drivers will not work for this console.

You can control connections between PgBouncer and WarehousePG from the console. You can also set PgBouncer configuration parameters.

Options

-p \<port> The PgBouncer port number.

Command Syntax

```
pgbouncer=# SHOW help;
NOTICE:  Console usage
DETAIL:
  SHOW HELP|CONFIG|DATABASES|POOLS|CLIENTS|SERVERS|USERS|VERSION
  SHOW PEERS|PEER_POOLS
  SHOW FDS|SOCKETS|ACTIVE_SOCKETS|LISTS|MEM|STATE

  SHOW STATS|STATS_TOTALS|STATS_AVERAGES|TOTALS
  SET key = arg
  RELOAD
  PAUSE [<db>]
  RESUME [<db>]
  DISABLE <db>
  ENABLE <db>
  RECONNECT [<db>]
  KILL <db>
  SUSPEND
  SHUTDOWN
  WAIT_CLOSE [<db>]
```

Administration Commands

The following PgBouncer administration commands control the running `pgbouncer` process.

PAUSE [\<db>] If no database is specified, PgBouncer tries to disconnect from all servers, first waiting for all queries to be released according to the server pool's pooling mode (in transaction pooling mode, the transaction must complete, in statement mode, the statement must complete, and in session pooling mode the client must disconnect). The command will not return before all queries are finished. This command is to be used to prepare to restart the database.

If a database name is specified, PgBouncer pauses only that database.

New client connections to a paused database will wait until a `RESUME` command is invoked.

DISABLE \<db> Reject all new client connections on the database.

ENABLE \<db> Allow new client connections after a previous `DISABLE` command.

RECONNECT Close each open server connection for the given database, or all databases, after it is released (according to the pooling mode), even if its lifetime is not up yet. New server connections can be made immediately and will connect as necessary according to the pool size settings.

This command is useful when the server connection setup has changed, for example to perform a gradual switchover to a new server. It is not necessary to run this command when the connection string in `pgbouncer.ini` has been changed and reloaded (see `RELOAD`) or when DNS resolution has changed, because then the equivalent of this command will be run automatically. This command is only necessary if something downstream of PgBouncer routes the connections.

After this command is run, there could be an extended period where some server connections go to an old destination and some server connections go to a new destination. This is likely only sensible when switching read-only traffic between read-only replicas, or when switching between nodes of a multimaster replication setup. If all connections need to be switched at the same time, `PAUSE` is recommended instead. To close server connections without waiting (for example, in emergency failover rather than gradual switchover scenarios), also consider `KILL`.

KILL \<db> Immediately drop all client and server connections to the named database.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

New client connections to a killed database will wait until `RESUME` is called.

SUSPEND All socket buffers are flushed and PgBouncer stops listening for data on them. The command will not return before all buffers are empty. To be used when rebooting PgBouncer online.

New client connections to a suspended database will wait until `RESUME` is called.

RESUME [\<db>] Resume work from a previous `KILL` , `PAUSE` , or `SUSPEND` command.

SHUTDOWN The PgBouncer process will exit. To exit from the `psql` command line session, enter `\q` .

RELOAD The PgBouncer process reloads the current configuration file and updates the changeable settings.

PgBouncer notices when a configuration file reload changes the connection parameters of a database definition. An existing server connection to the old destination will be closed when the server connection is next released (according to the pooling mode), and new server connections will immediately use the updated connection parameters

WAIT_CLOSE [\<db>] Wait until all server connections, either of the specified database or of all databases, have cleared the "close_needed" state (see `SHOW SERVERS`). This can be called after a `RECONNECT` or `RELOAD` to wait until the respective configuration change has been fully activated, for example in switchover scripts.

SET key = value Changes the specified configuration setting. See the `SHOW CONFIG;` command.

(Note that this command is run on the PgBouncer admin console and sets PgBouncer settings. A `SET` command run on another database will be passed to the PostgreSQL backend like any other SQL command.)

SHOW Command

The `SHOW <category>` command displays different types of PgBouncer information. You can specify one of the following categories:

- CLIENTS
- CONFIG
- DATABASES
- DNS_HOSTS
- DNS_ZONES
- FDS
- LISTS
- MEM
- POOLS
- PEERS
- PEER_POOLS
- SERVERS
- SOCKETS, ACTIVE_SOCKETS,
- STATS
- STATS_TOTALS
- STATS_AVERAGES
- TOTALS
- USERS
- VERSION

CLIENTS

Column	Description
type	C, for client.
user	Client connected user.
database	Database name.
state	State of the client connection, one of `active` , `waiting` , `active_cancel_req` , or `waiting_cancel_req` .
addr	IP address of client.
port	Port client is connected to.
local_addr	Connection end address on local machine.
local_port	Connection end port on local machine.
connect_time	Timestamp of connect time.
request_time	Timestamp of latest client request.
wait	Current Time waiting in seconds.
wait_us	Microsecond part of the current waiting time.
close_needed	Not used for clients.
ptr	Address of internal object for this connection. Used as unique ID.
link	Address of server connection the client is paired with.
remote_pid	Process ID, if client connects with Unix socket and the OS supports getting it.
tls	A string with TLS connection information, or empty if not using TLS.
application_name	A string containing the `application_name` set by the client for this connection, or empty if not set.
prepared_statements	The amount of prepared statements that the client has prepared.

CONFIG

Show the current PgBouncer configuration settings, one per row, with the following columns:

Column	Description
key	Configuration variable name
value	Configuration value

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Column	Description
default	Configuration default value
changeable	Either `yes` or `no`. Shows whether the variable can be changed while running. If `no`, the variable can be changed only at boot time. Use `SET` to change a variable at run time.

DATABASES

Column	Description
name	Name of configured database entry.
host	Host pgbouncer connects to.
port	Port pgbouncer connects to.
database	Actual database name pgbouncer connects to.
force_user	When user is part of the connection string, the connection between pgbouncer and the database server is forced to the given user, whatever the client user.
pool_size	Maximum number of server connections.
min_pool_size	Minimum number of server connections.
reserve_pool	The maximum number of additional connections for this database.
pool_mode	The database's override `pool_mode` or NULL if the default will be used instead.
max_connections	Maximum number of allowed connections for this database, as set by `max_db_connections`, either globally or per-database.
current_connections	The current number of connections for this database.
paused	Paused/unpaused state of the database. 1 if this database is currently paused, else 0.
disabled	Enabled/disabled state of the database. 1 if this database is currently disabled, else 0.

DNS_HOSTS

Show host names in DNS cache.

Column	Description
hostname	Host name
ttl	How many seconds until next lookup.
addrs	Comma-separated list of addresses.

DNS_ZONES

Show DNS zones in cache.

Column	Description
zonename	Zone name
serial	Current DNS serial number
count	Hostnames belonging to this zone

FDS

`SHOW FDS` is an internal command used for an online restart, for example when upgrading to a new PgBouncer version. It displays a list of file descriptors in use with the internal state attached to them. This command blocks the internal event loop, so it should not be used while PgBouncer is in use.

When the connected user has username "pgbouncer", connects through a Unix socket, and has the same UID as the running process, the actual file descriptors are passed over the connection. This mechanism is used to do an online restart.

Column	Description
fd	File descriptor numeric value.
task	One of `pooler`, `client`, or `server`.
user	User of the connection using the file descriptor.
database	Database of the connection using the file descriptor.
addr	IP address of the connection using the file descriptor, `unix` if a Unix socket is used.
port	Port used by the connection using the file descriptor.
cancel	Cancel key for this connection.
link	File descriptor for corresponding server/client. NULL if idle.

LISTS

Shows the following PgBouncer internal information, in columns (not rows):

Item	Description
databases	Count of databases.
users	Count of users.
pools	Count of pools.
free_clients	Count of free clients.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Item	Description
used_clients	Count of used clients.
login_clients	Count of clients in `login` state.
free_servers	Count of free servers.
used_servers	Count of used servers.
dns_names	Count of DNS names in the cache.
dns_zones	Count of DNS zones in the cache.
dns_queries	Count of in-flight DNS queries.
dns_pending	not used

MEM

Shows low-level information about the current sizes of various internal memory allocations. The information presented is subject to change.

PEERS

Column	Description
peer_id	ID of the configured peer entry.
host	Host PgBouncer connects to.
port	Port PgBouncer connects to.
pool_size	Maximum number of server connections that can be made to this peer.

PEER_POOLS

A new `peer_pool` entry is made for each configured peer.

Column	Description
Database	ID of the configured peer entry.
cl_active_cancel_req	Client connections that have forwarded query cancellations to the server and are waiting for the server response.
cl_waiting_cancel_req	Client connections that have not forwarded query cancellations to the server yet.
sv_active_cancel	Server connections that are currently forwarding a cancel request.
sv_login	Server connections currently in the process of logging in.

POOLS

A new pool entry is made for each pair of (database, user).

Column	Description
database	Database name.
user	User name.
cl_active	Client connections that are linked to server connection and can process queries.
cl_waiting	Client connections that have sent queries but have not yet got a server connection.
cl_active_cancel_req	Client connections that have forwarded query cancellations to the server and are waiting for the server response.
cl_waiting_cancel_req	Client connections that have not forwarded query cancellations to the server yet.
sv_active	Server connections that are linked to client.
sv_active_cancel	Server connections that are currently forwarding a cancel request.
sv_being_canceled	Servers that normally could become idle but are waiting to do so until all in-flight cancel requests have completed that were sent to cancel a query on this server.
sv_idle	Server connections that are unused and immediately usable for client queries.
sv_used	Server connections that have been idle more than `server_check_delay`. The `server_check_query` query must be run on them before they can be used again.
sv_tested	Server connections that are currently running either `server_reset_query` or `server_check_query`.
sv_login	Server connections currently in the process of logging in.
maxwait	How long the first (oldest) client in the queue has waited, in seconds. If this begins to increase, the current pool of servers does not handle requests quickly enough. The cause may be either an overloaded server or the `pool_size` setting is too small.
maxwait_us	Microsecond part of the maximum waiting time.
pool_mode	The pooling mode in use.

SERVERS

Column	Description
type	S, for server.
user	User name that `pgbouncer` uses to connect to server.
database	Database name.
state	State of the `pgbouncer` server connection, one of `active`, `idle`, `used`, `tested`, or `new`.
addr	IP address of the WarehousePG or PostgreSQL server.
port	Port of the WarehousePG or PostgreSQL server.
local_addr	Connection start address on local machine.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Column	Description
local_port	Connection start port on local machine.
connect_time	When the connection was made.
request_time	When the last request was issued.
wait	Current waiting time in seconds.
wait_us	Microsecond part of the current waiting time.
close_needed	1 if the connection will be closed as soon as possible, because a configuration file reload or DNS update changed the connection information or `RECONNECT` was issued.
ptr	Address of the internal object for this connection. Used as unique ID.
link	Address of the client connection the server is paired with.
remote_pid	Pid of backend server process. If the connection is made over Unix socket and the OS supports getting process ID info, it is the OS pid. Otherwise it is extracted from the cancel packet the server sent, which should be PID in case server is PostgreSQL, but it is a random number in case server is another PgBouncer.
tls	A string with TLS connection information, or empty if not using TLS.
application_name	A string containing the application_name set on the linked client connection, or empty if this is not set, or if there is no linked connection.
prepared_statements	The amount of prepared statements that are prepared on the server. This number is limited by the max_prepared_statements setting.

SOCKETS, ACTIVE_SOCKETS

Shows low-level information about sockets or only active sockets. This includes the information shown under `SHOW CLIENTS` and `SHOW SERVERS` as well as other more low-level information.

STATS

Shows statistics. In this and related commands, the total figures are since process start, the averages are updated every `stats_period`.

Column	Description
database	Statistics are presented per database.
total_xact_count	Total number of SQL transactions pooled by PgBouncer.
total_query_count	Total number of SQL queries pooled by PgBouncer.
total_received	Total volume in bytes of network traffic received by `pgbouncer`.
total_sent	Total volume in bytes of network traffic sent by `pgbouncer`.
total_xact_time	Total number of microseconds spent by PgBouncer when connected to WarehousePG in a transaction, either idle in transaction or executing queries.
total_query_time	Total number of microseconds spent by `pgbouncer` when actively connected to the database server.
total_wait_time	Time spent (in microseconds) by clients waiting for a server.
avg_xact_count	Average number of transactions per second in the last stat period.
avg_query_count	Average queries per second in the last stats period.
avg_recv	Average received (from clients) bytes per second.
avg_sent	Average sent (to clients) bytes per second.
avg_xact_time	Average transaction duration in microseconds.
avg_query_time	Average query duration in microseconds.
avg_wait_time	Time spent by clients waiting for a server in microseconds (average per second).

STATS_AVERAGES

Subset of `SHOW STATS` showing the average values for selected statistics (`avg_`)

STATS_TOTALS

Subset of `SHOW STATS` showing the total values for selected statistics (`total_`)

TOTALS

Like `SHOW STATS` but aggregated across all databases.

USERS

Column	Description
name	The user name
pool_mode	The user's override pool_mode, or NULL if the default will be used instead.

VERSION

Display PgBouncer version information.

> **Note** This reference documentation is based on the PgBouncer 1.21 documentation.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Signals

SIGHUP : Reload config. Same as issuing the command `RELOAD` on the console.

SIGINT : Safe shutdown. Same as issuing `PAUSE` and `SHUTDOWN` on the console.

SIGTERM : Immediate shutdown. Same as issuing `SHUTDOWN` on the console.

SIGUSR1 : Same as issuing `PAUSE` on the console.

SIGUSR2 : Same as issuing `RESUME` on the console.

Libevent Settings

From the Libevent documentation:

```
It is possible to disable support for epoll, kqueue, devpoll, poll or select by
setting the environment variable EVENT_NOEPOLL, EVENT_NOKQUEUE, EVENT_NODEVPOLL,
EVENT_NOPOLL or EVENT_NOSELECT, respectively.

By setting the environment variable EVENT_SHOW_METHOD, libevent displays the
kernel notification method that it uses.
```

pgbouncer, pgbouncer.ini

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.7.2.41 pgbouncer.ini

PgBouncer configuration file.

Synopsis

```
[databases]
db = ...

[pgbouncer]
...

[users]
...
```

Description

You specify PgBouncer configuration parameters and identify user-specific configuration parameters in a configuration file.

The PgBouncer configuration file (typically named `pgbouncer.ini`) is specified in `.ini` format. Files in `.ini` format are composed of sections, parameters, and values. Section names are enclosed in square brackets, for example, `[<section_name>]`. Parameters and values are specified in `key=value` format. Lines beginning with a semicolon (`;`) or pound sign (`#`) are considered comment lines and are ignored.

The PgBouncer configuration file can contain `%include` directives, which specify another file to read and process. This enables you to split the configuration file into separate parts. For example:

```
%include filename
```

If the filename provided is not an absolute path, the file system location is taken as relative to the current working directory.

The PgBouncer configuration file includes the following sections, described in detail below:

- [databases] Section
- [pgbouncer] Section
- [users] Section
- [peers] Section

[databases] Section

The `[databases]` section contains `key=value` pairs, where the `key` is a database name and the `value` is a `libpq` connect-string list of `key` = `value` pairs. Not all features known from `libpq` can be used (service=, .pgpass), since the actual `libpq` is not used.

A database name can contain characters `[0-9A-Za-z_.-]` without quoting. Names that contain other characters must be quoted with standard SQL identifier quoting:

- Enclose names in double quotes (`" "`).
- Represent a double-quote within an identifier with two consecutive double quote characters.

The database name `*` is the fallback database. PgBouncer uses the value for this key as a connect string for the requested database. Automatically-created database entries such as these are cleaned up if they remain idle longer than the time specified in `autodb_idle_timeout` parameter.

Database Connection Parameters

The following parameters may be included in the `value` to specify the location of the database.

dbname The destination database name.

```
Default: the client-specified database name
```

host The name or IP address of the WarehousePG coordinator host. Host names are resolved at connect time. If DNS returns several results, they are used in a round-robin manner. The DNS result is cached and the `dns_max_ttl` parameter determines when the cache entry expires.

When a host name's resolution changes, any existing server connections are automatically closed when they are released (according to the pooling mode).

If the value begins with `/`, then a Unix socket in the file-system namespace is used. If the value begins with `@`, then a Unix socket in the abstract namespace is used.

You may specify a comma-separated list of host names or addresses. In that case, connections are made in a round-robin manner. If a host list contains host names that in turn resolve via DNS to multiple addresses, the round-robin systems operate independently. Note that in a list, all hosts must be available at all times: There are no mechanisms to skip unreachable hosts or to select only available hosts from a list. Also note that this only affects how the destinations of new connections are chosen. See also the setting `server_round_robin` in the `[pgbouncer]` section for how clients are assigned to already established server connections.

Examples:

```
```
host=localhost
host=127.0.0.1
host=2001:0db8:85a3:0000:0000:8a2e:0370:7334
host=/var/run/postgresql
host=192.168.0.1,192.168.0.2,192.168.0.3
```
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Default: not set; the connection is made through a Unix socket

port The WarehousePG coordinator port.

Default: 5432

user If `user=` is set, all connections to the destination database are initiated as the specified user, resulting in a single connection pool for the database.

If the `user=` parameter is not set, PgBouncer attempts to log in to the destination database with the user name passed by the client. In this situation, there will be one pool for each user who connects to the database.

password If no password is specified here, the password from the `auth_file` or `auth_query` will be used.

auth_user Override of the global `auth_user` setting, if specified.

client_encoding Ask for specific `client_encoding` from server.

datestyle Ask for specific `datestyle` from server.

timezone Ask for specific `timezone` from server.

Pool Configuration

You can use the following parameters for database-specific pool configuration.

pool_size Set the maximum size of pools for this database. If not set, the `default_pool_size` is used.

min_pool_size Set the minimum pool size for this database. If not set, the global `min_pool_size` is used.

It is only enforced if at least one of the following is true:

```
- This entry in the `[database]` section has a value set for the `user`.
- There i at least one client connected to the pool.
```

reserve_pool Set additional connections for this database. If not set, `reserve_pool_size` is used.

connect_query Query to be run after a connection is established, but before allowing the connection to be used by any clients. If the query raises errors, they are logged but ignored otherwise.

pool_mode Set the pool mode specific to this database. If not set, the default `pool_mode` is used.

max_db_connections Set a database-wide maximum number of PgBouncer connections for this database. The total number of connections for all pools for this database will not exceed this value.

[pgbouncer] Section

Generic Settings

logfile The location of the log file. For daemonization (`-d`), either this or `syslog` need to be set. The log file is kept open. After log rotation, run `kill -HUP pgbouncer` or run the `RELOAD` command in the PgBouncer Administration Console.

Note that setting `logfile` does not by itself turn off logging to `stderr` . Use the command-line option `-q` or `-d` for that.

```
Default: not set
```

pidfile The name of the pid file. Without a `pidfile` , you cannot run PgBouncer as a background (daemon) process.

```
Default: not set
```

listen_addr Specifies a list of comma-separated interface addresses where PgBouncer listens for TCP connections. You may also use `*` , which means to listen on all interfaces. If not set, only Unix socket connections are accepted.

```
Specify addresses numerically \(IPv4/IPv6\) or by name.

Default: not set
```

listen_port The port PgBouncer listens on. Applies to both TCP and Unix sockets.

```
Default: 6432
```

unix_socket_dir Specifies the location for the Unix sockets. Applies to both listening socket and server connections. If set to an empty string, Unix sockets are deactivated. A value that starts with @ specifies that a Unix socket in the abstract namespace should be created.

For online reboot (`-R`) to work, a Unix socket needs to be configured, and it needs to be in the file-system namespace.

```
Default: `/tmp`
```

unix_socket_mode Filesystem mode for the Unix socket. Ignored for sockets in the abstract namespace.

```
Default: 0777
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

unix_socket_group Group name to use for Unix socket. Ignored for sockets in the abstract namespace.

```
Default: not set
```

user If set, specifies the Unix user to change to after startup. This works only if PgBouncer is started as root or if it is already running as the given user.

```
Default: not set
```

pool_mode Specifies when a server connection can be reused by other clients.

```
- `session`: Connection is returned to the pool when the client disconnects. Default.
- `transaction`: Connection is returned to the pool when the transaction finishes.
- `statement`: Connection is returned to the pool when the current query finishes. Transactions spanning multiple statements are disallowed in this mode.
```

max_client_conn Maximum number of client connections allowed. When increased, you should also increase the file descriptor limits. The actual number of file descriptors used is more than `max_client_conn`. The theoretical maximum used, when each user connects with its own username to the server is:

```
```
max_client_conn + (max pool_size * total databases * total users)
```
```

If a database user is specified in the connect string, all users connect using the same username. Then the theoretical maximum connections is:

```
```
max_client_conn + (max pool_size * total databases)
```

The theoretical maximum should be never reached, unless someone deliberately crafts a special load for it. Still, it means you should set the number of file descriptors to a safely high number. Search for `ulimit` in your operating system documentation.

Default: 100
```

default_pool_size The number of server connections to allow per user/database pair. This can be overridden in the per-database configuration.

```
Default: 20
```

min_pool_size Add more server connections to the pool when it is lower than this number. This improves behavior when the usual load drops and then returns suddenly after a period of total inactivity. The value is effectively capped at the pool size.

```
Default: 0 \(deactivated\)
```

reserve_pool_size The number of additional connections to allow for a pool (see `reserve_pool_timeout`). `0` deactivates.

```
Default: 0 \(deactivated\)
```

reserve_pool_timeout If a client has not been serviced in this many seconds, PgBouncer enables use of additional connections from the reserve pool. `0` deactivates.

```
Default: 5.0
```

max_db_connections Do not allow more than this many server connections per database (regardless of user). This considers the PgBouncer database that the client has connected to, not the PostgreSQL database of the outgoing connection.

This can also be set per database in the `[databases]` section.

Note that when you hit the limit, closing a client connection to one pool will not immediately allow a server connection to be established for another pool, because the server connection for the first pool is still open. Once the server connection closes (due to idle timeout), a new server connection will immediately be opened for the waiting pool.

Default: 0 (unlimited)

max_user_connections Do not allow more than this many server connections per user (regardless of database). This considers the PgBouncer user that is associated with a pool, which is either the user specified for the server connection or in absence of that the user the client has connected as.

This can also be set per user in the `[users]` section.

Note that when you hit the limit, closing a client connection to one pool will not immediately allow a server connection to be established for another pool, because the server connection for the first pool is still open. Once the server connection closes (due to idle timeout), a new server connection will immediately be opened for the waiting pool.

Default: 0 (unlimited)

server_round_robin By default, PgBouncer reuses server connections in LIFO (last-in, first-out) order, so that a few connections get the most load. This provides the best performance when a single server serves a database. But if there is TCP round-robin behind a database IP, then it is better if PgBouncer also uses connections in that manner to achieve uniform load.

```
Default: 0
```

track_extra_parameters By default, PgBouncer tracks the `client_encoding`, `datestyle`, `timezone`, `standard_conforming_strings`, and `application_name` parameters per client. To allow other parameters to be tracked, you may specify them under this parameter, so that PgBouncer knows that they should be maintained in the client variable cache and restored in the server whenever the client becomes active.

If you need to specify multiple values, use a comma-separated list.

Note that most parameters cannot be tracked this way. The only parameters that can be tracked are ones that WarehousePG reports to the client. WarehousePG has an official list of parameters that it reports to the client. WarehousePG extensions can change this list though, they can add parameters themselves that they also report, and they can start reporting already existing parameters that WarehousePG does not report.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

The WarehousePG protocol allows specifying parameters settings, both directly as a parameter in the startup packet, or inside the options startup packet. Parameters specified using both of these methods are supported by track_extra_parameters. However, it is not possible to include options itself in `track_extra_parameters`, only the parameters contained in `options`.

Default: IntervalStyle

ignore_startup_parameters By default, PgBouncer allows only parameters it can keep track of in startup packets: `client_encoding`, `datestyle`, `timezone`, and `standard_conforming_strings`. All others parameters raise an error. To allow other parameters, specify them here so that PgBouncer knows that they are handled by the admin and it can ignore them.

If you need to specify multiple values, use a comma-separated list.

The WarehousePG protocol allows specifying parameters settings, both directly as a parameter in the startup packet, or inside the `options` startup packet. Parameters specified using both of these methods are supported by `ignore_startup_parameters`. It is even possible to include `options` itself in `track_extra_parameters`, which results in any unknown parameters contained inside `options` to be ignored.

```
Default: empty
```

peer_id The peer id used to identify this PgBouncer process in a group of PgBouncer processes that are peered together. The `peer_id` value should be unique within a group of peered PgBouncer processes. When set to 0, PgBouncer peering is disabled. See the `[peers]` section for more information. The maximum value that can be used for the `peer_id` is 16383.

Default: 0

disable_pqexec Deactivates Simple Query protocol (PQexec). Unlike Extended Query protocol, Simple Query protocol allows multiple queries in one packet, which allows some classes of SQL-injection attacks. Deactivating it can improve security. This means that only clients that exclusively use Extended Query protocol will work.

```
Default: 0
```

application_name_add_host Add the client host address and port to the application name setting set on connection start. This helps in identifying the source of bad queries. This logic applies only on start of connection. If `application_name` is later changed with `SET`, PgBouncer does not change it again.

```
Default: 0
```

conffile Show location of the current configuration file. Changing this parameter will result in PgBouncer using another config file for next `RELOAD` / `SIGHUP`.

```
Default: file from command line
```

service_name Used during win32 service registration.

```
Default: pgbouncer
```

job_name Alias for `service_name`.

stats_period Sets how often the averages shown in various `SHOW` commands are updated and how often aggregated statistics are written to the log (but see `log_stats`). [seconds]

```
Default: 60
```

max_prepared_statements

When set to a non-zero value, PgBouncer tracks protocol-level named prepared statements related commands sent by the client in transaction and statement pooling mode. PgBouncer makes sure that any statement prepared by a client is available on the backing server connection, even when the statement was originally prepared on another server connection.

PgBouncer internally examines all the queries that are sent as a prepared statement by clients and gives each unique query string an internal name with the format `PGBOUNCER_{unique_id}`. Prepared statements are only prepared using this name on the corresponding WarehousePG cluster. PgBouncer keeps track of the name that the client gave to each prepared statement. It rewrites each command that uses a prepared statement to use the matching internal name (for example, `PGBOUNCER_123`) before forwarding that command to the server. More importantly, if the prepared statement that the client wants to use is not prepared on the server yet, it automatically prepares that statement before forwarding the command that the client sent.

Note that this tracking and rewriting of prepared statement commands does not work for SQL-level prepared statement commands such as `PREPARE`, `EXECUTE`, `DEALLOCATE`, `DEALLOCATE ALL`, and `DISCARD ALL`. Running `DEALLOCATE ALL` and `DISCARD ALL` is especially problematic, since those commands appear to run successfully, but they interfere with the state of the server connection significantly without PgBouncer noticing, which in turn will very likely break the execution of any further prepared statements on that server connection.

The actual value of this setting controls the number of prepared statements kept active on a single server connection. When the setting is set to 0, prepared statement support for transaction and statement pooling is disabled. To get the best performance, you should try to ensure that this setting is larger than the amount of commonly used prepared statements in your application. Keep in mind that the higher this value, the larger the memory footprint of each PgBouncer connection will have on your WarehousePG coordinator, because it will keep more queries prepared on those connections. It also increases the memory footprint of PgBouncer itself, because it now needs to keep track of query strings.

The impact on PgBouncer memory usage is not that big:

```
- Each unique query is stored once in a global query cache.
- Each client connection keeps a buffer that it uses to rewrite packets. This is at most four times the size of `pkt_buf`. This limit is often not reached though,
it only happens when the queries in your prepared statements are between two and four times the size of `pkt_buf`.
```

Consider the following example scenario:

```
- There are 1000 active clients.
- The clients prepare 200 unique queries.
- The average size of a query is 5 kB.
- `pkt_buf` is set to the default of 4096 (4kB).
```

In this scenario, PgBouncer needs at most the following amount of memory to handle these prepared statements:

```
```
200 x 5kB + 1000 x 4 x 4kB = ~17MB of memory.
```
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Tracking prepared statements does not only come with a memory cost, but also with increased CPU usage, because PgBouncer needs to inspect and rewrite the queries. Multiple PgBouncer instances can listen on the same port to use more than one core for processing, see the `so_reuseport` option for details.

There are also performance benefits to prepared statements. Just as when connecting to WarehousePG directly, by preparing a query that is executed many times, it reduces the total amount of parsing and planning that needs to be done. The way that PgBouncer tracks prepared statements is especially beneficial to performance when multiple clients prepare the same queries. Because client connections automatically reuse a prepared statement on a server connection even if it was prepared by another client. As an example, if you have a `pool_size` of 20 and you have 100 clients that all prepare the exact same query, then the query is prepared (and thus parsed) only 20 times on the WarehousePG coordinator.

The reuse of prepared statements has one downside. If the return or argument types of a prepared statement changes across executions, WarehousePG throws an error such as:

```
```
ERROR: cached plan must not change result type
```
```

You can avoid such errors by not having multiple clients that use the exact same query string in a prepared statement, but expecting different argument or result types. One of the most common ways of running into this issue is during a DDL migration where you add a new column or change a column type on an existing table. In those cases you can run `RECONNECT` on the PgBouncer admin console after doing the migration to force a re-prepare of the query and make the error goes away.

Default: 0

Authentication Settings

auth_file The name of the file containing the user names and passwords to load. The file format is the same as the WarehousePG pg_auth file. Refer to thePgBouncer Authentication File Format for more information.

```
Default: not set
```

auth_hba_file HBA configuration file to use when `auth_type` is `hba`. Refer to the Configuring HBA-based Authentication for PgBouncer and Configuring LDAP-based Authentication for PgBouncer for more information.

```
Default: not set
```

auth_type How to authenticate users.

```
- `pam`: Use PAM to authenticate users. `auth_file` is ignored. This method is not compatible with databases using the `auth_user` option. The service name
reported to PAM is `pgbouncer`. PAM is not supported in the HBA configuration file.
- `hba`:  The actual authentication type is loaded from the `auth_hba_file`. This setting allows different authentication methods for different access paths, for
example: connections over Unix socket use the `peer` auth method, connections over TCP must use TLS.
- `cert`:  Clients must connect with TLS using a valid client certificate. The client's username is taken from CommonName field in the certificate.
- `md5`: Use MD5-based password check. `auth_file` may contain both MD5-encrypted or plain-text passwords. If `md5` is configured and a user has a SCRAM secret,
then SCRAM authentication is used automatically instead. This is the default authentication method.
- `scram-sha-256`: Use password check with SCRAM-SHA-256. `auth_file` has to contain SCRAM secrets or plain-text passwords.
- `plain`:  Clear-text password is sent over wire. *Deprecated*.
- `trust`: No authentication is performed. The username must still exist in the `auth_file`.
- `any`: Like the `trust` method, but the username supplied is ignored. Requires that all databases are configured to log in with a specific user. Additionally,
the console database allows any user to log in as admin.
```

auth_key_file If you are connecting to LDAP with an encrypted password, `auth_key_file` identifies the file system location of the encryption key. Refer to About Specifying an Encrypted LDAP Password for more information.

```
Default: not set
```

auth_cipher If you are connecting to LDAP with an encrypted password, `auth_cipher` identifies the cipher algorithm for password authentication. PgBouncer accepts any cipher supported by OpenSSL on the system. When FIPS mode is enabled, specify only a cipher that is considered safe in FIPS mode. Refer to About Specifying an Encrypted LDAP Password for more information.

```
Default: `aes-256-cbc`
```

auth_query Query to load a user's password from the database.

Direct access to pg_shadow requires admin rights. It's preferable to use a non-superuser that calls a `SECURITY DEFINER` function instead.

Note that the query is run inside target database, so if a function is used it needs to be installed into each database.

```
Default: `SELECT usename, passwd FROM pg_shadow WHERE usename=$1`
```

auth_user If `auth_user` is set, any user who is not specified in `auth_file` is authenticated through the `auth_query` query from the `pg_shadow` database view. PgBouncer performs this query as the `auth_user` WarehousePG user. `auth_user`'s password must be set in the `auth_file`. (If the `auth_user` does not require a password then it does not need to be defined in `auth_file`.)

Direct access to `pg_shadow` requires WarehousePG administrative privileges. It is preferable to use a non-admin user that calls `SECURITY DEFINER` function instead.

Default: not set

auth_dbname Database name in the `[database]` section to be used for authentication purposes. This option can be either global or overridden in the connection string if this parameter is specified.

Log Settings

syslog Toggles syslog on and off.

```
Default: 0
```

syslog_ident Under what name to send logs to syslog.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
Default: `pgbouncer` (program name)
```

syslog_facility Under what facility to send logs to syslog. Some possibilities are: `auth`, `authpriv`, `daemon`, `user`, `local0-7`.

```
Default: `daemon`
```

log_connections Log successful logins.

```
Default: 1
```

log_disconnections Log disconnections, with reasons.

```
Default: 1
```

log_pooler_errors Log error messages that the pooler sends to clients.

```
Default: 1
```

log_stats Write aggregated statistics into the log, every `stats_period`. This can be deactivated if external monitoring tools are used to grab the same data from `SHOW` commands.

```
Default: 1
```

verbose Increase verbosity. Mirrors the `-v` switch on the command line. Using `-v -v` on the command line is the same as `verbose=2`.

```
Default: 0
```

Console Access Control

admin_users Comma-separated list of database users that are allowed to connect and run all commands on the PgBouncer Administration Console. Ignored when `auth_type=any`, in which case any username is allowed in as admin.

```
Default: empty
```

stats_users Comma-separated list of database users that are allowed to connect and run read-only queries on the console. This includes all `SHOW` commands except `SHOW FDS`.

```
Default: empty
```

Connection Sanity Checks, Timeouts

server_reset_query Query sent to server on connection release, before making it available to other clients. At that moment no transaction is in progress so it should not include `ABORT` or `ROLLBACK`.

```
The query should clean any changes made to a database session so that the next client gets a connection in a well-defined state. Default is `DISCARD ALL` which
cleans everything, but that leaves the next client no pre-cached state. It can be made lighter, e.g. `DEALLOCATE ALL` to just drop prepared statements, if the
application does not break when some state is kept around.

> **Note** WarehousePG does not support `DISCARD ALL`.

When transaction pooling is used, the `server_reset_query` is not used, as clients must not use any session-based features as each transaction ends up in a
different connection and thus gets a different session state.

Default: `DISCARD ALL;` \(Not supported by WarehousePG.\)
```

server_reset_query_always Whether `server_reset_query` should be run in all pooling modes. When this setting is off (default), the `server_reset_query` will be run only in pools that are in sessions-pooling mode. Connections in transaction-pooling mode should not have any need for reset query.

```
This setting is for working around broken setups that run applications that use session features over a transaction-pooled PgBouncer. It changes non-deterministic
breakage to deterministic breakage: Clients always lose their state after each transaction.

Default: 0
```

server_check_delay How long to keep released connections available for immediate re-use, without running sanity-check queries on it. If `0`, then the query is run always.

```
Default: 30.0
```

server_check_query A simple do-nothing query to test the server connection.

```
If an empty string, then sanity checking is deactivated.

Default: SELECT 1;
```

server_fast_close Disconnect a server in session pooling mode immediately or after the end of the current transaction if it is in “close_needed” mode (set by `RECONNECT`, `RELOAD` that changes connection settings, or DNS change), rather than waiting for the session end. In statement or transaction pooling mode, this has no effect since that is the default behavior there.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
If because of this setting a server connection is closed before the end of the client session, the client connection is also closed. This ensures that the client
notices that the session has been interrupted.

This setting makes connection configuration changes take effect sooner if session pooling and long-running sessions are used. The downside is that client sessions
are liable to be interrupted by a configuration change, so client applications will need logic to reconnect and reestablish session state. But note that no
transactions will be lost, because running transactions are not interrupted, only idle sessions.

Default: 0
```

server_lifetime The pooler will close an unused server connections that has been connected longer than this number of seconds. Setting it to `0` means the connection is to be used only once, then closed. [seconds]

```
Default: 3600.0
```

server_idle_timeout If a server connection has been idle more than this many seconds it is dropped. If this parameter is set to `0`, timeout is deactivated. [seconds]

```
Default: 600.0
```

server_connect_timeout If connection and login will not finish in this amount of time, the connection will be closed. [seconds]

```
Default: 15.0
```

server_login_retry If a login fails due to failure from `connect()` or authentication, that pooler waits this much before retrying to connect. [seconds]

```
Default: 15.0
```

client_login_timeout If a client connects but does not manage to login in this amount of time, it is disconnected. This is needed to avoid dead connections stalling `SUSPEND` and thus online restart. [seconds]

```
Default: 60.0
```

autodb_idle_timeout If database pools created automatically (via `*`) have been unused this many seconds, they are freed. Their statistics are also forgotten. [seconds]

```
Default: 3600.0
```

dns_max_ttl How long to cache DNS lookups, in seconds. If a DNS lookup returns several answers, PgBouncer round-robins between them in the meantime. The actual DNS TTL is ignored. [seconds]

```
Default: 15.0
```

dns_nxdomain_ttl How long error and NXDOMAIN DNS lookups can be cached. [seconds]

```
Default: 15.0
```

dns_zone_check_period Period to check if zone serial numbers have changed.

```
PgBouncer can collect DNS zones from hostnames \(everything after first dot\) and then periodically check if the zone serial numbers change. If changes are
detected, all hostnames in that zone are looked up again. If any host IP changes, its connections are invalidated.

Works only with UDNS and c-ares backend \(`--with-udns` or `--with-cares` to configure\).

Default: 0.0 \(deactivated\)
```

resolv_conf The location of a custom `resolv.conf` file. This is to allow specifying custom DNS servers and perhaps other name resolution options, independent of the global operating system configuration.

```
Requires evdns (>= 2.0.3) or c-ares (>= 1.15.0) backend.

The parsing of the file is done by the DNS backend library, not PgBouncer, so see the library's documentation for details on allowed syntax and directives.

Default: empty (use operating system defaults)
```

TLS settings

client_tls_sslmode TLS mode to use for connections from clients. TLS connections are deactivated by default. When enabled, `client_tls_key_file` and `client_tls_cert_file` must be also configured to set up the key and certificate PgBouncer uses to accept client connections.

```
-   `disable`: Plain TCP. If client requests TLS, it’s ignored. Default.
-   `allow`: If client requests TLS, it is used. If not, plain TCP is used. If client uses client-certificate, it is not validated.
-   `prefer`: Same as `allow`.
-   `require`: Client must use TLS. If not, client connection is rejected. If client presents a client-certificate, it is not validated.
-   `verify-ca`: Client must use TLS with valid client certificate.
-   `verify-full`: Same as `verify-ca`.
```

client_tls_key_file Private key for PgBouncer to accept client connections.

Default: not set

client_tls_cert_file Certificate for private key. CLients can validate it.

Default: unset

client_tls_ca_file Root certificate to validate client certificates.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Default: unset

client_tls_protocols Which TLS protocol versions are allowed.

Valid values: are `tlsv1.0`, `tlsv1.1`, `tlsv1.2`, `tlsv1.3`.

Shortcuts: `all` (`tlsv1.0`, `tlsv1.1`, `tlsv1.2`, `tlsv1.3`), `secure` (`tlsv1.2`, `tlsv1.3`), `legacy` (`all`).

Default: `secure`

client_tls_ciphers Allowed TLS ciphers, in OpenSSL syntax. Shortcuts: `default`/`secure`, `compat`/`legacy`, `insecure`/`all`, `normal`, `fast`.

```
Only connections using TLS version 1.2 and lower are affected. There is currently no setting that controls the cipher choices used by TLS version 1.3 connections.

Default: `fast`
```

client_tls_ecdhcurve Elliptic Curve name to use for ECDH key exchanges.

Allowed values: `none` (DH is deactivated), `auto` (256-bit ECDH), curve name.

Default: `auto`

client_tls_dheparams DHE key exchange type.

Allowed values: `none` (DH is deactivated), `auto` (2048-bit DH), `legacy` (1024-bit DH).

Default: `auto`

server_tls_sslmode TLS mode to use for connections to WarehousePG and PostgreSQL servers. TLS connections are deactivated by default.

```
-   `disable`: Plain TCP. TLS is not requested from the server. Default.
-   `allow`: If server rejects plain, try TLS. \(*PgBouncer Documentation is speculative on this.*\)
-   `prefer`: TLS connection is always requested first. When connection is refused, plain TPC is used. Server certificate is not validated.
-   `require`: Connection must use TLS. If server rejects it, plain TCP is not attempted. Server certificate is not validated.
-   `verify-ca`: Connection must use TLS and server certificate must be valid according to `server_tls_ca_file`. The server hostname is not verfied against the
certificate.
-   `verify-full`: Connection must use TLS and the server certificate must be valid according to `server_tls_ca_file`. The server hostname must match the hostname
in the certificate.
```

server_tls_ca_file Root certificate file used to validate WarehousePG and PostgreSQL server certificates.

Default: unset

server_tls_key_file Private key for PgBouncer to authenticate against WarehousePG or PostgreSQL server.

Default: not set

server_tls_cert_file Certificate for private key. WarehousePG or PostgreSQL servers can validate it.

Default: not set

server_tls_protocols Which TLS protocol versions are allowed. Allowed values: `tlsv1.0`, `tlsv1.1`, `tlsv1.2`, `tlsv1.3`. Shortcuts: `all` (`tlsv1.0`, `tlsv1.1`, `tlsv1.2`, `tlsv1.3`); `secure` (`tlsv1.2`, `tlsv1.3`); `legacy` (`all`).

Default: `secure`

server_tls_ciphers Allowed TLS ciphers, in OpenSSL syntax. Shortcuts: `default`/`secure`, `compat`/`legacy`, `insecure`/`all`, `normal`, `fast`.

```
Only connections using TLS version 1.2 and lower are affected. There is currently no setting that controls the cipher choices used by TLS version 1.3 connections.

Default: `fast`
```

Dangerous Timeouts

Setting the following timeouts can cause unexpected errors.

query_timeout Queries running longer than this (seconds) are canceled. This parameter should be used only with a slightly smaller server-side `statement_timeout`, to apply only for network problems. [seconds]

```
Default: 0.0 \(deactivated\)
```

query_wait_timeout The maximum time, in seconds, queries are allowed to wait for execution. If the query is not assigned to a server during that time, the client is disconnected. This is used to prevent unresponsive servers from grabbing up connections. [seconds]

```
Default: 120
```

cancel_wait_timeout The maximum time, in seconds, cancellation requests are allowed to spend waiting for execution. If the cancel request is not assigned to a server during that time, the client is disconnected. A value of 0 disables the timeout. If it is disabled, cancel requests will be queued indefinitely.

This setting is used to prevent a client locking up when a cancel cannot be forwarded due to the server being down.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Default: 10.0

client_idle_timeout Client connections idling longer than this many seconds are closed. This should be larger than the client-side connection lifetime settings, and only used for network problems. [seconds]

```
Default: 0.0 \(deactivated\)
```

idle_transaction_timeout If client has been in "idle in transaction" state longer than this (seconds), it is disconnected. [seconds]

```
Default: 0.0 \(deactivated\)
```

suspend_timeout How many seconds to wait for buffer flush during `SUSPEND` or reboot (`-R`). A connection is dropped if the flush does not succeed.

```
Default: 10
```

Low-level Network Settings

pkt_buf Internal buffer size for packets. Affects the size of TCP packets sent and general memory usage. Actual `libpq` packets can be larger than this so there is no need to set it large.

```
Default: 4096
```

max_packet_size Maximum size for packets that PgBouncer accepts. One packet is either one query or one result set row. A full result set can be larger.

```
Default: 2147483647
```

listen_backlog Backlog argument for the `listen(2)` system call. It determines how many new unanswered connection attempts are kept in queue. When the queue is full, further new connection attempts are dropped.

```
Default: 128
```

sbuf_loopcnt How many times to process data on one connection, before proceeding. Without this limit, one connection with a big result set can stall PgBouncer for a long time. One loop processes one `pkt_buf` amount of data. 0 means no limit.

```
Default: 5
```

so_reuseport Specifies whether to set the socket option `SO_REUSEPORT` on TCP listening sockets. On some operating systems, this allows running multiple PgBouncer instances on the same host listening on the same port and having the kernel distribute the connections automatically. This option is a way to get PgBouncer to use more CPU cores. (PgBouncer is single-threaded and uses one CPU core per instance.)

```
The behavior in detail depends on the operating system kernel. As of this writing, this setting has the desired effect on (sufficiently recent versions of) Linux, DragonFlyBSD, and FreeBSD. (On FreeBSD, it applies the socket option `SO_REUSEPORT_LB` instead.). Some other operating systems support the socket option but it won't have the desired effect: It will allow multiple processes to bind to the same port but only one of them will get the connections. See your operating system's `setsockopt()` documentation for details.

On systems that don’t support the socket option at all, turning this setting on will result in an error.

Each PgBouncer instance on the same host needs different settings for at least `unix_socket_dir` and `pidfile`, as well as `logfile` if that is used. Also note that if you make use of this option, you can no longer connect to a specific PgBouncer instance via TCP/IP, which might have implications for monitoring and metrics collection.

Default: 0
```

tcp_defer_accept For details on this and other TCP options, please see the tcp(7) man page.

```
Default: 45 on Linux, otherwise 0
```

tcp_socket_buffer Default: not set

tcp_keepalive Turns on basic keepalive with OS defaults.

```
On Linux, the system defaults are `tcp_keepidle=7200`, `tcp_keepintvl=75`, `tcp_keepcnt=9`. They are probably similar on other operating systems.

Default: 1
```

tcp_keepcnt Default: not set

tcp_keepidle Default: not set

tcp_keepintvl Default: not set

tcp_user_timeout Sets the `TCP_USER_TIMEOUT` socket option. This specifies the maximum amount of time in milliseconds that transmitted data may remain unacknowledged before the TCP connection is forcibly closed. If set to `0` , then the operating system's default is used.

Default: 0

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

[users] Section

This section contains `key` = `value` pairs, where the `key` is a user name and the `value` is a `libpq` connect-string list of `key` = `value` pairs of configuration settings specific for this user. Only a few settings are available here.

pool_mode Set the pool mode for all connections from this user. If not set, the database or default `pool_mode` is used.

max_user_connection Configure a maximum for the user (i.e. all pools with the user will not have more than this many server connections).

For example:

```
[users]

user1 = pool_mode=transaction max_user_connections=10
```

[peers] Section

This section defines the peers that PgBouncer can forward cancellation requests to and where those cancellation requests will be routed.

PgBouncer processes can be peered together in a group by defining a `peer_id` value and a `[peers]` section in the configurations of all the PgBouncer processes. These PgBouncer processes can then forward cancellations requests to the process that it originated from. This is needed to make cancellations work when multiple PgBouncer processes, possibly on different servers, are behind the same TCP load balancer. Cancellation requests are sent over different TCP connections than the query they are cancelling, so a TCP load balancer might send the cancellation request connection to a different process than the one that it was meant for. By peering them these cancellation requests eventually end up at the right process.

The section contains key=value lines like

```
peer_id = connection string
```

Where the key will be taken as a `peer_id` and the value as a connection string, consisting of key=value pairs of connection parameters, described below (similar to `libpq`, but the actual `libpq` is not used and the set of available features is different). For example:

```
1 = host=host1.example.com
2 = host=/tmp/pgbouncer-2  port=5555
```

Note that for peering to work, the `peer_id` of each PgBouncer process in the group must be unique within the peered group. And the `[peers]` section should contain entries for each of those peer ids. It is allowed, but not necessary, for the i `[peers]` section to contain the `peer_id` of the PgBouncer that the configuration is for. Such an entry will be ignored, but it is allowed to make configuration management easy, because it allows using the exact same `[peers]` section for multiple configurations.

Note that cross-version peering is supported as long as all peers are on running 1.21.0 version or higher. In 1.21.0 some breaking changes were made in how we encode the cancellation tokens that made them incompatible with the ones created by earlier versions.

host Host name or IP address to connect to. Host names are resolved at connection time, the result is cached per the `dns_max_ttl` parameter. If DNS returns several results, they are used in a round-robin manner. But in general it is not recommended to use a hostname that resolves to multiple IPs, because then the cancel request might still be forwarded to the wrong node and it would need to be forwarded again (which is only allowed up to three times).

If the value begins with `/`, a Unix socket in the file-system namespace is used. If the value begins with `@`, a Unix socket in the abstract namespace is used.

Examples:

```
```
host=localhost
host=127.0.0.1
host=2001:0db8:85a3:0000:0000:8a2e:0370:7334
host=/var/run/pgbouncer-1
```
```

port The port to connect to. Default: 6432

pool_size Set the maximum number of cancel requests that can be in flight to the peer at the same time. It is quite normal for cancel requests to arrive in bursts, for example, when the backing Postgres server slows down. So it is important for `pool_size` to not be so low that it cannot handle these bursts.

If not set, the `default_pool_size` is used.

Example Configuration Files

Minimal Configuration

```
[databases]
postgres = host=127.0.0.1 dbname=postgres auth_user=gpadmin

[pgbouncer]
pool_mode = session
listen_port = 6543
listen_addr = 127.0.0.1
auth_type = md5
auth_file = users.txt
logfile = pgbouncer.log
pidfile = pgbouncer.pid
admin_users = someuser
stats_users = stat_collector
```

Use connection parameters passed by the client:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
[databases]
* =

[pgbouncer]
listen_port = 6543
listen_addr = 0.0.0.0
auth_type = trust
auth_file = bouncer/users.txt
logfile = pgbouncer.log
pidfile = pgbouncer.pid
ignore_startup_parameters=options
```

Database Defaults

```
[databases]

; foodb over unix socket
foodb =

; redirect bardb to bazdb on localhost
bardb = host=127.0.0.1 dbname=bazdb

; access to destination database will go with single user
forcedb = host=127.0.0.1 port=300 user=baz password=foo client_encoding=UNICODE datestyle=ISO
```

Example of a secure function for `auth_query`:

```
CREATE OR REPLACE FUNCTION pgbouncer.user_lookup(in i_username text, out uname text, out phash text)
RETURNS record AS $$
BEGIN
    SELECT usename, passwd FROM
pg_catalog.pg_shadow
    WHERE usename = i_username INTO uname,
phash;
    RETURN;
END;
$$ LANGUAGE plpgsql SECURITY
DEFINER;
REVOKE ALL ON FUNCTION pgbouncer.user_lookup(text) FROM public, pgbouncer;
GRANT EXECUTE ON FUNCTION pgbouncer.user_lookup(text) TO pgbouncer;
```

Example configuration for two peered PgBouncer processes to create a multi-core PgBouncer setup using `so_reuseport`. The configuration for the first process is:

```
[databases]
postgres = host=localhost dbname=postgres

[peers]
1 = host=/tmp/pgbouncer1
2 = host=/tmp/pgbouncer2

[pgbouncer]
listen_addr=127.0.0.1
auth_file=auth_file.conf
so_reuseport=1
unix_socket_dir=/tmp/pgbouncer1
peer_id=1
```

The configuration for the second process is:

```
[databases]
postgres = host=localhost dbname=postgres

[peers]
1 = host=/tmp/pgbouncer1
2 = host=/tmp/pgbouncer2

[pgbouncer]
listen_addr=127.0.0.1
auth_file=auth_file.conf
so_reuseport=1
; only unix_socket_dir and peer_id are different
unix_socket_dir=/tmp/pgbouncer2
peer_id=2
```

7.7.3 Additional Supplied Utilities

Additional programs available in the WarehousePG installation.

The following PostgreSQL `contrib` server utility programs are installed:

- pg_xlogdump - Server utility program to display a human-readable rendering of the write-ahead log of a WarehousePG cluster.

Parent topic: WarehousePG Utility Guide

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.8 System Catalogs

This reference describes the WarehousePG cluster catalog tables, views, and functions. System tables prefixed with `gp_` relate to the parallel features of WarehousePG. Tables prefixed with `pg_` are either standard PostgreSQL system catalog tables supported in WarehousePG, or are related to features WarehousePG that provides to enhance PostgreSQL for data warehousing workloads. Note that the global system catalog for WarehousePG resides on the coordinator instance.

> **Caution** Changes to WarehousePG cluster catalog tables or views are not supported. If a catalog table or view is changedby the customer, the WarehousePG cluster is not supported. The cluster must be reinitialized and restored by the customer.

For more information about the standard system views supported in PostgreSQL and WarehousePG, see the following sections of the PostgreSQL documentation:

- System Views
- Statistics Collector Views
- The Information Schema

gp_backend_memory_contexts

The `gp_backend_memory_contexts` view is a cluster-wide view that displays the `pg_backend_memory_contexts` information from every primary segment.

column	type	references	description
`gp_segment_id`	integer		Unique identifier of a segment (or coordinator) instance.
`name`	text		The name of the memory context.
`ident`	text		Identification information of the memory context. This field is truncated at 1024 bytes.
`parent`	text		The name of the parent of this memory context.
`level`	int4		The distance from `TopMemoryContext` in context tree.
`total_bytes`	int8		The total number of bytes allocated for this memory context.
`total_nblocks`	int8		The total number of blocks allocated for this memory context.
`free_bytes`	int8		Free space in bytes.
`free_chunks`	int8		The total number of free chunks.
`used_bytes`	int8		Used space in bytes.

gp_config

The `gp_config` view is a cluster-wide view that displays the `pg_config` information from every primary segment.

column	type	references	description
`gp_segment_id`	integer		Unique identifier of a segment (or coordinator) instance.
`name`	text		The parameter name.
`setting`	text		The parameter value.

gp_cursors

The `gp_cursors` view is a cluster-wide view that displays the `pg_config` information from every primary segment.

name	type	references	description
`gp_segment_id`	integer		Unique identifier of a segment (or coordinator) instance.
`name`	text		The name of the cursor.
`statement`	text		The verbatim query string submitted to declare this cursor.
`is_holdable`	boolean		`true` if the cursor is holdable (that is, it can be accessed after the transaction that declared the cursor has committed); `false` otherwise. **Note** WarehousePG does not support holdable parallel retrieve cursors, this value is always `false` for such cursors.
`is_binary`	boolean		`true` if the cursor was declared `BINARY`; `false` otherwise.
`is_scrollable`	boolean		`true` if the cursor is scrollable (that is, it allows rows to be retrieved in a nonsequential manner); `false` otherwise. **Note** WarehousePG does not support scrollable cursors, this value is always `false`.
`creation_time`	timestamptz		The time at which the cursor was declared.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

name	type	references	description
`is_parallel`	boolean		`true` if the cursor was declared `PARALLEL RETRIEVE`; `false` otherwise.

gp_distributed_log

The `gp_distributed_log` view contains status information about distributed transactions and their associated local transactions. A distributed transaction is a transaction that involves modifying data on the segment instances. WarehousePG's distributed transaction manager ensures that the segments stay in synch. This view allows you to see the status of distributed transactions.

column	type	references	description
`segment_id`	smallint	gp_segment_configuration.content	The content id of the segment. The coordinator is always -1 (no content).
`dbid`	smallint	gp_segment_configuration.dbid	The unique id of the segment instance.
`distributed_xid`	xid		The global transaction id.
`distributed_id`	text		A system assigned ID for a distributed transaction.
`status`	text		The status of the distributed transaction (Committed or Aborted).
`local_transaction`	xid		The local transaction ID.

gp_distributed_xacts

The `gp_distributed_xacts` view contains information about WarehousePG distributed transactions. A distributed transaction is a transaction that involves modifying data on the segment instances. WarehousePG's distributed transaction manager ensures that the segments stay in synch. This view allows you to see the currently active sessions and their associated distributed transactions.

column	type	references	description
`distributed_xid`	xid		The transaction ID used by the distributed transaction across the WarehousePG cluster.
`distributed_id`	text		The distributed transaction identifier. It has 2 parts — a unique timestamp and the distributed transaction number.
`state`	text		The current state of this session with regards to distributed transactions.
`gp_session_id`	int		The ID number of the WarehousePG session associated with this transaction.
`xmin_distributed_snapshot`	xid		The minimum distributed transaction number found among all open transactions when this transaction was started. It is used for MVCC distributed snapshot purposes.

gp_endpoints

The `gp_endpoints` view lists the endpoints created for all active parallel retrieve cursors declared by the current session user in the current database. When the WarehousePG superuser accesses this view, it returns a list of all endpoints created for all parallel retrieve cursors declared by all users in the current database.

Endpoints exist only for the duration of the transaction that defines the parallel retrieve cursor, or until the cursor is closed.

name	type	references	description
gp_segment_id	integer		The QE's endpoint `gp_segment_id`.
auth_token	text		The authentication token for a retrieve session.
cursorname	text		The name of the parallel retrieve cursor.
sessionid	integer		The identifier of the session in which the parallel retrieve cursor was created.
hostname	varchar(64)		The name of the host from which to retrieve the data for the endpoint.
port	integer		The port number from which to retrieve the data for the endpoint.
username	text		The name of the session user (not the current user); *you must initiate the retrieve session as this user*.
state	text		The state of the endpoint; the valid states are: READY: The endpoint is ready to be retrieved. ATTACHED: The endpoint is attached to a retrieve connection. RETRIEVING: A retrieve session is retrieving data from the endpoint at this moment. FINISHED: The endpoint has been fully retrieved. RELEASED: Due to an error, the endpoint has been released and the connection closed.
endpointname	text		The endpoint identifier; you provide this identifier to the `RETRIEVE` command.

gp_file_settings

The `gp_file_settings` view is a cluster-wide view that displays the `pg_file_settings` information from every primary segment.

name	type	references	description
`gp_segment_id`	integer		Unique identifier of a segment (or coordinator) instance.
`sourcefile`	text		Full path name of the configuration file.
`sourceline`	integer		Line number within the configuration file where the entry appears.
`seqno`	integer		Order in which the entries are processed (1..n).

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

name	type	references	description
name	text		Configuration parameter name.
setting	text		Value to be assigned to the parameter.
applied	boolean		True if the value can be applied successfully.
error	text		If not null, an error message indicating why this entry could not be applied.

gp_pgdatabase

The gp_pgdatabase view displays the status of WarehousePG segment instances and whether they are acting as the mirror or the primary. The WarehousePG fault detection and recovery utilities use this view internally to identify failed segments.

column	type	references	description
dbid	smallint	gp_segment_configuration.dbid	System-assigned ID. The unique identifier of a segment (or coordinator) instance.
isprimary	boolean	gp_segment_configuration.role	Whether or not this instance is active. Is it currently acting as the primary segment (as opposed to the mirror).
content	smallint	gp_segment_configuration.content	The ID for the portion of data on an instance. A primary segment instance and its mirror will have the same content ID. For a segment the value is from 0-*N-1*, where *N* is the number of segments in WarehousePG. For the coordinator, the value is -1.
valid	boolean	gp_segment_configuration.mode	Whether or not this instance is up and the mode is either *s* (synchronized) or *n* (not in sync).
definedprimary	boolean	gp_segment_ configuration.preferred_role	Whether or not this instance was defined as the primary (as opposed to the mirror) at the time the system was initialized.

gp_replication_origin_status

The gp_replication_origin_status view is a cluster-wide view that displays the pg_replication_origin_status information from every primary segment.

name	type	references	description
gp_segment_id	integer		Unique identifier of a segment (or coordinator) instance.
local_id	oid	pg_replication_origin.roident	Internal node identifier.
external_id	text	pg_replication_origin.roname	External node identifier.
remote_lsn	pg_lsn		The origin node's LSN up to which data has been replicated.
local_lsn	pg_lsn		This node's LSN at which remote_lsn has been replicated. Used to flush commit records before persisting data to disk when using asynchronous commits.

gp_replication_slots

The gp_replication_slots view is a cluster-wide view that displays the pg_replication_slots information from every primary segment.

name	type	references	description
gp_segment_id	integer		Unique identifier of a segment (or coordinator) instance.
slot_name	name		A unique, cluster-wide identifier for the replication slot.
plugin	name		The base name of the shared object containing the output plugin this logical slot is using, or null for physical slots.
slot_type	text		The slot type - physical or logical.
datoid	oid	pg_database.oid	The OID of the database this slot is associated with, or null. Only logical slots have an associated database.
database	text	pg_database.datname	The name of the database this slot is associated with, or null. Only logical slots have an associated database.
temporary	boolean		True if this is a temporary replication slot. Temporary slots are not saved to disk and are automatically dropped on error or when the session has finished.
active	boolean		True if this slot is currently actively being used.
active_pid	integer		The process ID of the session using this slot if the slot is currently actively being used. NULL if inactive.
xmin	xid		The oldest transaction that this slot needs the database to retain. VACUUM cannot remove tuples deleted by any later transaction.
catalog_xmin	xid		The oldest transaction affecting the system catalogs that this slot needs the database to retain. VACUUM cannot remove catalog tuples deleted by any later transaction.
restart_ls n	pg_lsn		The address (LSN) of oldest WAL which still might be required by the consumer of this slot and thus won't be automatically removed during checkpoints. NULL if the LSN of this slot has never been reserved.
confirmed_flush_ lsn	pg_lsn		The address (LSN) up to which the logical slot's consumer has confirmed receiving data. Data older than this is not available anymore. NULL for physical slots.

gp_resgroup_config

The gp_toolkit.gp_resgroup_config view allows administrators to see the current CPU, memory, and concurrency limits for a resource group.

> **Note** The gp_resgroup_config view is valid only when resource group-based resource management is active.

column	type	references	description
groupid	oid	pg_resgroup.oid	The ID of the resource group.
groupname	name	pg_resgroup.rsgname	The name of the resource group.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

column	type	references	description
concurrency	text	pg_resgroupcapability.value for pg_resgroupcapability.reslimittype = 1	The concurrency (CONCURRENCY) value specified for the resource group.
cpu_max_percent	text	pg_resgroupcapability.value for pg_resgroupcapability.reslimittype = 2	The CPU limit (CPU_MAX_PERCENT) value specified for the resource group, or -1.
cpu_weight	text	pg_resgroupcapability.value for pg_resgroupcapability.reslimittype = 3	The scheduling priority of the resource group (CPU_WEIGHT).
cpuset	text	pg_resgroupcapability.value for pg_resgroupcapability.reslimittype = 4	The CPU cores reserved for the resource group (CPUSET), or -1.
memory_quota	text	pg_resgroupcapability.value for pg_resgroupcapability.reslimittype = 5	The memory quota (MEMORY_QUOTA) value specified for the resource group.
min_cost	text	pg_resgroupcapability.value for pg_resgroupcapability.reslimittype = 6	The minimum cost of a query plan to be included in the resource group (MIN_COST).
io_limit	text	pg_resgroupcapability.value for pg_resgroupcapability.reslimittype = 7	The maximum read/write sequential disk I/O throughput, and the maximum read/write I/O operations per second for the queries assigned to a specific tablespace (shown as the tablespace oid) and resource group (IO_LIMIT).

gp_resgroup_iostats_per_host

The gp_toolkit.gp_resgroup_iostats_per_host view allows administrators to see current disk I/O usage for each resource group on a per-host basis.

Memory amounts are specified in MBs.

> **Note** The gp_resgroup_iostats_per_host view is valid only when resource group-based resource management is active.

column	type	references	description
rsgname	name	pg_resgroup.rsgname	The name of the resource group
hostname	text	gp_segment_configuration.hostname	The hostname of the segment host
tablespace	name	pg_tablespace.spcname	The name of the tablespace
rbps	bigint		The real-time read sequential disk I/O throughput by the resource group on a host, in Bytes/s
wbps	bigint		The real-time write sequential disk I/O throughput by the resource group on a host, in Bytes/s
riops	bigint		The real-time read I/O operations per second by the resource group on a host
wiops	bigint		The real-time write I/O operations per second by the resource group on a host

Sample output for the gp_resgroup_iostats_per_host view:

```
SELECT * from gp_toolkit.gp_resgroup_iostats_per_host;
 rsgname        | hostname | tablespace       | rbps | wbps | riops | wiops
----------------+----------+------------------+------------------+------------------+-------------+-------------
 rg_test_group1 | mtspc    | pg_default       | 21356347               | 29369067               | 162           | 36
 rg_test_group2 | mtspc    | pg_default       | 0                | 0                | 0           | 0
 rg_test_group3 | mtspc    | pg_default       | 0                | 0                | 0           | 0

 rg_test_group5 | mtspc    | rg_io_limit_ts_1 | 0                | 0                | 0           | 0
(5 rows)
```

gp_resgroup_iostats_per_host

The gp_toolkit.gp_resgroup_iostats_per_host view allows administrators to see current disk I/O usage for each resource group on a per-host basis.

Memory amounts are specified in MBs.

> **Note** The gp_resgroup_iostats_per_host view is valid only when resource group-based resource management is active.

column	type	references	description
rsgname	name	pg_resgroup.rsgname	The name of the resource group.
hostname	text	gp_segment_configuration.hostname	The hostname of the segment host.
tablespace			
rbps			

|`

| cpu_usage |float| |The real-time CPU core usage by the resource group on a host. The value is the sum of the percentages of the CPU cores that are used by the resource group on the host.| | memory_usage |float| |The real-time memory usage of the resource group on each WarehousePG segment's host, in MB.|

Sample output for the gp_resgroup_iostats_per_host view:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
select * from gp_toolkit.gp_resgroup_status_per_host;
 rsgname       | hostname | tablespace | rbps (MB_read/s)
---------------+----------+------------+--------------
 admin_group   | zero     | pg_default | 80
 default_group | zero     | pg_default | 500
 system_group  | zero     | pg_default | 300
 rg_new_group  | zero     |
(4 rows)
```

gp_resgroup_status

The `gp_resgroup_status` view allows administrators to see status and activity for a resource group. It shows how many queries are waiting to run and how many queries are currently active in the system for each resource group. The view also displays current memory and CPU usage for the resource group.

> **Note** Resource groups use the Linux control groups (cgroups) configured on the host systems. The cgroups are used to manage host system resources. When resource groups use cgroups that are as part of a nested set of cgroups, resource group limits are relative to the parent cgroup allotment. For information about nested cgroups and WarehousePG resource group limits, see Using Resource Groups.

This view is accessible to all users.

column	type	references	description
rsgname	name	pg_resgroup.rsgname	The name of the resource group.
groupid	oid	pg_resgroup.oid	The ID of the resource group.
num_running	integer		The number of transactions currently running in the resource group.
num_queueing	integer		The number of currently queued transactions for the resource group.
num_queued	integer		The total number of queued transactions for the resource group since the WarehousePG cluster was last started, excluding the num_queueing.
num_executed	integer		The total number of transactions run in the resource group since the WarehousePG cluster was last started, excluding the num_running.
total_queue_duration	interval		The total time any transaction was queued since the WarehousePG cluster was last started.

Sample output for the `gp_resgroup_status` view:

```
select * from gp_toolkit.gp_resgroup_status;
 rsgname       | groupid | num_running | num_queueing | num_queued | num_executed | total_queue_duration |
---------------+---------+-------------+--------------+------------+--------------+----------------------------------
 default_group | 6437    | 0           | 0            | 0          | 0            | @ 0                  |
 admin_group   | 6438    | 1           | 0            | 0          | 13           | @ 0                  |
 system_group  | 6441    | 0           | 0            | 0          | 0            | @ 0                  |
(3 rows)
```

gp_resgroup_status_per_host

The `gp_toolkit.gp_resgroup_status_per_host` view allows administrators to see current memory and CPU usage and allocation for each resource group on a per-host basis.

Memory amounts are specified in MBs.

> **Note** The `gp_resgroup_status_per_host` view is valid only when resource group-based resource management is active.

column	type	references	description
rsgname	name	pg_resgroup.rsgname	The name of the resource group.
groupid	oid	pg_resgroup.oid	The ID of the resource group.
`hostname`	text	gp_segment_configuration.hostname	The hostname of the segment host.
`cpu_usage`	float		The real-time CPU core usage by the resource group on a host. The value is the sum of the percentages of the CPU cores that are used by the resource group on the host.
`memory_usage`	float		The real-time memory usage of the resource group on each WarehousePG segment's host, in MB.

Sample output for the `gp_resgroup_status_per_host` view:

```
select * from gp_toolkit.gp_resgroup_status_per_host;
 rsgname       | groupid | hostname | cpu_usage | memory_usage
---------------+---------+----------+-----------+--------------
 admin_group   | 6438    | zero     | 0.07      | 91.92
 default_group | 6437    | zero     | 0.00      | 0.00
 system_group  | 6441    | zero     | 0.02      | 53.04
(3 rows)
```

gp_resgroup_status_per_segment

The `gp_toolkit.gp_resgroup_status_per_segment` view allows administrators to see current memory usage usage calculated by vmem tracker and grouped by segment.

Memory amounts are specified in MBs.

> **Note** The `gp_resgroup_status_per_segment` view is valid only when resource group-based resource management is active.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

column	type	references	description
groupid	oid	pg_resgroup.oid	The ID of the resource group.
groupname	name	pg_resgroup.rsgname	The name of the resource group.
segment_id	smallint	gp_segment_configuration.content	The content ID for a segment instance on the segment host.
vmem_usage	The real-time memory usage of the resource group on each segment, in MB.		

gp_resqueue_status

The gp_toolkit.gp_resqueue_status view allows administrators to see status and activity for a resource queue. It shows how many queries are waiting to run and how many queries are currently active in the system from a particular resource queue.

> **Note** The gp_resqueue_status view is valid only when resource queue-based resource management is active.

column	type	references	description
queueid	oid	gp_toolkit.gp_resqueue_ queueid	The ID of the resource queue.
rsqname	name	gp_toolkit.gp_resqueue_ rsqname	The name of the resource queue.
rsqcountlimit	real	gp_toolkit.gp_resqueue_ rsqcountlimit	The active query threshold of the resource queue. A value of -1 means no limit.
rsqcountvalue	real	gp_toolkit.gp_resqueue_ rsqcountvalue	The number of active query slots currently being used in the resource queue.
rsqcostlimit	real	gp_toolkit.gp_resqueue_ rsqcostlimit	The query cost threshold of the resource queue. A value of -1 means no limit.
rsqcostvalue	real	gp_toolkit.gp_resqueue_ rsqcostvalue	The total cost of all statements currently in the resource queue.
rsqmemorylimit	real	gp_toolkit.gp_resqueue_ rsqmemorylimit	The memory limit for the resource queue.
rsqmemoryvalue	real	gp_toolkit.gp_resqueue_ rsqmemoryvalue	The total memory used by all statements currently in the resource queue.
rsqwaiters	integer	gp_toolkit.gp_resqueue_ rsqwaiter	The number of statements currently waiting in the resource queue.
rsqholders	integer	gp_toolkit.gp_resqueue_ rsqholders	The number of statements currently running on the system from this resource queue.

gp_segment_endpoints

The gp_segment_endpoints view lists the endpoints created in the QE for all active parallel retrieve cursors declared by the current session user. When the WarehousePG superuser accesses this view, it returns a list of all endpoints on the QE created for all parallel retrieve cursors declared by all users.

Endpoints exist only for the duration of the transaction that defines the parallel retrieve cursor, or until the cursor is closed.

column	type	references	description
auth_token	text		The authentication token for the retrieve session.
databaseid	oid		The identifier of the database in which the parallel retrieve cursor was created.
senderpid	integer		The identifier of the process sending the query results.
receiverpid	integer		The process identifier of the retrieve session that is receiving the query results.
state	text		The state of the endpoint; the valid states are: READY: The endpoint is ready to be retrieved. ATTACHED: The endpoint is attached to a retrieve connection. RETRIEVING: A retrieve session is retrieving data from the endpoint at this moment. FINISHED: The endpoint has been fully retrieved. RELEASED: Due to an error, the endpoint has been released and the connection closed.
gp_segment_id	integer		The QE's endpoint gp_segment_id.
sessionid	integer		The identifier of the session in which the parallel retrieve cursor was created.
username	text		The name of the session user (not the current user); *you must initiate the retrieve session as this user*.
endpointname	text		The endpoint identifier; you provide this identifier to the RETRIEVE command.
cursorname	text		The name of the parallel retrieve cursor.

gp_session_endpoints

The gp_session_endpoints view lists the endpoints created for all active parallel retrieve cursors declared by the current session user in the current session.

Endpoints exist only for the duration of the transaction that defines the parallel retrieve cursor, or until the cursor is closed.

column	type	references	description
gp_segment_id	integer		The QE's endpoint gp_segment_id.
auth_token	text		The authentication token for a retrieve session.
cursorname	text		The name of the parallel retrieve cursor.
sessionid	integer		The identifier of the session in which the parallel retrieve cursor was created.
hostname	varchar(64)		The name of the host from which to retrieve the data for the endpoint.
port	integer		The port number from which to retrieve the data for the endpoint.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

column	type	references	description
username	text		The name of the session user (not the current user); *you must initiate the retrieve session as this user.*
state	text		The state of the endpoint; the valid states are: READY: The endpoint is ready to be retrieved. ATTACHED: The endpoint is attached to a retrieve connection. RETRIEVING: A retrieve session is retrieving data from the endpoint at this moment. FINISHED: The endpoint has been fully retrieved. RELEASED: Due to an error, the endpoint has been released and the connection closed.
endpointname	text		The endpoint identifier; you provide this identifier to the `RETRIEVE` command.

gp_settings

The `gp_settings` view is a cluster-wide view that displays the `pg_settings` information from every primary segment.

name	type	references	description
`gp_segment_id`	integer		Unique identifier of a segment (or coordinator) instance.
`name`	text		Runtime configuration parameter name.
`setting`	text		Current value of the parameter.
`unit`	text		Implicit unit of the parameter.
`category`	text		Logical group of the parameter.
`short_desc`	text		A brief description of the parameter.
`extra_desc`	text		Additional, more detailed, description of the parameter.
`context`	text		Context required to set the parameter's value.
`vartype`	text		Parameter type (bool, enum, integer, real, or string)v
`source`	text		Source of the current parameter value.v
`min_val`	text		Minimum allowed value of the parameter (null for non-numeric values).
`max_val`	text		Maximum allowed value of the parameter (null for non-numeric values).
`enumvals`	text[]		Permitted values of an enum parameter (null for non-enum values).
`boot_val`	text		Parameter value assumed at server startup if the parameter is not otherwise set.
`reset_val`	text		Value that RESET would reset the parameter to in the current session.
`sourcefile`	text		Configuration file the current value was set in (null for values set from sources other than configuration files, or when examined by a user who is neither a superuser or a member of `pg_read_all_settings`); helpful when using include directives in configuration files.
`sourceline`	integer		Line number within the configuration file the current value was set at (null for values set from sources other than configuration files, or when examined by a user who is neither a superuser or a member of pg_read_all_settings).
`pending_restart`	boolean		`true` if the value has been changed in the configuration file but needs a restart; otherwise `false`.

gp_suboverflowed_backend

The `gp_suboverflowed_backend` view allows administrators to identify sessions in which a backend has subtransaction overflows, which can cause query performance degradation in the system, including catalog queries.

column	type	description
`segid`	integer	The id of the segment containing the suboverflowed backend.
`pids`	integer[]	A list of the pids of all suboverflowed backends on this segment.

For more information on handling suboverflowed backends to prevent performance issues, seeChecking for and Terminating Overflowed Backends.

gp_transaction_log

The `gp_transaction_log` view contains status information about transactions local to a particular segment. This view allows you to see the status of local transactions.

column	type	references	description
`segment_id`	smallint	gp_segment_configuration.content	The content id of the segment. The coordinator is always -1 (no content).
`dbid`	smallint	gp_segment_configuration.dbid	The unique id of the segment instance.
`transaction`	xid		The local transaction ID.
`status`	text		The status of the local transaction (Committed or Aborted).

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

gpexpand.expansion_progress

The `gpexpand.expansion_progress` view contains information about the status of a system expansion operation. The view provides calculations of the estimated rate of table redistribution and estimated time to completion.

Status for specific tables involved in the expansion is stored in gpexpand.status_detail.

column	type	references	description
`name`	text		Name for the data field provided. Includes: Bytes Left Bytes Done Estimated Expansion Rate Estimated Time to Completion Tables Expanded Tables Left
`value`	text		The value for the progress data. For example: `Estimated Expansion Rate - 9.75667095996092 MB/s`

gp_stat_activity

The `gp_stat_activity` view is a cluster-wide view that displays the `pg_stat_activity` information from every primary segment.

column	type	references	description
`gp_segment_id`	integer		Unique identifier of a segment (or coordinator) instance.
`datid`	oid	pg_database.oid	Database OID
`datname`	name		Database name
`pid`	integer		Process ID of this backend
`sess_id`	integer		Session ID
`usesysid`	oid	pg_authid.oid	OID of the user logged into this backend
`usename`	name		Name of the user logged into this backend
`application_name`	text		Name of the application that is connected to this backend
`client_addr`	inet		IP address of the client connected to this backend. If this field is null, it indicates either that the client is connected via a Unix socket on the server machine or that this is an internal process such as autovacuum.
`client_hostname`	text		Host name of the connected client, as reported by a reverse DNS lookup of `client_addr`. This field will only be non-null for IP connections, and only when log_hostname is enabled.
`client_port`	integer		TCP port number that the client is using for communication with this backend, or -1 if a Unix socket is used
`backend_start`	timestamptz		Time backend process was started
`xact_start`	timestamptz		Transaction start time
`query_start`	timestamptz		Time query began execution
`state_change`	timestampz		Time when the `state` was last changed
`wait_event_type`	text		Type of event for which the backend is waiting
`wait_event`	text		Wait event name if backend is currently waiting
`state`	text		Current overall state of this backend. Possible values are: - `active`: The backend is running a query. - `idle`: The backend is waiting for a new client command. - `idle in transaction`: The backend is in a transaction, but is not currently running a query. - `idle in transaction (aborted)`: This state is similar to idle in transaction, except one of the statements in the transaction caused an error. - `fastpath function call`: The backend is running a fast-path function. - `disabled`: This state is reported if `track_activities` is deactivated in this backend.
`query`	text		Text of this backend's most recent query. If `state` is active this field shows the currently running query. In all other states, it shows the last query that was run.
`rsgid`	oid	pg_resgroup.oid	Resource group OID or `0`. See Note.
`rsgname`	text	pg_resgroup.rsgname	Resource group name or `unknown`. See Note.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

gp_stat_all_indexes

The `gp_stat_all_indexes` view is a cluster-wide view that displays the `pg_stat_indexes` information from every primary segment.

column	type	references	description
`gp_segment_id`	integer		Unique identifier of a segment (or coordinator) instance.
`relid`	oid		ID of the table for this index.
`indexrelid`	oid		OID of this index.
`schemaname`	name		Name of the schema this index is in.
`relname`	name		Name of the table for this index.
`indexrelname`	name		Name for this index.
`idx_scan`	bigint		Number of index scans initiated on this index.
`idx_tup_read`	bigint		Number of index entries returned by scans on this index.
`idx_tup_fetch`	bigint		Number of live table rows fetched by simple index scans using this index

This system view is summarized in the `gp_stat_all_indexes_summary` system view.

gp_stat_all_tables

The `gp_stat_all_tables` view is a cluster-wide view that displays the `pg_stat_tables` information from every primary segment.

column	type	references	description
`gp_segment_id`	integer		Unique identifier of a segment (or coordinator) instance.
`relid`	oid		OID of a table.
`schemaname`	name		Name of the schema this table is on.
`relname`	name		Name of this table.
`seq_scan`	bigint		Number of sequential scans initiated on this table.
`seq_tup_read`	bigint		Number of live rows fetched by sequential scans.
`idx_scan`	bigint		Number of index scans initiated on this table.
`idx_tup_fetch`	bigint		Number of live rows fetched by index scans.
`n_tup_ins`	bigint		Number of rows inserted.
`n_tup_upd`	bigint		Number of rows updated (includes HOT updated rows).
`n_tup_del`	bigint		Number of rows deleted.
`n_tup_hot_upd`	bigint		Number of rows HOT updated (that is, with no separate index update required).
`n_live_tup`	bigint		Estimated number of live rows.
`n_dead_tup`	bigint		Estimated number of dead rows.
`n_mod_since_analyze`	bigint		Estimated number of rows modified since this table was last analyzed.
`n_ins_since_vacuum`	bigint		Estimated number of rows inserted since this table was last vacuumed.
`last_vacuum`	timestamp with time zone		Last time at which this table was manually vacuumed (not counting `VACUUM FULL`).
`last_autovacuum`	timestamp with time zone		Last time at which this table was vacuumed by the autovacuum daemon.
`last_analyze`	timestamp with time zone		Last time at which this table was manually analyzed.
`last_autoanalyze`	timestamp with time zone		Last time at which this table was analyzed by the autovacuum daemon.
`vacuum_count`	bigint		Number of times this table has been manually vacuumed (not counting `VACUUM FULL`).
`autovacuum_count`	bigint		Number of times this table has been vacuumed by the autovacuum daemon.
`analyze_count`	bigint		Number of times this table has been manually analyzed.
`autoanalyze_count`	bigint		Number of times this table has been analyzed by the autovacuum daemon.

This system view is summarized in the `gp_stat_all_tables_summary` system view.

gp_stat_archiver

column	type	references	description
`gp_segment_id`	integer		Unique identifier of a segment (or coordinator) instance.
`archived_count`	bigint		Number of WAL files that have been successfully archived.
`last_archived_wal`	text		Name of the WAL file most recently successfully archived.
`last_archived_time`	timestamp with time zone		Time of the most recent successful archive operation.
`failed_count`	bigint		Number of failed attempts for archiving WAL files.
`last_failed_wal`	timestamp with time zone		Name of the WAL file of the most recent failed archival operation.
`last_failed_time`	bigint		Time of the most recent failed archival operation.
`stats_reset`	timestamp with time zone		Time at which these statistics were last reset.

This system view is summarized in the `gp_stat_archiver_summary` system view.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

gp_stat_bgwriter

column	type	references	description
gp_segment_id	integer		Unique identifier of a segment (or coordinator) instance.
checkpoints_timed	bigint		Number of scheduled checkpoints that have been performed.
checkpoints_req	bigint		Number of requested checkpoints that have been performed.
checkpoint_write_time	double precision		Total amount of time that has been spent in the portion of checkpoint processing where files are written to disk, in milliseconds.
checkpoint_sync_time	double precision		Total amount of time that has been spent in the portion of checkpoint processing where files are synchronized to disk, in milliseconds.
buffers_checkpoint	bigint		Number of buffers written during checkpoints.
buffers_clean	bigint		Number of buffers written by the background writer.
maxwritten_clean bigint		Number of times the background writer stopped a cleaning scan because it had written too many buffers.	
buffers_backend bigint		Number of buffers written directly by a backend.	
buffers_backend_fsync bigint		Number of times the background writer stopped a cleaning scan because it had written too many buffers.	
buffers_alloc	bigint		Number of buffers allocated.
stats_reset	timestamp with time zone		Time at which these statistics were last reset.

This system view is summarized in the gp_stat_bgwriter_summary system view.

gp_stat_database

column	type	references	description
gp_segment_id	integer		Unique identifier of a segment (or coordinator) instance.
datid	oid		OID of this database, or 0 for objects belonging to a shared relation.
datname	name		Name of this database, or NULL for shared objects.
numbackends	integer		Number of backends currently connected to this database, or NULL for shared objects. This is the only column in this view that returns a value reflecting current state; all other columns return the accumulated values since the last reset.
xact_commit	bigint		Number of transactions in this database that have been committed.
xact_rollback	bigint		Number of transactions in this database that have been rolled back.
blks_read	bigint		Number of disk blocks read in this database.
blks_hit	bigint		Number of times disk blocks were found already in the buffer cache, so that a read was not necessary (this only includes hits in the PostgreSQL buffer cache, not the operating system's file system cache).
tup_returned	bigint		Number of live rows fetched by sequential scans and index entries returned by index scans in this database.
tup_fetched	bigint		Number of live rows fetched by index scans in this database.
tup_inserted	bigint		Number of rows inserted by queries in this database.
tup_updated	bigint		Number of rows updated by queries in this database.
tup_deleted bigint	bigint		Number of rows deleted by queries in this database.
conflicts	bigint		Number of queries canceled due to conflicts with recovery in this database.
temp_files	bigint		Number of temporary files created by queries in this database. All temporary files are counted, regardless of why the temporary file was created (for example, sorting or hashing), and regardless of the log_temp_files setting.
temp_bytes	bigint		Total amount of data written to temporary files by queries in this database. All temporary files are counted, regardless of why the temporary file was created, and regardless of the log_temp_files setting.
deadlocks	bigint		Number of deadlocks detected in this database.
checksum_failures	bigint		Number of data page checksum failures detected in this database (or on a shared object), or NULL if data checksums are not enabled.
checksum_last_failure	timestamp with time zone		Time at which the last data page checksum failure was detected in this database (or on a shared object), or NULL if data checksums are not enabled.
blk_read_time	double precision		Time spent reading data file blocks by backends in this database, in milliseconds (if track_io_timing is enabled, otherwise zero).
session_time	double precision		Time spent by database sessions in this database, in milliseconds (note that statistics are only updated when the state of a session changes, so if sessions have been idle for a long time, this idle time won't be included).
active_time	double precision		Time spent executing SQL statements in this database, in milliseconds (this corresponds to the states active and fastpath function call in pg_stat_activity).
idle_in_transaction_time	double precision		Time spent idling while in a transaction in this database, in milliseconds (this corresponds to the states idle in transaction and idle in transaction (aborted) in gp_stat_activity)
sessions	bigint		Total number of sessions established to this database.
sessions_abandoned	bigint		Number of database sessions to this database that were terminated because connection to the client was lost.
sessions_fatal	bigint		Number of database sessions to this database that were terminated by fatal errors.
sessions_killed	bigint		Number of database sessions to this database that were terminated by operator intervention.
stats_reset	timestamp with time zone		Time at which these statistics were last reset.

This system view is summarized in the gp_stat_database_summary system view.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

gp_stat_database_conflicts

column	type	references	description
gp_segment_id	integer		Unique identifier of a segment (or coordinator) instance.
datid	oid		OID of a database.
datname	name		Name of this database.
confl_tablespace	bigint		Number of queries in this database that have been canceled due to dropped tablespaces.
confl_lock	bigint		Number of queries in this database that have been canceled due to lock timeouts.
confl_snapshot	bigint		Number of queries in this database that have been canceled due to old snapshots.
client_port	integer		Client port number.
confl_bufferpin	bigint		Number of queries in this database that have been canceled due to pinned buffers.
confl_deadlock	bigint		Number of queries in this database that have been canceled due to deadlocks.

gp_stat_gssapi

column	type	references	description
gp_segment_id	integer		Unique identifier of a segment (or coordinator) instance.
pid	integer		Process ID of a backend.
gss_authenticated boolean	boolean		True if GSSAPI authentication was used for this connection.
principal	text		Principal used to authenticate this connection, or NULL if GSSAPI was not used to authenticate this connection. This field is truncated if the principal is longer than NAMEDATALEN (64 characters in a standard build).
encrypted	boolean		True if GSSAPI encryption is in use on this connection.

gp_stat_operations

The view gp_stat_operations shows details about the last operation performed on a database object (such as a table, index, view or database) or a global object (such as a role).

column	type	references	description
gp_segment_id	integer		Unique identifier of a segment (or coordinator) instance.
classname	text		The name of the system table in the pg_catalog schema where the record about this object is stored (pg_class =relations, pg_database =databases, pg_namespace =schemas, pg_authid =roles)
objname	name		The name of the object.
objid	oid		The OID of the object.
schemaname	name		The name of the schema where the object resides.
usestatus	text		The status of the role who performed the last operation on the object (CURRENT =a currently active role in the system, DROPPED =a role that no longer exists in the system, CHANGED =a role name that exists in the system, but has changed since the last operation was performed).
usename	name		The name of the role that performed the operation on this object.
actionname	name		The action that was taken on the object.
subtype	text		The type of object operated on or the subclass of operation performed.
statime	timestamptz		The timestamp of the operation. This is the same timestamp that is written to the WarehousePG server log files in case you need to look up more detailed information about the operation in the logs.

gp_stat_progress_analyze

The gp_stat_progress_analyze view is a cluster-wide view that displays the pg_stat_progress_analyze information from every primary segment for all currently-running ANALYZE operations.

The gp_stat_progress_analyze_summary view aggregates across the WarehousePG cluster the metrics reported by gp_stat_progress_analyze.

Column	Type	Description
gp_segment_id	integer	Unique identifier of a segment (or coordinator) instance. (This column is not present in the gp_stat_progress_analyze_summary view.)
pid	integer	The process identifier of the backend, or the coordinator process identifier if the gp_stat_progress_analyze_summary view.
datid	oid	The object identifier of the database to which this backend is connected.
datname	name	Name of the database to which this backend is connected.
relid	oid	The object identifier of the table being analyzed.
phase	text	Current processing phase. Refer to ANALYZE Progress Reporting for detailed information about the phases.
sample_blks_total	bigint	Total number of heap blocks that will be sampled.
sample_blks_scanned	bigint	Number of heap blocks scanned.
ext_stats_total	bigint	Number of extended statistics.
ext_stats_computed	bigint	Number of extended statistics computed. This counter only advances when the phase is computing extended statistics.
child_tables_total	bigint	Number of child tables.
child_tables_done	bigint	Number of child tables scanned. This counter only advances when the phase is acquiring inherited sample rows.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Column	Type	Description
current_child_table_relid	oid	The object identifier of the child table currently being scanned. This field is only valid when the phase is acquiring inherited sample rows. (This column is not present in the for gp_stat_progress_analyze_summary view.)

gp_stat_progress_basebackup

The gp_stat_progress_basebackup view is a cluster-wide view that displays the pg_stat_progress_basebackup information from every primary segment for all currently-running base backup operations (gprecoverseg).

The gp_stat_progress_basebackup_summary view aggregates across the WarehousePG cluster the metrics reported by gp_stat_progress_basebackup.

Column	Type	Description
gp_segment_id	integer	Unique identifier of a segment (or coordinator) instance. (This column is not present in the gp_stat_progress_basebackup_summary view.)
pid	integer	The process identifier of a WAL sender process, or the coordinator process identifier if the gp_stat_progress_basebackup_summary view.
phase	text	Current processing phase. Refer to Base Backup Progress Reporting for detailed information about the phases.
backup_total	bigint	Total amount of data that will be streamed. This is estimated and reported as of the beginning of streaming database files phase. Note that this is only an approximation since the database may change during streaming database files phase and WAL log may be included in the backup later. This is always the same value as backup_streamed once the amount of data streamed exceeds the estimated total size. NULL if the estimation is disabled in pg_basebackup.
backup_streamed	bigint	Amount of data streamed. This counter only advances when the phase is streaming database files or transferring wal files.
tablespaces_total	bigint	Total number of tablespaces that will be streamed.
tablespaces_streamed	bigint	Number of tablespaces streamed. This counter only advances when the phase is streaming database files.

gp_stat_progress_cluster

The gp_stat_progress_cluster view is a cluster-wide view that displays the pg_stat_progress_cluster information from every primary segment for all currently-running CLUSTER and VACUUM FULL (on a heap table) operations.

The gp_stat_progress_cluster_summary view aggregates across the WarehousePG cluster the metrics reported by gp_stat_progress_cluster.

Column	Type	Description
gp_segment_id	integer	Unique identifier of a segment (or coordinator) instance. (This column is not present in the gp_stat_progress_cluster_summary view.)
pid	integer	Process identifier of the backend, or the coordinator process identifier if the gp_stat_progress_cluster_summary view.
datid	oid	The object identifier of the database to which this backend is connected.
datname	name	Name of the database to which this backend is connected.
relid	oid	The object identifier of the table being clustered.
command	text	The name of the command that is running. Either CLUSTER or VACUUM FULL.
phase	text	Current processing phase. Refer to CLUSTER and VACUUM FULL Progress Reporting for detailed information about the phases.
cluster_index_relid	oid	If the table is being scanned using an index, this is the object identifier of the index being used; otherwise, it is zero. This field is not applicable to AO/CO tables.
heap_tuples_scanned	bigint	For heap tables, heap_tuples_scanned records the number of tuples scanned, including both live and dead tuples. For AO tables, heap_tuples_scanned records the number of live tuples scanned, excluding the dead tuples. This counter only advances when the phase is seq scanning append-optimized, seq scanning heap, index scanning heap, or writing new heap. For AO/CO tables, WarehousePG converts byte size into equivalent heap blocks in size.
heap_tuples_written	bigint	Number of tuples written. This counter only advances when the phase is seq scanning heap, index scanning heap, writing new append-optimized, or writing new heap.
heap_blks_total	bigint	Total number of heap blocks in the table. This number is reported as of the beginning of seq scanning heap. For AO/CO tables, WarehousePG converts byte size into equivalent heap blocks in size.
heap_blks_scanned	bigint	Number of heap blocks scanned. This counter only advances when the phase is seq scanning heap. For AO/CO tables, WarehousePG converts byte size into equivalent heap blocks in size.
index_rebuild_count	bigint	Number of indexes rebuilt. This counter only advances when the phase is rebuilding index, and is not applicable to AO/CO tables.

gp_stat_progress_copy

The gp_stat_progress_copy view is a cluster-wide view that displays the pg_stat_progress_copy information from every primary segment for all currently-running COPY operations.

The gp_stat_progress_copy_summary view aggregates across the WarehousePG cluster the metrics reported by gp_stat_progress_copy.

Column	Type	Description
gp_segment_id	integer	Unique identifier of a segment (or coordinator) instance. (This column is not present in the gp_stat_progress_copy_summary view.)
pid	integer	Process identifier of the backend, or the coordinator process identifier if the gp_stat_progress_copy_summary view.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Column	Type	Description
`datid`	oid	The object identifier of the database to which this backend is connected.
`datname`	name	Name of the database to which this backend is connected.
`relid`	oid	The object identifier of the table on which the `COPY` command is executed. It is set to `0` if copying from a `SELECT` query.
`command`	text	The command that is running: `COPY FROM`, `COPY TO`, `COPY FROM ON SEGMENT`, or `COPY TO ON SEGMENT`.
`type`	text	The io type that the data is read from or written to: `FILE`, `PROGRAM`, `PIPE` (for `COPY FROM STDIN` and `COPY TO STDOUT`), or `CALLBACK` (used for example during the initial table synchronization in logical replication).
`bytes_processed`	bigint	Number of bytes already processed by `COPY` command.
`bytes_total`	bigint	Size of source file for `COPY FROM` command in bytes. It is set to `0` if not available.
`tuples_processed`	bigint	Number of tuples already processed by `COPY` command.
`tuples_excluded`	bigint	Number of tuples not processed because they were excluded by the `WHERE` clause of the `COPY` command.

gp_stat_progress_create_index

The `gp_stat_progress_create_index` view is a cluster-wide view that displays the pg_stat_progress_create_index information from every primary segment for all currently-running `CREATE INDEX` and `REINDEX` operations.

The `gp_stat_progress_create_index_summary` view aggregates across the WarehousePG cluster the metrics reported by `gp_stat_progress_create_index`.

Column	Type	Description
`gp_segment_id`	integer	Unique identifier of a segment (or coordinator) instance. (This column is not present in the `gp_stat_progress_create_index_summary` view.)
`pid`	integer	Process identifier of the backend, or the coordinator process identifier if the `gp_stat_progress_create_index_summary` view.
`datid`	oid	The object identifer of the database to which this backend is connected.
`datname`	name	Name of the database to which this backend is connected.
`relid`	oid	The object identifer of the table on which the index is being created.
`index_relid`	oid	The object identifer of the index being created or reindexed. Because WarehousePG does not support concurrent (re)indexing, this value is always `0`.
`command`	text	The name of the command that is running: `CREATE INDEX` or `REINDEX`.
`phase`	text	Current processing phase of index creation. Refer to CREATE INDEX Progress Reporting for detailed information about the phases.
`lockers_total`	bigint	Total number of lockers to wait for, when applicable.
`lockers_done`	bigint	Number of lockers already waited for.
`current_locker_pid`	bigint	The process identifier of the locker currently being waited for.
`blocks_total`	bigint	Total number of blocks to be processed in the current phase.
`blocks_done`	bigint	Number of blocks already processed in the current phase.
`tuples_total`	bigint	Total number of tuples to be processed in the current phase.
`tuples_done`	bigint	Number of tuples already processed in the current phase.
`partitions_total`	bigint	When creating an index on a partitioned table, this column is set to the total number of partitions on which the index is to be created. This field is 0 during a `REINDEX`.
`partitions_done`	bigint	When creating an index on a partitioned table, this column is set to the number of partitions on which the index has been completed. This field is 0 during a `REINDEX`.

gp_stat_progress_dtx_recovery

The `gp_stat_progress_dtx_recovery` view is a cluster-wide view that displays the progress of the Distributed Transaction (DTX) Recovery process, which runs in the backgroup during Postgres startup.

This view may be useful if a coordinator restart remains in a recovery state for a long time. WarehousePG will not accept connections until all "in-doubt" transactions are resolved. In-doubt transactions are transactions that have been prepared but not committed yet. If there were many transactions running before the coordinator restarted, the recovery of the database may take longer than expected, and you may use this view to monitor the current phase of the recovery. Note that in this scenario, as WarehousePG is still starting up, you will need to access the database in utility mode to check this view.

Column	Type	Description
`phase`	text	Status of the recovery. The possible values are: 'initializing', 'recovering commited distributed transactions', 'gathering in-doubt transactions', 'aborting in-doubt transactions', 'gathering in-doubt orphaned transactions', and 'managing in-doubt orphaned transactions'.
`recover_commited_dtx_total`	integer	Total number of committed transactions found to recover.
`recover_commited_dtx_completed`	integer	Number of committed transactions that have been recovered.
in_doubt_tx_total`	integer	Total number of in-doubt transaction found, used in startup and non-startup phases.
`in_doubt_tx_in_progress`	integer	Number of in-progress, in-doubt transactions.
`in_doubt_tx_aborted`	integer	Number of aborted in-doubt transactions.

gp_stat_progress_vacuum

The `gp_stat_progress_vacuum` view is a cluster-wide view that displays the pg_stat_progress_vacuum information from every primary segment for all currently-running `VACUUM` and `vacuumdb` operations.

The `gp_stat_progress_vacuum_summary` view aggregates across the WarehousePG cluster the metrics reported by `gp_stat_progress_vacuum`.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Column	Type	Description
`gp_segment_id`	integer	Unique identifier of a segment (or coordinator) instance. (This column is not present in the `gp_stat_progress_vacuum_summary` view.)
`pid`	integer	Process identifier of the backend, or the coordinator process identifier if the `gp_stat_progress_vacuum_summary` view.
`datid`	oid	The object identifier of the database to which this backend is connected.
`datname`	name	Name of the database to which this backend is connected.
`relid`	oid	The object identifier of the table being vacuumed.
`phase`	text	Current processing phase of vacuum. Refer to VACUUM Progress Reporting for detailed information about the phases.
`heap_blks_total`	bigint	*Heap tables*: Total number of heap blocks in the table. This number is reported as of the beginning of the scan; blocks added later will not be (and need not be) visited by this `VACUUM`. *AO/CO tables*[1]: Collected at the beginning of the `append-optimized pre-cleanup` phase by adding up the on-disk file sizes of all segment files of the relation, and converting the size into the number of heap-equivalent blocks. The value should not change while `VACUUM` progresses.
`heap_blks_scanned`	bigint	*Heap tables*: Number of heap blocks scanned. Because the visibility map is used to optimize scans, some blocks will be skipped without inspection; skipped blocks are included in this total, so that this number will eventually become equal to `heap_blks_total` when the vacuum is complete. This counter only advances when the phase is `scanning heap`. *AO/CO tables*:[1] The counter only advances when the phase is `append-optimized compact`. For `ao_row` tables, updated every time WarehousePG finishes scanning a segment file. For `ao_column` tables, updated every time WarehousePG moves a tuple. `heap_blks_scanned` can be less than or equal to `heap_blks_total` at the end of the `VACUUM` operation because WarehousePG does not need to scan blocks after the logical EOF of a segment file.
`heap_blks_vacuumed`	bigint	*Heap tables*: Number of heap blocks vacuumed. Unless the table has no indexes, this counter only advances when the phase is `vacuuming heap`. Blocks that contain no dead tuples are skipped, so the counter may sometimes skip forward in large increments. *AO/CO tables*[1]: The counter advances when WarehousePG truncates a segment file, which may happen during both `append-optimized pre-cleanup` and `append-optimized post-cleanup` phases. Because WarehousePG truncates physical blocks after the logical EOF in a segment file, `heap_blks_vacuumed` may be either smaller or larger than `heap_blks_scanned`.
`index_vacuum_count`	bigint	*Heap tables*: Number of completed index vacuum cycles. *AO/CO tables*: Collected when WarehousePG recycles a dead segment file, which may happen both, any, or neither, during `append-optimized pre-cleanup` phase and `append-optimized post-cleanup phase`.
`max_dead_tuples`	bigint	*Heap tables*: Number of dead tuples that we can store before needing to perform an index vacuum cycle, based on maintenance_work_mem. *AO/CO tables*: Collected at the beginning of the `append-optimized pre-cleanup` phase, this is the total number of tuples before the logical EOF of all segment files. The value should not change while `VACUUM` progresses.
`num_dead_tuples`	bigint	*Heap tables*: Number of dead tuples collected since the last index vacuum cycle. *AO/CO tables*: Collected during `append-optimized compact` phase. For `ao_row` tables, updated every time WarehousePG discares a dead tuple. For `ao_column` tables, updated every time WarehousePG moves a live tuple, and also when the number of dead tuples advances.

[1] In WarehousePG, an AO/CO table vacuum behaves differently than a heap table vacuum. Because WarehousePG stores the logical EOF for each segment file, it does not need to scan physical blocks after the logical EOF, and WarehousePG can truncate them. Because of this, for AO/CO tables, `heap_blks_vacuumed` could be either smaller or larger than `heap_blks_scanned`. Neither `heap_blks_vacuumed` nor `heap_blks_scanned` can be larger than `heap_blks_total`. Similarly, `heap_blks_scanned` can be less than or equal to `heap_blks_total` at the end of `VACUUM` for AO/CO tables - there is no need to scan blocks after the logical EOF of a segment file.

gp_stat_replication

The `gp_stat_replication` view contains replication statistics of the `walsender` process that is used for WarehousePG Write-Ahead Logging (WAL) replication when coordinator or segment mirroring is enabled.

column	type	references	description
`gp_segment_id`	integer		Unique identifier of a segment (or coordinator) instance.
`pid`	integer		Process ID of the `walsender` backend process.
`usesysid`	oid		User system ID that runs the `walsender` backend process.
`usename`	name		User name that runs the `walsender` backend process.
`application_name`	text		Client application name.
`client_addr`	inet		Client IP address.
`client_hostname`	text		Client host name.
`client_port`	integer		Client port number.
`backend_start`	timestamp		Operation start timestamp.
`backend_xmin`	xid		The current backend's `xmin` horizon.

`state`	text		`walsender` state. The value can be:
			`startup`
			`backup`
			`catchup`
			`streaming`

`sent_location`	text		`walsender` xlog record sent location.
`write_location`	text		`walreceiver` xlog record write location.
`flush_location`	text		`walreceiver` xlog record flush location.
`replay_location`	text		Coordinator standby or segment mirror xlog record replay location.
`sync_priority`	integer		Priority. The value is `1`.
`sync_state`	text		`walsender` synchronization state. The value is `sync`.
`sync_error`	text		`walsender` synchronization error. `none` if no error.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

gp_stat_resqueues

The `gp_stat_resqueues` view is a cluster-wide view that displays the `pg_stat_resqueues` information from every primary segment.

column	type	references	description
`gp_segment_id`	integer		Unique identifier of a segment (or coordinator) instance.
`queueid`	oid		The OID of the resource queue.
`queuename`	name		The name of the resource queue.
`n_queries_exec`	bigint		Number of queries submitted for execution from this resource queue.
`n_queries_wait`	bigint		Number of queries submitted to this resource queue that had to wait before they could run.
`elapsed_exec`	bigint		Total elapsed execution time for statements submitted through this resource queue.
`elapsed_wait`	bigint		Total elapsed time that statements submitted through this resource queue had to wait before they were run.

gp_stat_slru

The `gp_stat_slru` view is a cluster-wide view that displays the `pg_stat_slru` information from every primary segment.

column	type	references	description
`gp_segment_id`	integer		Unique identifier of a segment (or coordinator) instance.
`name`	text		Name of the SLRU.
`blks_zeroed`	bigint		Number of blocks zeroed during initializations.
`blks_hit`	bigint		Number of times disk blocks were found already in the SLRU, so that a read was not necessary (this only includes hits in the SLR, not the operating system's file system cache).
`blks_read`	bigint		Number of disk blocks read for this SLRU.
`blks_written`	biging		Number of disk blocks written for this SLRU.
`blks_exists`	biging		Number of blocks checked for existence for this SLRU.
`flushes`	bigint		Number of flushes of dirty data for this SLRU.
`truncates`	bigint		Number of truncates for this SLRU.
`stats_reset`	timestamp with time zone		Time at which these statistics were last reset.

This system view is summarized in the `gp_stat_slru_summary` system view.

gp_stat_ssl

The `gp_stat_ssl` view is a cluster-wide view that displays the `pg_stat_ssl` information from every primary segment.

column	type	references	description
`gp_segment_id`	integer		Unique identifier of a segment (or coordinator) instance.
`pid`	integer		Process ID of a backend or WAL sender process.
`ssl`	boolean		True if SSL is used on this connection
`version`	text		Version of SSL in use, or `NULL` if SSL is not in use on this connection.
`cipher`	text		Name of SSL cipher in use, or `NULL` if SSL is not in use on this connection.
`bits`	integer		Number of bits in the encryption algorithm used, or `NULL` if SSL is not used on this connection.
`client_dn`	text		Distinguished Name (DN) field from the client certificate used, or `NUL` L if no client certificate was supplied or if SSL is not in use on this connection. This field is truncated if the DN field is longer than `NAMEDATALEN` (64 characters in a standard build).
`client_serial`	numeric		Serial number of the client certificate, or `NULL` if no client certificate was supplied or if SSL is not in use on this connection. The combination of certificate serial number and certificate issuer uniquely identifies a certificate (unless the issuer erroneously reuses serial numbers).
`issuer_dn`	text		DN of the issuer of the client certificate, or `NULL` if no client certificate was supplied or if SSL is not in use on this connection. This field is truncated like `client_dn` is.

gp_stat_subscription

The `gp_stat_subscription` view is a cluster-wide view that displays the `pg_stat_subscription` information from every primary segment.

column	type	references	description
`gp_segment_id`	integer		Unique identifier of a segment (or coordinator) instance.
`subid`	oid		OID of the subscription.
`subname`	name		Name of the subscription.
`pid`	integer		Process ID of the subscription worker process.
`relid`	oid		OID of the relation that the worker is synchronizing; `NULL` for the main apply worker.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

column	type	references	description
`received_lsn`	pg_lsn		Last write-ahead log location received, the initial value of this field being `0`.
`last_msg_send_time`	timestamp with time zone		Send time of last message received from origin WAL sender.
`last_msg_receipt_time`	timestamp with time zone		Receipt time of last message received from origin WAL sender.
`latest_end_lsn`	pg_lsn		Last write-ahead log location reported to origin WAL sender.
`latest_end_time`	timestamp with time zone		Time of last write-ahead log location reported to origin WAL sender.

gp_stat_sys_indexes

The `gp_stat_sys_indexes` view is a cluster-wide view that displays the `pg_stat_sys_indexes` information from every primary segment. It shows the same information as `gp_stat_all_indexes` but filtered to show system indexes only.

This system view is summarized in the `gp_stat_sys_indexes_summary` system view.

gp_stat_sys_tables

The `gp_stat_sys_tables` view is a cluster-wide view that displays the `pg_stat_sys_tables` information from every primary segment. It shows the same information as `gp_stat_all_tables` but filtered to show system tables only.

gp_stat_user_functions

The `gp_stat_user_functions` view is a cluster-wide view that displays the `pg_stat_user_functions` information from every primary segment.

column	type	references	description
`gp_segment_id`	integer		Unique identifier of a segment (or coordinator) instance.
`funcid`	oid		OID of a function.
`schemaname`	name		Name of the schema this function is in.
`funcname`	name		Name of this function.
`calls`	bigint		Number of times this function has been called.
`total_time`	double precision		Total time spent in this function and all other functions called by it, in milliseconds.
`self_time`	double precision		Total time spent in this function itself, not including other functions called by it, in milliseconds.

This system view is summarized in the `gp_stat_user_functions_summary` system view.

gp_stat_user_indexes

The `gp_stat_user_indexes` view is a cluster-wide view that displays the `pg_stat_user_indexes` information from every primary segment. It shows the same information as `gp_stat_all_indexes` but filtered to show indexes on user tables only.

This system view is summarized in the `gp_stat_user_functions_summary` system view.

gp_stat_user_tables

The `gp_stat_user_tables` view is a cluster-wide view that displays the `pg_stat_user_tables` information from every primary segment. It shows the same information as `gp_stat_all_tables` but filtered to show only user tables.

gp_stat_wal

The `gp_stat_wal` view is a cluster-wide view that displays the `pg_stat_wal` information from every primary segment.

column	type	references	description
`gp_segment_id`	integer		Unique identifier of a segment (or coordinator) instance.
`wal_records`	bigint		Total number of WAL records generated.
`wal_fpw`	bigint		Total number of WAL full page images generated.
`wal_bytes`	numeric		Total amount of WAL generated in bytes.
`wal_buffers_full`	bigint		Number of times WAL data was written to disk because WAL buffers became full.
`wal_write`	bigint		Number of times WAL buffers were written out to disk.
`wal_sync`	bigint		Number of times WAL files were synced to disk.
`wal_write_time`	double precision		Total amount of time spent writing WAL buffers to disk, in milliseconds (if track_wal_io_timing is enabled, otherwise zero).
`wal_sync_time`	double precision		Total amount of time spent syncing WAL files to disk, in milliseconds (if `track_wal_io_timing` is enabled, otherwise zero).
`stats_reset`	timestamp with time zone		Time at which these statistics were last reset.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

This system view is summarized in the `gp_stat_wal_summary` system view.

gp_stat_wal_receiver

The `gp_stat_wal_receiver` view is a cluster-wide view that displays the `pg_stat_wal_receiver` information from every primary segment.

column	type	references	description
`gp_segment_id`	integer		Unique identifier of a segment (or coordinator) instance.
`pid`	integer		Process ID of the WAL receiver process.
`status`	text		Activity status of the WAL receiver process.
`receive_start_lsn`	pg_lsn		First write-ahead log location used when WAL receiver is started.
`receive_start_tli`	integer.		First timeline number used when WAL receiver is started.
`written_lsn`	pg_lsn.		Last write-ahead log location already received and written to disk, but not flushed. This should not be used for data integrity checks.
`flushed_lsn`	pg_lsn		Last write-ahead log location already received and flushed to disk, the initial value of this field being the first log location used when WAL receiver is started.
`received_tli`	integer		Timeline number of last write-ahead log location received and flushed to disk, the initial value of this field being the timeline number of the first log location used when WAL receiver is started.
`last_msg_send_time`	timestamp with time zone		Send time of last message received from origin WAL sender.
`last_msg_receipt_time`	timestamp with time zone		Receipt time of last message received from origin WAL sender.
`latest_end_lsn`	pg_lsn		Last write-ahead log location reported to origin WAL sender.
`latest_end_time`	timestamp with time zone		Time of last write-ahead log location reported to origin WAL sender.
`slot_name`	text		Replication slot name used by this WAL receiver.
`sender_host`	text		Host of the PostgreSQL instance this WAL receiver is connected to. This can be a host name, an IP address, or a directory path if the connection is via Unix socket. (The path case can be distinguished because it will always be an absolute path, beginning with `/.`).
`sender_port`	integer		Port number of the PostgreSQL instance this WAL receiver is connected to.
`conninfo`	text		Connection string used by this WAL receiver, with security-sensitive fields obfuscated.

gp_stat_xact_all_tables

The `gp_stat_xact_all_tables` view is a cluster-wide view that displays the `pg_stat_xact_all_tables` information from every primary segment. It shows the same information as `gp_stat_all_tables` but counts actions taken so far within the current transaction (which are not yet included in `gp_stat_all_tables` and related views). The columns for numbers of live and dead rows and vacuum and analyze actions are not present in this view.

This system view is summarized in the `gp_stat_xact_all_tables_summary` system view.

gp_stat_xact_sys_tables

The `gp_stat_xact_sys_tables` view is a cluster-wide view that displays the `pg_stat_xact_sys_tables` information from every primary segment. It shows the same information as `gp_stat_xact_all_tables` but filtered to show system tables only.

This system view is summarized in the `gp_stat_xact_sys_tables_summary` system view.

gp_stat_xact_user_functions

The `gp_stat_xact_user_functions` view is a cluster-wide view that displays the `pg_stat_xact_user_functions` information from every primary segment. It shows the same information as `gp_stat_xact_user_functions` but counts only calls during the current transaction (which are not yet included in `gp_stat_user_functions`).

This system view is summarized in the `gp_stat_xact_user_functions_summary` system view.

gp_stat_xact_user_tables

The `gp_stat_xact_user_tables` view is a cluster-wide view that displays the `pg_stat_xact_user_tables` information from every primary segment. It shows the same information as `gp_stat_xact_all_tables` but filtered to show user tables only.

This system view is summarized in the `gp_stat_xact_user_tables_summary` system view.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

gp_statio_all_indexes

The `gp_statio_all_indexes` view is a cluster-wide view that displays the `pg_statio_all_indexes` information from every primary segment.

column	type	references	description
`gp_segment_id`	integer		Unique identifier of a segment (or coordinator) instance.
`relid`	oid		OID of the table for this index.
`indexrelid`	oid		OID of this index.
`schemaname`	name		Name of the schema containing this index.
`relname`	name		Name of the table for this index.
`indexrelname`	name		Name of this index.
`idx_blks_read`	bigint		Number of disk blocks read from this index.
`idx_blks_hit`	bigint		Number of buffer hits in this index.

This system view is summarized in the `gp_statio_all_indexes_summary` system view.

gp_statio_all_sequences

The `gp_statio_all_sequences` view is a cluster-wide view that displays the `pg_statio_all_sequences` information from every primary segment.

column	type	references	description
`gp_segment_id`	integer		Unique identifier of a segment (or coordinator) instance.
`relid`	oid		OID of a sequence.
`schemaname`	name		Name of the schema this sequence is in.
`relname`	name		Name of this sequence.
`blks_read`	bigint		Number of disk blocks read from this sequence.
`blks_hit`	bigint		Number of buffer hits in this sequence.

This system view is summarized in the `gp_statio_all_sequences_summary` system view.

gp_statio_all_tables

The `gp_statio_all_tables` view is a cluster-wide view that displays the `pg_statio_all_tables` information from every primary segment.

column	type	references	description
`gp_segment_id`	integer		Unique identifier of a segment (or coordinator)
reli	oid	OID of a table.	
`schemaname`	name		Name of the schema containing this table.
`relname`	name		Name of this table.
`heap_blks_read`	bigint		Number of disk blocks read from this table.
`heap_blks_hit`	bigint		Number of buffer hits in this table.
`idx_blks_read`	bigint		Number of disk blocks read from all indexes on this table.
`idx_blks_hit`	bigint		Number of buffer hits in all indexes on this table.
`toast_blks_read`	bigint.		Number of disk blocks read from this table's TOAST table (if any).
`toast_blks_hit`	bigint		Number of buffer hits in this table's TOAST table (if any).
`tidx_blks_read`	bigint		Number of disk blocks read from this table's TOAST table indexes (if any).
`tidx_blks_hit`	bigint		Number of buffer hits in this table's TOAST table indexes (if any).

This system view is summarized in the `gp_statio_all_tables_summary` system view.

gp_statio_sys_indexes

The `gp_statio_sys_indexes` view is a cluster-wide view that displays the `pg_statio_sys_indexes` information from every primary segment. It shows the same information as `gp_statio_all_indexes` but filtered to show indexes on system tables only.

This system view is summarized in the `gp_statio_sys_indexes_summary` system view.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

gp_statio_sys_sequences

The `gp_statio_sys_sequences` view is a cluster-wide view that displays the `pg_statio_sys_sequences` information from every primary segment. It shows the same information as `gp_statio_all_sequences` but filtered to system sequences only.

This system view is summarized in the `gp_statio_sys_indexes_summary` system view.

gp_statio_sys_tables

The `gp_statio_sys_tables` view is a cluster-wide view that displays the `pg_statio_sys_tables` information from every primary segment. It shows the same information as `gp_statio_all_tables` but filtered to show system tables only.

This system view is summarized in the `gp_statio_sys_tables_summary` system view.

gp_statio_user_indexes

The `gp_statio_user_indexes` view is a cluster-wide view that displays the `pg_statio_user_indexes` information from every primary segment. It shows the same information as `gp_statio_all_indexes` but filtered to show indexes on user tables only.

This system view is summarized in the `gp_statio_sys_user_indexes_summary` system view.

gp_statio_user_sequences

The `gp_statio_user_sequences` view is a cluster-wide view that displays the `pg_statio_user_sequences` information from every primary segment. It shows the same information as `gp_statio_all_sequences` but filtered to show user sequences only.

This system view is summarized in the `gp_statio_sys_user_sequences_summary` system view.

gp_statio_user_tables

The `gp_statio_user_tables` view is a cluster-wide view that displays the `pg_statio_user_tables` information from every primary segment. It shows the same information as `gp_statio_all_tables` but filtered to show user tables only.

This system view is summarized in the `gp_statio_sys_user_tables_summary` system view.

gp_stats

The `gp_stats` view is a cluster-wide view that displays the `pg_stats` information from every primary segment.

column	type	references	description
`gp_segment_id`	integer		Unique identifier of a segment (or coordinator)
`schemaname`	name	pg_namespace.nspname	The name of the schema containing table.
`tablename`	name	pg_class.relname	The name of the table.
`attname`	name	pg_attribute.attname	The name of the column described by this row.
`inherited`	bool		If true, this row includes inheritance child columns, not just the values in the specified table.
`null_frac`	real		The fraction of column entries that are null.
`avg_width`	integer		The average width in bytes of column's entries.
`n_distinct`	real		If greater than zero, the estimated number of distinct values in the column. If less than zero, the negative of the number of distinct values divided by the number of rows. (The negated form is used when ANALYZE believes that the number of distinct values is likely to increase as the table grows; the positive form is used when the column seems to have a fixed number of possible values.) For example, `-1` indicates a unique column in which the number of distinct values is the same as the number of rows.
`most_common_vals`	anyarray		A list of the most common values in the column. (Null if no values seem to be more common than any others.)
`most_common_freqs`	real[]		A list of the frequencies of the most common values, i.e., number of occurrences of each divided by total number of rows. (Null when `most_common_vals` is.)
`histogram_bounds`	anyarray		A list of values that divide the column's values into groups of approximately equal population. The values in `most_common_vals`, if present, are omitted from this histogram calculation. (This column is null if the column data type does not have a `<` operator or if the `most_common_vals` list accounts for the entire population.)
`correlation`	real		Statistical correlation between physical row ordering and logical ordering of the column values. This ranges from -1 to +1. When the value is near -1 or +1, an index scan on the column will be estimated to be cheaper than when it is near zero, due to reduction of random access to the disk. (This column is null if the column data type does not have a `<` operator.)
`most_common_elems`	anyarray		A list of non-null element values most often appearing within values of the column. (Null for scalar types.)

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

column	type	references	description
most_common_elem_freqs	real[]		A list of the frequencies of the most common element values, i.e., the fraction of rows containing at least one instance of the given value. Two or three additional values follow the per-element frequencies; these are the minimum and maximum of the preceding per-element frequencies, and optionally the frequency of null elements. (Null when most_common_elems is.)
element_count_histogram	real[]		A histogram of the counts of distinct non-null element values within the values of the column, followed by the average number of distinct non-null elements. (Null for scalar types.)

The maximum number of entries in the array fields can be controlled on a column-by-column basis using the `ALTER TABLE SET STATISTICS` command, or globally by setting the default_statistics_target run-time configuration parameter.

gp_stats_ext

The `gp_stats_ext` view is a cluster-wide view that displays the `pg_stats_ext` information from every primary segment.

column	type	references	description
gp_segment_id	integer		Unique identifier of a segment (or coordinator)
schemaname	name	pg_namespace.nspname	The name of the schema containing table.
tablename	name	pg_class.relname	The name of the table.
statistics_schemaname	name	pg_namespace.nspname	The name of the schema containing the extended statistic.
statistics_name	name	pg_statistic_ext.stxname	The name of the extended statistic.
statistics_owner	oid	pg_authid.oid	The owner of the extended statistic.
attnames	name[]	pg_attribute.attname	The names of the columns on which the extended statistics is defined.
kinds	text[]		The types of extended statistics enabled for this record.
n_distinct	pg_ndistinct		N-distinct counts for combinations of column values. If greater than zero, the estimated number of distinct values in the combination. If less than zero, the negative of the number of distinct values divided by the number of rows. (The negated form is used when `ANALYZE` believes that the number of distinct values is likely to increase as the table grows; the positive form is used when the column seems to have a fixed number of possible values.) For example, `-1` indicates a unique combination of columns in which the number of distinct combinations is the same as the number of rows.
dependencies	pg_dependencies		Functional dependency statistics.
most_common_vals	anyarray		A list of the most common values in the column. (Null if no combinations seem to be more common than any others.)
most_common_vals_null	anyarray		A list of NULL flags for the most combinations of values. (Null when `most_common_vals` is.)
most_common_freqs	real[]		A list of the frequencies of the most common combinations, i.e., number of occurrences of each divided by total number of rows. (Null when `most_common_vals` is.)
most_common_base_freqs	real[]		A list of the base frequencies of the most common combinations, i.e., product of per-value frequencies. (Null when `most_common_vals` is.)

The maximum number of entries in the array fields can be controlled on a column-by-column basis using the `ALTER TABLE SET STATISTICS` command, or globally by setting the default_statistics_target run-time configuration parameter.

pg_backend_memory_contexts

The `pg_backend_memory_contexts` system view displays all of the memory contexts in use by the server process attached to the current session.

`pg_backend_memory_contexts` contains one row for each memory context.

column	type	description
name	text	The name of the memory context.
ident	text	Identification information of the memory context. This field is truncated at 1024 bytes.
parent	text	The name of the parent of this memory context.
level	int4	The distance from `TopMemoryContext` in context tree.
total_bytes	int8	The total number of bytes allocated for this memory context.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

column	type	description
`total_nblocks`	int8	The total number of blocks allocated for this memory context.
`free_bytes`	int8	Free space in bytes.
`free_chunks`	int8	The total number of free chunks.
`used_bytes`	int8	Used space in bytes.

pg_cursors

The `pg_cursors` view lists the currently available cursors. Cursors can be defined in one of the following ways:

- via the DECLARE SQL statement
- via the Bind message in the frontend/backend protocol
- via the Server Programming Interface (SPI)

> **Note** WarehousePG does not support the definition, or access of, parallel retrieve cursors via SPI.

Cursors exist only for the duration of the transaction that defines them, unless they have been declared `WITH HOLD`. Non-holdable cursors are only present in the view until the end of their creating transaction.

> **Note** WarehousePG does not support holdable parallel retrieve cursors.

name	type	references	description
`name`	text		The name of the cursor.
`statement`	text		The verbatim query string submitted to declare this cursor.
`is_holdable`	boolean		`true` if the cursor is holdable (that is, it can be accessed after the transaction that declared the cursor has committed); `false` otherwise. > **Note** WarehousePG does not support holdable parallel retrieve cursors, this value is always `false` for such cursors.
`is_binary`	boolean		`true` if the cursor was declared `BINARY`; `false` otherwise.
`is_scrollable`	boolean		`true` if the cursor is scrollable (that is, it allows rows to be retrieved in a nonsequential manner); `false` otherwise. > **Note** WarehousePG does not support scrollable cursors, this value is always `false`.
`creation_time`	timestamptz		The time at which the cursor was declared.
`is_parallel`	boolean		`true` if the cursor was declared `PARALLEL RETRIEVE`; `false` otherwise.

pg_exttable

The `pg_exttable` system catalog view is used to track external tables and web tables created by the `CREATE EXTERNAL TABLE` command.

column	type	references	description
`reloid`	oid	pg_class.oid	The OID of this external table.
`urilocation`	text[]		The URI location(s) of the external table files.
`execlocation`	text[]		The ON segment locations defined for the external table.
`fmttype`	char		Format of the external table files: `t` for text, `c` for csv, or `b` for custom.
`fmtopts`	text		Formatting options of the external table files, such as the field delimiter, null string, escape character, etc.
`options`	text[]		The options defined for the external table.
`command`	text		The OS command to run when the external table is accessed.
`rejectlimit`	integer		The per segment reject limit for rows with errors, after which the load will fail.
`rejectlimittype`	char		Type of reject limit threshold: `r` for number of rows, or `p` for percent.
`logerrors`	bool		`1` to log errors, `0` to not.
`encoding`	text		The client encoding.
`writable`	boolean		`false` for readable external tables, `true` for writable external tables.

pg_matviews

The view `pg_matviews` provides access to information about each materialized view in the database.

column	type	references	description
`schemaname`	name	pg_namespace.nspname	Name of the schema containing the materialized view
`matviewname`	name	pg_class.relname	Name of the materialized view
`matviewowner`	name	pg_authid.rolname	Name of the materialized view's owner
`tablespace`	name	pg_tablespace.spcname	Name of the tablespace containing the materialized view (NULL if default for the database)
`hasindexes`	boolean		True if the materialized view has (or recently had) any indexes
`ispopulated`	boolean		True if the materialized view is currently populated
`definition`	text		Materialized view definition (a reconstructed `SELECT` command)

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

pg_max_external_files

The `pg_max_external_files` view shows the maximum number of external table files allowed per segment host when using the external table `file` protocol.

column	type	references	description
`hostname`	name		The host name used to access a particular segment instance on a segment host.
`maxfiles`	bigint		Number of primary segment instances on the host.

pg_policies

The `pg_policies` view provides access to information about each row-level security policy in the database.

Column Name	Type	References	Description
`schemaname`	name	pg_namespace.nspname	The name of schema that contas the table the policy is on
`tablename`	name	pg_class.relname	The name of the table the policy is on
`policyname`	name	pg_policy.polname	The name of policy
`polpermissive`	text		Is the policy permissive or restrictive?
`roles`	name[]		The roles to which this policy applies
`cmd`	text		The command type to which the policy is applied
`qual`	text		The expression added to the security barrier qualifications for queries to which this policy applies
`with_check`	text		The expression added to the `WITH CHECK` qualifications for queries that attempt to add rows to this table

> **Note** Policies stored in `pg_policy` are applied only when `pg_class.relrowsecurity` is set for their table.

pg_resqueue_attributes

> **Note** The `pg_resqueue_attributes` view is valid only when resource queue-based resource management is active.

The `pg_resqueue_attributes` view allows administrators to see the attributes set for a resource queue, such as its active statement limit, query cost limits, and priority.

column	type	references	description
`rsqname`	name	pg_resqueue.rsqname	The name of the resource queue.
`resname`	text		The name of the resource queue attribute.
`resetting`	text		The current value of a resource queue attribute.
`restypid`	integer		System assigned resource type id.

pg_stat_activity

The `pg_stat_activity` view shows one row per server process with details about the associated user session and query. The columns that report data on the current query are available unless the parameter `stats_command_string` has been turned off. Furthermore, these columns are only visible if the user examining the view is a superuser or the same as the user owning the process being reported on.

The maximum length of the query text string stored in the column `query` can be controlled with the server configuration parameter `track_activity_query_size`.

column	type	references	description
`datid`	oid	pg_database.oid	Database OID
`datname`	name		Database name
`pid`	integer		Process ID of this backend
`sess_id`	integer		Session ID
`usesysid`	oid	pg_authid.oid	OID of the user logged into this backend
`usename`	name		Name of the user logged into this backend
`application_name`	text		Name of the application that is connected to this backend
`client_addr`	inet		IP address of the client connected to this backend. If this field is null, it indicates either that the client is connected via a Unix socket on the server machine or that this is an internal process such as autovacuum.
`client_hostname`	text		Host name of the connected client, as reported by a reverse DNS lookup of `client_addr`. This field will only be non-null for IP connections, and only when log_hostname is enabled.
`client_port`	integer		TCP port number that the client is using for communication with this backend, or -1 if a Unix socket is used
`backend_start`	timestamptz		Time backend process was started
`xact_start`	timestamptz		Transaction start time
`query_start`	timestamptz		Time query began execution
`state_change`	timestampz		Time when the `state` was last changed
`wait_event_type`	text		Type of event for which the backend is waiting

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

column	type	references	description
wait_event	text		Wait event name if backend is currently waiting
state	text		Current overall state of this backend. Possible values are: - active : The backend is running a query. - idle : The backend is waiting for a new client command. - idle in transaction : The backend is in a transaction, but is not currently running a query. - idle in transaction (aborted) : This state is similar to idle in transaction, except one of the statements in the transaction caused an error. - fastpath function call : The backend is running a fast-path function. - disabled : This state is reported if track_activities is deactivated in this backend.
backend_xid	xid		The top-level transaction identifier of this backend, if any.
backend_xmin	xid		The current backend's xmin horizon.
query	text		Text of this backend's most recent query. If state is active this field shows the currently running query. In all other states, it shows the last query that was run.
backend_type	text		The type of the current backend.
rsgid	oid	pg_resgroup.oid	Resource group OID or 0 . See Note.
rsgname	text	pg_resgroup.rsgname	Resource group name or unknown . See Note.

> **Note** When resource groups are enabled. Only query dispatcher (QD) processes will have a rsgid and rsgname . Other server processes such as a query executer (QE) process or session connection processes will have a rsgid value of 0 and a rsgname value of unknown . QE processes are managed by the same resource group as the dispatching QD process.

pg_stat_all_indexes

The pg_stat_all_indexes view shows one row for each index in the current database that displays statistics about accesses to that specific index.

The pg_stat_user_indexes and pg_stat_sys_indexes views contain the same information, but filtered to only show user and system indexes respectively.

Column	Type	Description
relid	oid	OID of the table for this index
indexrelid	oid	OID of this index
schemaname	name	Name of the schema this index is in
relname	name	Name of the table for this index
indexrelname	name	Name of this index
idx_scan	bigint	Total number of index scans initiated on this index from all segment instances
idx_tup_read	bigint	Number of index entries returned by scans on this index
idx_tup_fetch	bigint	Number of live table rows fetched by simple index scans using this index

pg_stat_all_tables

The pg_stat_all_tables view shows one row for each table in the current database (including TOAST tables) to display statistics about accesses to that specific table.

The pg_stat_user_tables and pg_stat_sys_table views contain the same information, but filtered to only show user and system tables respectively.

Column	Type	Description
relid	oid	OID of a table
schemaname	name	Name of the schema that this table is in
relname	name	Name of this table
seq_scan	bigint	Total number of sequential scans initiated on this table from all segment instances
seq_tup_read	bigint	Number of live rows fetched by sequential scans
idx_scan	bigint	Total number of index scans initiated on this table from all segment instances
idx_tup_fetch	bigint	Number of live rows fetched by index scans
n_tup_ins	bigint	Number of rows inserted
n_tup_upd	bigint	Number of rows updated (includes HOT updated rows)
n_tup_del	bigint	Number of rows deleted
n_tup_hot_upd	bigint	Number of rows HOT updated (i.e., with no separate index update required)
n_live_tup	bigint	Estimated number of live rows
n_dead_tup	bigint	Estimated number of dead rows
n_mod_since_analyze	bigint	Estimated number of rows modified since this table was last analyzed
last_vacuum	timestamp with time zone	Last time this table was manually vacuumed (not counting VACUUM FULL)
last_autovacuum	timestamp with time zone	Last time this table was vacuumed by the autovacuum daemon
last_analyze	timestamp with time zone	Last time this table was manually analyzed

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Column	Type	Description
last_autoanalyze	timestamp with time zone	Last time this table was analyzed by the autovacuum daemon
vacuum_count	bigint	Number of times this table has been manually vacuumed (not counting VACUUM FULL)
autovacuum_count	bigint	Number of times this table has been vacuumed by the autovacuum daemon
analyze_count	bigint	Number of times this table has been manually analyzed
autoanalyze_count	bigint	Number of times this table has been analyzed by the autovacuum daemon

pg_stat_operations

The view pg_stat_operations shows details about the last operation performed on a database object (such as a table, index, view or database) or a global object (such as a role).

column	type	references	description
classname	text		The name of the system table in the pg_catalog schema where the record about this object is stored (pg_class =relations, pg_database =databases, pg_namespace =schemas, pg_authid =roles)
objname	name		The name of the object.
objid	oid		The OID of the object.
schemaname	name		The name of the schema where the object resides.
usestatus	text		The status of the role who performed the last operation on the object (CURRENT =a currently active role in the system, DROPPED =a role that no longer exists in the system, CHANGED =a role name that exists in the system, but has changed since the last operation was performed).
usename	name		The name of the role that performed the operation on this object.
actionname	name		The action that was taken on the object.
subtype	text		The type of object operated on or the subclass of operation performed.
statime	timestamptz		The timestamp of the operation. This is the same timestamp that is written to the WarehousePG server log files in case you need to look up more detailed information about the operation in the logs.

pg_stat_replication

The pg_stat_replication view contains metadata of the walsender process that is used for WarehousePG coordinator mirroring.

column	type	references	description
pid	integer		Process ID of WAL sender backend process.
usesysid	integer		User system ID that runs the WAL sender backend process
usename	name		User name that runs WAL sender backend process.
application_name	oid		Client application name.
client_addr	name		Client IP address.
client_hostname	text		The host name of the client machine.
client_port	integer		Client port number.
backend_start	timestamp		Operation start timestamp.
backend_xmin	xid		The current backend's xmin horizon.
state	text		WAL sender state. The value can be: startup backup catchup streaming
sent_location	text		WAL sender xlog record sent location.
write_location	text		WAL receiver xlog record write location.
flush_location	text		WAL receiver xlog record flush location.
replay_location	text		Standby xlog record replay location.
sync_priority	text		Priority. the value is 1.
sync_state	text		WAL sender synchronization state. The value is sync.

pg_stat_resqueues

> **Note** The pg_stat_resqueues view is valid only when resource queue-based resource management is active.

The pg_stat_resqueues view allows administrators to view metrics about a resource queue's workload over time. To allow statistics to be collected for this view, you must enable the stats_queue_level server configuration parameter on the WarehousePG coordinator instance. Enabling the collection of these metrics does incur a small performance penalty, as each statement submitted through a resource queue must be logged in the system catalog tables.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

column	type	references	description
queueid	oid		The OID of the resource queue.
queuename	name		The name of the resource queue.
n_queries_exec	bigint		Number of queries submitted for execution from this resource queue.
n_queries_wait	bigint		Number of queries submitted to this resource queue that had to wait before they could run.
elapsed_exec	bigint		Total elapsed execution time for statements submitted through this resource queue.
elapsed_wait	bigint		Total elapsed time that statements submitted through this resource queue had to wait before they were run.

pg_stat_slru

WarehousePG accesses certain on-disk information via SLRU (simple least-recently-used) caches. The pg_stat_slru view contains one row for each tracked SLRU cache, showing statistics about access to cached pages.

column	type	references	description
name	text		Name of the SLRU.
blks_zeroed	bigint		Number of blocks zeroed during initializations.
blks_hit	bigint		Number of times disk blocks were found already in the SLRU, so that a read was not necessary (this only includes hits in the SLR, not the operating system's file system cache).
blks_read	bigint		Number of disk blocks read for this SLRU.
blks_written	biging		Number of disk blocks written for this SLRU.
blks_exists	biging		Number of blocks checked for existence for this SLRU.
flushes	bigint		Number of flushes of dirty data for this SLRU.
truncates	bigint		Number of truncates for this SLRU.
stats_reset	timestamp with time zone		Time at which these statistics were last reset.

pg_stat_wal

The pg_stat_wal view shows data about the WAL activity of the cluster. It contains always a single row.

column	type	references	description
wal_records	bigint		Total number of WAL records generated.
wal_fpw	bigint		Total number of WAL full page images generated.
wal_bytes	numeric		Total amount of WAL generated in bytes.
wal_buffers_full	bigint		Number of times WAL data was written to disk because WAL buffers became full.
wal_write	bigint		Number of times WAL buffers were written out to disk.
wal_sync	bigint		Number of times WAL files were synced to disk.
wal_write_time	double precision		Total amount of time spent writing WAL buffers to disk, in milliseconds (if track_wal_io_timing is enabled, otherwise zero).
wal_sync_time	double precision		Total amount of time spent syncing WAL files to disk, in milliseconds (if track_wal_io_timing is enabled, otherwise zero).
stats_reset	timestamp with time zone		Time at which these statistics were last reset.

pg_stats

The pg_stats view provides access to the information stored in the pg_statistic catalog. This view allows access only to rows of pg_statistic that correspond to tables the user has permission to read, and therefore it is safe to allow public read access to this view.

pg_stats is also designed to present the information in a more readable format than the underlying catalog — at the cost that its schema must be extended whenever new slot types are defined fo pg_statistic .

column	type	references	description
schemaname	name	pg_namespace.nspname	The name of the schema containing table.
tablename	name	pg_class.relname	The name of the table.
attname	name	pg_attribute.attname	The name of the column described by this row.
inherited	bool		If true, this row includes inheritance child columns, not just the values in the specified table.
null_frac	real		The fraction of column entries that are null.
avg_width	integer		The average width in bytes of column's entries.
n_distinct	real		If greater than zero, the estimated number of distinct values in the column. If less than zero, the negative of the number of distinct values divided by the number of rows. (The negated form is used when ANALYZE believes that the number of distinct values is likely to increase as the table grows; the positive form is used when the column seems to have a fixed number of possible values.) For example, -1 indicates a unique column in which the number of distinct values is the same as the number of rows.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

column	type	references	description
most_common_vals	anyarray		A list of the most common values in the column. (Null if no values seem to be more common than any others.)
most_common_freqs	real[]		A list of the frequencies of the most common values, i.e., number of occurrences of each divided by total number of rows. (Null when most_common_vals is.)
histogram_bounds	anyarray		A list of values that divide the column's values into groups of approximately equal population. The values in most_common_vals, if present, are omitted from this histogram calculation. (This column is null if the column data type does not have a < operator or if the most_common_vals list accounts for the entire population.)
correlation	real		Statistical correlation between physical row ordering and logical ordering of the column values. This ranges from -1 to +1. When the value is near -1 or +1, an index scan on the column will be estimated to be cheaper than when it is near zero, due to reduction of random access to the disk. (This column is null if the column data type does not have a < operator.)
most_common_elems	anyarray		A list of non-null element values most often appearing within values of the column. (Null for scalar types.)
most_common_elem_freqs	real[]		A list of the frequencies of the most common element values, i.e., the fraction of rows containing at least one instance of the given value. Two or three additional values follow the per-element frequencies; these are the minimum and maximum of the preceding per-element frequencies, and optionally the frequency of null elements. (Null when most_common_elems is.)
element_count_histogram	real[]		A histogram of the counts of distinct non-null element values within the values of the column, followed by the average number of distinct non-null elements. (Null for scalar types.)

The maximum number of entries in the array fields can be controlled on a column-by-column basis using the ALTER TABLE SET STATISTICS command, or globally by setting the default_statistics_target run-time configuration parameter.

pg_stats_ext

The pg_stats view provides access to the information stored in the pg_statistic_ext and pg_statistic_ext_data catalog tables. This view allows access only to rows of pg_statistic_ext and pg_statistic_ext_data that correspond to tables the user has permission to read, and therefore it is safe to allow public read access to this view.

pg_stats_ext is also designed to present the information in a more readable format than the underlying catalogs — at the cost that its schema must be extended whenever new types of extended statistics are added to pg_statistic_ext.

column	type	references	description
schemaname	name	pg_namespace.nspname	The name of the schema containing table.
tablename	name	pg_class.relname	The name of the table.
statistics_schemaname	name	pg_namespace.nspname	The name of the schema containing the extended statistic.
statistics_name	name	pg_statistic_ext.stxname	The name of the extended statistic.
statistics_owner	oid	pg_authid.oid	The owner of the extended statistic.
attnames	name[]	pg_attribute.attname	The names of the columns on which the extended statistics is defined.
kinds	text[]		The types of extended statistics enabled for this record.
n_distinct	pg_ndistinct		N-distinct counts for combinations of column values. If greater than zero, the estimated number of distinct values in the combination. If less than zero, the negative of the number of distinct values divided by the number of rows. (The negated form is used when ANALYZE believes that the number of distinct values is likely to increase as the table grows; the positive form is used when the column seems to have a fixed number of possible values.) For example, -1 indicates a unique combination of columns in which the number of distinct combinations is the same as the number of rows.
dependencies	pg_dependencies		Functional dependency statistics.
most_common_vals	anyarray		A list of the most common values in the column. (Null if no combinations seem to be more common than any others.)
most_common_vals_null	anyarray		A list of NULL flags for the most combinations of values. (Null when most_common_vals is.)
most_common_freqs	real[]		A list of the frequencies of the most common combinations, i.e., number of occurrences of each divided by total number of rows. (Null when most_common_vals is.)
most_common_base_freqs	real[]		A list of the base frequencies of the most common combinations, i.e., product of per-value frequencies. (Null when most_common_vals is.)

The maximum number of entries in the array fields can be controlled on a column-by-column basis using the ALTER TABLE SET STATISTICS command, or globally by setting the default_statistics_target run-time configuration parameter.

Summary Views

WarehousePG includes a number of summary views -- all related to collected statistics -- which aggregate across the WarehousePG cluster the metrics reported by their corresponding `gp_` view. For example, `gp_stat_archiver_summary` aggregates the metrics reported by `gp_stat_archiver`. These metrics are reported as sum, average, or last, depending on the column. For more information, see thesummary view code in Github.

The following is a list of summary views:

- gp_stat_all_indexes_summary
- gp_stat_all_tables_summary
- gp_stat_archiver_summary
- gp_stat_bgwriter_summary
- gp_stat_database_summary
- gp_stat_slru_summary
- gp_stat_progress_analyze_summary
- gp_stat_progress_basebackup_summary
- gp_stat_progress_cluster_summary

7.8.3.1 foreign_data_wrapper_options

The `foreign_data_wrapper_options` view contains all of the otpions defined for foreign-data wrappers in the current database. WarehousePG displays only those foreign-data wrappers to which the current user has access (by way of being the owner or having some privilege).

column	type	references	description
`foreign_data_wrapper_catalog`	sql_identifier		Name of the database in which the foreign-data wrapper is defined (always the current database).
`foreign_data_wrapper_name`	sql_identifier		Name of the foreign-data wrapper.
`option_name`	sql_identifier		Name of an option.
`option_value`	character_data		Value of the option.

Parent topic: System Catalogs Definitions

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.8.3.2 foreign_data_wrappers

The `foreign_data_wrappers` view contains all foreign-data wrappers defined in the current database. WarehousePG displays only those foreign-data wrappers to which the current user has access (by way of being the owner or having some privilege).

column	type	references	description
`foreign_data_wrapper_catalog`	sql_identifier		Name of the database in which the foreign-data wrapper is defined (always the current database).
`foreign_data_wrapper_name`	sql_identifier		Name of the foreign-data wrapper.
`authorization_identifier`	sql_identifier		Name of the owner of the foreign server.
`library_name`	character_data		File name of the library that implements this foreign-data wrapper.
`foreign_data_wrapper_language`	character_data		Language used to implement the foreign-data wrapper.

Parent topic: System Catalogs Definitions

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.8.3.3 foreign_server_options

The `foreign_server_options` view contains all of the options defined for foreign servers in the current database. WarehousePG displays only those foreign servers to which the current user has access (by way of being the owner or having some privilege).

column	type	references	description
`foreign_server_catalog`	sql_identifier		Name of the database in which the foreign server is defined (always the current database).
`foreign_server_name`	sql_identifier		Name of the foreign server.
`option_name`	sql_identifier		Name of an option.
`option_value`	character_data		Value of the option.

Parent topic: System Catalogs Definitions

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.8.3.4 foreign_servers

The `foreign_servers` view contains all foreign servers defined in the current database. WarehousePG displays only those foreign servers to which the current user has access (by way of being the owner or having some privilege).

column	type	references	description
`foreign_server_catalog`	sql_identifier		Name of the database in which the foreign server is defined (always the current database).
`foreign_server_name`	sql_identifier		Name of the foreign server.
`foreign_data_wrapper_catalog`	sql_identifier		Name of the database in which the foreign-data wrapper used by the foreign server is defined (always the current database).
`foreign_data_wrapper_name`	sql_identifier		Name of the foreign-data wrapper used by the foreign server.
`foreign_server_type`	character_data		Foreign server type information, if specified upon creation.
`foreign_server_version`	character_data		Foreign server version information, if specified upon creation.
`authorization_identifier`	sql_identifier		Name of the owner of the foreign server.

Parent topic: System Catalogs Definitions

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.8.3.5 foreign_table_options

The `foreign_table_options` view contains all of the options defined for foreign tables in the current database. WarehousePG displays only those foreign tables to which the current user has access (by way of being the owner or having some privilege).

column	type	references	description
`foreign_table_catalog`	sql_identifier		Name of the database in which the foreign table is defined (always the current database).
`foreign_table_schema`	sql_identifier		Name of the schema that contains the foreign table.
`foreign_table_name`	sql_identifier		Name of the foreign table.
`option_name`	sql_identifier		Name of an option.
`option_value`	character_data		Value of the option.

Parent topic: System Catalogs Definitions

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.8.3.6 foreign_tables

The `foreign_tables` view contains all foreign tables defined in the current database. WarehousePG displays only those foreign tables to which the current user has access (by way of being the owner or having some privilege).

column	type	references	description
`foreign_table_catalog`	sql_identifier		Name of the database in which the foreign table is defined (always the current database).
`foreign_table_schema`	sql_identifier		Name of the schema that contains the foreign table.
`foreign_table_name`	sql_identifier		Name of the foreign table.
`foreign_server_catalog`	sql_identifier		Name of the database in which the foreign server is defined (always the current database).
`foreign_server_name`	sql_identifier		Name of the foreign server.

Parent topic: System Catalogs Definitions

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.8.3.7 gp_configuration_history

The `gp_configuration_history` table contains information about system changes related to fault detection and recovery operations. The `fts_probe` process logs data to this table, as do certain related management utilities such as `gprecoverseg` and `gpinitsystem`. For example, when you add a new segment and mirror segment to the system, records for these events are logged to `gp_configuration_history`.

The event descriptions stored in this table may be helpful for troubleshooting serious system issues in collaboration with support technicians.

This table is populated only on the coordinator. This table is defined in the `pg_global` tablespace, meaning it is globally shared across all databases in the system.

column	type	references	description
`time`	timestamp with time zone		Timestamp for the event recorded.
`dbid`	smallint	gp_segment_configuration.dbid	System-assigned ID. The unique identifier of a segment (or coordinator) instance.
`description`	text		Text description of the event.

For information about `gprecoverseg` and `gpinitsystem`, see the WarehousePG Utility Guide.

Parent topic: System Catalogs Definitions

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.8.3.8 gp_distribution_policy

The `gp_distribution_policy` table contains information about WarehousePG tables and their policy for distributing table data across the segments. This table is populated only on the coordinator. This table is not globally shared, meaning each database has its own copy of this table.

column	type	references	description
`localoid`	oid	pg_class.oid	The table object identifier (OID).
`policytype`	char		The table distribution policy: `p` - Partitioned policy. Table data is distributed among segment instances. `r` - Replicated policy. Table data is replicated on each segment instance.
`numsegments`	integer		The number of segment instances on which the table data is distributed.
`distkey`	int2vector	pg_attribute.attnum	The column number(s) of the distribution column(s).
`distclass`	oidvector	pg_opclass.oid	The operator class identifier(s) of the distribution column(s).

Parent topic: System Catalogs Definitions

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.8.3.9 gpexpand.status

The `gpexpand.status` table contains information about the status of a system expansion operation. Status for specific tables involved in the expansion is stored in gpexpand.status_detail.

In a normal expansion operation it is not necessary to modify the data stored in this table.

column	type	references	description

`status`	text		Tracks the status of an expansion operation. Valid values are:
			`SETUP`
			`SETUP DONE`
			`EXPANSION STARTED`
			`EXPANSION STOPPED`
			`COMPLETED`

`updated`	timestamp without time zone		Timestamp of the last change in status.

Parent topic: System Catalogs Definitions

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.8.3.10 gpexpand.status_detail

The `gpexpand.status_detail` table contains information about the status of tables involved in a system expansion operation. You can query this table to determine the status of tables being expanded, or to view the start and end time for completed tables.

This table also stores related information about the table such as the oid and disk size. Overall status information for the expansion is stored in gpexpand.status.

In a normal expansion operation it is not necessary to modify the data stored in this table.

column	type	references	description
`table_oid`	oid		OID of the table.
`dbname`	text		Name of the database to which the table belongs.
`fq_name`	text		Fully qualified name of the table.
`root_partition_oid`	oid		For a partitioned table, the OID of the root partition. Otherwise, `None`.
`rank`	int		Rank determines the order in which tables are expanded. The expansion utility will sort on rank and expand the lowest-ranking tables first.
`external_writable`	boolean		Identifies whether or not the table is an external writable table. (External writable tables require a different syntax to expand).
`status`	text		Status of expansion for this table. Valid values are: NOT STARTED IN PROGRESS COMPLETED NO LONGER EXISTS
`expansion_started`	timestamp without time zone		Timestamp for the start of the expansion of this table. This field is only populated after a table is successfully expanded.
`expansion_finished`	timestamp without time zone		Timestamp for the completion of expansion of this table.
`source_bytes`			The size of disk space associated with the source table. Due to table bloat in heap tables and differing numbers of segments after expansion, it is not expected that the final number of bytes will equal the source number. This information is tracked to help provide progress measurement to aid in duration estimation for the end-to-end expansion operation.

Parent topic: System Catalogs Definitions

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.8.3.11 gp_fastsequence

The `gp_fastsequence` table contains information about append-optimized and column-oriented tables. The `last_sequence` value indicates maximum row number currently used by the table.

column	type	references	description
`objid`	oid	pg_class.oid	Object id of the `pg_aoseg.pg_aocsseg_*` table used to track append-optimized file segments.
`objmod`	bigint		Object modifier.
`last_sequence`	bigint		The last sequence number used by the object.

Parent topic: System Catalogs Definitions

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.8.3.12 gp_id

The `gp_id` system catalog table identifies the WarehousePG cluster name and number of segments for the system. It also has `local` values for the particular database instance (segment or coordinator) on which the table resides. This table is defined in the `pg_global` tablespace, meaning it is globally shared across all databases in the system.

column	type	references	description
`gpname`	name		The name of this WarehousePG cluster.
`numsegments`	smallint		The number of segments in the WarehousePG cluster.
`dbid`	smallint		The unique identifier of this segment (or coordinator) instance.
`content`	smallint		The ID for the portion of data on this segment instance. A primary and its mirror will have the same content ID. For a segment the value is from 0-*N-1*, where *N* is the number of segments in WarehousePG. For the coordinator, the value is -1.

Parent topic: System Catalogs Definitions

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.8.3.13 gp_partition_template

The `gp_partition_template` system catalog table describes the relationship between a partitioned table and the sub-partition template defined at each level in the partition hierarchy.

> **Note** WarehousePG Data supports sub-partition templates only for partitioned tables that you create with the classic syntax.

Each sub-partition template has a dependency on the existence of a template at the next lower level of the hierarchy.

column	type	references	description
`relid`	oid	pg_class.oid	The object identifier of the root partitioned table.
`level`	smallint		The level of the partition in the hierarchy. The levels are numbered as follows: level `0` is the root partitioned table itself, level `1` represents the direct child/children of the root partitioned table, and so forth. The leaf partitions have the highest level number.
`template`	pg_node_tree		Expression representation of the sub-partition template defined for each partition at this level of the hierarchy.

Parent topic: System Catalogs Definitions

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.8.3.14 gp_segment_configuration

The `gp_segment_configuration` table contains information about mirroring and segment instance configuration.

column	type	references	description
`dbid`	smallint		Unique identifier of a segment (or coordinator) instance.
`content`	smallint		The content identifier for a segment instance. A primary segment instance and its corresponding mirror will always have the same content identifier. For a segment the value is from 0 to *N*-1, where *N* is the number of primary segments in the system. For the coordinator, the value is always -1.
`role`	char		The role that a segment is currently running as. Values are `p` (primary) or `m` (mirror).
`preferred_role`	char		The role that a segment was originally assigned at initialization time. Values are `p` (primary) or `m` (mirror).
`mode`	char		The synchronization status of a segment instance with its mirror copy. Values are `s` (Synchronized) or `n` (Not In Sync). > **Note** This column always shows `n` for the coordinator segment and `s` for the standby coordinator segment, but these values do not describe the synchronization state for the coordinator segment. Use gp_stat_replication to determine the synchronization state between the coordinator and standby coordinator.
`status`	char		The fault status of a segment instance. Values are `u` (up) or `d` (down).
`port`	integer		The TCP port the database server listener process is using.
`hostname`	text		The hostname of a segment host.
`address`	text		The hostname used to access a particular segment instance on a segment host. This value may be the same as `hostname` on systems that do not have per-interface hostnames configured.
`datadir`	text		Segment instance data directory.

Parent topic: System Catalogs Definitions

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.8.3.15 gp_version_at_initdb

The `gp_version_at_initdb` table is populated on the coordinator and each segment in the WarehousePG cluster. It identifies the version of WarehousePG used when the system was first initialized. This table is defined in the `pg_global` tablespace, meaning it is globally shared across all databases in the system.

column	type	references	description
`schemaversion`	smallint		Schema version number.
`productversion`	text		Product version number.

Parent topic: System Catalogs Definitions

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.8.3.16 pg_aggregate

The `pg_aggregate` table stores information about aggregate functions. An aggregate function is a function that operates on a set of values (typically one column from each row that matches a query condition) and returns a single value computed from all these values. Typical aggregate functions are `sum`, `count`, and `max`. Each entry in `pg_aggregate` is an extension of an entry in `pg_proc`. The `pg_proc` entry carries the aggregate's name, input and output data types, and other information that is similar to ordinary functions.

column	type	references	description
`aggfnoid`	regproc	pg_proc.oid	OID of the aggregate function
`aggkind`	char		Aggregate kind: `n` for *normal* aggregates, `o` for *ordered-set* aggregates, or `h` for *hypothetical-set* aggregates
`aggnumdirectargs`	smallint		Number of direct (non-aggregated) arguments of an ordered-set or hypothetical-set aggregate, counting a variadic array as one argument. If equal to `pronargs`, the aggregate must be variadic and the variadic array describes the aggregated arguments as well as the final direct arguments. Always zero for normal aggregates.
`aggtransfn`	regproc	pg_proc.oid	Transition function OID
`aggfinalfn`	regproc	pg_proc.oid	Final function OID (zero if none)
`aggcombinefn`	regproc	pg_proc.oid	Combine function OID (zero if none)
`aggserialfn`	regproc	pg_proc.oid	OID of the serialization function to convert transtype to `bytea` (zero if none)
`aggdeserialfn`	regproc	pg_proc.oid	OID of the deserialization function to convert `bytea` to transtype (zero if none)
`aggmtransfn`	regproc	pg_proc.oid	Forward transition function OID for moving-aggregate mode (zero if none)
`aggminvtransfn`	regproc	pg_proc.oid	Inverse transition function OID for moving-aggregate mode (zero if none)
`aggmfinalfn`	regproc	pg_proc.oid	Final function OID for moving-aggregate mode (zero if none)
`aggfinalextra`	bool		True to pass extra dummy arguments to `aggfinalfn`
`aggmfinalextra`	bool		True to pass extra dummy arguments to `aggmfinalfn`
`aggfinalmodify`	char		Indicates whether `aggfinalfn` modifies the transition state
`aggmfinalmodify`	char		Indicates whether `aggmfinalfn` modifies the transition state
`aggsortop`	oid	pg_operator.oid	Associated sort operator OID (zero if none)
`aggtranstype`	oid	pg_type.oid	Data type of the aggregate function's internal transition (state) data
`aggtransspace`	integer		Approximate average size (in bytes) of the transition state data, or zero to use a default estimate
`aggmtranstype`	oid	pg_type.oid	Data type of the aggregate function's internal transition (state) data for moving-aggregate mode (zero if none)
`aggmtransspace`	integer		Approximate average size (in bytes) of the transition state data for moving-aggregate mode, or zero to use a default estimate
`agginitval`	text		The initial value of the transition state. This is a text field containing the initial value in its external string representation. If this field is NULL, the transition state value starts out NULL.
`aggminitval`	text		The initial value of the transition state for moving- aggregate mode. This is a text field containing the initial value in its external string representation. If this field is NULL, the transition state value starts out NULL.
`aggrepsafeexec`	bool		True to specify that the aggregate can be safely executed on replicated slices. An order-agnostic aggregate would be considered safe in this context.

Parent topic: System Catalogs Definitions

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.8.3.17 pg_am

The `pg_am` table stores information about index access methods. There is one row for each index access method supported by the system.

column	type	references	description
`oid`	oid		Row identifier (hidden attribute; must be explicitly selected)
`amname`	name		Name of the access method
`amhandler`	regproc		OID of a handler function responsible for supplying information about the access method
`amtype`	char		`t` for table (including materialized views), `i` for index

Parent topic: System Catalogs Definitions

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.8.3.18 pg_amop

The `pg_amop` table stores information about operators associated with index access method operator classes. There is one row for each operator that is a member of an operator class.

An entry's `amopmethod` must match the `opfmethod` of its containing operator family (including `amopmethod` here is an intentional denormalization of the catalog structure for performance reasons). Also, `amoplefttype` and `amoprighttype` must match the `oprleft` and `oprright` fields of the referenced `pg_operator` entry.

column	type	references	description
`oid`	oid		Row identifier (hidden attribute; must be explicitly selected)
`amopfamily`	oid	pg_opfamily.oid	The operator family that this entry is for
`amoplefttype`	oid	pg_type.oid	Left-hand input data type of operator
`amoprighttype`	oid	pg_type.oid	Right-hand input data type of operator
`amopstrategy`	smallint		Operator strategy number
`amoppurpose`	char		Operator purpose, either `s` for search or `o` for ordering
`amopopr`	oid	pg_operator.oid	OID of the operator
`amopmethod`	oid	pg_am.oid	Index access method for the operator family
`amopsortfamily`	oid	pg_opfamily.oid	If an ordering operator, the B-tree operator family that this entry sorts according to; zero if a search operator

Parent topic: System Catalogs Definitions

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.8.3.19 pg_amproc

The `pg_amproc` table stores information about support procedures associated with index access method operator classes. There is one row for each support procedure belonging to an operator class.

column	type	references	description
`oid`	oid		Row identifier (hidden attribute; must be explicitly selected)
`amprocfamily`	oid	pg_opfamily.oid	The operator family this entry is for
`amproclefttype`	oid	pg_type.oid	Left-hand input data type of associated operator
`amprocrighttype`	oid	pg_type.oid	Right-hand input data type of associated operator
`amprocnum`	smallint		Support procedure number
`amproc`	regproc	pg_proc.oid	OID of the procedure

Parent topic: System Catalogs Definitions

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.8.3.20 pg_appendonly

The `pg_appendonly` table contains information about the storage options and other characteristics of append-optimized tables.

column	type	references	description
`relid`	oid		The table object identifier (OID) of the table.
`segrelid`	oid		Table on-disk segment file id.
`blkdirrelid`	oid		Block used for on-disk column-oriented table file.
`visimaprelid`	oid		Visibility map for the table.
`version`	smallint		AO relation version.

Parent topic: System Catalogs Definitions

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.8.3.21 pg_attrdef

The `pg_attrdef` table stores column default values. The main information about columns is stored in pg_attribute. Only columns that explicitly specify a default value (when the table is created or the column is added) will have an entry here.

column	type	references	description
`oid`	oid		The object ID
`adrelid`	oid	pg_class.oid	The table this column belongs to
`adnum`	smallint	pg_attribute.attnum	The number of the column
`adbin`	pg_node_tree		The internal representation of the column default value

Parent topic: System Catalogs Definitions

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.8.3.22 pg_attribute

The `pg_attribute` table stores information about table columns. There will be exactly one `pg_attribute` row for every column in every table in the database. (There will also be attribute entries for indexes, and all objects that have `pg_class` entries.) The term attribute is equivalent to column.

In a dropped column's `pg_attribute` entry, `atttypid` is reset to zero, but `attlen` and the other fields copied from `pg_type` are still valid. This arrangement is needed to address the situation where the dropped column's data type was later dropped, and so there is no `pg_type` row anymore. `attlen` and the other fields can be used to interpret the contents of a row of the table

column	type	references	description
`attrelid`	oid	pg_class.oid	The table this column belongs to.
`attname`	name		The column name.
`atttypid`	oid	pg_type.oid	The data type of this column.
`attstattarget`	integer		Controls the level of detail of statistics accumulated for this column by ANALYZE. A zero value indicates that no statistics should be collected. A negative value says to use the system default statistics target. The exact meaning of positive values is data type-dependent. For scalar data types, it is both the target number of "most common values" to collect, and the target number of histogram bins to create.
`attlen`	smallint		A copy of `pg_type.typlen` of this column's type.
`attnum`	smallint		The number of the column. Ordinary columns are numbered from 1 up. System columns, such as `ctid`, have (arbitrary) negative numbers.
`attndims`	integer		Number of dimensions, if the column is an array type; otherwise `0`. (Presently, the number of dimensions of an array is not enforced, so any nonzero value effectively means it is an array.)
`attcacheoff`	integer		Always `-1` in storage, but when loaded into a row descriptor in memory this may be updated to cache the offset of the attribute within the row.
`atttypmod`	integer		Records type-specific data supplied at table creation time (for example, the maximum length of a `varchar` column). It is passed to type-specific input functions and length coercion functions. The value will generally be `-1` for types that do not need it.
`attbyval`	boolean		A copy of `pg_type.typbyval` of this column's type.
`attstorage`	char		Normally a copy of `pg_type.typstorage` of this column's type. For TOAST-able data types, this can be altered after column creation to control storage policy.
`attalign`	char		A copy of `pg_type.typalign` of this column's type.
`attnotnull`	boolean		This represents a not-null constraint.
`atthasdef`	boolean		This column has a default expression or generation expression, in which case there will be a corresponding entry in the `pg_attrdef` catalog that actually defines the value. (Check `attgenerated` to determine whether this is a default or a generation expression.)
`atthasmissing`	boolean		This column has a value which is used where the column is entirely missing from the row, as happens when a column is added with a non-volatile `DEFAULT` value after the row is created. The actual value used is stored in the `attmissingval` column.
`attidentity`	char		If a zero byte (''), then not an identity column. Otherwise, `a` = generated always, `d` = generated by default.
`attgenerated`	char		If a zero byte (''), then not a generated column. Otherwise, `s` = stored. (Other values might be added in the future.)
`attisdropped`	boolean		This column has been dropped and is no longer valid. A dropped column is still physically present in the table, but is ignored by the parser and so cannot be accessed via SQL.
`attislocal`	boolean		This column is defined locally in the relation. Note that a column may be locally defined and inherited simultaneously.
`attinhcount`	integer		The number of direct ancestors this column has. A column with a nonzero number of ancestors cannot be dropped nor renamed.
`attcollation`	oid	pg_collation.oid	The defined collation of the column, or zero if the is not of a collatable data type.
`attacl`	aclitem[]		Column-level access privileges, if any have been granted specifically on this column.
`attoptions`	text[]		Attribute-level options, as "keyword=value" strings.
`attfdwoptions`	text[]		Attribute-level foreign data wrapper options, as "keyword=value" strings.
`attmissingval`	anyarray		This column has a one element array containing the value used when the column is entirely missing from the row, as happens when the column is added with a non-volatile `DEFAULT` value after the row is created. The value is only used when `atthasmissing` is `true`. If there is no value the column is null.

Parent topic: System Catalogs Definitions

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.8.3.23 pg_attribute_encoding

The `pg_attribute_encoding` system catalog table contains column storage information.

column	type	modifers	storage	description
`attrelid`	oid	not null	plain	Foreign key to `pg_attribute.attrelid`
`attnum`	smallint	not null	plain	Foreign key to `pg_attribute.attnum`
`filenum`	smallint	not null	plain	Shorthand for the file range assigned to the column
`lastrownums`	bigint		extended	The last row number of each segfile when this attribute is added.
`attoptions`	text [ ]		extended	The options

For a column with `filenum = f`, the column files on disk use the suffix `(f - 1)*128 to f*128 - 1`. For example:

- Column with `filenum = 1` has files `relfilenode`, `relfilenode.1` .. `relfilenode.127`.
- Column with `filenum = 2` has files `relfilenode.128`, `relfilenode.129` .. `relfilenode.255`.
- Column with `filenum = 3` has files `relfilenode.256`, `relfilenode.257` .. `relfilenode.383`.

Parent topic: System Catalogs Definitions

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.8.3.24 pg_auth_members

The `pg_auth_members` system catalog table shows the membership relations between roles. Any non-circular set of relationships is allowed. Because roles are system-wide, `pg_auth_members` is shared across all databases of a WarehousePG cluster.

column	type	references	description
`roleid`	oid	pg_authid.oid	ID of the parent-level (group) role
`member`	oid	pg_authid.oid	ID of a member role
`grantor`	oid	pg_authid.oid	ID of the role that granted this membership
`admin_option`	boolean		True if role member may grant membership to others

Parent topic: System Catalogs Definitions

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.8.3.25 pg_authid

The `pg_authid` table contains information about database authorization identifiers (roles). A role subsumes the concepts of users and groups. A user is a role with the `rolcanlogin` flag set. Any role (with or without `rolcanlogin`) may have other roles as members. See pg_auth_members.

Since this catalog contains passwords, it must not be publicly readable. pg_roles is a publicly readable view on `pg_authid` that blanks out the password field.

Because user identities are system-wide, `pg_authid` is shared across all databases in a WarehousePG cluster: there is only one copy of `pg_authid` per system, not one per database.

column	type	references	description
`oid`	oid		Row identifier
`rolname`	name		Role name
`rolsuper`	boolean		Role has superuser privileges
`rolinherit`	boolean		Role automatically inherits privileges of roles it is a member of
`rolcreaterole`	boolean		Role may create more roles
`rolcreatedb`	boolean		Role may create databases
`rolcanlogin`	boolean		Role may log in. That is, this role can be given as the initial session authorization identifier
`rolreplication`	boolean		Role is a replication role. That is, this role can initiate streaming replication and set/unset the system backup mode using `pg_start_backup` and `pg_stop_backup`.
`rolbypassrls`	boolean		Roles bypasses every row-level security policy.
`rolconnlimit`	int4		For roles that can log in, this sets maximum number of concurrent connections this role can make. `-1` means no limit
`rolpassword`	text		Password (possibly encrypted); NULL if none. If the password is encrypted, this column will begin with the string `md5` followed by a 32-character hexadecimal MD5 hash. The MD5 hash will be the user's password concatenated to their user name. For example, if user `joe` has password `xyzzy`, WarehousePG will store the md5 hash of `xyzzyjoe`. WarehousePG assumes that a password that does not follow that format is unencrypted.
`rolvaliduntil`	timestamptz		Password expiry time (only used for password authentication); NULL if no expiration
`rolresqueue`	oid		Object ID of the associated resource queue ID in *pg_resqueue*
`rolcreaterextgpfd`	boolean		Privilege to create read external tables with the `gpfdist` or `gpfdists` protocol
`rolcreaterexhttp`	boolean		Privilege to create read external tables with the `http` protocol
`rolcreatewextgpfd`	boolean		Privilege to create write external tables with the `gpfdist` or `gpfdists` protocol
`rolresgroup`	oid		Object ID of the associated resource group ID in *pg_resgroup*

7.8.3.26 pg_available_extension_versions

The `pg_available_extension_versions` view lists the specific extension versions that are available for installation. The pg_extension system catalog table shows the extensions currently installed.

The view is read only.

column	type	description
`name`	name	Extension name.
`version`	text	Version name.
`installed`	boolean	`True` if this version of this extension is currently installed, `False` otherwise.
`superuser`	boolean	`True` if only superusers are allowed to install the extension, `False` otherwise.
`relocatable`	boolean	`True` if extension can be relocated to another schema, `False` otherwise.
`schema`	name	Name of the schema that the extension must be installed into, or `NULL` if partially or fully relocatable.
`requires`	name[]	Names of prerequisite extensions, or `NULL` if none
`comment`	text	Comment string from the extension control file.

Parent topic: System Catalogs Definitions

7.8.3.27 pg_available_extensions

The `pg_available_extensions` view lists the extensions that are available for installation. The *pg_extension* system catalog table shows the extensions currently installed.

The view is read only.

column	type	description
`name`	name	Extension name.
`default_version`	text	Name of default version, or `NULL` if none is specified.
`installed_version`	text	Currently installed version of the extension, or `NULL` if not installed.
`comment`	text	Comment string from the extension control file.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.8.3.28 pg_cast

The `pg_cast` table stores data type conversion paths, both built-in paths and those defined with `CREATE CAST`.

Note that `pg_cast` does not represent every type conversion known to the system, only those that cannot be deduced from some generic rule. For example, casting between a domain and its base type is not explicitly represented in `pg_cast`. Another important exception is that "automatic I/O conversion casts", those performed using a data type's own I/O functions to convert to or from `text` or other string types, are not explicitly represented in `pg_cast`.

The cast functions listed in `pg_cast` must always take the cast source type as their first argument type, and return the cast destination type as their result type. A cast function can have up to three arguments. The second argument, if present, must be type `integer`; it receives the type modifier associated with the destination type, or `-1` if there is none. The third argument, if present, must be type `boolean`; it receives `true` if the cast is an explicit cast, `false` otherwise.

It is legitimate to create a `pg_cast` entry in which the source and target types are the same, if the associated function takes more than one argument. Such entries represent 'length coercion functions' that coerce values of the type to be legal for a particular type modifier value.

When a `pg_cast` entry has different source and target types and a function that takes more than one argument, the entry converts from one type to another and applies a length coercion in a single step. When no such entry is available, coercion to a type that uses a type modifier involves two steps, one to convert between data types and a second to apply the modifier.

column	type	references	description
`oid`	oid		The object ID.
`castsource`	oid	pg_type.oid	OID of the source data type.
`casttarget`	oid	pg_type.oid	OID of the target data type.
`castfunc`	oid	pg_proc.oid	The OID of the function to use to perform this cast. Zero is stored if the cast method does not require a function.
`castcontext`	char		Indicates what contexts the cast may be invoked in. `e` means only as an explicit cast (using `CAST` or `::` syntax). `a` means implicitly in assignment to a target column, as well as explicitly. `i` means implicitly in expressions, as well as the other cases*.*
`castmethod`	char		Indicates how the cast is performed: `f` - The function identified in the `castfunc` field is used. `i` - The input/output functions are used. `b` - The types are binary-coercible, and no conversion is required.

Parent topic: System Catalogs Definitions

7.8.3.29 pg_class

The system catalog table `pg_class` catalogs tables and most everything else that has columns or is otherwise similar to a table. This includes indexes (see also pg_index), sequences, views, materialized views, composite types, and TOAST tables. Below, when we mean all of these kinds of objects we speak of "relations". Not all columns are meaningful for all relation types.

column	type	references	description
`oid`	oid		Row identifier
`relname`	name		Name of the table, index, view, etc.
`relnamespace`	oid	pg_namespace.oid	The object identifier of the namespace (schema) that contains this relation
`reltype`	oid	pg_type.oid	The object identifier of the data type that corresponds to this table's row type, if any (zero for indexes, which have no `pg_type` entry)
`reloftype`	oid	pg_type.oid	For typed tables, the object identifier of the underlying composite type, zero for all other relations
`relowner`	oid	pg_authid.oid	Owner of the relation
`relam`	oid	pg_am.oid	If this is a table or an index, the access method used (heap, B-tree, hash, etc.)
`relfilenode`	oid		Name of the on-disk file of this relation; zero means this is a "mapped" relation whose disk file name is determined by low-level state
`reltablespace`	oid	pg_tablespace.oid	The tablespace in which this relation is stored. If zero, the database's default tablespace is implied. (Not meaningful if the relation has no on-disk file.)
`relpages`	int4		Size of the on-disk representation of this table in pages (of size `BLCKSZ`). This is only an estimate used by the planner. It is updated by `VACUUM`, `ANALYZE`, and a few DDL commands such as `CREATE INDEX`.
`reltuples`	float4		Number of rows in the table. This is only an estimate used by the planner. It is updated by `VACUUM`, `ANALYZE`, and a few DDL commands such as `CREATE INDEX`.
`relallvisible`	int4		Number of pages that are marked all-visible in the table's visibility map. This is only an estimate used by the planner. It is updated by `VACUUM`, `ANALYZE`, and a few DDL commands such as `CREATE INDEX`.
`reltoastrelid`	oid	pg_class.oid	The object identifier of the TOAST table associated with this table, `0` if none. The TOAST table stores large attributes "out of line" in a secondary table.
`relhasindex`	boolean		True if this is a table and it has (or recently had) any indexes.
`relisshared`	boolean		True if this table is shared across all databases in the system. Only certain system catalog tables (such as `pg_database`) are shared.
`relpersistence`	char		The type of object persistence: `p` = heap or append-optimized permanent table, `u` = unlogged temporary table, `t` = temporary table.
`relkind`	char		The type of object `r` = heap or append-optimized ordinary table, `i` = index, `S` = sequence, `t` = TOAST table, `v` = view, `m` = materialized view, `c` = composite type, `f` = foreign table, `p` = partitioned table, `I` = partitioned index, `u` = uncatalogued temporary heap table, `o` = internal append-optimized segment files and EOFs, `b` = append-only block directory, `M` = append-only visibility map.
`relnatts`	int2		Number of user columns in the relation (system columns not counted). There must be this many corresponding entries in `pg_attribute`. See also `pg_attribute.attnum`.
`relchecks`	int2		Number of `CHECK` constraints on the table; see pg_constraint catalog.
`relhasrules`	boolean		True if table has (or once had) rules; see pg_rewrite catalog.
`relhastriggers`	boolean		True if table has (or once had) triggers.
`relhassubclass`	boolean		True if table has (or once had) any inheritance children.
`relrowsecurity`	boolean		True if table has row level security enabled; see `pg_policy` catalog.
`relforcerowsecurity`	boolean		True if row level security (when enabled) will also apply to the table owner; see `pg_policy` catalog.
`relispopulated`	boolean		True if relation is populated (this is true for all relations other than some materialized views).
`relreplident`	char		Columns used to form "replica identity" for rows: `d` = default (primary key, if any), `n` = nothing, `f` = all columns, `i` = index with `indisreplident` set (same as nothing if the index used has been dropped).
`relispartition`	boolean		True if table or index is a partition.
`relrewrite`	oid	pg_class.oid	For new relations being written during a DDL operation that requires a table rewrite, this contains the object identifier of the original relation; otherwise 0. That state is only visible internally; this field should never contain anything other than 0 for a user-visible relation.
`relfrozenxid`	xid		All transaction IDs before this one have been replaced with a permanent (frozen) transaction ID in this table. This is used to track whether the table needs to be vacuumed in order to prevent transaction ID wraparound or to allow `pg_xact` to be shrunk. The value is `0` (`InvalidTransactionId`) if the relation is not a table or if the table does not require vacuuming to prevent transaction ID wraparound. The table still might require vacuuming to reclaim disk space.
`relminmxid`	xid		All multixact IDs before this one have been replaced by a transaction ID in this table. This is used to track whether the table needs to be vacuumed in order to prevent multixact ID wraparound or to allow `pg_multixact` to be shrunk. Zero (`InvalidMultiXactId`) if the relation is not a table.
`relacl`	aclitem[]		Access privileges assigned by `GRANT` and `REVOKE`.
`reloptions`	text[]		Access-method-specific options, as "keyword=value" strings.
`relpartbound`	pg_node_tree		If table is a partition (see `relispartition`), internal representation of the partition bound.

Several of the Boolean flags in `pg_class` are maintained lazily: they are guaranteed to be true if that's the correct state, but may not be reset to false immediately when the condition is no longer true. For example, `relhasindex`

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

is set by `CREATE INDEX`, but it is never cleared by `DROP INDEX`. Instead, `VACUUM` clears `relhasindex` if it finds the table has no indexes. This arrangement avoids race conditions and improves concurrency.

7.8.3.30 pg_compression

The `pg_compression` system catalog table describes the compression methods available.

column	type	modifers	storage	description
`compname`	name	not null	plain	Name of the compression
`compconstructor`	regproc	not null	plain	Name of compression constructor
`compdestructor`	regproc	not null	plain	Name of compression destructor
`compcompressor`	regproc	not null	plain	Name of the compressor
`compdecompressor`	regproc	not null	plain	Name of the decompressor
`compvalidator`	regproc	not null	plain	Name of the compression validator
`compowner`	oid	not null	plain	oid from pg_authid

Parent topic: System Catalogs Definitions

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.8.3.31 pg_constraint

The `pg_constraint` system catalog table stores check, primary key, unique, foreign key, and exclusion constraints on tables. (Column constraints are not treated specially. Every column constraint is equivalent to some table constraint.) Not-null constraints are represented in the pg_attribute catalog table. Check constraints on domains are stored here, too.

column	type	references	description
`oid`	oid		Row identifier
`conname`	name		Constraint name (not necessarily unique!)
`connamespace`	oid	pg_namespace.oid	The object identifier of the namespace (schema) that contains this constraint.
`contype`	char		`c` = check constraint, `f` = foreign key constraint, `p` = primary key constraint, `u` = unique constraint, `x` = exclusion constraint.
`condeferrable`	boolean		Is the constraint deferrable?
`condeferred`	boolean		Is the constraint deferred by default?
`convalidated`	boolean		Has the constraint been validated? Currently, can only be false for foreign keys and `CHECK` constraints.
`conrelid`	oid	pg_class.oid	The table this constraint is on; 0 if not a table constraint.
`contypid`	oid	pg_type.oid	The domain this constraint is on; 0 if not a domain constraint.
`conindid`	oid	pg_class.oid	The index supporting this constraint, if it's a unique, primary key, foreign key, or exclusion constraint; else 0
`conparentid`	oid	pg_constraint.oid	The corresponding constraint in the parent partitioned table, if this is a constraint in a partition; else 0
`confrelid`	oid	pg_class.oid	If a foreign key, the referenced table; else 0.
`confupdtype`	char		Foreign key update action code.
`confdeltype`	char		Foreign key deletion action code.
`confmatchtype`	char		Foreign key match type.
`conislocal`	boolean		This constraint is defined locally for the relation. Note that a constraint can be locally defined and inherited simultaneously.
`coninhcount`	integer		The number of direct inheritance ancestors this constraint has. A constraint with a nonzero number of ancestors cannot be dropped nor renamed.
`connoinherit`	boolean		This constraint is defined locally for the relation. It is a non-inheritable constraint.
`conkey`	smallint[]	pg_attribute.attnum	If a table constraint, list of columns which the constraint constrains.
`confkey`	smallint[]	pg_attribute.attnum	If a foreign key, list of the referenced columns.
`conpfeqop`	oid[]	pg_operator.oid	If a foreign key, list of the equality operators for PK = FK comparisons.
`conppeqop`	oid[]	pg_operator.oid	If a foreign key, list of the equality operators for PK = PK comparisons.
`conffeqop`	oid[]	pg_operator.oid	If a foreign key, list of the equality operators for FK = FK comparisons.
`conexclop`	oid[]	pg_operator.oid	If an exclusion constraint, list of the per-column exclusion operators.
`conbin`	pg_node_tree		If a check constraint, an internal representation of the expression. (It is recommended to use `pg_get_constraintdef()` to extract the definition of a check constraint.)

Parent topic: System Catalogs Definitions

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.8.3.32 pg_conversion

The `pg_conversion` system catalog table describes the available encoding conversion procedures as defined by `CREATE CONVERSION`.

column	type	references	description
`oid`	oid		The object ID
`conname`	name		Conversion name (unique within a namespace)
`connamespace`	oid	pg_namespace.oid	The OID of the namespace (schema) that contains this conversion
`conowner`	oid	pg_authid.oid	Owner of the conversion
`conforencoding`	integer		Source encoding ID
`contoencoding`	integer		Destination encoding ID
`conproc`	regproc	pg_proc.oid	Conversion procedure
`condefault`	boolean		True if this is the default conversion

Parent topic: System Catalogs Definitions

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.8.3.33 pg_database

The `pg_database` system catalog table stores information about the available databases. Databases are created with the `CREATE DATABASE` SQL command. Unlike most system catalogs, `pg_database` is shared across all databases in the system. There is only one copy of `pg_database` per system, not one per database.

column	type	references	description
`oid`	oid		The object ID
`datname`	name		Database name
`datdba`	oid	pg_authid.oid	Owner of the database, usually the user who created it
`encoding`	integer		Character encoding for this database. `pg_encoding_to_char()` can translate this number to the encoding name
`datcollate`	name		`LC_COLLATE` for this database
`datctype`	name		`LC_CTYPE` for this database
`datistemplate`	boolean		If true then this database can be used in the `TEMPLATE` clause of `CREATE DATABASE` to create a new database as a clone of this one
`datallowconn`	boolean		If false then no one can connect to this database. This is used to protect the `template0` database from being altered
`datconnlimit`	integer		Sets the maximum number of concurrent connections that can be made to this database. `-1` means no limit
`datlastsysoid`	oid		Last system OID in the database
`datfrozenxid`	xid		All transaction IDs (XIDs) before this one have been replaced with a permanent (frozen) transaction ID in this database. This is used to track whether the database needs to be vacuumed in order to prevent transaction ID wraparound or to allow pg_xact to be shrunk. It is the minimum of the per-table *pg_class.relfrozenxid* values
`datminmxid`	xid		A *Multixact ID* is used to support row locking by multiple transactions. All multixact IDs before this one have been replaced with a transaction ID in this database. This is used to track whether the database needs to be vacuumed in order to prevent multixact ID wraparound or to allow `pg_multixact` to be shrunk. It is the minimum of the per-table *pg_class.relminmxid* values
`dattablespace`	oid	pg_tablespace.oid	The default tablespace for the database. Within this database, all tables for which *pg_class.reltablespace* is zero will be stored in this tablespace. All non-shared system catalogs will also be there
`datacl`	aclitem[]		Database access privileges as given by `GRANT` and `REVOKE`

Parent topic: System Catalogs Definitions

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.8.3.34 pg_db_role_setting

The `pg_db_role_setting` system catalog table records the default values of server configuration settings for each role and database combination.

There is a single copy of `pg_db_role_settings` per WarehousePG cluster. This system catalog table is shared across all databases.

You can view the server configuration settings for your WarehousePG cluster with `psql`'s `\drds` meta-command.

column	type	references	description
`setdatabase`	oid	pg_database.oid	The database to which the setting is applicable, or zero if the setting is not database-specific.
`setrole`	oid	pg_authid.oid	The role to which the setting is applicable, or zero if the setting is not role-specific.
`setconfig`	text[]		Per-database- and per-role-specific defaults for user-settable server configuration parameters.

Parent topic: System Catalogs Definitions

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.8.3.35 pg_depend

The `pg_depend` system catalog table records the dependency relationships between database objects. This information allows `DROP` commands to find which other objects must be dropped by `DROP CASCADE` or prevent dropping in the `DROP RESTRICT` case. See also pg_shdepend, which performs a similar function for dependencies involving objects that are shared across a WarehousePG cluster.

In all cases, a `pg_depend` entry indicates that the referenced object may not be dropped without also dropping the dependent object. However, there are several subtypes identified by `deptype`:

- **DEPENDENCY_NORMAL (n)** — A normal relationship between separately-created objects. The dependent object may be dropped without affecting the referenced object. The referenced object may only be dropped by specifying `CASCADE`, in which case the dependent object is dropped, too. Example: a table column has a normal dependency on its data type.
- **DEPENDENCY_AUTO (a)** — The dependent object can be dropped separately from the referenced object, and should be automatically dropped (regardless of `RESTRICT` or `CASCADE` mode) if the referenced object is dropped. Example: a named constraint on a table is made auto-dependent on the table, so that it will go away if the table is dropped.
- **DEPENDENCY_INTERNAL (i)** — The dependent object was created as part of creation of the referenced object, and is really just a part of its internal implementation. A direct `DROP` of the dependent object will be disallowed outright (issue a `DROP` against the referenced object instead). A `DROP` of the referenced object will be propagated through to drop the dependent object whether `CASCADE` is specified or not. If the dependent object has to be dropped due to a dependency on some other object being removed, its drop is converted to a drop of the referenced object, so that `NORMAL` and `AUTO` dependencies of the dependent object behave much like they were dependencies of the referenced object. Example: a view's `ON SELECT` rule is made internally dependent on the view, preventing it from being dropped while the view remains. Dependencies of the rule (such as tables it refers to) act as if they were dependencies of the view.
- **DEPENDENCY_PARTITION_PRI (P)**, **DEPENDENCY_PARTITION_SEC (S)** - The dependent object was created as part of creation of the referenced object, and is really just a part of its internal implementation; however, unlike `INTERNAL`, there is more than one such referenced object. The dependent object must not be dropped unless at least one of these referenced objects is dropped; if any one is, the dependent object should be dropped whether or not `CASCADE` is specified. Also unlike `INTERNAL`, a drop of some other object that the dependent object depends on does not result in automatic deletion of any partition-referenced object. Hence, if the drop does not cascade to at least one of these objects via some other path, it will be refused. (In most cases, the dependent object shares all its non-partition dependencies with at least one partition-referenced object, so that this restriction does not result in blocking any cascaded delete.) Primary and secondary partition dependencies behave identically except that the primary dependency is preferred for use in error messages; hence, a partition-dependent object should have one primary partition dependency and one or more secondary partition dependencies. Note that partition dependencies are made in addition to, not instead of, any dependencies the object would normally have. This simplifies `ATTACH/DETACH PARTITION` operations: the partition dependencies need only be added or removed. Example: a child partitioned index is made partition-dependent on both the partition table it is on and the parent partitioned index, so that it goes away if either of those is dropped, but not otherwise. The dependency on the parent index is primary, so that if the user tries to drop the child partitioned index, the error message will suggest dropping the parent index instead (not the table).
- **DEPENDENCY_EXTENSION (e)** - The dependent object is a member of the extension that is the referenced object (see pg_extension). The dependent object can be dropped only via `DROP EXTENSION` on the referenced object. Functionally, this dependency type acts the same as an `INTERNAL` dependency, but it's kept separate for clarity and to simplify pg_dump.
- **DEPENDENCY_AUTO_EXTENSION (x)** - The dependent object is not a member of the extension that is the referenced object (and so it should not be ignored by pg_dump), but it cannot function without the extension and should be auto-dropped if the extension is. The dependent object may be dropped on its own as well. Functionally this dependency type acts the same as an `AUTO` dependency, but it's kept separate for clarity and to simplify pg_dump.
- **DEPENDENCY_PIN (p)** — There is no dependent object; this type of entry is a signal that the system itself depends on the referenced object, and so that object must never be deleted. Entries of this type are created only by system initialization. The columns for the dependent object contain zeroes.

Note that it's quite possible for two objects to be linked by more than one `pg_depend` entry. For example, a child partitioned index would have both a partition-type dependency on its associated partition table, and an auto dependency on each column of that table that it indexes. This sort of situation expresses the union of multiple dependency semantics. A dependent object can be dropped without `CASCADE` if any of its dependencies satisfies its condition for automatic dropping. Conversely, all the dependencies' restrictions about which objects must be dropped together must be satisfied.

column	type	references	description
`classid`	oid	pg_class.oid	The object identifier of the system catalog the dependent object is in.
`objid`	oid	any OID column	The object identifier of the specific dependent object.
`objsubid`	integer		For a table column, this is the column number (the `objid` and `classid` refer to the table itself). For all other object types, this column is zero.
`refclassid`	oid	pg_class.oid	The object identifier of the system catalog the referenced object is in.
`refobjid`	oid	any OID column	The object identifier of the specific referenced object.
`refobjsubid`	integer		For a table column, this is the referenced column number (the `refobjid` and `refclassid` refer to the table itself). For all other object types, this column is zero.
`deptype`	char		The code defining the specific semantics of this dependency relationship.

Parent topic: System Catalogs Definitions

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.8.3.36 pg_description

The `pg_description` system catalog table stores optional descriptions (comments) for each database object. Descriptions can be manipulated with the `COMMENT` command and viewed with `psql`'s `\d` meta-commands. Descriptions of many built-in system objects are provided in the initial contents of `pg_description`. See also pg_shdescription, which performs a similar function for descriptions involving objects that are shared across a WarehousePG cluster.

column	type	references	description
`objoid`	oid	any OID column	The OID of the object this description pertains to.
`classoid`	oid	pg_class.oid	The OID of the system catalog this object appears in
`objsubid`	integer		For a comment on a table column, this is the column number. For all other object types, this column is zero.
`description`	text		Arbitrary text that serves as the description of this object.

Parent topic: System Catalogs Definitions

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.8.3.37 pg_enum

The `pg_enum` table contains entries matching enum types to their associated values and labels. The internal representation of a given enum value is actually the OID of its associated row in `pg_enum`. The OIDs for a particular enum type are guaranteed to be ordered in the way the type should sort, but there is no guarantee about the ordering of OIDs of unrelated enum types.

Column	Type	References	Description
`oid`	oid		The object ID
`enumtypid`	oid	pgtype.oid	The OID of the `pg_type` entry owning this enum value
`enumsortorder`	float4		The sort position of this enum value within its enum type
`enumlabel`	name		The textual label for this enum value

Parent topic: System Catalogs Definitions

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.8.3.38 pg_extension

The system catalog table `pg_extension` stores information about installed extensions.

column	type	references	description
`oid`	oid		The object ID
`extname`	name		Name of the extension
`extowner`	oid	pg_authid.oid	Owner of the extension
`extnamespace`	oid	pg_namespace.oid	Schema containing the extension exported objects
`extrelocatable`	boolean		True if the extension can be relocated to another schema
`extversion`	text		Version name for the extension
`extconfig`	oid[]	pg_class.oid	Array of `regclass` OIDs for the extension configuration tables, or `NULL` if none.
`extcondition`	text[]		Array of `WHERE` -clause filter conditions for the extension configuration tables, or `NULL` if none.

Unlike most catalogs with a namespace column, `extnamespace` does not imply that the extension belongs to that schema. Extension names are never schema-qualified. The `extnamespace` schema indicates the schema that contains most or all of the extension objects. If `extrelocatable` is `true` , then this schema must contain all schema-qualifiable objects that belong to the extension.

Parent topic: System Catalogs Definitions

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.8.3.39 pg_foreign_data_wrapper

The system catalog table `pg_foreign_data_wrapper` stores foreign-data wrapper definitions. A foreign-data wrapper is a mechanism by which you access external data residing on foreign servers.

column	type	references	description
`oid`	oid		The object ID
`fdwname`	name		Name of the foreign-data wrapper
`fdwowner`	oid	pg_authid.oid	Owner of the foreign-data wrapper
`fdwhandler`	oid	pg_proc.oid	A reference to a handler function that is responsible for supplying execution routines for the foreign-data wrapper. Zero if no handler is provided
`fdwvalidator`	oid	pg_proc.oid	A reference to a validator function that is responsible for checking the validity of the options provided to the foreign-data wrapper. This function also checks the options for foreign servers and user mappings using the foreign-data wrapper. Zero if no validator is provided
`fdwacl`	aclitem[]		Access privileges; see GRANT and REVOKE for details
`fdwoptions`	text[]		Foreign-data wrapper-specific options, as "keyword=value" strings

Parent topic: System Catalogs Definitions

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.8.3.40 pg_foreign_server

The system catalog table `pg_foreign_server` stores foreign server definitions. A foreign server describes a source of external data, such as a remote server. You access a foreign server via a foreign-data wrapper.

column	type	references	description
`oid`	oid		The object ID
`srvname`	name		Name of the foreign server
`srvowner`	oid	pg_authid.oid	Owner of the foreign server
`srvfdw`	oid	pg_foreign_data_wrapper.oid	OID of the foreign-data wrapper of this foreign server
`srvtype`	text		Type of server (optional)
`srvversion`	text		Version of the server (optional)
`srvacl`	aclitem[]		Access privileges; see GRANT and REVOKE for details
`srvoptions`	text[]		Foreign server-specific options, as "keyword=value" strings

Parent topic: System Catalogs Definitions

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.8.3.41 pg_foreign_table

The system catalog table `pg_foreign_table` contains auxiliary information about foreign tables. A foreign table is primarily represented by a `pg_class` entry, just like a regular table. Its `pg_foreign_table` entry contains the information that is pertinent only to foreign tables and not any other kind of relation.

column	type	references	description
`ftrelid`	oid	pg_class.oid	OID of the `pg_class` entry for this foreign table.
`ftserver`	oid	pg_foreign_server.oid	OID of the foreign server for this foreign table.
`ftoptions`	text[]		Foreign table options, as "keyword=value" strings.

Parent topic: System Catalogs Definitions

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.8.3.42 pg_index

The `pg_index` system catalog table contains part of the information about indexes. The rest is mostly in`pg_class`.

column	type	references	description
`indexrelid`	oid	pg_class.oid	The OID of the pg_class entry for this index
`indrelid`	oid	pg_class.oid	The OID of the pg_class entry for the table this index is for
`indnatts`	smallint		The number of columns in the index (duplicates pg_class.relnatts)
`indnkeyatts`	smallint		The number of key columns in the index
`indisunique`	boolean		If true, this is a unique index
`indisprimary`	boolean		If true, this index represents the primary key of the table. (indisunique should always be true when this is true.)
`indisexclusion`	boolean		If true, this index supports an exclusion constraint
indimmediate	boolean		If true, the uniqueness check is enforced immediately on insertion (irrelevant if `indisunique` is not true)
`indisclustered`	boolean		If true, the table was last clustered on this index via the `CLUSTER` command
`indisvalid`	boolean		If true, the index is currently valid for queries. False means the index is possibly incomplete: it must still be modified by `INSERT` / `UPDATE` operations, but it cannot safely be used for queries.
`indcheckxmin`	boolean		If true, queries must not use the index until the `xmin` of this `pg_index` row is below their `TransactionXmin` event horizon, because the table may contain broken HOT chains with incompatible rows that they can see
`indisready`	boolean		If true, the index is currently ready for inserts. False means the index must be ignored by `INSERT` / `UPDATE` operations
`indislive`	boolean		If false, the index is in process of being dropped, and should be ignored for all purposes
`indisreplident`	boolean		If true this index has been chosen as "replica identity" using `ALTER TABLE ... REPLICA IDENTITY USING INDEX ...`
`indkey`	int2vector	pg_attribute.attnum	This is an array of `indnatts` values that indicate which table columns this index indexes. For example a value of 1 3 would mean that the first and the third table columns make up the index key. A zero in this array indicates that the corresponding index attribute is an expression over the table columns, rather than a simple column reference.
`indcollation`	oidvector		For each column in the index key, this contains the OID of the collation to use for the index.
`indclass`	oidvector	pg_opclass.oid	For each column in the index key this contains the OID of the operator class to use
`indoption`	int2vector		This is an array of `indnatts` values that store per-column flag bits. The meaning of the bits is defined by the index's access method.
`indexprs`	pg_node_tree		Expression trees (in `nodeToString()` representation) for index attributes that are not simple column references. This is a list with one element for each zero entry in indkey. NULL if all index attributes are simple references.
`indpred`	pg_node_tree		Expression tree (in `nodeToString()` representation) for partial index predicate. NULL if not a partial index.

Parent topic: System Catalogs Definitions

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.8.3.43 pg_inherits

The `pg_inherits` system catalog table records information about table and index inheritance hierarchies. There is one entry for each direct parent-child table or index relationship in the database. (Indirect inheritance can be determined by following chains of entries.)

In WarehousePG, inheritance relationships are created by both the `INHERITS` clause (standalone inheritance) and the `PARTITION BY` clause (partitioned child table inheritance) of `CREATE TABLE`.

column	type	references	description
`inhrelid`	oid	pg_class.oid	The object identifier of the child table.
`inhparent`	oid	pg_class.oid	The object identifier of the parent table.
`inhseqno`	integer		If there is more than one direct parent for a child table (multiple inheritance), this number tells the order in which the inherited columns are to be arranged. The count starts at 1. Indexes can not have multiple inheritance, since they can only inherit when using declarative partitioning.

Parent topic: System Catalogs Definitions

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.8.3.44 pg_language

The `pg_language` system catalog table registers languages in which you can write functions or stored procedures. See CREATE LANGUAGE for more information about language handlers.

column	type	references	description
`oid`	oid		The object ID
`lanname`	name		Name of the language
`lanowner`	oid	pg_authid.oid	Owner of the language
`lanispl`	boolean		This is false for internal languages (such as SQL) and true for user-defined languages. Currently, `pg_dump` still uses this to determine which languages need to be dumped, but this may be replaced by a different mechanism in the future.
`lanpltrusted`	boolean		True if this is a trusted language, which means that it is believed not to grant access to anything outside the normal SQL execution environment. Only superusers may create functions in untrusted languages.
`lanplcallfoid`	oid	pg_proc.oid	For noninternal languages this references the language handler, which is a special function that is responsible for running all functions that are written in the particular language.
`laninline`	oid	pg_proc.oid	This references a function that is responsible for running inline anonymous code blocks (see the DO command). Zero if inline blocks are not supported.
`lanvalidator`	oid	pg_proc.oid	This references a language validator function that is responsible for checking the syntax and validity of new functions when they are created. Zero if no validator is provided.
`lanacl`	aclitem[]		Access privileges for the language

Parent topic: System Catalogs Definitions

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.8.3.45 pg_largeobject

Note WarehousePG does not support the PostgreSQL large object facility for streaming user data that is stored in large-object structures.

The `pg_largeobject` system catalog table holds the data making up 'large objects'. A large object is identified by an OID assigned when it is created. Each large object is broken into segments or 'pages' small enough to be conveniently stored as rows in `pg_largeobject`. The amount of data per page is defined to be `LOBLKSIZE` (which is currently `BLCKSZ`/4, or typically 8K).

Each row of `pg_largeobject` holds data for one page of a large object, beginning at byte offset (*pageno* `* LOBLKSIZE`) within the object. The implementation allows sparse storage: pages may be missing, and may be shorter than `LOBLKSIZE` bytes even if they are not the last page of the object. Missing regions within a large object read as zeroes.

column	type	references	description
`loid`	oid		Identifier of the large object that includes this page
`pageno`	integer		Page number of this page within its large object (counting from zero)
`data`	bytea		Actual data stored in the large object. This will never be more than `LOBLKSIZE` bytes and may be less.

Parent topic: System Catalogs Definitions

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.8.3.46 pg_locks

The `pg_locks` view provides access to information about the locks held by open transactions within WarehousePG.

`pg_locks` contains one row per active lockable object, requested lock mode, and relevant transaction. Thus, the same lockable object may appear many times if multiple transactions are holding or waiting for locks on it. An object with no current locks on it will not appear in the view at all.

There are several distinct types of lockable objects: whole relations (such as tables), individual pages of relations, individual tuples of relations, transaction IDs (both virtual and permanent IDs), and general database objects. Also, the right to extend a relation is represented as a separate lockable object.

column	type	references	description
`locktype`	text		Type of the lockable object: `relation`, `extend`, `page`, `tuple`, `transactionid`, `object`, `userlock`, `resource queue`, or `advisory`
`database`	oid	pg_database.oid	OID of the database in which the object exists, zero if the object is a shared object, or NULL if the object is a transaction ID
`relation`	oid	pg_class.oid	OID of the relation, or NULL if the object is not a relation or part of a relation
`page`	integer		Page number within the relation, or NULL if the object is not a tuple or relation page
`tuple`	smallint		Tuple number within the page, or NULL if the object is not a tuple
`virtualxid`	text		Virtual ID of a transaction, or NULL if the object is not a virtual transaction ID
`transactionid`	xid		ID of a transaction, or NULL if the object is not a transaction ID
`classid`	oid	pg_class.oid	OID of the system catalog containing the object, or NULL if the object is not a general database object
`objid`	oid	any OID column	OID of the object within its system catalog, or NULL if the object is not a general database object
`objsubid`	smallint		For a table column, this is the column number (the classid and objid refer to the table itself). For all other object types, this column is zero. NULL if the object is not a general database object
`virtualtransaction`	text		Virtual ID of the transaction that is holding or awaiting this lock
`pid`	integer		Process ID of the server process holding or awaiting this lock. NULL if the lock is held by a prepared transaction
`mode`	text		Name of the lock mode held or desired by this process
`granted`	boolean		True if lock is held, false if lock is awaited.
`fastpath`	boolean		True if lock was taken via fastpath, false if lock is taken via main lock table.
`mppsessionid`	integer		The id of the client session associated with this lock.
`mppiswriter`	boolean		Specifies whether the lock is held by a writer process.
`gp_segment_id`	integer		The WarehousePG segment id (`dbid`) where the lock is held.

Parent topic: System Catalogs Definitions

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.8.3.47 pg_namespace

The `pg_namespace` system catalog table stores namespaces. A namespace is the structure underlying SQL schemas: each namespace can have a separate collection of relations, types, etc. without name conflicts.

column	type	references	description
`oid`	oid		Row identifier (hidden attribute; must be explicitly selected)
`nspname`	name		Name of the namespace
`nspowner`	oid	pg_authid.oid	Owner of the namespace
`nspacl`	aclitem[]		Access privileges as given by `GRANT` and `REVOKE`

Parent topic: System Catalogs Definitions

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.8.3.48 pg_opclass

The `pg_opclass` system catalog table defines index access method operator classes. Each operator class defines semantics for index columns of a particular data type and a particular index access method. An operator class essentially specifies that a particular operator family is applicable to a particular indexable column data type. The set of operators from the family that are actually usable with the indexed column are those that accept the column's data type as their left-hand input.

An operator class's `opcmethod` must match the `opfmethod` of its containing operator family. Also, there must be no more than one `pg_opclass` row having `opcdefault` true for any given combination of `opcmethod` and `opcintype`.

The PostgreSQL Interfacing Extensions to Indexes documentation describes operator classes at length.

column	type	references	description
`oid`	oid		Row identifier (hidden attribute; must be explicitly selected)
`opcmethod`	oid	pg_am.oid	Index access method operator class is for
`opcname`	name		Name of this operator class
`opcnamespace`	oid	pg_namespace.oid	Namespace of this operator class
`opcowner`	oid	pg_authid.oid	Owner of the operator class
`opcfamily`	oid	pg_opfamily.oid	Operator family containing the operator class
`opcintype`	oid	pg_type.oid	Data type that the operator class indexes
`opcdefault`	boolean		True if this operator class is the default for the data type `opcintype`
`opckeytype`	oid	pg_type.oid	Type of data stored in index, or zero if same as `opcintype`

Parent topic: System Catalogs Definitions

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.8.3.49 pg_operator

The `pg_operator` system catalog table stores information about operators, both built-in and those defined by `CREATE OPERATOR`. Unused column contain zeroes. For example, `oprleft` is zero for a prefix operator.

column	type	references	description
`oid`	oid		Row identifier (hidden attribute, must be explicityly selected)
`oprname`	name		Name of the operator
`oprnamespace`	oid	pg_namespace.oid	The OID of the namespace that contains this operator
`oprowner`	oid	pg_authid.oid	Owner of the operator
`oprkind`	char		`b` = infix (both), `l` = prefix (left), `r` = postfix (right)
`oprcanmerge`	boolean		This operator supports merge joins
`oprcanhash`	boolean		This operator supports hash joins
`oprleft`	oid	pg_type.oid	Type of the left operand
`oprright`	oid	pg_type.oid	Type of the right operand
`oprresult`	oid	pg_type.oid	Type of the result
`oprcom`	oid	pg_operator.oid	Commutator of this operator, if any
`oprnegate`	oid	pg_operator.oid	Negator of this operator, if any
`oprcode`	regproc	pg_proc.oid	Function that implements this operator
`oprrest`	regproc	pg_proc.oid	Restriction selectivity estimation function for this operator
`oprjoin`	regproc	pg_proc.oid	Join selectivity estimation function for this operator

Parent topic: System Catalogs Definitions

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.8.3.50 pg_opfamily

The catalog `pg_opfamily` defines operator families. Each operator family is a collection of operators and associated support routines that implement the semantics specified for a particular index access method. Furthermore, the operators in a family are all compatible in a way that is specified by the access method. The operator family concept allows cross-data-type operators to be used with indexes and to be reasoned about using knowledge of access method semantics.

The majority of the information defining an operator family is not in its `pg_opfamily` row, but in the associated rows in pg_amop, pg_amproc, and pg_opclass.

Name	Type	References	Description
`oid`	oid		Row identifier (hidden attribute; must be explicitly selected)
`opfmethod`	oid	pg_am.oid	Index access method operator for this family
`opfname`	name		Name of this operator family
`opfnamespace`	oid	pg_namespace.oid	Namespace of this operator family
`opfowner`	oid	pg_authid.oid	Owner of the operator family

Parent topic: System Catalogs Definitions

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.8.3.51 pg_partitioned_table

The `pg_partitioned_table` system catalog stores information about how tables are partitioned.

column	type	references	description
`partrelid`	oid	pg_class.oid	The object identifier of the `pg_class` entry for this partitioned table.
`partstrat`	char		The partitioning strategy: `h` = hash partitioned table, `l` = list partitioned table, `r` = range partitioned table.
`partnatts`	smallint		The number of columns in the partition key.
`partdefid`	oid	pg_class.oid	The object identifier of the `pg_class` entry for the default partition of this partitioned table, or zero if this partitioned table does not have a default partition.
`partattrs`	int2vector	pg_attribute.attnum	An array of `partnatts` values that indicate which table columns are part of the partition key. For example, a value of `1 3` would mean that the first and the third table columns make up the partition key. A zero in this array indicates that the corresponding partition key column is an expression, rather than a simple column reference.
`partclass`	oidvector	pg_opclass.oid	For each column in the partition key, contains the object identifier of the operator class to use. See pg_opclass for details.
`partcollation`	oidvector	pg_opclass.oid	For each column in the partition key, contains the object identifier of the collation to use for partitioning, or zero if the column is not of a collatable data type.
`partexprs`	pg_node_tree		Expression trees (in `nodeToString()` representation) for partition key columns that are not simple column references. This list contains one element for each zero entry in `partattrs`. Null if all partition key columns are simple references. *WarehousePG classic partition syntax does not support specifying an expression in a partition key.*

Parent topic: System Catalogs Definitions

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.8.3.52 pg_pltemplate

The `pg_pltemplate` system catalog table stores template information for procedural languages. A template for a language allows the language to be created in a particular database by a simple `CREATE LANGUAGE` command, with no need to specify implementation details. Unlike most system catalogs, `pg_pltemplate` is shared across all databases of WarehousePG cluster: there is only one copy of `pg_pltemplate` per system, not one per database. This allows the information to be accessible in each database as it is needed.

There are not currently any commands that manipulate procedural language templates; to change the built-in information, a superuser must modify the table using ordinary `INSERT`, `DELETE`, or `UPDATE` commands.

column	type	references	description
`tmplname`	name		Name of the language this template is for
`tmpltrusted`	boolean		True if language is considered trusted
`tmpldbacreate`	boolean		True if language may be created by a database owner
`tmplhandler`	text		Name of call handler function
`tmplinline`	text		Name of anonymous-block handler function, or null if none
`tmplvalidator`	text		Name of validator function, or NULL if none
`tmpllibrary`	text		Path of shared library that implements language
`tmplacl`	aclitem[]		Access privileges for template (not yet implemented).

Parent topic: System Catalogs Definitions

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.8.3.53 pg_policy

The catalog `pg_policy` stores row level security policies for tables. A policy includes the kind of command that it applies to (possibly all commands), the roles that it applies to, the expression to be added as a security-barrier qualification to queries that include the table, and the expression to be added as a `WITH CHECK` option for queries that attempt to add new records to the table.

Column Name	Type	References	Description
`oid`	oid		The object ID
`polname`	name		The name of the policy
`polerelid`	oid	pg_class.oid	The table to which the policy applies
`polcmd`	char		The command type to which the policy is applied: `r` for `SELECT`, `a` for `INSERT`, `w` for `UPDATE`, `d` for `DELETE`, or `*` for all
`polpermissive`	boolean		Is the policy permissive or restrictive?
`polroles`	oid[]	pg_authid.oid	The roles to which the policy is applied
`polqual`	pg_node_tree		The expression tree to be added to the security barrier qualifications for queries that use the table
`polwithcheck`	pg_node_tree		The expression tree to be added to the `WITH CHECK` qualifications for queries that attempt to add rows to the table

> **Note** WarehousePG applies policies stored in `pg_policy` only when `pg_class.relrowsecurity` is set for their table.

Parent topic: System Catalogs Definitions

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.8.3.54 pg_prepared_statements

The `pg_prepared_statements` view displays all of the prepared statements that are available in the current session. See PREPARE for more information about prepared statements.

`pg_prepared_statements` contains one row for each prepared statement. Rows are added to the view when a new prepared statement is created and removed when a prepared statement is released (for example, with the DEALLOCATE command).

The `pg_prepared_statements` view is read-only.

name	type	description
`name`	text	The identifier of the prepared statement.
`statement`	text	The query string submitted by the client to create this prepared statement. For prepared statements created via SQL, this is the `PREPARE` statement submitted by the client. For prepared statements created via the frontend/backend protocol, this is the text of the prepared statement itself.
`prepare_time`	timestamptz	The time at which the prepared statement was created.
`parameter_types`	regtype[]	The expected parameter types for the prepared statement in the form of an array of `regtype`. The object identifier corresponding to an element of this array can be obtained by casting the `regtype` value to `oid`.
`from_sql`	boolean	`true` if the prepared statement was created via the `PREPARE` SQL command, `false` if the statement was prepared via the frontend/backend protocol.

Parent topic: System Catalogs Definitions

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.8.3.55 pg_proc

The `pg_proc` system catalog table stores information about functions (or procedures), both built-in functions and those defined by `CREATE FUNCTION`. The table contains data for aggregate and window functions as well as plain functions. If `proisagg` is true, there should be a matching row in `pg_aggregate`.

For compiled functions, both built-in and dynamically loaded, `prosrc` contains the function's C-language name (link symbol). For all other currently-known language types, `prosrc` contains the function's source text. `probin` is unused except for dynamically-loaded C functions, for which it gives the name of the shared library file containing the function.

column	type	references	description
`oid`	oid		Row identifier (hidden attribute; must be explicitly selected).
`proname`	name		Name of the function.
`pronamespace`	oid	pg_namespace.oid	The OID of the namespace that contains this function.
`proowner`	oid	pg_authid.oid	Owner of the function.
`prolang`	oid	pg_language.oid	Implementation language or call interface of this function.
`procost`	float4		Estimated execution cost (in cpu_operator_cost units); if `proretset` is `true`, identifies the cost per row returned.
`prorows`	float4		Estimated number of result rows (zero if not `proretset`).
`provariadic`	oid	pg_type.oid	Data type of the variadic array parameter's elements, or zero if the function does not have a variadic parameter.
`prosupport`	regproc	pg_proc.oid	Planner support function for this function
`prokind`	char		`f` for a normal function, `p` for a procedure, `a` for an aggregate function, or `w` for a window function
`prosecdef`	boolean		Function is a security definer (for example, a 'setuid' function).
`proleakproof`	boolean		The function has no side effects. No information about the arguments is conveyed except via the return value. Any function that might throw an error depending on the values of its arguments is not leak-proof.
`proisstrict`	boolean		Function returns NULL if any call argument is NULL. In that case the function will not actually be called at all. Functions that are not strict must be prepared to handle NULL inputs.
`proretset`	boolean		Function returns a set (multiple values of the specified data type).
`provolatile`	char		Tells whether the function's result depends only on its input arguments, or is affected by outside factors. `i` = *immutable* (always delivers the same result for the same inputs), `s` = *stable* (results (for fixed inputs) do not change within a scan), or `v` = *volatile* (results may change at any time or functions with side-effects).
`proparallel`	char		Indicates whether a function can be safely run in a parallel backend, or only in non-parallel mode
`pronargs`	smallint		Number of arguments.
`pronargdefaults`	smallint		Number of arguments that have default values.
`prorettype`	oid	pg_type.oid	Data type of the return value, or null for a procedure.
`proargtypes`	oidvector	pg_type.oid	An array with the data types of the function arguments. This includes only input arguments (including `INOUT` and `VARIADIC` arguments), and thus represents the call signature of the function.
`proallargtypes`	oid[]	pg_type.oid	An array with the data types of the function arguments. This includes all arguments (including `OUT` and `INOUT` arguments); however, if all of the arguments are `IN` arguments, this field will be null. Note that subscripting is 1-based, whereas for historical reasons `proargtypes` is subscripted from 0.
`proargmodes`	char[]		An array with the modes of the function arguments: `i` = `IN`, `o` = `OUT`, `b` = `INOUT`, `v` = `VARIADIC`. If all the arguments are IN arguments, this field will be null. Note that subscripts correspond to positions of `proallargtypes`, not `proargtypes`.
`proargnames`	text[]		An array with the names of the function arguments. Arguments without a name are set to empty strings in the array. If none of the arguments have a name, this field will be null. Note that subscripts correspond to positions of `proallargtypes` not `proargtypes`.
`proargdefaults`	pg_node_tree		Expression trees (in `nodeToString()` representation) for default argument values. This is a list with `pronargdefaults` elements, corresponding to the last N input arguments (i.e., the last N `proargtypes` positions). If none of the arguments have defaults, this field will be null.
`protrftypes`	oid[]		Types for which to apply transforms
`prosrc`	text		This tells the function handler how to invoke the function. It might be the actual source code of the function for interpreted languages, a link symbol, a file name, or just about anything else, depending on the implementation language/call convention.
`probin`	text		Additional information about how to invoke the function. Again, the interpretation is language-specific.
`proconfig`	text[]		Function's local settings for run-time configuration variables.
`proacl`	aclitem[]		Access privileges for the function as given by `GRANT` / `REVOKE`.
`proexeclocation`	char		Where the function runs when it is invoked: `m` - coordinator only, `a` - any segment instance, `s` - all segment instances, `i` - initplan.

Parent topic: System Catalogs Definitions

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.8.3.56 pg_resgroup

> **Note** The `pg_resgroup` system catalog table is valid only when resource group-based resource management is active.

The `pg_resgroup` system catalog table contains information about WarehousePG resource groups, which are used for managing concurrent statements, CPU, and memory resources. This table, defined in the `pg_global` tablespace, is globally shared across all databases in the system.

column	type	references	description
`oid`	oid		The object ID
`rsgname`	name		The name of the resource group.
`parent`	oid		Unused; reserved for future use.

Parent topic: System Catalogs Definitions

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.8.3.57 pg_resgroupcapability

Note The `pg_resgroupcapability` system catalog table is valid only when resource group-based resource management is active.

The `pg_resgroupcapability` system catalog table contains information about the capabilities and limits of defined WarehousePG resource groups. You can join this table to thepg_resgroup table by resource group object ID.

The `pg_resgroupcapability` table, defined in the `pg_global` tablespace, is globally shared across all databases in the system.

column	type	references	description
`resgroupid`	oid	`pg_resgroup.oid`	The object ID of the associated resource group.
`reslimittype`	smallint	``	The resource group limit type: 1 - Concurrency 2 - CPU_MAX_WEIGHT 3 - CPU_WEIGHT 4 - CPUSET 5 - MEMORY_QUOTA 6 - MIN_COST 7 - IO_LIMIT
`value`	opaque type		The specific value set for the resource limit referenced in this record. This value has the fixed type `text`, and will be converted to a different data type depending upon the limit referenced.

Parent topic: System Catalogs Definitions

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.8.3.58 pg_resourcetype

The `pg_resourcetype` system catalog table contains information about the extended attributes that can be assigned to WarehousePG resource queues. Each row details an attribute and inherent qualities such as its default setting, whether it is required, and the value to deactivate it (when allowed).

This table is populated only on the coordinator. This table is defined in the `pg_global` tablespace, meaning it is globally shared across all databases in the system.

column	type	references	description
`oid`	oid		The object ID
`resname`	name		The name of the resource type
`restypid`	smallint		The resource type ID
`resrequired`	boolean		Whether the resource type is required for a valid resource queue
`reshasdefault`	boolean		Whether the resource type has a default value. When true, the default value is specified in reshasdefaultsetting.
`rescandisable`	boolean		Whether the type can be removed or deactivated. When true, the default value is specified in resdisabledsetting.
`resdefaultsetting`	text		Default setting for the resource type, when applicable
`resdisabledsetting`	text		The value that deactivates this resource type (when allowed)

Parent topic: System Catalogs Definitions

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.8.3.59 pg_resqueue

Note The `pg_resqueue` system catalog table is valid only when resource queue-based resource management is active.

The `pg_resqueue` system catalog table contains information about WarehousePG resource queues, which are used for the resource management feature. This table is populated only on the coordinator. This table is defined in the `pg_global` tablespace, meaning it is globally shared across all databases in the system.

column	type	references	description
`oid`	oid		The object id
`rsqname`	name		The name of the resource queue
`rsqcountlimit`	real		The active query threshold of the resource queue
`rsqcostlimit`	real		The query cost threshold of the resource queue
`rsqovercommit`	boolean		Allows queries that exceed the cost threshold to run when the system is idle
`rsqignorecostlimit`	real		The query cost limit of what is considered a 'small query'. Queries with a cost under this limit will not be queued and run immediately.

Parent topic: System Catalogs Definitions

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.8.3.60 pg_resqueuecapability

Note The `pg_resqueuecapability` system catalog table is valid only when resource queue-based resource management is active.

The `pg_resqueuecapability` system catalog table contains information about the extended attributes, or capabilities, of existing WarehousePG resource queues. Only resource queues that have been assigned an extended capability, such as a priority setting, are recorded in this table. This table is joined to the pg_resqueue table by resource queue object ID, and to the pg_resourcetype table by resource type ID (`restypid`).

This table is populated only on the coordinator. This table is defined in the `pg_global` tablespace, meaning it is globally shared across all databases in the system.

column	type	references	description
`rsqueueid`	oid	`pg_resqueue.oid`	The object ID of the associated resource queue.
`restypid`	smallint	`pg_resourcetype.restypid`	The resource type, derived from the *pg_resqueuecapability* system table.
`resetting`	text		The specific value set for the capability referenced in this record. Depending on the actual resource type, this value may have different data types.

Parent topic: System Catalogs Definitions

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.8.3.61 pg_rewrite

The `pg_rewrite` system catalog table stores rewrite rules for tables and views. `pg_class.relhasrules` must be true if a table has any rules in this catalog.

column	type	references	description
`oid`	oid		The object ID
`rulename`	name		Rule name
`ev_class`	oid	pg_class.oid	The table this rule is for
`ev_type`	char		Event type that the rule is for: 1 = SELECT, 2 = UPDATE, 3 = INSERT, 4 = DELETE
`ev_enabled`	char		Controls in which session replication role mode the rule fires. Always O, rule fires in origin mode.
`is_instead`	boolean		True if the rule is an `INSTEAD` rule
`ev_qual`	pg_node_tree		Expression tree (in the form of a `nodeToString()` representation) for the rule's qualifying condition
`ev_action`	pg_node_tree		Query tree (in the form of a `nodeToString()` representation) for the rule's action

Parent topic: System Catalogs Definitions

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.8.3.62 pg_roles

The view `pg_roles` provides access to information about database roles. This is simply a publicly readable view of pg_authid that blanks out the password field. This view explicitly exposes the OID column of the underlying table, since that is needed to do joins to other catalogs.

column	type	references	description
`rolname`	name		Role name
`rolsuper`	bool		Role has superuser privileges
`rolinherit`	bool		Role automatically inherits privileges of roles it is a member of
`rolcreaterole`	bool		Role may create more roles
`rolcreatedb`	bool		Role may create databases
`rolcatupdate`	bool		Role may update system catalogs directly. (Even a superuser may not do this unless this column is true.)
`rolcanlogin`	bool		Role may log in. That is, this role can be given as the initial session authorization identifier
`rolconnlimit`	int4		For roles that can log in, this sets maximum number of concurrent connections this role can make. -1 means no limit
`rolpassword`	text		Not the password (always reads as ********)
`rolvaliduntil`	timestamptz		Password expiry time (only used for password authentication); NULL if no expiration
`rolconfig`	text[]		Role-specific defaults for run-time configuration variables
`rolresqueue`	oid	pg_resqueue.oid	Object ID of the resource queue this role is assigned to.
`oid`	oid	pg_authid.oid	Object ID of role
`rolcreaterextgpfd`	bool		Role may create readable external tables that use the gpfdist protocol.
`rolcreaterexthttp`	bool		Role may create readable external tables that use the http protocol.
`rolcreatewextgpfd`	bool		Role may create writable external tables that use the gpfdist protocol.
`rolresgroup`	oid	pg_resgroup.oid	Object ID of the resource group to which this role is assigned.

Parent topic: System Catalogs Definitions

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.8.3.63 pg_rules

The view `pg_rules` provides access to useful information about query rewrite rules.

The `pg_rules` view excludes the `ON SELECT` rules of views and materialized views; those can be seen in `pg_views` and `pg_matviews`.

column	type	references	description
`schemaname`	name	pg_namespace.nspname	Name of schema containing table
`tablename`	name	pg_class.relname	Name of table the rule is for
`rulename`	name	pg_rewrite.rulename	Name of rule
`definition`	text		Rule definition (a reconstructed creation command)

Parent topic: System Catalogs Definitions

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.8.3.64 pg_shdepend

The `pg_shdepend` system catalog table records the dependency relationships between database objects and shared objects, such as roles. This information allows WarehousePG to ensure that those objects are unreferenced before attempting to delete them. See also pg_depend, which performs a similar function for dependencies involving objects within a single database. Unlike most system catalogs, `pg_shdepend` is shared across all databases of WarehousePG cluster: there is only one copy of `pg_shdepend` per system, not one per database.

In all cases, a `pg_shdepend` entry indicates that the referenced object may not be dropped without also dropping the dependent object. However, there are several subflavors identified by `deptype`:

- **SHARED_DEPENDENCY_OWNER (o)** — The referenced object (which must be a role) is the owner of the dependent object.
- **SHARED_DEPENDENCY_ACL (a)** — The referenced object (which must be a role) is mentioned in the ACL (access control list) of the dependent object.
- **SHARED_DEPENDENCY_PIN (p)** — There is no dependent object; this type of entry is a signal that the system itself depends on the referenced object, and so that object must never be deleted. Entries of this type are created only by system initialization. The columns for the dependent object contain zeroes.

column	type	references	description
`dbid`	oid	pg_database.oid	The OID of the database the dependent object is in, or zero for a shared object.
`classid`	oid	pg_class.oid	The OID of the system catalog the dependent object is in.
`objid`	oid	any OID column	The OID of the specific dependent object.
`objsubid`	integer		For a table column, this is the column number. For all other object types, this column is zero.
`refclassid`	oid	pg_class.oid	The OID of the system catalog the referenced object is in (must be a shared catalog).
`refobjid`	oid	any OID column	The OID of the specific referenced object.
`deptype`	char		A code defining the specific semantics of this dependency relationship.

Parent topic: System Catalogs Definitions

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.8.3.65 pg_shdescription

The `pg_shdescription` system catalog table stores optional descriptions (comments) for shared database objects. Descriptions can be manipulated with the `COMMENT` command and viewed with `psql`'s `\d` meta-commands. See also pg_description, which performs a similar function for descriptions involving objects within a single database. Unlike most system catalogs, `pg_shdescription` is shared across all databases of a WarehousePG cluster: there is only one copy of `pg_shdescription` per system, not one per database.

column	type	references	description
`objoid`	oid	any OID column	The OID of the object this description pertains to.
`classoid`	oid	pg_class.oid	The OID of the system catalog this object appears in
`description`	text		Arbitrary text that serves as the description of this object.

Parent topic: System Catalogs Definitions

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.8.3.66 pg_stat_last_operation

The pg_stat_last_operation table contains metadata tracking information about database objects (tables, views, etc.).

column	type	references	description
`classid`	oid	pg_class.oid	OID of the system catalog containing the object.
`objid`	oid	any OID column	OID of the object within its system catalog.
`staactionname`	name		The action that was taken on the object.
`stasysid`	oid	pg_authid.oid	A foreign key to pg_authid.oid.
`stausename`	name		The name of the role that performed the operation on this object.
`stasubtype`	text		The type of object operated on or the subclass of operation performed.
`statime`	timestamp with timezone		The timestamp of the operation. This is the same timestamp that is written to the WarehousePG server log files in case you need to look up more detailed information about the operation in the logs.

The `pg_stat_last_operation` table contains metadata tracking information about operations on database objects. This information includes the object id, DDL action, user, type of object, and operation timestamp. WarehousePG updates this table when a database object is created, altered, truncated, vacuumed, analyzed, or partitioned, and when privileges are granted to an object.

If you want to track the operations performed on a specific object, use the `objid` value. Because the `stasubtype` value can identify either the type of object operated on or the subclass of operation performed, it is not a suitable parameter when querying the `pg_stat_last_operation` table.

The following example creates and replaces a view, and then shows how to use `objid` as a query parameter on the `pg_stat_last_operation` table.

```
testdb=# CREATE VIEW trial AS SELECT * FROM gp_segment_configuration;
CREATE VIEW
testdb=# CREATE OR REPLACE VIEW trial AS SELECT * FROM gp_segment_configuration;
CREATE VIEW
testdb=# SELECT * FROM pg_stat_last_operation WHERE objid='trial'::regclass::oid;
 classid | objid | staactionname | stasysid | stausename | stasubtype |            statime
---------+-------+---------------+----------+------------+------------+-------------------------------
  1259   | 24735 | CREATE        |       10 | gpadmin    | VIEW       | 2020-04-07 16:44:28.808811+00
  1259   | 24735 | ALTER         |       10 | gpadmin    | SET        | 2020-04-07 16:44:38.110615+00
(2 rows)
```

Notice that the `pg_stat_last_operation` table entry for the view `REPLACE` operation specifies the `ALTER` action (`staactionname`) and the `SET` subtype (`stasubtype`).

Parent topic: System Catalogs Definitions

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.8.3.67 pg_stat_last_shoperation

The pg_stat_last_shoperation table contains metadata tracking information about global objects (roles, tablespaces, etc.).

column	type	references	description
`classid`	oid	pg_class.oid	OID of the system catalog containing the object
`objid`	oid	any OID column	OID of the object within its system catalog
`staactionname`	name		The action that was taken on the object
`stasysid`	oid		The OID of the role that performed the operation in this object
`stausename`	name		The name of the role that performed the operation on this object
`stasubtype`	text		The type of object operated on or the subclass of operation performed
`statime`	timestamp with timezone		The timestamp of the operation. This is the same timestamp that is written to the WarehousePG server log files in case you need to look up more detailed information about the operation in the logs.

Parent topic: System Catalogs Definitions

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.8.3.68 pg_stat_operations

The view `pg_stat_operations` shows details about the last operation performed on a database object (such as a table, index, view or database) or a global object (such as a role).

column	type	references	description
`classname`	text		The name of the system table in the `pg_catalog` schema where the record about this object is stored (`pg_class` =relations, `pg_database` =databases, `pg_namespace` =schemas, `pg_authid` =roles)
`objname`	name		The name of the object.
`objid`	oid		The OID of the object.
`schemaname`	name		The name of the schema where the object resides.
`usestatus`	text		The status of the role who performed the last operation on the object (`CURRENT` =a currently active role in the system, `DROPPED` =a role that no longer exists in the system, `CHANGED` =a role name that exists in the system, but has changed since the last operation was performed).
`usename`	name		The name of the role that performed the operation on this object.
`actionname`	name		The action that was taken on the object.
`subtype`	text		The type of object operated on or the subclass of operation performed.
`statime`	timestamptz		The timestamp of the operation. This is the same timestamp that is written to the WarehousePG server log files in case you need to look up more detailed information about the operation in the logs.

Parent topic: System Catalogs Definitions

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.8.3.69 pg_statistic

The `pg_statistic` system catalog table stores statistical data about the contents of the database. Entries are created by ANALYZE and subsequently used by the query planner. Note that all the statistical data is inherently approximate, even assuming that it is up-to-date.

Normally, there is one entry, with `stainherit = false`, for each table column that has been analyzed. If the table has inheritance children, WarehousePG creates a second entry with `stainherit = true`. This row represents the column's statistics over the inheritance tree, for example, statistics for the data you would see with `SELECT column FROM table*`, whereas the `stainherit = false` row represents the results of `SELECT column FROM ONLY table`.

`pg_statistic` also stores statistical data about the values of index expressions. These are described as if they were actual data columns; in particular, `starelid` references the index. No entry is made for an ordinary non-expression index column, however, since it would be redundant with the entry for the underlying table column. Currently, entries for index expressions always have `stainherit = false`.

Since different kinds of statistics may be appropriate for different kinds of data, `pg_statistic` is designed not to assume very much about what sort of statistics it stores. Only extremely general statistics (such as nullness) are given dedicated columns in `pg_statistic`. Everything else is stored in slots, which are groups of associated columns whose content is identified by a code number in one of the slot's columns.

`pg_statistic` should not be readable by the public, since even statistical information about a table's contents should be considered sensitive. (Example: minimum and maximum values of a salary column). pg_stats is a publicly readable view on `pg_statistic` that only exposes information about those tables that are readable by the current user.

> **Caution** Diagnostic tools such as `gpsd` and `minirepro` collect sensitive information from `pg_statistic`, such as histogram boundaries, in a clear, readable form. Always review the output files of these utilities to ensure that the contents are acceptable for transport outside of the database in your organization.

column	type	references	description
`starelid`	oid	pg_class.oid	The table or index that the described column belongs to
`staattnum`	smallint	pg_attribute.attnum	The number of the described column
`stainherit`	boolean		If true, the statistics include inheritance child columns, not just the values in the specified relations.
`stanullfrac`	float4		The fraction of the column's entries that are null
`stawidth`	integer		The average stored width, in bytes, of nonnull entries
`stadistinct`	float4		The number of distinct nonnull data values in the column. A value greater than zero is the actual number of distinct values. A value less than zero is the negative of a multiplier for the number rows in the table (for example, a column in which about 80% of the values are nonnull and each nonnull value appears about twice on the average could be represented by `stadistinct` = -0.4). A zero value means the number of distinct values is unknown.
`stakind*N*`	integer		A code number indicating the kind of statistics stored in the `N` th slot of the `pg_statistic` row
`staop*N*`	oid	pg_operator.oid	An operator used to derive the statistics stored in the `N` th slot. For example, a histogram slot would show the `<` operator that defines the sort order of the data.
`stacoll*N*`	oid	pg_collation.oid	The collation used to derive the statistics stored in the `N` th slot. For example, a histogram slot for a collatable column would show the collation that defines the sort order of the data. Zero for noncollatable data.
`stanumbers*N*`	float4[]		Numerical statistics of the appropriate kind for the `N` th slot, or NULL if the slot kind does not involve numerical values.
`stavalues*N*`	anyarray		Column data values of the appropriate kind for the `N` th slot, or NULL if the slot kind does not store any data values. Each array's element values are actually of the specific column's data type, or a related type such as an array's element type, so there is no way to define these columns' type more specifically than `anyarray`.

Parent topic: System Catalogs Definitions

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.8.3.70 pg_statistic_ext

The `pg_statistic_ext` system catalog table holds definitions of extended planner statistics. Each row in this catalog corresponds to a *statistics object* created with CREATE STATISTICS.

column	type	references	description
`oid`	oid		The object ID
`stxrelid`	oid	pg_class.oid	The table containing the columns described by this object
`stxname`	name		The name of the statistics object
`stxnamespace`	oid	pg_namespace.oid	The object identifier of the namespace that contains this statistics object
`stxowner`	oid	pg_authid.oid	The owner of the statistics object
`stxkeys`	int2vector	pg_attribute.oid	An array of attribute numbers, indicating which table columns are covered by this statistics object; for example, a value of `1 3` would mean that the first and the third table columns are covered
`stxkind`	char[]		An array containing codes for the enabled statistics kinds; valid values are: `d` for n-distinct statistics, `f` for functional dependency statistics, and `m` for most common values (MCV) list statistics

The `pg_statistic_ext` entry is filled in completely during `CREATE STATISTICS`, but the actual statistical values are not computed then. Subsequent `ANALYZE` commands compute the desired values and populate an entry in the pg_statistic_ext_data catalog.

Parent topic: System Catalogs Definitions

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.8.3.71 pg_statistic_ext_data

The `pg_statistic_ext_data` system catalog table holds data for extended planner statistics defined in pg_statistic_ext. Each row in this catalog corresponds to a *statistics object* created with CREATE STATISTICS.

Like `pg_statistic`, `pg_statistic_ext_data` should not be readable by the public, since the contents might be considered sensitive. (Example: most common combinations of values in columns might be quite interesting.) pg_stats_ext is a publicly readable view on `pg_statistic_ext_data` (after joining with `pg_statistic_ext`) that only exposes information about those tables and columns that are readable by the current user.

column	type	references	description
`stxoid`	oid	pg_statistic_ext.oid	The extended statistic object containing the definition for this data.
`stxdndistinct`	pg_ndistinct		N-distinct counts, serialized as `pg_ndistinct` type.
`stxddependencies`	pg_dependencies		Functional dependency statistics, serialized as `pg_dependencies` type.
`stxdmcv`	pg_mcv_list		MCV (most-common values) list statistics, serialized as `pg_mcv_list` type.

Parent topic: System Catalogs Definitions

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.8.3.72 pg_tablespace

The `pg_tablespace` system catalog table stores information about the available tablespaces. Tables can be placed in particular tablespaces to aid administration of disk layout. Unlike most system catalogs, `pg_tablespace` is shared across all databases of a WarehousePG cluster: there is only one copy of `pg_tablespace` per system, not one per database.

column	type	references	description
`oid`	oid		The object ID
`spcname`	name		Tablespace name.
`spcowner`	oid	pg_authid.oid	Owner of the tablespace, usually the user who created it.
`spcacl`	aclitem[]		Tablespace access privileges.
`spcoptions`	text[]		Tablespace contentID locations.

Parent topic: System Catalogs Definitions

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.8.3.73 pg_trigger

The `pg_trigger` system catalog table stores triggers on tables.

> **Note** WarehousePG does not support triggers.

column	type	references	description
`oid`	oid		The object ID
`tgrelid`	oid	*pg_class.oid* Note that WarehousePG does not enforce referential integrity.	The table this trigger is on.
`tgname`	name		Trigger name (must be unique among triggers of same table).
`tgfoid`	oid	*pg_proc.oid* Note that WarehousePG does not enforce referential integrity.	The function to be called.
`tgtype`	smallint		Bit mask identifying trigger conditions.
`tgenabled`	char		True if trigger is enabled.
`tgisinternal`	boolean		True if trigger is internally generated (usually, to enforce the constraint identified by tgconstraint).
`tgconstrrelid`	oid	*pg_class.oid* Note that WarehousePG does not enforce referential integrity.	The table referenced by an referential integrity constraint.
`tgconstrindid`	oid	*pg_class.oid*	The index supporting a unique, primary key, or referential integrity constraint.
`tgconstraint`	oid	*pg_constraint.oid*	The `pg_constraint` entry associated with the trigger, if any.
`tgdeferrable`	boolean		True if deferrable.
`tginitdeferred`	boolean		True if initially deferred.
`tgnargs`	smallint		Number of argument strings passed to trigger function.
`tgattr`	int2vector		Currently not used.
`tgargs`	bytea		Argument strings to pass to trigger, each NULL-terminated.
`tgqual`	pg_node_tree		Expression tree (in `nodeToString()` representation) for the trigger's `WHEN` condition, or null if none.
`tgoldtable`	name		The name of the old transition table, or NULL if none.
`tgnewtable`	name		The name of the new transition table, or NULL if none.

Parent topic: System Catalogs Definitions

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.8.3.74 pg_type

The `pg_type` system catalog table stores information about data types. Base types (scalar types) are created with `CREATE TYPE`, and domains with `CREATE DOMAIN`. A composite type is automatically created for each table in the database, to represent the row structure of the table. It is also possible to create composite types with `CREATE TYPE AS`.

column	type	references	description
`oid`	oid		Row identifier (hidden attribute; must be explicitly selected)
`typname`	name		Data type name
`typnamespace`	oid	pg_namespace.oid	The OID of the namespace that contains this type
`typowner`	oid	pg_authid.oid	Owner of the type
`typlen`	smallint		For a fixed-size type, `typlen` is the number of bytes in the internal representation of the type. But for a variable-length type, `typlen` is negative. `-1` indicates a 'varlena' type (one that has a length word), `-2` indicates a null-terminated C string.
`typbyval`	boolean		Determines whether internal routines pass a value of this type by value or by reference. `typbyval` had better be false if `typlen` is not 1, 2, or 4 (or 8 on machines where Datum is 8 bytes). Variable-length types are always passed by reference. Note that `typbyval` can be false even if the length would allow pass-by-value.
`typtype`	char		`b` for a base type, `c` for a composite type, `d` for a domain, `e` for an enum type, `p` for a pseudo-type, or `r` for a range type. See also `typrelid` and `typbasetype`.
`typcategory`	char		Arbitrary classification of data types that is used by the parser to determine which implicit casts should be preferred. SeeCategory Codes.
`typispreferred`	boolean		True if the type is a preferred cast target within its `typcategory`
`typisdefined`	boolean		True if the type is defined, false if this is a placeholder entry for a not-yet-defined type. When false, nothing except the type name, namespace, and OID can be relied on.
`typdelim`	char		Character that separates two values of this type when parsing array input. Note that the delimiter is associated with the array element data type, not the array data type.
`typrelid`	oid	pg_class.oid	If this is a composite type (see `typtype`), then this column points to the `pg_class` entry that defines the corresponding table. (For a free-standing composite type, the `pg_class` entry does not really represent a table, but it is needed anyway for the type's `pg_attribute` entries to link to.) Zero for non-composite types.
`typelem`	oid	pg_type.oid	If not `0` then it identifies another row in `pg_type`. The current type can then be subscripted like an array yielding values of type `typelem`. A "true" array type is variable length (`typlen` = `-1`), but some fixed-length (`typlen` > `0`) types also have nonzero `typelem`, for example `name` and `point`. If a fixed-length type has a `typelem` then its internal representation must be some number of values of the `typelem` data type with no other data. Variable-length array types have a header defined by the array subroutines.
`typarray`	oid	pg_type.oid	If not 0, identifies another row in `pg_type`, which is the "true" array type having this type as its element. Use `pg_type.typarray` to locate the array type associated with a specific type.
`typinput`	regproc	pg_proc.oid	Input conversion function (text format)
`typoutput`	regproc	pg_proc.oid	Output conversion function (text format)
`typreceive`	regproc	pg_proc.oid	Input conversion function (binary format), or 0 if none
`typsend`	regproc	pg_proc.oid	Output conversion function (binary format), or 0 if none
`typmodin`	regproc	pg_proc.oid	Type modifier input function, or 0 if the type does not support modifiers
`typmodout`	regproc	pg_proc.oid	Type modifier output function, or 0 to use the standard format
`typanalyze`	regproc	pg_proc.oid	Custom `ANALYZE` function, or 0 to use the standard function
`typalign`	char		The alignment required when storing a value of this type. It applies to storage on disk as well as most representations of the value inside WarehousePG. When multiple values are stored consecutively, such as in the representation of a complete row on disk, padding is inserted before a datum of this type so that it begins on the specified boundary. The alignment reference is the beginning of the first datum in the sequence. Possible values are: `c` = char alignment (no alignment needed). `s` = short alignment (2 bytes on most machines). `i` = int alignment (4 bytes on most machines). `d` = double alignment (8 bytes on many machines, but not all).
`typstorage`	char		For varlena types (those with `typlen` = -1) tells if the type is prepared for toasting and what the default strategy for attributes of this type should be. Possible values are: `p`: Value must always be stored plain. `e`: Value can be stored in a secondary relation (if relation has one, see `pg_class.reltoastrelid`). `m`: Value can be stored compressed inline. `x`: Value can be stored compressed inline or stored in secondary storage. Note that `m` columns can also be moved out to secondary storage, but only as a last resort (`e` and `x` columns are moved first).
`typnotnull`	boolean		Represents a not-null constraint on a type. Used for domains only.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

column	type	references	description
`typbasetype`	oid	pg_type.oid	Identifies the type that a domain is based on. Zero if this type is not a domain.
`typtypmod`	integer		Domains use `typtypmod` to record the `typmod` to be applied to their base type (-1 if base type does not use a `typmod`). -1 if this type is not a domain.
`typndims`	integer		The number of array dimensions for a domain over an array (if `typbasetype` is an array type). Zero for types other than domains over array types.
`typcollation`	oid	pg_collation.oid	Specifies the collation of the type. Zero if the type does not support collations. The value is `DEFAULT_COLLATION_OID` for a base type that supports collations. A domain over a collatable type can have some other collation OID if one was specified for the domain.
`typdefaultbin`	pg_node_tree		If not null, it is the `nodeToString()` representation of a default expression for the type. This is only used for domains.
`typdefault`	text		Null if the type has no associated default value. If `typdefaultbin` is not null, `typdefault` must contain a human-readable version of the default expression represented by `typdefaultbin`. If `typdefaultbin` is null and `typdefault` is not, then `typdefault` is the external representation of the type's default value, which may be fed to the type's input converter to produce a constant.
`typacl`	aclitem[]		Access privileges; see GRANT and REVOKE for details.

The following table lists the system-defined values of `typcategory`. Any future additions to this list will also be upper-case ASCII letters. All other ASCII characters are reserved for user-defined categories.

Code	Category
A	Array types
B	Boolean types
C	Composite types
D	Date/time types
E	Enum types
G	Geometric types
I	Network address types
N	Numeric types
P	Pseudo-types
R	Range types
S	String types
T	Timespan types
U	User-defined types
V	Bit-string types
X	`unknown` type

Parent topic: System Catalogs Definitions

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.8.3.75 pg_type_encoding

The `pg_type_encoding` system catalog table contains the column storage type information.

column	type	modifers	storage	description
`typeid`	oid	not null	plain	Foreign key to pg_attribute
`typoptions`	text [ ]		extended	The actual options

Parent topic: System Catalogs Definitions

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.8.3.76 pg_user_mapping

The system catalog table `pg_user_mapping` stores the mappings from local user to remote user. You must have administrator privileges to view this catalog. Access to this catalog is restricted from normal users, use the `pg_user_mappings` view instead.

column	type	references	description
`oid`	oid		The object ID
`umuser`	oid	pg_authid.oid	OID of the local role being mapped, 0 if the user mapping is public.
`umserver`	oid	pg_foreign_server.oid	OID of the foreign server that contains this mapping
`umoptions`	text[]		User mapping-specific options, as "keyword=value" strings.

Parent topic: System Catalogs Definitions

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.8.3.77 pg_user_mappings

The `pg_user_mappings` view provides access to information about user mappings. This view is essentially a public-readble view of the `pg_user_mapping` system catalog table that omits the options field if the user does not have access rights to view it.

column	type	references	description
`umid`	oid	pg_user_mapping.oid	OID of the user mapping.
`srvid`	oid	pg_foreign_server.oid	OID of the foreign server that contains this mapping.
`srvname`	text	pg_foreign_server.srvname	Name of the foreign server.
`umuser`	oid	pg_authid.oid	OID of the local role being mapped, 0 if the user mapping is public.
`usename`	name		Name of the local user to be mapped.
`umoptions`	text[]		User mapping-specific options, as "keyword=value" strings.

To protect password information stored as a user mapping option, the `umoptions` column reads as null unless one of the following applies:

- The current user is the user being mapped, and owns the server or holds `USAGE` privilege on it.
- The current user is the server owner and the mapping is for `PUBLIC`.
- The current user is a superuser.

Parent topic: System Catalogs Definitions

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.8.3.78 user_mapping_options

The `user_mapping_options` view contains all of the options defined for user mappings in the current database. WarehousePG displays only those user mappings to which the current user has access (by way of being the owner or having some privilege).

column	type	references	description
`authorization_identifier`	sql_identifier		Name of the user being mapped, or `PUBLIC` if the mapping is public.
`foreign_server_catalog`	sql_identifier		Name of the database in which the foreign server used by this mapping is defined (always the current database).
`foreign_server_name`	sql_identifier		Name of the foreign server used by this mapping.
`option_name`	sql_identifier		Name of an option.
`option_value`	character_data		Value of the option. This column will display null unless: - The current user is the user being mapped. - The mapping is for `PUBLIC` and the current user is the foreign server owner. - The current user is a superuser. The intent is to protect password information stored as a user mapping option.

Parent topic: System Catalogs Definitions

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.8.3.79 user_mappings

The `user_mappings` view contains all of the user mappings defined in the current database. WarehousePG displays only those user mappings to which the current user has access (by way of being the owner or having some privilege).

column	type	references	description
`authorization_identifier`	sql_identifier		Name of the user being mapped, or `PUBLIC` if the mapping is public.
`foreign_server_catalog`	sql_identifier		Name of the database in which the foreign server used by this mapping is defined (always the current database).
`foreign_server_name`	sql_identifier		Name of the foreign server used by this mapping.

Parent topic: System Catalogs Definitions

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.8.3.80 pg_sequence

The system catalog table `pg_sequence` contains information about sequences. Some information about sequences, such as the name and the schema, is stored in the`pg_class` system table.

column	type	references	description
`seqrelid`	oid	`pg_class.oid`	OID of the `pg_class` entry for this sequence
`seqtypid`	oid	`pg_type.oid`	Data type of the sequence
`seqstart`	bigint		Start value of the sequence
`seqincrement`	bigint		Increment value of the sequence
`seqmax`	bigint		Maximum value of the sequence
`seqmin`	bigint		Minimum value of the sequence
`seqcache`	bigint		Cache size of the sequence
`seqcycle`	boolean		Whether the sequence cycles

Parent topic: System Catalogs Definitions

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.8.4 System Catalog Functions

WarehousePG provides the following system catalog functions:

> **Note** This list is provisional and may be incomplete.

- gp_get_suboverflowed_backends
- pg_stat_get_backend_subxact

Statistics Functions

The following functions support collection and reporting of information about server activity.

gp_get_suboverflowed_backends

`gp_get_suboverflowed_backends()` return type is `integer[]`.

Returns an array of integers which indicate the process IDs of all the sessions in which a backend has subtransaction overflows on the running segment. For a cluster-wide view of the suboverflowed backends on every segment, use the view gp_suboverflowed_backend.

pg_stat_get_backend_subxacts

`pg_stat_get_backend_subxact(integer)` return type is `record`.

Returns a record of information about the subtransactions of the backend with the specified ID. The fields returned are `subxact_count`, which is the number of subtransactions in the backend's subtransaction cache, and `subxact_overflow`, which indicates whether the backend's subtransaction cache is overflowed or not.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.9 The gp_toolkit Administrative Schema

WarehousePG provides an administrative schema called `gp_toolkit` that you can use to query the system catalogs, log files, and operating environment for system status information. The `gp_toolkit` schema contains a number of views that you can access using SQL commands. The `gp_toolkit` schema is accessible to all database users, although some objects may require superuser permissions. For convenience, you may want to add the `gp_toolkit` schema to your schema search path. For example:

```
=> ALTER ROLE myrole SET search_path TO myschema,gp_toolkit;
```

This documentation describes the most useful views and user-defined functions (UDFs) in `gp_toolkit`. You may notice other objects (views, functions, and external tables) within the `gp_toolkit` schema that are not described in this documentation (these are supporting objects to the views described in this section).

> **Caution** Do not change database objects in the gp_toolkit schema. Do not create database objects in the schema. Changes to objects in the schema might affect the accuracy of administrative information returned by schema objects. Any changes made in the gp_toolkit schema are lost when the database is backed up and then restored with the `gpbackup` and `gprestore` utilities.

These are the categories for views in the `gp_toolkit` schema.

- Checking for Tables that Need Routine Maintenance
- Checking for Locks
- Checking Append-Optimized Tables
- Viewing WarehousePG Server Log Files
- Checking Server Configuration Files
- Checking for Failed Segments
- Checking Resource Group Activity and Status
- Checking Resource Queue Activity and Status
- Checking Query Disk Spill Space Usage
- Viewing Users and Groups (Roles)
- Checking Database Object Sizes and Disk Space
- Checking for Missing and Orphaned Data Files
- Moving Orphaned Data Files
- Checking for Uneven Data Distribution
- Maintaining Partitions

About the Extension

`gp_toolkit` is implemented as an extension in WarehousePG 7. Because this extension is registered in the `template1` database, it is both registered an immediately available to use in every WarehousePG that you create.

Upgrading the Extension

The `gp_toolkit` extension is installed when you install or upgrade WarehousePG. A previous version of the extension will continue to work in existing databases after you upgrade WarehousePG. To upgrade to the most recent version of the extension, you must:

```
ALTER EXTENSION gp_toolkit UPDATE TO '1.4';
```

in **every** database in which you use the extension.

Checking for Tables that Need Routine Maintenance

The following views can help identify tables that need routine table maintenance (`VACUUM` and/or `ANALYZE`).

- gp_bloat_diag
- gp_stats_missing

The `VACUUM` or `VACUUM FULL` command reclaims disk space occupied by deleted or obsolete rows. Because of the MVCC transaction concurrency model used in WarehousePG, data rows that are deleted or updated still occupy physical space on disk even though they are not visible to any new transactions. Expired rows increase table size on disk and eventually slow down scans of the table.

The `ANALYZE` command collects column-level statistics needed by the query optimizer. WarehousePG uses a cost-based query optimizer that relies on database statistics. Accurate statistics allow the query optimizer to better estimate selectivity and the number of rows retrieved by a query operation in order to choose the most efficient query plan.

Parent topic: The gp_toolkit Administrative Schema

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

gp_bloat_diag

This view shows regular heap-storage tables that have bloat (the actual number of pages on disk exceeds the expected number of pages given the table statistics). Tables that are bloated require a `VACUUM` or a `VACUUM FULL` in order to reclaim disk space occupied by deleted or obsolete rows. This view is accessible to all users, however non-superusers will only be able to see the tables that they have permission to access.

> **Note** For diagnostic functions that return append-optimized table information, see Checking Append-Optimized Tables.

Column	Description
bdirelid	Table object id.
bdinspname	Schema name.
bdirelname	Table name.
bdirelpages	Actual number of pages on disk.
bdiexppages	Expected number of pages given the table data.
bdidiag	Bloat diagnostic message.

gp_stats_missing

This view shows tables that do not have statistics and therefore may require an `ANALYZE` be run on the table.

Column	Description
smischema	Schema name.
smitable	Table name.
smisize	Does this table have statistics? False if the table does not have row count and row sizing statistics recorded in the system catalog, which may indicate that the table needs to be analyzed. This will also be false if the table does not contain any rows. For example, the parent tables of partitioned tables are always empty and will always return a false result.
smicols	Number of columns in the table.
smirecs	The total number of columns in the table that have statistics recorded.

Checking for Locks

When a transaction accesses a relation (such as a table), it acquires a lock. Depending on the type of lock acquired, subsequent transactions may have to wait before they can access the same relation. For more information on the types of locks, see the Managing Datatopic. WarehousePG resource queues (used for resource management) also use locks to control the admission of queries into the system.

The `gp_locks_*` family of views can help diagnose queries and sessions that are waiting to access an object due to a lock.

- gp_locks_on_relation
- gp_locks_on_resqueue

Parent topic: The gp_toolkit Administrative Schema

gp_locks_on_relation

This view shows any locks currently being held on a relation, and the associated session information about the query associated with the lock. For more information on the types of locks, see theManaging Data topic. This view is accessible to all users, however non-superusers will only be able to see the locks for relations that they have permission to access.

Column	Description
lorlocktype	Type of the lockable object: `relation`, `extend`, `page`, `tuple`, `transactionid`, `object`, `userlock`, `resource queue`, or `advisory`
lordatabase	Object ID of the database in which the object exists, zero if the object is a shared object.
lorrelname	The name of the relation.
lorrelation	The object ID of the relation.
lortransaction	The transaction ID that is affected by the lock.
lorpid	Process ID of the server process holding or awaiting this lock. NULL if the lock is held by a prepared transaction.
lormode	Name of the lock mode held or desired by this process.
lorgranted	Displays whether the lock is granted (true) or not granted (false).
lorcurrentquery	The current query in the session.

gp_locks_on_resqueue

> **Note** The `gp_locks_on_resqueue` view is valid only when resource queue-based resource management is active.

This view shows any locks currently being held on a resource queue, and the associated session information about the query associated with the lock. This view is accessible to all users, however non-superusers will only be able to see the locks associated with their own sessions.

Column	Description
lorusename	Name of the user running the session.
lorrsqname	The resource queue name.
lorlocktype	Type of the lockable object: `resource queue`
lorobjid	The ID of the locked transaction.
lortransaction	The ID of the transaction that is affected by the lock.
lorpid	The process ID of the transaction that is affected by the lock.
lormode	The name of the lock mode held or desired by this process.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Column	Description
lorgranted	Displays whether the lock is granted (true) or not granted (false).
lorwaiting	Displays whether or not the session is waiting.

Checking Append-Optimized Tables

The `gp_toolkit` schema includes a set of diagnostic functions you can use to investigate the state of append-optimized tables.

When an append-optimized table (or column-oriented append-optimized table) is created, another table is implicitly created, containing metadata about the current state of the table. The metadata includes information such as the number of records in each of the table's segments.

Append-optimized tables may have non-visible rows—rows that have been updated or deleted, but remain in storage until the table is compacted using `VACUUM`. The hidden rows are tracked using an auxiliary visibility map table, or visimap.

The following functions let you access the metadata for append-optimized and column-oriented tables and view non-visible rows.

For most of the functions, the input argument is `regclass`, either the table `name` or the `oid` of a table.

Parent topic: The gp_toolkit Administrative Schema

__gp_aovisimap_compaction_info(oid)

This function displays compaction information for an append-optimized table. The information is for the on-disk data files on database segments that store the table data. You can use the information to determine the data files that will be compacted by a `VACUUM` operation on an append-optimized table.

> **Note** Until a VACUUM operation deletes the row from the data file, deleted or updated data rows occupy physical space on disk even though they are hidden to new transactions. The configuration parameter gp_appendonly_compaction controls the functionality of the `VACUUM` command.

This table describes the __gp_aovisimap_compaction_info function output table.

Column	Description
content	Database segment ID.
datafile	ID of the data file on the segment.
compaction_possible	The value is either `t` or `f`. The value `t` indicates that the data in data file be compacted when a VACUUM operation is performed. The server configuration parameter `gp_appendonly_compaction_threshold` affects this value.
hidden_tupcount	In the data file, the number of hidden (deleted or updated) rows.
total_tupcount	In the data file, the total number of rows.
percent_hidden	In the data file, the ratio (as a percentage) of hidden (deleted or updated) rows to total rows.

__gp_aoseg(regclass)

This function returns metadata information contained in the append-optimized table's on-disk segment file.

The input argument is the name or the oid of an append-optimized table.

Column	Description
segno	The file segment number.
eof	The effective end of file for this file segment.
tupcount	The total number of tuples in the segment, including invisible tuples.
varblockcount	The total number of varblocks in the file segment.
eof_uncompressed	The end of file if the file segment were uncompressed.
modcount	The number of data modification operations.
state	The state of the file segment. Indicates if the segment is active or ready to be dropped after compaction.

__gp_aoseg_history(regclass)

This function returns metadata information contained in the append-optimized table's on-disk segment file. It displays all different versions (heap tuples) of the aoseg meta information. The data is complex, but users with a deep understanding of the system may find it useful for debugging.

The input argument is the name or the oid of an append-optimized table.

Column	Description
gp_tid	The id of the tuple.
gp_xmin	The id of the earliest transaction.
gp_xmin_status	Status of the gp_xmin transaction.
gp_xmin_commit_	The commit distribution id of the gp_xmin transaction.
gp_xmax	The id of the latest transaction.
gp_xmax_status	The status of the latest transaction.
gp_xmax_commit_	The commit distribution id of the gp_xmax transaction.
gp_command_id	The id of the query command.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Column	Description
gp_infomask	A bitmap containing state information.
gp_update_tid	The ID of the newer tuple if the row is updated.
gp_visibility	The tuple visibility status.
segno	The number of the segment in the segment file.
tupcount	The number of tuples, including hidden tuples.
eof	The effective end of file for the segment.
eof_uncompressed	The end of file for the segment if data were uncompressed.
modcount	A count of data modifications.
state	The status of the segment.

__gp_aocsseg(regclass)

This function returns metadata information contained in a column-oriented append-optimized table's on-disk segment file, excluding non-visible rows. Each row describes a segment for a column in the table.

The input argument is the name or the oid of a column-oriented append-optimized table.

Column	Description
gp_tid	The table id.
segno	The segment number.
column_num	The column number.
physical_segno	The number of the segment in the segment file.
tupcount	The number of rows in the segment, excluding hidden tuples.
eof	The effective end of file for the segment.
eof_uncompressed	The end of file for the segment if the data were uncompressed.
modcount	A count of data modification operations for the segment.
state	The status of the segment.

__gp_aocsseg_history(regclass)

This function returns metadata information contained in a column-oriented append-optimized table's on-disk segment file. Each row describes a segment for a column in the table. The data is complex, but users with a deep understanding of the system may find it useful for debugging.

The input argument is the name or the oid of a column-oriented append-optimized table.

Column	Description
gp_tid	The oid of the tuple.
gp_xmin	The earliest transaction.
gp_xmin_status	The status of the gp_xmin transaction.
gp_xmin_	Text representation of gp_xmin.
gp_xmax	The latest transaction.
gp_xmax_status	The status of the gp_xmax transaction.
gp_xmax_	Text representation of gp_max.
gp_command_id	ID of the command operating on the tuple.
gp_infomask	A bitmap containing state information.
gp_update_tid	The ID of the newer tuple if the row is updated.
gp_visibility	The tuple visibility status.
segno	The segment number in the segment file.
column_num	The column number.
physical_segno	The segment containing data for the column.
tupcount	The total number of tuples in the segment.
eof	The effective end of file for the segment.
eof_uncompressed	The end of file for the segment if the data were uncompressed.
modcount	A count of the data modification operations.
state	The state of the segment.

__gp_aovisimap(regclass)

This function returns the tuple ID, the segment file, and the row number of each non-visible tuple according to the visibility map.

The input argument is the name or the oid of an append-optimized table.

Column	Description
tid	The tuple id.
segno	The number of the segment file.
row_num	The row number of a row that has been deleted or updated.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

__gp_aovisimap_hidden_info(regclass)

This function returns the numbers of hidden and visible tuples in the segment files for an append-optimized table.

The input argument is the name or the oid of an append-optimized table.

Column	Description
segno	The number of the segment file.
hidden_tupcount	The number of hidden tuples in the segment file.
total_tupcount	The total number of tuples in the segment file.

__gp_aovisimap_entry(regclass)

This function returns information about each visibility map entry for the table.

The input argument is the name or the oid of an append-optimized table.

Column	Description
segno	Segment number of the visibility map entry.
first_row_num	The first row number of the entry.
hidden_tupcount	The number of hidden tuples in the entry.
bitmap	A text representation of the visibility bitmap.

__gp_aoblkdir(regclass)

For a given AO/AOCO table that had or has an index, this function returns a row for each block directory entry recorded in the block directory relation; it flattens the `minipage` column of block directory relations and returns a row for each `minipage` entry.

The input argument is the name or the oid of an append-optimized table.

You must execute this function in utility mode against every segment, or with `gp_dist_random()` as shown here:

```
SELECT
(gp_toolkit.__gp_aoblkdir('<table_name>')).*
    FROM gp_dist_random('gp_id');
```

Column	Description
tupleid	The tuple id of the block directory row containing this block directory entry.
segno	The physical segment file number.
columngroup_no	The `attnum` of the column described by this `minipage` entry (always `0` for row-oriented tables).
entry_no	The entry serial number inside this `minipage` containing this block directory entry.
first_row_no	The first row number of the rows covered by this block directory entry.
file_offset	The starting file offset of the rows covered by this block directory entry.
row_count	The count of rows covered by this block directory entry.

get_column_size(oid)

For a given AOCO table, this function returns the column size and compression ratio for all columns in the table.

The input argument is the object identifier of a column-oriented append-optimized table.

Column	Description
segment	The segment id.
attnum	The attribute number of the column.
size	The size of the column in bytes.
size_uncompressed	The size of the column in bytes if the column was not compressed.
compression_ratio	The compression ratio.

gp_column_size

This view gathers the column size and compression ratio for column-oriented append-optimized tables from all segments.

Column	Description
relname	The table name.
segment	The segment id.
attnum	The attribute number of the column.
attname	The column name.
size	The size of the column in bytes.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Column	Description
size_uncompressed	The size of the column in bytes if the column was not compressed.
compression_ratio	The compression ratio.

gp_column_size_summary

This view shows a summary of the `gp_column_size` view. It aggregates the column size and compression ratio for each column in each column-oriented append-optimized table from all segments.

Column	Description
relname	The table name.
attnum	The attribute number of the column.
size	The size of the column in bytes.
size_uncompressed	The size of the column in bytes if the column were uncompressed.
compression_ratio	The compression ratio.

Viewing WarehousePG Server Log Files

Each component of a WarehousePG cluster (coordinator, standby coordinator, primary segments, and mirror segments) keeps its own server log files. The `gp_log_*` family of views allows you to issue SQL queries against the server log files to find particular entries of interest. The use of these views require superuser permissions.

- gp_log_command_timings
- gp_log_database
- gp_log_coordinator_concise
- gp_log_system

Parent topic: The gp_toolkit Administrative Schema

gp_log_command_timings

This view uses an external table to read the log files on the coordinator and report the run time of SQL commands in a database session. The use of this view requires superuser permissions.

Column	Description
logsession	The session identifier (prefixed with "con").
logcmdcount	The command number within a session (prefixed with "cmd").
logdatabase	The name of the database.
loguser	The name of the database user.
logpid	The process id (prefixed with "p").
logtimemin	The time of the first log message for this command.
logtimemax	The time of the last log message for this command.
logduration	Statement duration from start to end time.

gp_log_database

This view uses an external table to read the server log files of the entire WarehousePG cluster (coordinator, segments, and mirrors) and lists log entries associated with the current database. Associated log entries can be identified by the session id (logsession) and command id (logcmdcount). The use of this view requires superuser permissions.

Column	Description
logtime	The timestamp of the log message.
loguser	The name of the database user.
logdatabase	The name of the database.
logpid	The associated process id (prefixed with "p").
logthread	The associated thread count (prefixed with "th").
loghost	The segment or coordinator host name.
logport	The segment or coordinator port.
logsessiontime	Time session connection was opened.
logtransaction	Global transaction id.
logsession	The session identifier (prefixed with "con").
logcmdcount	The command number within a session (prefixed with "cmd").
logsegment	The segment content identifier (prefixed with "seg" for primary or "mir" for mirror. The coordinator always has a content id of -1).
logslice	The slice id (portion of the query plan being run).
logdistxact	Distributed transaction id.
loglocalxact	Local transaction id.
logsubxact	Subtransaction id.
logseverity	LOG, ERROR, FATAL, PANIC, DEBUG1 or DEBUG2.
logstate	SQL state code associated with the log message.
logmessage	Log or error message text.
logdetail	Detail message text associated with an error message.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Column	Description
loghint	Hint message text associated with an error message.
logquery	The internally-generated query text.
logquerypos	The cursor index into the internally-generated query text.
logcontext	The context in which this message gets generated.
logdebug	Query string with full detail for debugging.
logcursorpos	The cursor index into the query string.
logfunction	The function in which this message is generated.
logfile	The log file in which this message is generated.
logline	The line in the log file in which this message is generated.
logstack	Full text of the stack trace associated with this message.

gp_log_coordinator_concise

This view uses an external table to read a subset of the log fields from the coordinator log file. The use of this view requires superuser permissions.

Column	Description
logtime	The timestamp of the log message.
logdatabase	The name of the database.
logsession	The session identifier (prefixed with "con").
logcmdcount	The command number within a session (prefixed with "cmd").
logseverity	The log severity level.
logmessage	Log or error message text.

gp_log_system

This view uses an external table to read the server log files of the entire WarehousePG cluster (coordinator, segments, and mirrors) and lists all log entries. Associated log entries can be identified by the session id (logsession) and command id (logcmdcount). The use of this view requires superuser permissions.

Column	Description
logtime	The timestamp of the log message.
loguser	The name of the database user.
logdatabase	The name of the database.
logpid	The associated process id (prefixed with "p").
logthread	The associated thread count (prefixed with "th").
loghost	The segment or coordinator host name.
logport	The segment or coordinator port.
logsessiontime	Time session connection was opened.
logtransaction	Global transaction id.
logsession	The session identifier (prefixed with "con").
logcmdcount	The command number within a session (prefixed with "cmd").
logsegment	The segment content identifier (prefixed with "seg" for primary or "mir" for mirror. The coordinator always has a content id of -1).
logslice	The slice id (portion of the query plan being run).
logdistxact	Distributed transaction id.
loglocalxact	Local transaction id.
logsubxact	Subtransaction id.
logseverity	LOG, ERROR, FATAL, PANIC, DEBUG1 or DEBUG2.
logstate	SQL state code associated with the log message.
logmessage	Log or error message text.
logdetail	Detail message text associated with an error message.
loghint	Hint message text associated with an error message.
logquery	The internally-generated query text.
logquerypos	The cursor index into the internally-generated query text.
logcontext	The context in which this message gets generated.
logdebug	Query string with full detail for debugging.
logcursorpos	The cursor index into the query string.
logfunction	The function in which this message is generated.
logfile	The log file in which this message is generated.
logline	The line in the log file in which this message is generated.
logstack	Full text of the stack trace associated with this message.

Checking Server Configuration Files

Each component of a WarehousePG cluster (coordinator, standby coordinator, primary segments, and mirror segments) has its own server configuration file (`postgresql.conf`). The following `gp_toolkit` objects can be used to check parameter settings across all primary `postgresql.conf` files in the system:

- gp_param_setting('parameter_name')
- gp_param_settings_seg_value_diffs

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Parent topic: The gp_toolkit Administrative Schema

gp_param_setting('parameter_name')

This function takes the name of a server configuration parameter and returns the `postgresql.conf` value for the coordinator and each active segment. This function is accessible to all users.

Column	Description
paramsegment	The segment content id (only active segments are shown). The coordinator content id is always -1.
paramname	The name of the parameter.
paramvalue	The value of the parameter.

Example:

```
SELECT * FROM gp_param_setting('max_connections');
```

gp_param_settings_seg_value_diffs

Server configuration parameters that are classified as *local* parameters (meaning each segment gets the parameter value from its own `postgresql.conf` file), should be set identically on all segments. This view shows local parameter settings that are inconsistent. Parameters that are supposed to have different values (such as `port`) are not included. This view is accessible to all users.

Column	Description
psdname	The name of the parameter.
psdvalue	The value of the parameter.
psdcount	The number of segments that have this value.

Checking for Failed Segments

The gp_pgdatabase_invalid view can be used to check for down segments.

Parent topic: The gp_toolkit Administrative Schema

gp_pgdatabase_invalid

This view shows information about segments that are marked as down in the system catalog. This view is accessible to all users.

Column	Description
pgdbidbid	The segment dbid. Every segment has a unique dbid.
pgdbiisprimary	Is the segment currently acting as the primary (active) segment? (t or f)
pgdbicontent	The content id of this segment. A primary and mirror will have the same content id.
pgdbivalid	Is this segment up and valid? (t or f)
pgdbidefinedprimary	Was this segment assigned the role of primary at system initialization time? (t or f)

Checking Resource Group Activity and Status

> **Note** The resource group activity and status views described in this section are valid only when resource group-based resource management is active.

Resource groups manage transactions to avoid exhausting system CPU and memory resources. Every database user is assigned a resource group. WarehousePG evaluates every transaction submitted by a user against the limits configured for the user's resource group before running the transaction.

You can use the `gp_resgroup_config` view to check the configuration of each resource group. You can use the `gp_resgroup_status*` views to display the current transaction status and resource usage of each resource group.

- gp_resgroup_config
- gp_resgroup_role
- gp_resgroup_status
- gp_resgroup_status_per_host

Parent topic: The gp_toolkit Administrative Schema

gp_resgroup_config

The `gp_resgroup_config` view allows administrators to see the current CPU, memory, and concurrency limits for a resource group.

This view is accessible to all users.

Column	Description
groupid	The ID of the resource group.
groupname	The name of the resource group.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Column	Description
concurrency	The concurrency (`CONCURRENCY`) value specified for the resource group.
cpu_max_percent	The CPU limit (`CPU_MAX_PERCENT`) value specified for the resource group, or `-1`.
cpu_weight	The scheduling priority of the resource group (CPU_WEIGHT).
cpuset	The CPU cores reserved for the resource group (CPUSET), or `-1`.
memory_quota	The memory quota (`MEMORY_QUOTA`) value specified for the resource group.
min_cost	The minimum cost of a query plan to be included in the resource group (MIN_COST).
io_limit	The maximum read/write sequential disk I/O throughput, and the maximum read/write I/O operations per second for the queries assigned to a specific tablespace (shown as the tablespace oid) and resource group (IO_LIMIT).

gp_resgroup_role

The `gp_resgroup_role` view allows administrators to see the resource group assigned to every role.

This view is accessible to all users.

Column	Description
rrrolname	The name of the role
rrrsgname	The name of the resource group

gp_resgroup_status

The `gp_resgroup_status` view allows administrators to see status and activity for a resource group. It shows how many queries are waiting to run and how many queries are currently active in the system for each resource group. The view also displays current memory and CPU usage for the resource group.

> **Note** Resource groups use the Linux control groups (cgroups) configured on the host systems. The cgroups are used to manage host system resources. When resource groups use cgroups that are as part of a nested set of cgroups, resource group limits are relative to the parent cgroup allotment. For information about nested cgroups and WarehousePG resource group limits, see Using Resource Groups.

This view is accessible to all users.

Column	Description
rsgname	The name of the resource group.
groupid	The ID of the resource group.
num_running	The number of transactions currently running in the resource group.
num_queueing	The number of currently queued transactions for the resource group.
num_queued	The total number of queued transactions for the resource group since the WarehousePG cluster was last started, excluding the num_queueing.
num_executed	The total number of transactions run in the resource group since the WarehousePG cluster was last started, excluding the num_running.
total_queue_duration	The total time any transaction was queued since the WarehousePG cluster was last started.

Sample output for the `gp_resgroup_status` view:

```
select * from gp_toolkit.gp_resgroup_status;
 rsgname       | groupid | num_running | num_queueing | num_queued | num_executed | total_queue_duration |
---------------+---------+-------------+--------------+------------+--------------+----------------------------------------------------------------------------
 default_group | 6437    | 0           | 0            | 0          | 0            | @ 0                  |
 admin_group   | 6438    | 1           | 0            | 0          | 13           | @ 0                  |
 system_group  | 6441    | 0           | 0            | 0          | 0            | @ 0                  |
(3 rows)
```

gp_resgroup_status_per_host

The gp_resgroup_status_per_host view displays the real-time CPU and memory usage (MBs) for each resource group on a per-host basis. The view also displays available and granted group fixed and shared memory for each resource group on a host.

Column	Description
`rsgname`	The name of the resource group.
`groupid`	The ID of the resource group.
`hostname`	The hostname of the segment host.
`cpu_usage`	The real-time CPU core usage by the resource group on a host. The value is the sum of the percentages (as a float value) of the CPU cores that are used by the resource group on the host.
`memory_usage`	The real-time memory usage of the resource group on each database segment's host, in MB.

Sample output for the `gp_resgroup_status_per_host` view:

```
select * from gp_toolkit.gp_resgroup_status_per_host;
 rsgname       | groupid | hostname | cpu_usage | memory_usage
---------------+---------+----------+-----------+--------------
 admin_group   | 6438    | zero     | 0.07      | 91.92
 default_group | 6437    | zero     | 0.00      | 0.00
 system_group  | 6441    | zero     | 0.02      | 53.04
(3 rows)
```

Checking Resource Queue Activity and Status

> **Note** The resource queue activity and status views described in this section are valid only when resource queue-based resource management is active.

The purpose of resource queues is to limit the number of active queries in the system at any given time in order to avoid exhausting system resources such as memory, CPU, and disk I/O. All database users are assigned to a resource queue, and every statement submitted by a user is first evaluated against the resource queue limits before it can run. The `gp_resq_*` family of views can be used to check the status of statements currently submitted to the system through their respective resource queue. Note that statements issued by superusers are exempt from resource queuing.

- gp_resq_activity
- gp_resq_activity_by_queue
- gp_resq_priority_statement
- gp_resq_role
- gp_resqueue_status

Parent topic: The gp_toolkit Administrative Schema

gp_resq_activity

For the resource queues that have active workload, this view shows one row for each active statement submitted through a resource queue. This view is accessible to all users.

Column	Description
resqprocpid	Process ID assigned to this statement (on the coordinator).
resqrole	User name.
resqoid	Resource queue object id.
resqname	Resource queue name.
resqstart	Time statement was issued to the system.
resqstatus	Status of statement: running, waiting or cancelled.

gp_resq_activity_by_queue

For the resource queues that have active workload, this view shows a summary of queue activity. This view is accessible to all users.

Column	Description
resqoid	Resource queue object id.
resqname	Resource queue name.
resqlast	Time of the last statement issued to the queue.
resqstatus	Status of last statement: running, waiting or cancelled.
resqtotal	Total statements in this queue.

gp_resq_priority_statement

This view shows the resource queue priority, session ID, and other information for all statements currently running in the WarehousePG cluster. This view is accessible to all users.

Column	Description
rqpdatname	The database name that the session is connected to.
rqpusename	The user who issued the statement.
rqpsession	The session ID.
rqpcommand	The number of the statement within this session (the command id and session id uniquely identify a statement).
rqppriority	The resource queue priority for this statement (MAX, HIGH, MEDIUM, LOW).
rqpweight	An integer value associated with the priority of this statement.
rqpquery	The query text of the statement.

gp_resq_role

This view shows the resource queues associated with a role. This view is accessible to all users.

Column	Description
rrrolname	Role (user) name.
rrrsqname	The resource queue name assigned to this role. If a role has not been explicitly assigned to a resource queue, it will be in the default resource queue (*pg_default*).

gp_resqueue_status

This view allows administrators to see status and activity for a resource queue. It shows how many queries are waiting to run and how many queries are currently active in the system from a particular resource queue.

Column	Description
`queueid`	The ID of the resource queue.
`rsqname`	The name of the resource queue.
`rsqcountlimit`	The active query threshold of the resource queue. A value of -1 means no limit.
`rsqcountvalue`	The number of active query slots currently being used in the resource queue.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Column	Description
rsqcostlimit	The query cost threshold of the resource queue. A value of -1 means no limit.
rsqcostvalue	The total cost of all statements currently in the resource queue.
rsqmemorylimit	The memory limit for the resource queue.
rsqmemoryvalue	The total memory used by all statements currently in the resource queue.
rsqwaiters	The number of statements currently waiting in the resource queue.
rsqholders	The number of statements currently running on the system from this resource queue.

Checking Query Disk Spill Space Usage

The *gp_workfile_** views show information about all the queries that are currently using disk spill space. WarehousePG creates work files on disk if it does not have sufficient memory to run the query in memory. This information can be used for troubleshooting and tuning queries. The information in the views can also be used to specify the values for the WarehousePG configuration parameters `gp_workfile_limit_per_query` and `gp_workfile_limit_per_segment`.

- gp_workfile_entries
- gp_workfile_usage_per_query
- gp_workfile_usage_per_segment

Parent topic: The gp_toolkit Administrative Schema

gp_workfile_entries

This view contains one row for each operator using disk space for workfiles on a segment at the current time. The view is accessible to all users, however non-superusers only to see information for the databases that they have permission to access.

Column	Type	References	Description
datname	name		Database name.
pid	integer		Process ID of the server process.
sess_id	integer		Session ID.
command_cnt	integer		Command ID of the query.
usename	name		Role name.
query	text		Current query that the process is running.
segid	integer		Segment ID.
slice	integer		The query plan slice. The portion of the query plan that is being run.
optype	text		The query operator type that created the work file.
size	bigint		The size of the work file in bytes.
numfiles	integer		The number of files created.
prefix	text		Prefix used when naming a related set of workfiles.

gp_workfile_usage_per_query

This view contains one row for each query using disk space for workfiles on a segment at the current time. The view is accessible to all users, however non-superusers only to see information for the databases that they have permission to access.

Column	Type	References	Description
datname	name		Database name.
pid	integer		Process ID of the server process.
sess_id	integer		Session ID.
command_cnt	integer		Command ID of the query.
usename	name		Role name.
query	text		Current query that the process is running.
segid	integer		Segment ID.
size	numeric		The size of the work file in bytes.
numfiles	bigint		The number of files created.

gp_workfile_usage_per_segment

This view contains one row for each segment. Each row displays the total amount of disk space used for workfiles on the segment at the current time. The view is accessible to all users, however non-superusers only to see information for the databases that they have permission to access.

Column	Type	References	Description
segid	smallint		Segment ID.
size	numeric		The total size of the work files on a segment.
numfiles	bigint		The number of files created.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Viewing Users and Groups (Roles)

It is frequently convenient to group users (roles) together to ease management of object privileges: that way, privileges can be granted to, or revoked from, a group as a whole. In WarehousePG, this is done by creating a role that represents the group, and then granting membership in the group role to individual user roles.

The gp_roles_assigned view can be used to see all of the roles in the system, and their assigned members (if the role is also a group role).

Parent topic: The gp_toolkit Administrative Schema

gp_roles_assigned

This view shows all of the roles in the system, and their assigned members (if the role is also a group role). This view is accessible to all users.

Column	Description
raroleid	The role object ID. If this role has members (users), it is considered a *group* role.
rarolename	The role (user or group) name.
ramemberid	The role object ID of the role that is a member of this role.
ramembername	Name of the role that is a member of this role.

Checking Database Object Sizes and Disk Space

The `gp_size_*` family of views can be used to determine the disk space usage for a distributed WarehousePG, schema, table, or index. The following views calculate the total size of an object across all primary segments (mirrors are not included in the size calculations).

- gp_size_of_all_table_indexes
- gp_size_of_database
- gp_size_of_index
- gp_size_of_schema_disk
- gp_size_of_table_and_indexes_disk
- gp_size_of_table_and_indexes_licensing
- gp_size_of_table_disk
- gp_size_of_table_uncompressed
- gp_disk_free

The table and index sizing views list the relation by object ID (not by name). To check the size of a table or index by name, you must look up the relation name (`relname`) in the `pg_class` table. For example:

```
SELECT relname as name, sotdsize as size, sotdtoastsize as
toast, sotdadditionalsize as other
FROM gp_size_of_table_disk as sotd, pg_class
WHERE sotd.sotdoid=pg_class.oid ORDER BY relname;
```

Parent topic: The gp_toolkit Administrative Schema

gp_size_of_all_table_indexes

This view shows the total size of all indexes for a table. This view is accessible to all users, however non-superusers will only be able to see relations that they have permission to access.

Column	Description
soatioid	The object ID of the table
soatisize	The total size of all table indexes in bytes
soatischemaname	The schema name
soatitablename	The table name

gp_size_of_database

This view shows the total size of a database. This view is accessible to all users, however non-superusers will only be able to see databases that they have permission to access.

Column	Description
sodddatname	The name of the database
sodddatsize	The size of the database in bytes

gp_size_of_index

This view shows the total size of an index. This view is accessible to all users, however non-superusers will only be able to see relations that they have permission to access.

Column	Description
soioid	The object ID of the index
soitableoid	The object ID of the table to which the index belongs
soisize	The size of the index in bytes
soiindexschemaname	The name of the index schema
soiindexname	The name of the index

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Column	Description
soitableschemaname	The name of the table schema
soitablename	The name of the table

gp_size_of_schema_disk

This view shows schema sizes for the public schema and the user-created schemas in the current database. This view is accessible to all users, however non-superusers will be able to see only the schemas that they have permission to access.

Column	Description
sosdnsp	The name of the schema
sosdschematablesize	The total size of tables in the schema in bytes
sosdschemaidxsize	The total size of indexes in the schema in bytes

gp_size_of_table_and_indexes_disk

This view shows the size on disk of tables and their indexes. This view is accessible to all users, however non-superusers will only be able to see relations that they have permission to access.

Column	Description
sotaidoid	The object ID of the parent table
sotaidtablesize	The disk size of the table
sotaididxsize	The total size of all indexes on the table
sotaidschemaname	The name of the schema
sotaidtablename	The name of the table

gp_size_of_table_and_indexes_licensing

This view shows the total size of tables and their indexes for licensing purposes. The use of this view requires superuser permissions.

Column	Description
sotailoid	The object ID of the table
sotailtablesizedisk	The total disk size of the table
sotailtablesizeuncompressed	If the table is a compressed append-optimized table, shows the uncompressed table size in bytes.
sotailindexessize	The total size of all indexes in the table
sotailschemaname	The schema name
sotailtablename	The table name

gp_size_of_table_disk

This view shows the size of a table on disk. This view is accessible to all users, however non-superusers will only be able to see tables that they have permission to access

Column	Description
sotdoid	The object ID of the table
sotdsize	The size of the table in bytes. The size is only the main table size. The size does not include auxiliary objects such as oversized (toast) attributes, or additional storage objects for AO tables.
sotdtoastsize	The size of the TOAST table (oversized attribute storage), if there is one.
sotdadditionalsize	Reflects the segment and block directory table sizes for append-optimized (AO) tables.
sotdschemaname	The schema name
sotdtablename	The table name

gp_size_of_table_uncompressed

This view shows the uncompressed table size for append-optimized (AO) tables. Otherwise, the table size on disk is shown. The use of this view requires superuser permissions.

Column	Description
sotuoid	The object ID of the table
sotusize	The uncomressed size of the table in bytes if it is a compressed AO table. Otherwise, the table size on disk.
sotuschemaname	The schema name
sotutablename	The table name

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

gp_disk_free

This external table runs the `df` (disk free) command on the active segment hosts and reports back the results. Inactive mirrors are not included in the calculation. The use of this external table requires superuser permissions.

Column	Description
dfsegment	The content id of the segment (only active segments are shown)
dfhostname	The hostname of the segment host
dfdevice	The device name
dfspace	Free disk space in the segment file system in kilobytes

Checking for Missing and Orphaned Data Files

WarehousePG considers a relation data file that is present in the catalog, but not on disk, to be missing. Conversely, when WarehousePG encounters an unexpected data file on disk that is not referenced in any relation, it considers that file to be orphaned.

WarehousePG provides the following views to help identify if missing or orphaned files exist in the current database:

- gp_check_orphaned_files
- gp_check_missing_files
- gp_check_missing_files_ext

Consider it a best practice to check for these conditions prior to expanding the cluster or before offline maintenance.

By default, the views identified in this section are available to `PUBLIC`.

gp_check_orphaned_files

The `gp_check_orphaned_files` view scans the default and user-defined tablespaces for orphaned data files. WarehousePG considers normal data files, files with an underscore (`_`) in the name, and extended numbered files (files that contain a `.<N>` in the name) in this check. `gp_check_orphaned_files` gathers results from the WarehousePG coordinator and all segments.

Column	Description
gp_segment_id	The database segment identifier.
tablespace	The identifier of the tablespace in which the orphaned file resides.
filename	The file name of the orphaned data file.
filepath	The file system path of the orphaned data file, relative to the data directory of the coordinator or segment.

> **Caution** Use this view as one of many data points to identify orphaned data files. Do not delete files based solely on results from querying this view.

gp_check_missing_files

The `gp_check_missing_files` view scans heap and append-optimized, column-oriented tables for missing data files. WarehousePG considers only normal data files (files that do not contain a `.` or an `_` in the name) in this check. `gp_check_missing_files` gathers results from the WarehousePG coordinator and all segments.

Column	Description
gp_segment_id	The database segment identifier.
tablespace	The identifier of the tablespace in which the table resides.
relname	The name of the table that has a missing data file(s).
filename	The file name of the missing data file.

gp_check_missing_files_ext

The `gp_check_missing_files_ext` view scans only append-optimized, column-oriented tables for missing extended data files. WarehousePG considers both normal data files and extended numbered files (files that contain a `.<N>` in the name) in this check. Files that contain an `_` in the name are not considered. `gp_check_missing_files_ext` gathers results from the WarehousePG segments only.

Column	Description
gp_segment_id	The database segment identifier.
tablespace	The identifier of the tablespace in which the table resides.
relname	The name of the table that has a missing extended data file(s).
filename	The file name of the missing extended data file.

Moving Orphaned Data Files

The `gp_move_orphaned_files()` user-defined function (UDF) moves orphaned files found by thegp_check_orphaned_files view into a file system location that you specify.

The function signature is: `gp_move_orphaned_files( <target_directory> TEXT )`.

`<target_directory>` must exist on all segment hosts before you move the files, and the specified directory must be accessible by the `gpadmin` user. If you specify a relative path for `<target_directory>`, it is considered relative to the data directory of the coordinator or segment.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

WarehousePG renames each moved data file to one that reflects the original location of the file in the data directory. The file name format differs depending on the tablespace in which the orphaned file resides:

Tablespace	Renamed File Format
default	`seg<num>_base_<database-oid>_<relfilenode>`
global	`seg<num>_global_<relfilenode>`
user-defined	`seg<num>_pg_tblspc_<tablespace-oid>_<gpdb-version>_<database-oid>_<relfilenode>`

For example, if a file named `12345` in the default tablespace is orphaned on primary segment 2,

```
SELECT * FROM gp_move_orphaned_files('/home/gpadmin/orphaned');
```

moves and renames the file as follows:

Original Location	New Location and File Name
`<data_directory>/base/13700/12345`	`/home/gpadmin/orphaned/seg2_base_13700_12345`

`gp_move_orphaned_files()` returns both the original and the new file system locations for each file that it moves, and also provides an indication of the success or failure of the move operation. For example:

```
SELECT * FROM gp_toolkit.gp_move_orphaned_files('/home/gpadmin/orphaned');
 gp_segment_id | move_success |           oldpath          |         newpath
---------------+--------------+----------------------------+-----------------------------------
            -1 | t            | /<data_dir>/base/13715/99999 | /home/gpadmin/orphaned/seg-1_base_13715_99999
             1 | t            | /<data_dir>/base/13715/99999 | /home/gpadmin/orphaned/seg1_base_13715_99999
             2 | t            | /<data_dir>/base/13715/99999 | /home/gpadmin/orphaned/seg2_base_13715_99999
(3 rows)
```

Once you move the files, you may choose to remove them or to back them up.

Checking for Uneven Data Distribution

All tables in WarehousePG are distributed, meaning their data is divided across all of the segments in the system. If the data is not distributed evenly, then query processing performance may decrease. The following views can help diagnose if a table has uneven data distribution:

- gp_skew_coefficients
- gp_skew_idle_fractions

Parent topic: The gp_toolkit Administrative Schema

gp_skew_coefficients

This view shows data distribution skew by calculating the coefficient of variation (CV) for the data stored on each segment. This view is accessible to all users, however non-superusers will only be able to see tables that they have permission to access

Column	Description
skcoid	The object id of the table.
skcnamespace	The namespace where the table is defined.
skcrelname	The table name.
skccoeff	The coefficient of variation (CV) is calculated as the standard deviation divided by the average. It takes into account both the average and variability around the average of a data series. The lower the value, the better. Higher values indicate greater data skew.

gp_skew_idle_fractions

This view shows data distribution skew by calculating the percentage of the system that is idle during a table scan, which is an indicator of processing data skew. This view is accessible to all users, however non-superusers will only be able to see tables that they have permission to access

Column	Description
sifoid	The object id of the table.
sifnamespace	The namespace where the table is defined.
sifrelname	The table name.
siffraction	The percentage of the system that is idle during a table scan, which is an indicator of uneven data distribution or query processing skew. For example, a value of 0.1 indicates 10% skew, a value of 0.5 indicates 50% skew, and so on. Tables that have more than 10% skew should have their distribution policies evaluated.

Maintaining Partitions

If your database employs partitions you will need to perform certain tasks regularly to help maintain those partitions. WarehousePG includes a view and a number of user-defined functions to help with these tasks.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

The gp_partitions View

The `gp_partitions` view shows all leaf partitions in a database.

This view provides backwards compatibility with the legacy `pg_partitions` view (available in earlier major versions of WarehousePG).

Column	Type	Description
schemaname	name	The name of the schema the partitioned table is in.
tablename	name	The name of the top-level parent table.
partitionschemaname	name	The schema of the partition table.
partitiontablename	name	The relation name of the partitioned table (this is the table name to use if accessing the partition directly).
parentpartitiontablename	regclass	The relation name of the parent table one level up from this partition.
partitiontype	text	The type of partition (range or list).
partitionlevel	integer	The level of this partition in the hierarchy.
partitionrank	integer	For range partitions, the rank of the partition compared to other partitions of the same level.
partitionlistvalues	text	For list partitions, the list value(s) associated with this partition.
partitionrangestart	text	For range partitions, the start value of this partition.
partitionrangeend	text	For range partitions, the end value of this partition.
partitionisdefault	boolean	T if this is a default partition, otherwise F.
partitionboundary	text	The entire partition specification for this partition.
parenttablespace	name	The tablespace of the parent table one level up from this partition.
partitiontablespace	name	The tablespace of this partition.

User-Defined Functions for Partition Maintenance

The following table summarizes the functions WarehousePG provides to help you maintain partitions:

Function	Return Type	Description
`pg_partition_rank(rp regclass)`	integer	For range partitions, returns the rank of the partition compared to other partitions of the same level.For other partition types, it returns `NULL`.
`pg_partition_range_from(rp regclass)`	text	Returns the lower bound of a range partition.
`pg_partition_range_to(rp regclass)`	text	Returns the upper bound of a range partition.
`pg_partition_bound_value(rp regclass)`	text	Returns a textual representation of the bounds of a range partition.
`pg_partition_isdefault(rp regclass)`	boolean	Evaluates whether a given partition is a default partition.
`pg_partition_lowest_child(rp regclass)`	regclass	Finds the lowest ranked child of given partition.
`pg_partition_highest_child(rp regclass)`	regclass	Finds the highest ranked child of given partition.

7.10 SQL Features, Reserved and Key Words, and Compliance

This section includes topics that identify SQL features and compliance in WarehousePG:

- Summary of WarehousePG Features
- Reserved Identifiers and SQL Key Words
- SQL 2008 Optional Feature Compliance

Parent topic: WarehousePG Reference Guide

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.10.1 Summary of WarehousePG Features

This section provides a high-level overview of the system requirements and feature set of WarehousePG. It contains the following topics:

- WarehousePG SQL Standard Conformance
- WarehousePG and PostgreSQL Compatibility

WarehousePG SQL Standard Conformance

The SQL language was first formally standardized in 1986 by the American National Standards Institute (ANSI) as SQL 1986. Subsequent versions of the SQL standard have been released by ANSI and as International Organization for Standardization (ISO) standards: SQL 1989, SQL 1992, SQL 1999, SQL 2003, SQL 2006, and finally SQL 2008, which is the current SQL standard. The official name of the standard is ISO/IEC 9075-14:2008. In general, each new version adds more features, although occasionally features are deprecated or removed.

It is important to note that there are no commercial database systems that are fully compliant with the SQL standard. WarehousePG is almost fully compliant with the SQL 1992 standard, with most of the features from SQL 1999. Several features from SQL 2003 have also been implemented (most notably the SQL OLAP features).

This section addresses the important conformance issues of WarehousePG as they relate to the SQL standards. For a feature-by-feature list of WarehousePG's support of the latest SQL standard, see SQL 2008 Optional Feature Compliance.

Core SQL Conformance

In the process of building a parallel, shared-nothing database system and query optimizer, certain common SQL constructs are not currently implemented in WarehousePG. The following SQL constructs are not supported:

1. Some set returning subqueries in `EXISTS` or `NOT EXISTS` clauses that WarehousePG's parallel optimizer cannot rewrite into joins.
2. Backwards scrolling cursors, including the use of `FETCH PRIOR`, `FETCH FIRST`, `FETCH ABSOLUTE`, and `FETCH RELATIVE`.
3. In `CREATE TABLE` statements (on hash-distributed tables): a `UNIQUE` or `PRIMARY KEY` clause must include all of (or a superset of) the distribution key columns. Because of this restriction, only one `UNIQUE` clause or `PRIMARY KEY` clause is allowed in a `CREATE TABLE` statement. `UNIQUE` or `PRIMARY KEY` clauses are not allowed on randomly-distributed tables.
4. `CREATE UNIQUE INDEX` statements that do not contain all of (or a superset of) the distribution key columns. `CREATE UNIQUE INDEX` is not allowed on randomly-distributed tables.

   Note that `UNIQUE INDEXES` (but not `UNIQUE CONSTRAINTS`) are enforced on a part basis within a partitioned table. They guarantee the uniqueness of the key within each part or sub-part.
5. `VOLATILE` or `STABLE` functions cannot run on the segments, and so are generally limited to being passed literal values as the arguments to their parameters.
6. Triggers are not generally supported because they typically rely on the use of `VOLATILE` functions. PostgreSQL Event Triggers are supported because they capture only DDL events.
7. Referential integrity constraints (foreign keys) are not enforced in WarehousePG. Users can declare foreign keys and this information is kept in the system catalog, however.
8. Sequence manipulation functions `CURRVAL` and `LASTVAL`.

SQL 1992 Conformance

The following features of SQL 1992 are not supported in WarehousePG:

1. `NATIONAL CHARACTER` (`NCHAR`) and `NATIONAL CHARACTER VARYING` (`NVARCHAR`). Users can declare the `NCHAR` and `NVARCHAR` types, however they are just synonyms for `CHAR` and `VARCHAR` in WarehousePG.
2. `CREATE ASSERTION` statement.
3. `INTERVAL` literals are supported in WarehousePG, but do not conform to the standard.
4. `GET DIAGNOSTICS` statement.
5. `GLOBAL TEMPORARY TABLE`s and `LOCAL TEMPORARY TABLE`s. WarehousePG `TEMPORARY TABLE`s do not conform to the SQL standard, but many commercial database systems have implemented temporary tables in the same way. WarehousePG temporary tables are the same as `VOLATILE TABLE`s in Teradata.
6. `UNIQUE` predicate.
7. `MATCH PARTIAL` for referential integrity checks (most likely will not be implemented in WarehousePG).

SQL 1999 Conformance

The following features of SQL 1999 are not supported in WarehousePG:

1. Large Object data types: `BLOB`, `CLOB`, `NCLOB`. However, the `BYTEA` and `TEXT` columns can store very large amounts of data in WarehousePG (hundreds of megabytes).
2. `MODULE` (SQL client modules).
3. `CREATE PROCEDURE` (`SQL/PSM`). This can be worked around in WarehousePG by creating a `FUNCTION` that returns `void`, and invoking the function as follows:

   ```
   SELECT *myfunc*(*args*);
   ```
4. The PostgreSQL/WarehousePG function definition language (`PL/PGSQL`) is a subset of Oracle's `PL/SQL`, rather than being compatible with the `SQL/PSM` function definition language. WarehousePG also supports function definitions written in Python, Perl, Java, and R.
5. `BIT` and `BIT VARYING` data types (intentionally omitted). These were deprecated in SQL 2003, and replaced in SQL 2008.
6. WarehousePG supports identifiers up to 63 characters long. The SQL standard requires support for identifiers up to 128 characters long.
7. Prepared transactions (`PREPARE TRANSACTION`, `COMMIT PREPARED`, `ROLLBACK PREPARED`). This also means WarehousePG does not support `XA` Transactions (2 phase commit coordination of database transactions with external transactions).

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

8. `CHARACTER SET` option on the definition of `CHAR()` or `VARCHAR()` columns.
9. Specification of `CHARACTERS` or `OCTETS` (`BYTES`) on the length of a `CHAR()` or `VARCHAR()` column. For example, `VARCHAR(15 CHARACTERS)` or `VARCHAR(15 OCTETS)` or `VARCHAR(15 BYTES)`.
10. `CREATE DISTINCT TYPE` statement. `CREATE DOMAIN` can be used as a work-around in WarehousePG.
11. The *explicit table* construct.

SQL 2003 Conformance

The following features of SQL 2003 are not supported in WarehousePG:

1. `MERGE` statements.
2. `IDENTITY` columns and the associated `GENERATED ALWAYS/GENERATED BY DEFAULT` clause. The `SERIAL` or `BIGSERIAL` data types are very similar to `INT` or `BIGINT GENERATED BY DEFAULT AS IDENTITY`.
3. `MULTISET` modifiers on data types.
4. `ROW` data type.
5. WarehousePG syntax for using sequences is non-standard. For example, `nextval('seq')` is used in WarehousePG instead of the standard `NEXT VALUE FOR seq`.
6. `GENERATED ALWAYS AS` columns. Views can be used as a work-around.
7. The sample clause (`TABLESAMPLE`) on `SELECT` statements. The `random()` function can be used as a work-around to get random samples from tables.
8. The *partitioned join tables* construct (`PARTITION BY` in a join).
9. WarehousePG cluster data types are almost SQL standard compliant with some exceptions. Generally customers should not encounter any problems using them.

SQL 2008 Conformance

The following features of SQL 2008 are not supported in WarehousePG:

1. `BINARY` and `VARBINARY` data types. `BYTEA` can be used in place of `VARBINARY` in WarehousePG.
2. The `ORDER BY` clause is ignored in views and subqueries unless a `LIMIT` clause is also used. This is intentional, as the WarehousePG optimizer cannot determine when it is safe to avoid the sort, causing an unexpected performance impact for such `ORDER BY` clauses. To work around, you can specify a really large `LIMIT`. For example:

   ```
   SELECT * FROM mytable ORDER BY 1 LIMIT 9999999999
   ```

3. The *row subquery* construct is not supported.
4. `TRUNCATE TABLE` does not accept the `CONTINUE IDENTITY` and `RESTART IDENTITY` clauses.

WarehousePG and PostgreSQL Compatibility

WarehousePG is based on PostgreSQL 9.4. To support the distributed nature and typical workload of a WarehousePG cluster, some SQL commands have been added or modified, and there are a few PostgreSQL features that are not supported. WarehousePG has also added features not found in PostgreSQL, such as physical data distribution, parallel query optimization, external tables, resource queues, and enhanced table partitioning. For full SQL syntax and references, see the SQL Commands.

> **Note** WarehousePG does not support the PostgreSQL large object facility for streaming user data that is stored in large-object structures.

> **Note** Unsupported: using `WITH OIDS` or `oids=TRUE` to assign an OID system column when creating or altering a table. This syntax is deprecated and will be removed in a future WarehousePG release.

WarehousePG and PostgreSQL Compatibility SQL Support

SQL Command	Supported in WarehousePG	Modifications, Limitations, Exceptions
`ALTER AGGREGATE`	YES	
`ALTER CONVERSION`	YES	
`ALTER DATABASE`	YES	
`ALTER DOMAIN`	YES	
`ALTER EVENT TRIGGER`	YES	
`ALTER EXTENSION`	YES	Changes the definition of a WarehousePG extension - based on PostgreSQL 9.6.
`ALTER FUNCTION`	YES	
`ALTER GROUP`	YES	An alias for ALTER ROLE
`ALTER INDEX`	YES	
`ALTER LANGUAGE`	YES	
`ALTER OPERATOR`	YES	
`ALTER OPERATOR CLASS`	YES	
`ALTER OPERATOR FAMILY`	YES	
`ALTER PROTOCOL`	YES	
`ALTER PUBLICATION`	NO	

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

`ALTER RESOURCE QUEUE`	YES	WarehousePG resource management feature - not in PostgreSQL.
`ALTER ROLE`	YES	**WarehousePG Clauses:** `RESOURCE QUEUE` *queue_name* | `none`
`ALTER SCHEMA`	YES	
`ALTER SEQUENCE`	YES	
`ALTER SUBSCRIPTION`	NO	
`ALTER SYSTEM`	**NO**	

`ALTER TABLE`	YES	**Unsupported Clauses / Options:**
		`ENABLE/DISABLE TRIGGER`
		WarehousePG Database Clauses:
		`ADD | DROP | RENAME | SPLIT | EXCHANGE PARTITION | SET SUBPARTITION TEMPLATE | SET WITH (REORGANIZE=true | false) | SET DISTRIBUTED BY`

`ALTER TABLESPACE`	YES	
`ALTER TRIGGER`	**NO**	
`ALTER TYPE`	YES	**WarehousePG Clauses:** `SET DEFAULT ENCODING`
`ALTER USER`	YES	An alias for ALTER ROLE
`ALTER VIEW`	YES	
`ANALYZE`	YES	
`BEGIN`	YES	
`CHECKPOINT`	YES	
`CLOSE`	YES	
`CLUSTER`	YES	
`COMMENT`	YES	
`COMMIT`	YES	
`COMMIT PREPARED`	**NO**	

`COPY`	YES	**Modified Clauses:**
		`ESCAPE [ AS ] '` *escape* `' | 'OFF'`
		WarehousePG Clauses:
		`[LOG ERRORS] SEGMENT REJECT LIMIT` *count* `[ROWS|PERCENT]`

`CREATE AGGREGATE`	YES	**Unsupported Clauses / Options:**
		`[ , SORTOP =` *sort_operator* `]`
		WarehousePG Clauses:
		`[ , COMBINEFUNC =` *combinefunc* `]`
		Limitations:
		The functions used to implement the aggregate must be `IMMUTABLE` functions.

`CREATE CAST`	YES	
`CREATE CONSTRAINT TRIGGER`	**NO**	
`CREATE CONVERSION`	YES	
`CREATE DATABASE`	YES	
`CREATE DOMAIN`	YES	
`CREATE EVENT TRIGGER`	YES	
`CREATE EXTENSION`	YES	Loads a new extension into WarehousePG - based on PostgreSQL 9.6.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

`CREATE EXTERNAL TABLE`	YES	WarehousePG parallel ETL feature - not in PostgreSQL 9.4.
`CREATE FUNCTION`	YES	**Limitations:** Functions defined as `STABLE` or `VOLATILE` can be run in WarehousePG provided that they are run on the coordinator only. `STABLE` and `VOLATILE` functions cannot be used in statements that run at the segment level.
`CREATE GROUP`	YES	An alias for CREATE ROLE
`CREATE INDEX`	YES	**WarehousePG Clauses:** `USING bitmap` (bitmap indexes) **Limitations:** `UNIQUE` indexes are allowed only if they contain all of (or a superset of) the WarehousePG distribution key columns. On partitioned tables, a unique index is only supported within an individual partition - not across all partitions. `CONCURRENTLY` keyword not supported in WarehousePG.
`CREATE LANGUAGE`	YES	
`CREATE MATERIALIZED VIEW`	YES	Based on PostgreSQL 9.4.
`CREATE OPERATOR`	YES	**Limitations:** The function used to implement the operator must be an `IMMUTABLE` function.
`CREATE OPERATOR CLASS`	YES	
`CREATE OPERATOR FAMILY`	YES	
`CREATE PROTOCOL`	YES	
`CREATE PUBLICATION`	NO	
`CREATE RESOURCE QUEUE`	YES	WarehousePG resource management feature - not in PostgreSQL 9.4.
`CREATE ROLE`	YES	**WarehousePG Clauses:** `RESOURCE QUEUE` *queue_name* `| none`
`CREATE RULE`	YES	
`CREATE SCHEMA`	YES	
`CREATE SEQUENCE`	YES	**Limitations:** The `lastval()` and `currval()` functions are not supported. The `setval()` function is only allowed in queries that do not operate on distributed data.
`CREATE SUBSCRIPTION`	NO	

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

		Unsupported Clauses / Options:
		`[GLOBAL | LOCAL]`
		`REFERENCES`
		`FOREIGN KEY`
		`[DEFERRABLE | NOT DEFERRABLE]`
		Limited Clauses:
		`UNIQUE` or `PRIMARY KEY` constraints are only allowed on hash-distributed tables (`DISTRIBUTED BY`), and the constraint columns must be the same as or a superset of the distribution key columns of the table and must include all the distribution key columns of the partitioning key.
		WarehousePG Clauses:
		`DISTRIBUTED BY (column, [ ... ] ) |`
		`DISTRIBUTED RANDOMLY`
		`PARTITION BY type (column [, ...])`
		`( partition_specification, [...] )`
		`WITH (appendoptimized=true [,compresslevel=value,blocksize=value] )`

`CREATE TABLE AS`	YES	See CREATE TABLE
`CREATE TABLESPACE`	**YES**	**WarehousePG Clauses:** Specify host file system locations for specific segment instances. `WITH (contentID_1='/path/to/dir1...)`
`CREATE TRIGGER`	**NO**	
`CREATE TYPE`	YES	**WarehousePG Clauses:** `COMPRESSTYPE | COMPRESSLEVEL | BLOCKSIZE` **Limitations:** The functions used to implement a new base type must be `IMMUTABLE` functions.
`CREATE USER`	YES	An alias for CREATE ROLE
`CREATE VIEW`	YES	
`DEALLOCATE`	YES	

`DECLARE`	YES	**Unsupported Clauses / Options:**
		`SCROLL`
		`FOR UPDATE [ OF column [, ...] ]`
		Limitations:
		Cursors cannot be backward-scrolled. Forward scrolling is supported.
		PL/pgSQL does not have support for updatable cursors.

`DELETE`	YES	
`DISCARD`	YES	**Limitation:** `DISCARD ALL` is not supported.
`DO`	YES	PostgreSQL 9.0 feature
`DROP AGGREGATE`	YES	
`DROP CAST`	YES	
`DROP CONVERSION`	YES	
`DROP DATABASE`	YES	
`DROP DOMAIN`	YES	
`DROP EVENT TRIGGER`	YES	

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

`DROP EXTENSION`	YES	Removes an extension from WarehousePG – based on PostgreSQL 9.6.
`DROP EXTERNAL TABLE`	YES	WarehousePG parallel ETL feature - not in PostgreSQL 9.4.
`DROP FUNCTION`	YES	
`DROP GROUP`	YES	An alias for DROP ROLE
`DROP INDEX`	YES	
`DROP LANGUAGE`	YES	
`DROP OPERATOR`	YES	
`DROP OPERATOR CLASS`	YES	
`DROP OPERATOR FAMILY`	YES	
`DROP OWNED`	**NO**	
`DROP PROTOCOL`	YES	
`DROP PUBLICATION`	NO	
`DROP RESOURCE QUEUE`	YES	WarehousePG resource management feature - not in PostgreSQL 9.4.
`DROP ROLE`	YES	
`DROP RULE`	YES	
`DROP SCHEMA`	YES	
`DROP SEQUENCE`	YES	
`DROP SUBSCRIPTION`	NO	
`DROP TABLE`	YES	
`DROP TABLESPACE`	YES	
`DROP TRIGGER`	**NO**	
`DROP TYPE`	YES	
`DROP USER`	YES	An alias for DROP ROLE
`DROP VIEW`	YES	
`END`	YES	
`EXECUTE`	YES	
`EXPLAIN`	YES	

`FETCH`	YES	**Unsupported Clauses / Options:**
		`LAST`
		`PRIOR`
		`BACKWARD`
		`BACKWARD ALL`
		Limitations:
		Cannot fetch rows in a nonsequential fashion; backward scan is not supported.

`GRANT`	YES	
`INSERT`	YES	
`LATERAL` Join Type	**NO**	
`LISTEN`	**YES**	
`LOAD`	YES	
`LOCK`	YES	
`MOVE`	YES	See FETCH
`NOTIFY`	**YES**	
`PREPARE`	YES	
`PREPARE TRANSACTION`	**NO**	
`REASSIGN OWNED`	YES	
`REFRESH MATERIALIZED VIEW`	YES	Based on PostgreSQL 9.4.
`REINDEX`	YES	
`RELEASE SAVEPOINT`	YES	
`RESET`	YES	
`RETRIEVE`	YES	WarehousePG parallel retrieve cursor - not in PostgreSQL 9.4.
`REVOKE`	YES	
`ROLLBACK`	YES	

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

`ROLLBACK PREPARED`	**NO**	
`ROLLBACK TO SAVEPOINT`	YES	
`SAVEPOINT`	YES	

`SELECT`	YES	**Limitations:**
		Limited use of `VOLATILE` and `STABLE` functions in `FROM` or `WHERE` clauses
		Text search (`Tsearch2`) is not supported
		WarehousePG Clauses (OLAP):
		`[GROUP BY` *grouping_element* `[, ...]]`
		`[WINDOW` *window_name* `AS (` *window_specification* `)]`
		`[FILTER (WHERE` *condition* `)]` applied to an aggregate function in the `SELECT` list

`SELECT INTO`	YES	See SELECT
`SET`	YES	
`SET CONSTRAINTS`	**NO**	In PostgreSQL, this only applies to foreign key constraints, which are currently not enforced in WarehousePG.
`SET ROLE`	YES	
`SET SESSION AUTHORIZATION`	YES	Deprecated as of PostgreSQL 8.1 - see SET ROLE
`SET TRANSACTION`	YES	**Limitations:** `DEFERRABLE` clause has no effect.
`SHOW`	YES	
`START TRANSACTION`	YES	
`TRUNCATE`	YES	
`UNLISTEN`	**YES**	
`UPDATE`	YES	**Limitations:** `SET` not allowed for WarehousePG distribution key columns.
`VACUUM`	YES	**Limitations:** `VACUUM FULL` is not recommended in WarehousePG.
`VALUES`	YES	

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.10.2 Reserved Identifiers and SQL Key Words

This topic describes WarehousePG reserved identifiers and object names, and SQL key words recognized by the WarehousePG and PostgreSQL command parsers.

Reserved Identifiers

In the WarehousePG cluster, names beginning with `gp_` and `pg_` are reserved and should not be used as names for user-created objects, such as tables, views, and functions.

The resource group names `admin_group`, `default_group`, and `none` are reserved. The resource queue name `pg_default` is reserved.

The tablespace names `pg_default` and `pg_global` are reserved.

The role name `gpadmin` is reserved. `gpadmin` is the default WarehousePG superuser role.

In data files, the characters that delimit fields (columns) and rows have a special meaning. If they appear within the data you must escape them so that WarehousePG treats them as data and not as delimiters. The backslash character (`\`) is the default escape character. See Escaping for details.

See SQL Syntax in the PostgreSQL documentation for more information about SQL identifiers, constants, operators, and expressions.

SQL Key Words

SQL keyword status lists all tokens that are key words in WarehousePG 6 and PostgreSQL 9.4.

ANSI SQL distinguishes between *reserved* and *unreserved* key words. According to the standard, reserved key words are the only real key words; they are never allowed as identifiers. Unreserved key words only have a special meaning in particular contexts and can be used as identifiers in other contexts. Most unreserved key words are actually the names of built-in tables and functions specified by SQL. The concept of unreserved key words essentially only exists to declare that some predefined meaning is attached to a word in some contexts.

In the WarehousePG and PostgreSQL parsers there are several different classes of tokens ranging from those that can never be used as an identifier to those that have absolutely no special status in the parser as compared to an ordinary identifier. (The latter is usually the case for functions specified by SQL.) Even reserved key words are not completely reserved, but can be used as column labels (for example, `SELECT 55 AS CHECK`, even though `CHECK` is a reserved key word).

SQL keyword status classifies as "unreserved" those key words that are explicitly known to the parser but are allowed as column or table names. Some key words that are otherwise unreserved cannot be used as function or data type names and are marked accordingly. (Most of these words represent built-in functions or data types with special syntax. The function or type is still available but it cannot be redefined by the user.) Key words labeled "reserved" are not allowed as column or table names. Some reserved key words are allowable as names for functions or data types; this is also shown in the table. If not so marked, a reserved key word is only allowed as an "AS" column label name.

If you get spurious parser errors for commands that contain any of the listed key words as an identifier you should try to quote the identifier to see if the problem goes away.

Before studying the table, note the fact that a key word is not reserved does not mean that the feature related to the word is not implemented. Conversely, the presence of a key word does not indicate the existence of a feature.

7.10.3 SQL 2008 Optional Feature Compliance

The following table lists the features described in the 2008 SQL standard. Features that are supported in WarehousePG are marked as YES in the 'Supported' column, features that are not implemented are marked as NO.

For information about WarehousePG features and SQL compliance, see the *WarehousePG Administrator Guide*.

ID	Feature	Supported	Comments
B011	Embedded Ada	NO	
B012	Embedded C	NO	Due to issues with PostgreSQL `ecpg`
B013	Embedded COBOL	NO	
B014	Embedded Fortran	NO	
B015	Embedded MUMPS	NO	
B016	Embedded Pascal	NO	
B017	Embedded PL/I	NO	
B021	Direct SQL	YES	
B031	Basic dynamic SQL	NO	
B032	Extended dynamic SQL	NO	
B033	Untyped SQL-invoked function arguments	NO	
B034	Dynamic specification of cursor attributes	NO	
B035	Non-extended descriptor names	NO	
B041	Extensions to embedded SQL exception declarations	NO	
B051	Enhanced execution rights	NO	
B111	Module language Ada	NO	
B112	Module language C	NO	
B113	Module language COBOL	NO	
B114	Module language Fortran	NO	
B115	Module language MUMPS	NO	
B116	Module language Pascal	NO	
B117	Module language PL/I	NO	
B121	Routine language Ada	NO	
B122	Routine language C	NO	
B123	Routine language COBOL	NO	
B124	Routine language Fortran	NO	
B125	Routine language MUMPS	NO	
B126	Routine language Pascal	NO	
B127	Routine language PL/I	NO	
B128	Routine language SQL	NO	
E011	Numeric data types	YES	
E011-01	`INTEGER` and `SMALLINT` data types	YES	
E011-02	`DOUBLE PRECISION` and `FLOAT` data types	YES	
E011-03	`DECIMAL` and `NUMERIC` data types	YES	
E011-04	Arithmetic operators	YES	
E011-05	Numeric comparison	YES	
E011-06	Implicit casting among the numeric data types	YES	
E021	Character data types	YES	
E021-01	`CHARACTER` data type	YES	
E021-02	`CHARACTER VARYING` data type	YES	
E021-03	Character literals	YES	
E021-04	`CHARACTER_LENGTH` function	YES	Trims trailing spaces from `CHARACTER` values before counting
E021-05	`OCTET_LENGTH` function	YES	
E021-06	`SUBSTRING` function	YES	
E021-07	Character concatenation	YES	
E021-08	`UPPER` and `LOWER` functions	YES	
E021-09	`TRIM` function	YES	
E021-10	Implicit casting among the character string types	YES	
E021-11	`POSITION` function	YES	

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

ID	Feature	Supported	Comments
E021-12	Character comparison	YES	
E031	Identifiers	YES	
E031-01	Delimited identifiers	YES	
E031-02	Lower case identifiers	YES	
E031-03	Trailing underscore	YES	
E051	Basic query specification	YES	
E051-01	`SELECT DISTINCT`	YES	
E051-02	`GROUP BY` clause	YES	
E051-03	`GROUP BY` can contain columns not in `SELECT` list	YES	
E051-04	`SELECT` list items can be renamed	YES	
E051-05	`HAVING` clause	YES	
E051-06	Qualified * in `SELECT` list	YES	
E051-07	Correlation names in the `FROM` clause	YES	
E051-08	Rename columns in the `FROM` clause	YES	
E061	Basic predicates and search conditions	YES	
E061-01	Comparison predicate	YES	
E061-02	`BETWEEN` predicate	YES	
E061-03	`IN` predicate with list of values	YES	
E061-04	`LIKE` predicate	YES	
E061-05	`LIKE` predicate `ESCAPE` clause	YES	
E061-06	`NULL` predicate	YES	
E061-07	Quantified comparison predicate	YES	
E061-08	`EXISTS` predicate	YES	Not all uses work in WarehousePG
E061-09	Subqueries in comparison predicate	YES	
E061-11	Subqueries in IN predicate	YES	
E061-12	Subqueries in quantified comparison predicate	YES	
E061-13	Correlated subqueries	YES	
E061-14	Search condition	YES	
E071	Basic query expressions	YES	
E071-01	`UNION DISTINCT` table operator	YES	
E071-02	`UNION ALL` table operator	YES	
E071-03	`EXCEPT DISTINCT` table operator	YES	
E071-05	Columns combined via table operators need not have exactly the same data type	YES	
E071-06	Table operators in subqueries	YES	
E081	Basic Privileges	NO	Partial sub-feature support
E081-01	`SELECT` privilege	YES	
E081-02	`DELETE` privilege	YES	
E081-03	`INSERT` privilege at the table level	YES	
E081-04	`UPDATE` privilege at the table level	YES	
E081-05	`UPDATE` privilege at the column level	YES	
E081-06	`REFERENCES` privilege at the table level	NO	
E081-07	`REFERENCES` privilege at the column level	NO	

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

ID	Feature	Supported	Comments
E081-08	`WITH GRANT OPTION`	YES	
E081-09	`USAGE` privilege	YES	
E081-10	`EXECUTE` privilege	YES	
E091	Set Functions	YES	
E091-01	`AVG`	YES	
E091-02	`COUNT`	YES	
E091-03	`MAX`	YES	
E091-04	`MIN`	YES	
E091-05	`SUM`	YES	
E091-06	`ALL` quantifier	YES	
E091-07	`DISTINCT` quantifier	YES	
E101	Basic data manipulation	YES	
E101-01	`INSERT` statement	YES	
E101-03	Searched `UPDATE` statement	YES	
E101-04	Searched `DELETE` statement	YES	
E111	Single row `SELECT` statement	YES	
E121	Basic cursor support	YES	
E121-01	`DECLARE CURSOR`	YES	
E121-02	`ORDER BY` columns need not be in select list	YES	
E121-03	Value expressions in `ORDER BY` clause	YES	
E121-04	`OPEN` statement	YES	
E121-06	Positioned `UPDATE` statement	NO	
E121-07	Positioned `DELETE` statement	NO	
E121-08	`CLOSE` statement	YES	
E121-10	`FETCH` statement implicit `NEXT`	YES	
E121-17	`WITH HOLD` cursors	YES	
E131	Null value support	YES	
E141	Basic integrity constraints	YES	
E141-01	`NOT NULL` constraints	YES	
E141-02	`UNIQUE` constraints of `NOT NULL` columns	YES	Must be the same as or a superset of the WarehousePG distribution key
E141-03	`PRIMARY KEY` constraints	YES	Must be the same as or a superset of the WarehousePG distribution key
E141-04	Basic `FOREIGN KEY` constraint with the `NO ACTION` default for both referential delete action and referential update action	NO	
E141-06	`CHECK` constraints	YES	
E141-07	Column defaults	YES	
E141-08	`NOT NULL` inferred on `PRIMARY KEY`	YES	
E141-10	Names in a foreign key can be specified in any order	YES	Foreign keys can be declared but are not enforced in WarehousePG
E151	Transaction support	YES	
E151-01	`COMMIT` statement	YES	
E151-02	`ROLLBACK` statement	YES	
E152	Basic SET TRANSACTION statement	YES	
E152-01	`ISOLATION LEVEL SERIALIZABLE` clause	NO	Can be declared but is treated as a synonym for `REPEATABLE READ`
E152-02	`READ ONLY` and `READ WRITE` clauses	YES	
E153	Updatable queries with subqueries	NO	
E161	SQL comments using leading double minus	YES	

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

ID	Feature	Supported	Comments
E171	SQLSTATE support	YES	
E182	Module language	NO	
F021	Basic information schema	YES	
F021-01	`COLUMNS` view	YES	
F021-02	`TABLES` view	YES	
F021-03	`VIEWS` view	YES	
F021-04	`TABLE_CONSTRAINTS` view	YES	
F021-05	`REFERENTIAL_CONSTRAINTS` view	YES	
F021-06	`CHECK_CONSTRAINTS` view	YES	
F031	Basic schema manipulation	YES	
F031-01	`CREATE TABLE` statement to create persistent base tables	YES	
F031-02	`CREATE VIEW` statement	YES	
F031-03	`GRANT` statement	YES	
F031-04	`ALTER TABLE` statement: `ADD COLUMN` clause	YES	
F031-13	`DROP TABLE` statement: `RESTRICT` clause	YES	
F031-16	`DROP VIEW` statement: `RESTRICT` clause	YES	
F031-19	`REVOKE` statement: `RESTRICT` clause	YES	
F032	`CASCADE` drop behavior	YES	
F033	`ALTER TABLE` statement: `DROP COLUMN` clause	YES	
F034	Extended REVOKE statement	YES	
F034-01	`REVOKE` statement performed by other than the owner of a schema object	YES	
F034-02	`REVOKE` statement: `GRANT OPTION FOR` clause	YES	
F034-03	`REVOKE` statement to revoke a privilege that the grantee has `WITH GRANT OPTION`	YES	
F041	Basic joined table	YES	
F041-01	Inner join (but not necessarily the `INNER` keyword)	YES	
F041-02	`INNER` keyword	YES	
F041-03	`LEFT OUTER JOIN`	YES	
F041-04	`RIGHT OUTER JOIN`	YES	
F041-05	Outer joins can be nested	YES	
F041-07	The inner table in a left or right outer join can also be used in an inner join	YES	
F041-08	All comparison operators are supported (rather than just `=`)	YES	
F051	Basic date and time	YES	
F051-01	`DATE` data type (including support of `DATE` literal)	YES	
F051-02	`TIME` data type (including support of `TIME` literal) with fractional seconds precision of at least 0	YES	
F051-03	`TIMESTAMP` data type (including support of `TIMESTAMP` literal) with fractional seconds precision of at least 0 and 6	YES	
F051-04	Comparison predicate on `DATE`, `TIME`, and `TIMESTAMP` data types	YES	
F051-05	Explicit `CAST` between datetime types and character string types	YES	
F051-06	`CURRENT_DATE`	YES	
F051-07	`LOCALTIME`	YES	
F051-08	`LOCALTIMESTAMP`	YES	
F052	Intervals and datetime arithmetic	YES	
F053	`OVERLAPS` predicate	YES	
F081	`UNION` and `EXCEPT` in views	YES	
F111	Isolation levels other than SERIALIZABLE	YES	
F111-01	`READ UNCOMMITTED` isolation level	NO	Can be declared but is treated as a synonym for `READ COMMITTED`

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

ID	Feature	Supported	Comments
F111-02	`READ COMMITTED` isolation level	YES	
F111-03	`REPEATABLE READ` isolation level	YES	
F121	Basic diagnostics management	NO	
F122	Enhanced diagnostics management	NO	
F123	All diagnostics	NO	
F131-	Grouped operations	YES	
F131-01	`WHERE`, `GROUP BY`, and `HAVING` clauses supported in queries with grouped views	YES	
F131-02	Multiple tables supported in queries with grouped views	YES	
F131-03	Set functions supported in queries with grouped views	YES	
F131-04	Subqueries with `GROUP BY` and `HAVING` clauses and grouped views	YES	
F131-05	Single row `SELECT` with `GROUP BY` and `HAVING` clauses and grouped views	YES	
F171	Multiple schemas per user	YES	
F181	Multiple module support	NO	
F191	Referential delete actions	NO	
F200	`TRUNCATE TABLE` statement	YES	
F201	`CAST` function	YES	
F202	`TRUNCATE TABLE`: identity column restart option	YES	
F221	Explicit defaults	YES	
F222	`INSERT` statement: `DEFAULT VALUES` clause	YES	
F231	Privilege tables	YES	
F231-01	`TABLE_PRIVILEGES` view	YES	
F231-02	`COLUMN_PRIVILEGES` view	YES	
F231-03	`USAGE_PRIVILEGES` view	YES	
F251	Domain support		
F261	CASE expression	YES	
F261-01	Simple `CASE`	YES	
F261-02	Searched `CASE`	YES	
F261-03	`NULLIF`	YES	
F261-04	`COALESCE`	YES	
F262	Extended `CASE` expression	NO	
F263	Comma-separated predicates in simple `CASE` expression	NO	
F271	Compound character literals	YES	
F281	`LIKE` enhancements	YES	
F291	`UNIQUE` predicate	NO	
F301	`CORRESPONDING` in query expressions	NO	
F302	INTERSECT table operator	YES	
F302-01	`INTERSECT DISTINCT` table operator	YES	
F302-02	`INTERSECT ALL` table operator	YES	
F304	`EXCEPT ALL` table operator		
F311	Schema definition statement	YES	Partial sub-feature support
F311-01	`CREATE SCHEMA`	YES	
F311-02	`CREATE TABLE` for persistent base tables	YES	
F311-03	`CREATE VIEW`	YES	
F311-04	`CREATE VIEW: WITH CHECK OPTION`	NO	
F311-05	`GRANT` statement	YES	
F312	`MERGE` statement	NO	consider `INSERT ... ON CONFLICT DO UPDATE`
F313	Enhanced `MERGE` statement	NO	
F321	User authorization	YES	
F341	Usage Tables	NO	
F361	Subprogram support	YES	
F381	Extended schema manipulation	YES	
F381-01	`ALTER TABLE` statement: `ALTER COLUMN` clause		Some limitations on altering distribution key columns

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

ID	Feature	Supported	Comments
F381-02	`ALTER TABLE` statement: `ADD CONSTRAINT` clause		
F381-03	`ALTER TABLE` statement: `DROP CONSTRAINT` clause		
F382	Alter column data type	YES	Some limitations on altering distribution key columns
F384	Drop identity property clause	YES	
F386	Set identity column generation clause	YES	
F391	Long identifiers	YES	
F392	Unicode escapes in identifiers	NO	
F393	Unicode escapes in literals	NO	
F394	Optional normal form specification	NO	
F401	Extended joined table	YES	
F401-01	`NATURAL JOIN`	YES	
F401-02	`FULL OUTER JOIN`	YES	
F401-04	`CROSS JOIN`	YES	
F402	Named column joins for LOBs, arrays, and multisets	NO	
F403	Partitioned joined tables	NO	
F411	Time zone specification	YES	Differences regarding literal interpretation
F421	National character	YES	
F431	Read-only scrollable cursors	YES	Forward scrolling only
01	`FETCH` with explicit `NEXT`	YES	
02	`FETCH FIRST`	NO	
03	`FETCH LAST`	YES	
04	`FETCH PRIOR`	NO	
05	`FETCH ABSOLUTE`	NO	
06	`FETCH RELATIVE`	NO	
F441	Extended set function support	YES	
F442	Mixed column references in set functions	YES	
F451	Character set definition	NO	
F461	Named character sets	NO	
F471	Scalar subquery values	YES	
F481	Expanded `NULL` predicate	YES	
F491	Constraint management	YES	
F501	Features and conformance views	YES	
F501-01	`SQL_FEATURES` view	YES	
F501-02	`SQL_SIZING` view	YES	
F501-03	`SQL_LANGUAGES` view	YES	
F502	Enhanced documentation tables	YES	
F502-01	`SQL_SIZING_PROFILES` view	YES	
F502-02	`SQL_IMPLEMENTATION_INFO` view	YES	
F502-03	`SQL_PACKAGES` view	YES	
F521	Assertions	NO	
F531	Temporary tables	YES	Non-standard form
F555	Enhanced seconds precision	YES	
F561	Full value expressions	YES	
F571	Truth value tests	YES	
F591	Derived tables	YES	
F611	Indicator data types	YES	
F641	Row and table constructors	NO	
F651	Catalog name qualifiers	YES	
F661	Simple tables	NO	
F671	Subqueries in `CHECK`	NO	Intentionally omitted
F672	Retrospective check constraints	YES	
F690	Collation support	NO	
F692	Enhanced collation support	NO	
F693	SQL-session and client module collations	NO	
F695	Translation support	NO	
F696	Additional translation documentation	NO	
F701	Referential update actions	NO	
F711	`ALTER` domain	YES	
F721	Deferrable constraints	NO

ID	Feature	Supported	Comments
F731	`INSERT` column privileges	YES	
F741	Referential `MATCH` types	NO	No partial match
F751	View `CHECK` enhancements	NO	
F761	Session management	YES	
F762	`CURRENT_CATALOG`	NO	
F763	`CURRENT_SCHEMA`	NO	
F771	Connection management	YES	
F781	Self-referencing operations	YES	
F791	Insensitive cursors	YES	
F801	Full set function	YES	
F812	Basic flagging	NO	
F813	Extended flagging	NO	
F831	Full cursor update	NO	
F841	`LIKE_REGEX` predicate	NO	Non-standard syntax for regex
F842	`OCCURENCES_REGEX` function	NO	
F843	`POSITION_REGEX` function	NO	
F844	`SUBSTRING_REGEX` function	NO	
F845	`TRANSLATE_REGEX` function	NO	
F846	Octet support in regular expression operators	NO	
F847	Nonconstant regular expressions	NO	
F850	Top-level `ORDER BY` clause in *query expression*	YES	
F851	Top-level `ORDER BY` clause in subqueries	NO	
F852	Top-level `ORDER BY` clause in views	NO	
F855	Nested `ORDER BY` clause in *query expression*	NO	
F856	Nested `FETCH FIRST` clause in *query expression*	NO	
F857	Top-level `FETCH FIRST` clause in *query expression*	NO	
F858	`FETCH FIRST` clause in subqueries	NO	
F859	Top-level `FETCH FIRST` clause in views	NO	
F860	`FETCH FIRST ROW` *count* in `FETCH FIRST` clause	NO	
F861	Top-level `RESULT OFFSET` clause in *query expression*	NO	
F862	`RESULT OFFSET` clause in subqueries	NO	
F863	Nested `RESULT OFFSET` clause in *query expression*	NO	
F864	Top-level `RESULT OFFSET` clause in views	NO	
F865	`OFFSET ROW` *count* in `RESULT OFFSET` clause	NO	
S011	Distinct data types	NO	
S023	Basic structured types	NO	
S024	Enhanced structured types	NO	
S025	Final structured types	NO	
S026	Self-referencing structured types	NO	
S027	Create method by specific method name	NO	
S028	Permutable UDT options list	NO	
S041	Basic reference types	NO	
S043	Enhanced reference types	NO	
S051	Create table of type	NO	
S071	SQL paths in function and type name resolution	YES	
S091	Basic array support	NO	WarehousePG has arrays, but is not fully standards compliant
S091-01	Arrays of built-in data types	NO	Partially compliant
S091-02	Arrays of distinct types	NO	
S091-03	Array expressions	NO	
S092	Arrays of user-defined types	NO	
S094	Arrays of reference types	NO	
S095	Array constructors by query	NO	
S096	Optional array bounds	NO	
S097	Array element assignment	NO	
S098	`array_agg`	Partially	Supported: Using `array_agg` without a window specification, for example: `SELECT array_agg(x) FROM ...`, `SELECT array_agg (x order by y) FROM ...` Not supported: Using `array_agg` as an aggregate derived window function, for example: `SELECT array_agg(x) over (ORDER BY y) FROM ...`, `SELECT array_agg(x order by y) over (PARTITION BY z) FROM ...`, `SELECT array_agg(x order by y) over (ORDER BY z) FROM ...`
S111	`ONLY` in query expressions	YES	
S151	Type predicate	NO

ID	Feature	Supported	Comments
S161	Subtype treatment	NO	
S162	Subtype treatment for references	NO	
S201	SQL-invoked routines on arrays	NO	Functions can be passed WarehousePG cluster types
S202	SQL-invoked routines on multisets	NO	
S211	User-defined cast functions	YES	
S231	Structured type locators	NO	
S232	Array locators	NO	
S233	Multiset locators	NO	
S241	Transform functions	NO	
S242	Alter transform statement	NO	
S251	User-defined orderings	NO	
S261	Specific type method	NO	
S271	Basic multiset support	NO	
S272	Multisets of user-defined types	NO	
S274	Multisets of reference types	NO	
S275	Advanced multiset support	NO	
S281	Nested collection types	NO	
S291	Unique constraint on entire row	NO	
S301	Enhanced `UNNEST`	NO	
S401	Distinct types based on array types	NO	
S402	Distinct types based on distinct types	NO	
S403	`MAX_CARDINALITY`	NO	
S404	`TRIM_ARRAY`	NO	
T011	Timestamp in Information Schema	NO	
T021	`BINARY` and `VARBINARY` data types	NO	
T022	Advanced support for `BINARY` and `VARBINARY` data types	NO	
T023	Compound binary literal	NO	
T024	Spaces in binary literals	NO	
T031	`BOOLEAN` data type	YES	
T041	Basic `LOB` data type support	NO	
T042	Extended `LOB` data type support	NO	
T043	Multiplier T	NO	
T044	Multiplier P	NO	
T051	Row types	NO	
T052	`MAX` and `MIN` for row types	NO	
T053	Explicit aliases for all-fields reference	NO	
T061	UCS support	NO	
T071	`BIGINT` data type	YES	
T101	Enhanced nullability determiniation	NO	
T111	Updatable joins, unions, and columns	NO	
T121	`WITH` (excluding `RECURSIVE`) in query expression	NO	
T122	`WITH` (excluding `RECURSIVE`) in subquery	NO	
T131	Recursive query	NO	
T132	Recursive query in subquery	NO	
T141	`SIMILAR` predicate	YES	
T151	`DISTINCT` predicate	YES	
T152	`DISTINCT` predicate with negation	NO	
T171	`LIKE` clause in table definition	YES	
T172	`AS` subquery clause in table definition	YES	
T173	Extended `LIKE` clause in table definition	YES	
T174	Identity columns	YES	
T175	Generated columns	NO	
T176	Sequence generator support	NO	
T177	Sequence generator support: simple restart option	NO	
T178	Identity columns: simple restart option	YES	
T191	Referential action `RESTRICT`	NO	
T201	Comparable data types for referential constraints	NO	
T211	Basic trigger capability	NO	
T211-01	Triggers activated on `UPDATE`, `INSERT`, or `DELETE` of one base table	NO	
T211-02	`BEFORE` triggers	NO	
T211-03	`AFTER` triggers	NO	
T211-04	`FOR EACH ROW` triggers	NO	
T211-05	Ability to specify a search condition that must be true before the trigger is invoked	NO

ID	Feature	Supported	Comments
T211-06	Support for run-time rules for the interaction of triggers and constraints	NO	
T211-07	`TRIGGER` privilege	YES	
T211-08	Multiple triggers for the same event are run in the order in which they were created in the catalog	NO	Intentionally omitted
T212	Enhanced trigger capability	NO	
T213	`INSTEAD OF` triggers	NO	
T231	Sensitive cursors	YES	
T241	`START TRANSACTION` statement	YES	
T251	`SET TRANSACTION` statement: `LOCAL` option	NO	
T261	Chained transactions	NO	
T271	Savepoints	YES	
T272	Enhanced savepoint management	NO	
T281	`SELECT` privilege with column granularity	YES	
T285	Enhanced derived column names	NO	
T301	Functional dependencies	NO	
T312	OVERLAY function	YES	
T321	Basic SQL-invoked routines	NO	Partial support
T321-01	User-defined functions with no overloading	YES	
T321-02	User-defined stored procedures with no overloading	NO	
T321-03	Function invocation	YES	
T321-04	CALL statement	NO	
T321-05	RETURN statement	NO	
T321-06	ROUTINES view	YES	
T321-07	PARAMETERS view	YES	
T322	Overloading of SQL-invoked functions and procedures	YES	
T323	Explicit security for external routines	YES	
T324	Explicit security for SQL routines	NO	
T325	Qualified SQL parameter references	NO	
T326	Table functions	NO	
T331	Basic roles	NO	
T332	Extended roles	NO	
T351	Bracketed SQL comments (`/*...*/` comments)	YES	
T431	Extended grouping capabilities	NO	
T432	Nested and concatenated `GROUPING SETS`	NO	
T433	Multiargument `GROUPING` function	NO	
T434	`GROUP BY DISTINCT`	NO	
T441	`ABS` and `MOD` functions	YES	
T461	Symmetric `BETWEEN` predicate	YES	
T471	Result sets return value	NO	
T491	`LATERAL` derived table	NO	
T501	Enhanced `EXISTS` predicate	NO	
T511	Transaction counts	NO	
T541	Updatable table references	NO	
T561	Holdable locators	NO	
T571	Array-returning external SQL-invoked functions	NO	
T572	Multiset-returning external SQL-invoked functions	NO	
T581	Regular expression substring function	YES	
T591	`UNIQUE` constraints of possibly null columns	YES	
T601	Local cursor references	NO	
T611	Elementary OLAP operations	YES	
T612	Advanced OLAP operations	NO	Partially supported
T613	Sampling	NO	
T614	`NTILE` function	YES	
T615	`LEAD` and `LAG` functions	YES	
T616	Null treatment option for `LEAD` and `LAG` functions	NO	
T617	`FIRST_VALUE` and `LAST_VALUE` function	YES	
T618	`NTH_VALUE`	NO	Function exists in WarehousePG but not all options are supported
T621	Enhanced numeric functions	YES	
T631	N predicate with one list element	NO	
T641	Multiple column assignment	NO	Some syntax variants supported
T651	SQL-schema statements in SQL routines	NO

7.11 Server Configuration Parameter Changes from WarehousePG 6 to WarehousePG 7

WarehousePG 7 includes new server configuration parameters, and removes or updates the default values of certain server configuration parameters as described below.

New Parameters

The following new server configuration parameters are available in WarehousePG 7:

- `allow_in_place_tablespaces`
- `archive_cleanup_command`
- `backend_flush_after`
- `bgwriter_flush_after`
- `checkpoint_flush_after`
- `cluster_name`
- `data_directory_mode`
- `debug_deadlocks`
- `default_table_access_method`
- `dtx_phase2_retry_second`
- `enable_gathermerge`
- `enable_groupingsets_hash_disk`
- `enable_hashagg_disk`
- `enable_parallel_append`
- `enable_parallel_hash`
- `enable_partition_pruning`
- `enable_partitionwise_aggregate`
- `enable_partitionwise_join`
- `force_parallel_mode`
- `gin_pending_list_limit`
- `gp_autovacuum_scope`
- `gp_detect_data_correctness`
- `gp_explain_jit`
- `gp_force_random_redistribution`
- `gp_gxid_prefetch_num`
- `gp_max_alloc_size`
- `gp_pause_on_restore_point_replay`
- `gp_quicklz_fallback`
- `gp_resgroup_memory_query_fixed_mem`
- `gp_resource_group_bypass_direct_dispatch`
- `gp_workfile_compression_overhead_limit`
- `idle_in_transaction_session_timeout`
- `jit`
- `jit_above_cost`
- `jit_debugging_support`
- `jit_dump_bitcode`
- `jit_expressions`
- `jit_inline_above_cost`
- `jit_optimize_above_cost`
- `jit_profiling_support`
- `jit_provider`
- `jit_tuple_deforming`
- `log_btree_build_stats`
- `log_replication_commands`
- `log_statement_sample_rate`
- `log_transaction_sample_rate`
- `max_logical_replication_workers`
- `max_parallel_maintenance_workers`
- `max_parallel_workers`
- `max_parallel_workers_per_gather`
- `max_pred_locks_per_page`
- `max_pred_locks_per_relation`
- `max_sync_workers_per_subscription`
- `max_wal_size`
- `min_parallel_index_scan_size`
- `min_parallel_table_scan_size`
- `min_wal_size`
- `old_snapshot_threshold`
- `operator_precedence_warning`
- `optimize_bounded_sort`
- `optimizer_enable_coordinator_only_queries`
- `optimizer_enable_dynamicindexonlyscan`
- `optimizer_enable_foreign_table`
- `optimizer_enable_motions_coordinatoronly_queries`
- `optimizer_enable_nljoin`
- `optimizer_enable_push_join_below_union_all`
- `optimizer_jit_above_cost`
- `optimizer_jit_inline_above_cost`
- `optimizer_jit_optimize_above_cost`
- `parallel_leader_participation`
- `parallel_setup_cost`
- `parallel_tuple_cost`
- `primary_conninfo`
- `primary_slot_name`
- `promote_trigger_file`
- `recovery_end_command`
- `recovery_min_apply_delay`
- `recovery_target`
- `recovery_target_action`
- `recovery_target_inclusive`
- `recovery_target_lsn`
- `recovery_target_name`

- wal_recycle
- wal_retrieve_retry_interval
- wal_writer_flush_after

Removed Parameters

The following server configuration parameters are removed in WarehousePG 7:

- checkpoint_segments
- debug_latch
- dev_opt_unsafe_truncate_in_subtransaction
- dtx_phase2_retry_count
- enable_implicit_timeformat_YYYYMMDDHH24MISS
- gp_add_column_inherits_table_setting
- gp_allow_rename_relation_without_lock
- gp_count_host_segments_using_address
- gp_eager_agg_distinct_pruning
- gp_eager_one_phase_agg
- gp_eager_preunique
- gp_enable_exchange_default_partition
- gp_enable_gpperfmon
- gp_enable_mk_sort
- gp_enable_motion_mk_sort
- gp_enable_sort_distinct
- gp_gpperfmon_send_interval
- gp_hashagg_default_nbatches
- gp_hashagg_groups_per_bucket
- gp_hashagg_streambottom
- gp_ignore_window_exclude
- gp_indexcheck_vacuum
- gp_keep_all_xlog
- gp_log_resqueue_priority_sleep_time
- gp_max_partition_level
- gp_mk_sort_check
- gp_partitioning_dynamic_selection_log
- gpperfmon_log_alert_level
- gpperfmon_port
- gp_perfmon_print_packet_info
- gp_perfmon_segment_interval
- gp_resgroup_print_operator_memory_limits
- gp_resource_group_cpu_ceiling_enforcement
- gp_resource_group_enable_recalculate_query_mem
- gp_resource_group_memory_limit
- gp_safefswritesize
- gp_sort_flags
- gp_sort_max_distinct
- gp_use_synchronize_seqscans_catalog_vacuum_full

Changed Parameters

These server configuration parameters are changed in WarehousePG 7:

- The server configuration paramater `optimizer_enable_orderedagg` has a new default value of `on`.
- The server configuration parameter `vacuum_cost_page_miss` has a new default value of 2.
- The default value for the server configuration parameter `gp_interconnect_address_type` changed from `wildcard` to `unicast`.
- The `wal_keep_segments` server configuration parameter has been replaced by the `wal_keep_size` parameter.
- The `autovacuum` server configuration parameter is now enabled for all databases by default, rather than just for the `template0` and `template1` databases.
- The `gp_autostats_mode` server configuration parameter default value has been changed to `none`.
- The `gp_default_storage_options` parameter no longer supports the `appendonly` and `appendoptimized` keywords. Use the `default_table_access_method` parameter instead.

7.12 Features and Objects Removed in WarehousePG 7

WarehousePG 7 removes several database features and objects. These changes can potentially affect successfully upgrading from one major version to another. Review this list of removed features and objects before upgrading from WarehousePG 6 to WarehousePG 7.

Removed Features

The following features have been removed in WarehousePG 7:

- Support for Quicklz compression. To avoid breaking applications that use Quicklz, set the `gp_quicklz_fallback` server configuration parameter to `true`.
- The `--skip_root_stats` option of the `analyzedb` utility. `analyzedb` populates root statistics required by the optimizer by default.
- The WarehousePG R Client.
- WarehousePG MapReduce.
- The `ARRAY_NAME` variable. It is no longer used by WarehousePG.
- The PL/Container 3.0 Beta extension. Instead, use the regular PL/Container extension.
- The `gp_percentil_agg` extension. This is not part of the core WarehousePG product.
- The `createlang` and `droplang` utilties. Instead, use `CREATE EXTENSION` and `DROP EXTENSION` directly.
- Support for python2 and the `plpythonu` extension.

Removed Objects

This section summarizes objects removed in WarehousePG 7.

- Removed Tables and Views
- Removed Columns
- Removed Functions and Procedures
- Removed Types, Domains, and Composite Types
- Removed Operators

Removed Tables and Views

The following list includes the tables and views removed in WarehousePG 7.

- gp_toolkit.gp_size_of_partition_and_indexes_disk
- gp_toolkit.__gp_user_data_tables
- pg_catalog.pg_partition
- pg_catalog.pg_partition_columns
- pg_catalog.pg_partition_encoding
- pg_catalog.pg_partition_rule
- pg_catalog.pg_partitions
- pg_catalog.pg_partition_templates
- pg_catalog.pg_stat_partition_operations

Removed Columns

The following list includes the columns removed in WarehousePG 7.

- gp_toolkit.gp_locks_on_resqueue.lorwaiting
- gp_toolkit.gp_resgroup_config.cpu_rate_limit
- gp_toolkit.gp_resgroup_config.memory_auditor
- gp_toolkit.gp_resgroup_config.memory_shared_quota
- gp_toolkit.gp_resgroup_config.memory_spill_ratio
- gp_toolkit.gp_resgroup_status.cpu_usage
- gp_toolkit.gp_resgroup_status.memory_usage
- gp_toolkit.gp_resgroup_status_per_host.cpu
- gp_toolkit.gp_resgroup_status_per_host.memory_available
- gp_toolkit.gp_resgroup_status_per_host.memory_quota_available
- gp_toolkit.gp_resgroup_status_per_host.memory_quota_used
- gp_toolkit.gp_resgroup_status_per_host.memory_shared_available
- gp_toolkit.gp_resgroup_status_per_host.memory_shared_used
- gp_toolkit.gp_resgroup_status_per_host.memory_used
- gp_toolkit.gp_resgroup_status_per_host.rsgname
- gp_toolkit.gp_resgroup_status_per_segment.cpu
- gp_toolkit.gp_resgroup_status_per_segment.hostname
- gp_toolkit.gp_resgroup_status_per_segment.memory_available
- gp_toolkit.gp_resgroup_status_per_segment.memory_quota_available

7.13 System Catalog Changes between WarehousePG 6 and WarehousePG 7

This topic documents changes to existing system views, system catalogs, and functions between WarehousePG 6 and WarehousePG 7.

Changes to Both System Views and System Tables

The following changes pertain to both system views and system tables:

- The `Unknown` datatype has been changed from a base type to a pseudo type.
- Sequence for `SERIAL` columns now generate positive 32-bit wide values instead of 64-bit.
- Prior to WarehousePG 7, sequence metadata was stored in separate sequence relation table; each sequence created had its own table. In WarehousePG 7, the new `pg_sequence` system table contains all sequence-related metadata.
- The `gp_toolkit` schema is now an extension.

System Table Changes

This section describes changes to existing system tables.

- The `pg_appendonly` table no longer records append-only storage options. They are now listed in `pg_class` table's `reloptions` column instead. In addition, the following columns have been removed from the `pg_appendonly` table: `blocksize`, `safefswritesize`, `compresslevel`, `checksum`, `compresstype`, `columnstore`, `blkdiridxid`, and `visimapidxid`.
- To identify the storage type of a table, search `pg_class_relam` your table. Previously, used the `relstorage` column in `pg_class`.
- In the `gp_configuration_history` table, the `desc` column has been renamed to `description`.
- A new colum, `pg_proc.prokind`, column replaces `pg_proc.proisagg` and `pg_proc.proiswindow`.
- `pg_proc.protransform` has been renamed to `pg_proc.prosupport`.
- The `pg_am` table now stores possible table access methods.
- The `relam` column of the `pg_class` table now stores per-table access method information.
- To indicate that a table is of type external, set the `relkind` column in the `pg_class` table to `f`.
- The `adsrc` column has been removed from the `pg_attdref` table.

Changed Functions

This section lists functions whose signatures have changed across their overloaded versions between WarehousePG 6 and WarehousePG 7:

7.14 Server Programmatic Interfaces

This section describes programmatic interfaces to the WarehousePG server.

- WarehousePG Partner Connector API
- Background Worker Processes

Parent topic: WarehousePG Reference Guide

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7.14.1 WarehousePG Partner Connector API

With the WarehousePG Partner Connector API (GPPC API), you can write portable WarehousePG user-defined functions (UDFs) in the C and C++ programming languages. Functions that you develop with the GPPC API require no recompilation or modification to work with older or newer WarehousePG versions.

Functions that you write to the GPPC API can be invoked using SQL in WarehousePG. The API provides a set of functions and macros that you can use to issue SQL commands through the Server Programming Interface (SPI), manipulate simple and composite data type function arguments and return values, manage memory, and handle data.

You compile the C/C++ functions that you develop with the GPPC API into a shared library. The GPPC functions are available to WarehousePG users after the shared library is installed in the WarehousePG cluster and the GPPC functions are registered as SQL UDFs.

This topic contains the following information:

- Using the GPPC API
  - Requirements
  - Header and Library Files
  - Data Types
  - Function Declaration, Arguments, and Results
  - Memory Handling
  - Working With Variable-Length Text Types
  - Error Reporting and Logging
  - SPI Functions
  - About Tuple Descriptors and Tuples
  - Set-Returning Functions
  - Table Functions
  - Limitations
  - Sample Code
- Building a GPPC Shared Library with PGXS
- Registering a GPPC Function with WarehousePG
- Packaging and Deployment Considerations
- GPPC Text Function Example
- GPPC Set-Returning Function Example

Using the GPPC API

The GPPC API shares some concepts with C language functions as defined by PostgreSQL. Refer to C-Language Functions in the PostgreSQL documentation for detailed information about developing C language functions.

The GPPC API is a wrapper that makes a C/C++ function SQL-invokable in WarehousePG. This wrapper shields GPPC functions that you write from WarehousePG library changes by normalizing table and data manipulation and SPI operations through functions and macros defined by the API.

The GPPC API includes functions and macros to:

- Operate on base and composite data types.
- Process function arguments and return values.
- Allocate and free memory.
- Log and report errors to the client.
- Issue SPI queries.
- Return a table or set of rows.
- Process tables as function input arguments.

Requirements

When you develop with the GPPC API:

- You must develop your code on a system with the same hardware and software architecture as that of your WarehousePG hosts.
- You must write the GPPC function(s) in the C or C++ programming languages.
- The function code must use the GPPC API, data types, and macros.
- The function code must *not* use the PostgreSQL C-Language Function API, header files, functions, or macros.
- The function code must *not* `#include` the `postgres.h` header file or use `PG_MODULE_MAGIC`.
- You must use only the GPPC-wrapped memory functions to allocate and free memory. See Memory Handling.
- Symbol names in your object files must not conflict with each other nor with symbols defined in the WarehousePG server. You must rename your functions or variables if you get error messages to this effect.

Header and Library Files

The GPPC header files and libraries are installed in `$GPHOME`:

- $GPHOME/include/gppc.h - the main GPPC header file
- $GPHOME/include/gppc_config.h - header file defining the GPPC version
- $GPHOME/lib/libgppc.[a, so, so.1, so.1.2] - GPPC archive and shared libraries

Data Types

The GPPC functions that you create will operate on data residing in WarehousePG. The GPPC API includes data type definitions for equivalent WarehousePG SQL data types. You must use these types in your GPPC functions.

The GPPC API defines a generic data type that you can use to represent any GPPC type. This data type is named `GppcDatum`, and is defined as follows:

```
typedef int64_t GppcDatum;
```

The following table identifies each GPPC data type and the SQL type to which it maps.

SQL Type	GPPC Type	GPPC Oid for Type
boolean	GppcBool	GppcOidBool

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

SQL Type	GPPC Type	GPPC Oid for Type
char (single byte)	GppcChar	GppcOidChar
int2/smallint	GppcInt2	GppcOidInt2

text	*GppcText	GppcOidText
varchar	*GppcVarChar	GppcOidVarChar
char	*GppcBpChar	GppcOidBpChar
bytea	*GppcBytea	GppcOidBytea
numeric	*GppcNumeric	GppcOidNumeric
date	GppcDate	GppcOidDate
time	GppcTime	GppcOidTime
timetz	*GppcTimeTz	GppcOidTimeTz
timestamp	GppcTimestamp	GppcOidTimestamp
timestamptz	GppcTimestampTz	GppcOidTimestampTz
anytable	GppcAnyTable	GppcOidAnyTable
oid	GppcOid	

The GPPC API treats text, numeric, and timestamp data types specially, providing functions to operate on these types.

Example GPPC base data type declarations:

```
GppcText       message;
GppcInt4       arg1;
GppcNumeric    total_sales;
```

The GPPC API defines functions to convert between the generic `GppcDatum` type and the GPPC specific types. For example, to convert from an integer to a datum:

```
GppcInt4 num = 13;
GppcDatum num_dat = GppcInt4GetDatum(num);
```

Composite Types

A composite data type represents the structure of a row or record, and is comprised of a list of field names and their data types. This structure information is typically referred to as a tuple descriptor. An instance of a composite type is typically referred to as a tuple or row. A tuple does not have a fixed layout and can contain null fields.

The GPPC API provides an interface that you can use to define the structure of, to access, and to set tuples. You will use this interface when your GPPC function takes a table as an input argument or returns table or set of record types. Using tuples in table and set returning functions is covered later in this topic.

Function Declaration, Arguments, and Results

The GPPC API relies on macros to declare functions and to simplify the passing of function arguments and results. These macros include:

Task	Macro Signature	Description
Make a function SQL-invokable	`GPPC_FUNCTION_INFO(function\_name)`	Glue to make function `function\_name` SQL-invokable.
Declare a function	`GppcDatum function\_name(GPPC_FUNCTION_ARGS)`	Declare a GPPC function named `function\_name`; every function must have this same signature.
Return the number of arguments	`GPPC_NARGS()`	Return the number of arguments passed to the function.
Fetch an argument	`GPPC_GETARG_<ARGTYPE>(arg\_num)`	Fetch the value of argument number arg_num (starts at 0), where `<ARGTYPE>` identifies the data type of the argument. For example, `GPPC_GETARG_FLOAT8(0)`.
Fetch and make a copy of a text-type argument	`GPPC_GETARG_<ARGTYPE>_COPY(arg\_num)`	Fetch and make a copy of the value of argument number arg_num (starts at 0). `<ARGTYPE>` identifies the text type (text, varchar, bpchar, bytea). For example, `GPPC_GETARG_BYTEA_COPY(1)`.
Determine if an argument is NULL	`GPPC_ARGISNULL(arg\_num)`	Return whether or not argument number `arg\_num` is NULL.
Return a result	`GPPC_RETURN_<ARGTYPE>(return\_val)`	Return the value `return\_val`, where `<ARGTYPE>` identifies the data type of the return value. For example, `GPPC_RETURN_INT4(131)`.

When you define and implement your GPPC function, you must declare it with the GPPC API using the two declarations identified above. For example, to declare a GPPC function named `add_int4s()`:

```
GPPC_FUNCTION_INFO(add_int4s);
GppcDatum add_int4s(GPPC_FUNCTION_ARGS);

GppcDatum
add_int4s(GPPC_FUNCTION_ARGS)
{
  // code here
}
```

If the `add_int4s()` function takes two input arguments of type `int4`, you use the `GPPC_GETARG_INT4(arg\_num)` macro to access the argument values. The argument index starts at 0. For example:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
GppcInt4  first_int = GPPC_GETARG_INT4(0);
GppcInt4  second_int = GPPC_GETARG_INT4(1);
```

If `add_int4s()` returns the sum of the two input arguments, you use the `GPPC_RETURN_INT8(return\_val)` macro to return this sum. For example:

```
GppcInt8  sum = first_int + second_int;
GPPC_RETURN_INT8(sum);
```

The complete GPPC function:

```
GPPC_FUNCTION_INFO(add_int4s);
GppcDatum add_int4s(GPPC_FUNCTION_ARGS);

GppcDatum
add_int4s(GPPC_FUNCTION_ARGS)
{
  // get input arguments
  GppcInt4    first_int = GPPC_GETARG_INT4(0);
  GppcInt4    second_int = GPPC_GETARG_INT4(1);

  // add the arguments
  GppcInt8    sum = first_int + second_int;

  // return the sum
  GPPC_RETURN_INT8(sum);
}
```

Memory Handling

The GPPC API provides functions that you use to allocate and free memory, including text memory. You must use these functions for all memory operations.

Function Name	Description
void *GppcAlloc(size_t num)	Allocate num bytes of uninitialized memory.
void *GppcAlloc0(size_t num)	Allocate num bytes of 0-initialized memory.
void *GppcRealloc(void *ptr, size_t num)	Resize pre-allocated memory.
void GppcFree(void *ptr)	Free allocated memory.

After you allocate memory, you can use system functions such as `memcpy()` to set the data.

The following example allocates an array of `GppcDatum`s and sets the array to datum versions of the function input arguments:

```
GppcDatum  *values;
int attnum = GPPC_NARGS();

// allocate memory for attnum values
values = GppcAlloc( sizeof(GppcDatum) * attnum );

// set the values
for( int i=0; i<attnum; i++ ) {
    GppcDatum d = GPPC_GETARG_DATUM(i);
    values[i] = d;
}
```

When you allocate memory for a GPPC function, you allocate it in the current context. The GPPC API includes functions to return, create, switch, and reset memory contexts.

Function Name	Description
GppcMemoryContext GppcGetCurrentMemoryContext(void)	Return the current memory context.
GppcMemoryContext GppcMemoryContextCreate(GppcMemoryContext parent)	Create a new memory context under parent.
GppcMemoryContext GppcMemoryContextSwitchTo(GppcMemoryContext context)	Switch to the memory context context.
void GppcMemoryContextReset(GppcMemoryContext context)	Reset (free) the memory in memory context context.

WarehousePG typically calls a SQL-invoked function in a per-tuple context that it creates and deletes every time the server backend processes a table row. Do not assume that memory allocated in the current memory context is available across multiple function calls.

Working With Variable-Length Text Types

The GPPC API supports the variable length text, varchar, blank padded, and byte array types. You must use the GPPC API-provided functions when you operate on these data types. Variable text manipulation functions provided in the GPPC API include those to allocate memory for, determine string length of, get string pointers for, and access these types:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Function Name	Description
GppcText GppcAllocText(size_t len)	
GppcVarChar GppcAllocVarChar(size_t len)	
GppcBpChar GppcAllocBpChar(size_t len)	Allocate len bytes of memory for the varying length type.
GppcBytea GppcAllocBytea(size_t len)	
size_t GppcGetTextLength(GppcText s)	
size_t GppcGetVarCharLength(GppcVarChar s)	
size_t GppcGetBpCharLength(GppcBpChar s)	Return the number of bytes in the memory chunk.
size_t GppcGetByteaLength(GppcBytea b)	
char *GppcGetTextPointer(GppcText s)	
char *GppcGetVarCharPointer(GppcVarChar s)	
char *GppcGetBpCharPointer(GppcBpChar s)	Return a string pointer to the head of the memory chunk. The string is not null-terminated.
char *GppcGetByteaPointer(GppcBytea b)	
char *GppcTextGetCString(GppcText s)	
char *GppcVarCharGetCString(GppcVarChar s)	Return a string pointer to the head of the memory chunk. The string is null-terminated.
char *GppcBpCharGetCString(GppcBpChar s)	
GppcText *GppcCStringGetText(const char *s)	
GppcVarChar *GppcCStringGetVarChar(const char *s)	Build a varying-length type from a character string.
GppcBpChar *GppcCStringGetBpChar(const char *s)	

Memory returned by the `GppcGet<VLEN_ARGTYPE>Pointer()` functions may point to actual database content. Do not modify the memory content. The GPPC API provides functions to allocate memory for these types should you require it. After you allocate memory, you can use system functions such as `memcpy()` to set the data.

The following example manipulates text input arguments and allocates and sets result memory for a text string concatenation operation:

```
GppcText first_textstr = GPPC_GETARG_TEXT(0);
GppcText second_textstr = GPPC_GETARG_TEXT(1);

// determine the size of the concatenated string and allocate
// text memory of this size
size_t arg0_len = GppcGetTextLength(first_textstr);
size_t arg1_len = GppcGetTextLength(second_textstr);
GppcText retstring = GppcAllocText(arg0_len + arg1_len);

// construct the concatenated return string; copying each string
// individually
memcpy(GppcGetTextPointer(retstring), GppcGetTextPointer(first_textstr), arg0_len);
memcpy(GppcGetTextPointer(retstring) + arg0_len, GppcGetTextPointer(second_textstr), arg1_len);
```

Error Reporting and Logging

The GPPC API provides error reporting and logging functions. The API defines reporting levels equivalent to those in WarehousePG:

```
typedef enum GppcReportLevel
{
        GPPC_DEBUG1                             = 10,
        GPPC_DEBUG2                             = 11,
        GPPC_DEBUG3                             = 12,
        GPPC_DEBUG4                             = 13,
        GPPC_DEBUG                              = 14,
        GPPC_LOG                                = 15,
        GPPC_INFO                               = 17,
        GPPC_NOTICE                             = 18,
        GPPC_WARNING                          = 19,
        GPPC_ERROR                              = 20,
} GppcReportLevel;
```

(The WarehousePG `client_min_messages` server configuration parameter governs the current client logging level. The `log_min_messages` configuration parameter governs the current log-to-logfile level.)

A GPPC report includes the report level, a report message, and an optional report callback function.

Reporting and handling functions provide by the GPPC API include:

Function Name	Description
GppcReport()	Format and print/log a string of the specified report level.
GppcInstallReportCallback()	Register/install a report callback function.
GppcUninstallReportCallback()	Uninstall a report callback function.
GppcGetReportLevel()	Retrieve the level from an error report.
GppcGetReportMessage()	Retrieve the message from an error report.
GppcCheckForInterrupts()	Error out if an interrupt is pending.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

The `GppcReport()` function signature is:

```
void GppcReport(GppcReportLevel elevel, const char *fmt, ...);
```

`GppcReport()` takes a format string input argument similar to `printf()`. The following example generates an error level report message that formats a GPPC text argument:

```
GppcText  uname = GPPC_GETARG_TEXT(1);
GppcReport(GPPC_ERROR, "Unknown user name: %s", GppcTextGetCString(uname));
```

Refer to the GPPC example code for example report callback handlers.

SPI Functions

The WarehousePG Server Programming Interface (SPI) provides writers of C/C++ functions the ability to run SQL commands within a GPPC function. For additional information on SPI functions, refer toServer Programming Interface in the PostgreSQL documentation.

The GPPC API exposes a subset of PostgreSQL SPI functions. This subset enables you to issue SPI queries and retrieve SPI result values in your GPPC function. The GPPC SPI wrapper functions are:

SPI Function Name	GPPC Function Name	Description
SPI_connect()	GppcSPIConnect()	Connect to the WarehousePG server programming interface.
SPI_finish()	GppcSPIFinish()	Disconnect from the WarehousePG server programming interface.
SPI_exec()	GppcSPIExec()	Run a SQL statement, returning the number of rows.
SPI_getvalue()	GppcSPIGetValue()	Retrieve the value of a specific attribute by number from a SQL result as a character string.
GppcSPIGetDatum()	Retrieve the value of a specific attribute by number from a SQL result as a `GppcDatum`.	
GppcSPIGetValueByName()	Retrieve the value of a specific attribute by name from a SQL result as a character string.	
GppcSPIGetDatumByName()	Retrieve the value of a specific attribute by name from a SQL result as a `GppcDatum`.	

When you create a GPPC function that accesses the server programming interface, your function should comply with the following flow:

```
GppcSPIConnect();
GppcSPIExec(...)
// process the results - GppcSPIGetValue(...), GppcSPIGetDatum(...)
GppcSPIFinish()
```

You use `GppcSPIExec()` to run SQL statements in your GPPC function. When you call this function, you also identify the maximum number of rows to return. The function signature of `GppcSPIExec()` is:

```
GppcSPIResult GppcSPIExec(const char *sql_statement, long rcount);
```

`GppcSPIExec()` returns a `GppcSPIResult` structure. This structure represents SPI result data. It includes a pointer to the data, information about the number of rows processed, a counter, and a result code. The GPPC API defines this structure as follows:

```
typedef struct GppcSPIResultData
{
    struct GppcSPITupleTableData   *tuptable;
    uint32_t                       processed;
    uint32_t                       current;
    int                            rescode;
} GppcSPIResultData;
typedef GppcSPIResultData *GppcSPIResult;
```

You can set and use the `current` field in the `GppcSPIResult` structure to examine each row of the `tuptable` result data.

The following code excerpt uses the GPPC API to connect to SPI, run a simple query, loop through query results, and finish processing:

```
GppcSPIResult   result;
char            *attname = "id";
char            *query = "SELECT i, 'foo' || i AS val FROM generate_series(1, 10)i ORDER BY 1";
bool            isnull = true;

// connect to SPI
if( GppcSPIConnect() < 0 ) {
    GppcReport(GPPC_ERROR, "cannot connect to SPI");
}

// execute the query, returning all rows
result = GppcSPIExec(query, 0);

// process result
while( result->current < result->processed ) {
    // get the value of attname column as a datum, making a copy
    datum = GppcSPIGetDatumByName(result, attname, &isnull, true);

    // do something with value

    // move on to next row
    result->current++;
}

// complete processing
GppcSPIFinish();
```

About Tuple Descriptors and Tuples

A table or a set of records contains one or more tuples (rows). The structure of each attribute of a tuple is defined by a tuple descriptor. A tuple descriptor defines the following for each attribute in the tuple:

- attribute name
- object identifier of the attribute data type
- byte length of the attribute data type
- object identifier of the attribute modifer

The GPPC API defines an abstract type, `GppcTupleDesc`, to represent a tuple/row descriptor. The API also provides functions that you can use to create, access, and set tuple descriptors:

Function Name	Description
GppcCreateTemplateTupleDesc()	Create an empty tuple descriptor with a specified number of attributes.
GppcTupleDescInitEntry()	Add an attribute to the tuple descriptor at a specified position.
GppcTupleDescNattrs()	Fetch the number of attributes in the tuple descriptor.
GppcTupleDescAttrName()	Fetch the name of the attribute in a specific position (starts at 0) in the tuple descriptor.
GppcTupleDescAttrType()	Fetch the type object identifier of the attribute in a specific position (starts at 0) in the tuple descriptor.
GppcTupleDescAttrLen()	Fetch the type length of an attribute in a specific position (starts at 0) in the tuple descriptor.
GppcTupleDescAttrTypmod()	Fetch the type modifier object identifier of an attribute in a specific position (starts at 0) in the tuple descriptor.

To construct a tuple descriptor, you first create a template, and then fill in the descriptor fields for each attribute. The signatures for these functions are:

```
GppcTupleDesc GppcCreateTemplateTupleDesc(int natts);
void GppcTupleDescInitEntry(GppcTupleDesc desc, uint16_t attno,
                            const char *attname, GppcOid typid, int32_t typmod);
```

In some cases, you may want to initialize a tuple descriptor entry from an attribute definition in an existing tuple. The following functions fetch the number of attributes in a tuple descriptor, as well as the definition of a specific attribute (by number) in the descriptor:

```
int GppcTupleDescNattrs(GppcTupleDesc tupdesc);
const char *GppcTupleDescAttrName(GppcTupleDesc tupdesc, int16_t attno);
GppcOid GppcTupleDescAttrType(GppcTupleDesc tupdesc, int16_t attno);
int16_t GppcTupleDescAttrLen(GppcTupleDesc tupdesc, int16_t attno);
int32_t GppcTupleDescAttrTypmod(GppcTupleDesc tupdesc, int16_t attno);
```

The following example initializes a two attribute tuple descriptor. The first attribute is initialized with the definition of an attribute from a different descriptor, and the second attribute is initialized to a boolean type attribute:

```
GppcTupleDesc       tdesc;
GppcTupleDesc       indesc = some_input_descriptor;

// initialize the tuple descriptor with 2 attributes
tdesc = GppcCreateTemplateTupleDesc(2);

// use third attribute from the input descriptor
GppcTupleDescInitEntry(tdesc, 1,
          GppcTupleDescAttrName(indesc, 2),
          GppcTupleDescAttrType(indesc, 2),
          GppcTupleDescAttrTypmod(indesc, 2));

// create the boolean attribute
GppcTupleDescInitEntry(tdesc, 2, "is_active", GppcOidBool, 0);
```

The GPPC API defines an abstract type, `GppcHeapTuple`, to represent a tuple/record/row. A tuple is defined by its tuple descriptor, the value for each tuple attribute, and an indicator of whether or not each value is NULL.

The GPPC API provides functions that you can use to set and access a tuple and its attributes:

Function Name	Description
GppcHeapFormTuple()	Form a tuple from an array of `GppcDatum`s.
GppcBuildHeapTupleDatum()	Form a `GppcDatum` tuple from an array of `GppcDatum`s.
GppcGetAttributeByName()	Fetch an attribute from the tuple by name.
GppcGetAttributeByNum()	Fetch an attribute from the tuple by number (starts at 1).

The signatures for the tuple-building GPPC functions are:

```
GppcHeapTuple GppcHeapFormTuple(GppcTupleDesc tupdesc, GppcDatum *values, bool *nulls);
GppcDatum    GppcBuildHeapTupleDatum(GppcTupleDesc tupdesc, GppcDatum *values, bool *nulls);
```

The following code excerpt constructs a `GppcDatum` tuple from the tuple descriptor in the above code example, and from integer and boolean input arguments to a function:

```
GppcDatum intarg = GPPC_GETARG_INT4(0);
GppcDatum boolarg = GPPC_GETARG_BOOL(1);
GppcDatum result, values[2];
bool nulls[2] = { false, false };

// construct the values array
values[0] = intarg;
values[1] = boolarg;
result = GppcBuildHeapTupleDatum( tdesc, values, nulls );
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Set-Returning Functions

WarehousePG UDFs whose signatures include `RETURNS SETOF RECORD` or `RETURNS TABLE( ... )` are set-returning functions.

The GPPC API provides support for returning sets (for example, multiple rows/tuples) from a GPPC function. WarehousePG calls a set-returning function (SRF) once for each row or item. The function must save enough state to remember what it was doing and to return the next row on each call. Memory that you allocate in the SRF context must survive across multiple function calls.

The GPPC API provides macros and functions to help keep track of and set this context, and to allocate SRF memory. They include:

Function/Macro Name	Description
GPPC_SRF_RESULT_DESC()	Get the output row tuple descriptor for this SRF. The result tuple descriptor is determined by an output table definition or a `DESCRIBE` function.
GPPC_SRF_IS_FIRSTCALL()	Determine if this is the first call to the SRF.
GPPC_SRF_FIRSTCALL_INIT()	Initialize the SRF context.
GPPC_SRF_PERCALL_SETUP()	Restore the context on each call to the SRF.
GPPC_SRF_RETURN_NEXT()	Return a value from the SRF and continue processing.
GPPC_SRF_RETURN_DONE()	Signal that SRF processing is complete.
GppSRFAlloc()	Allocate memory in this SRF context.
GppSRFAlloc0()	Allocate memory in this SRF context and initialize it to zero.
GppSRFSave()	Save user state in this SRF context.
GppSRFRestore()	Restore user state in this SRF context.

The `GppcFuncCallContext` structure provides the context for an SRF. You create this context on the first call to your SRF. Your set-returning GPPC function must retrieve the function context on each invocation. For example:

```
// set function context
GppcFuncCallContext fctx;
if (GPPC_SRF_IS_FIRSTCALL()) {
    fctx = GPPC_SRF_FIRSTCALL_INIT();
}
fctx = GPPC_SRF_PERCALL_SETUP();
// process the tuple
```

The GPPC function must provide the context when it returns a tuple result or to indicate that processing is complete. For example:

```
GPPC_SRF_RETURN_NEXT(fctx, result_tuple);
// or
GPPC_SRF_RETURN_DONE(fctx);
```

Use a `DESCRIBE` function to define the output tuple descriptor of a function that uses the `RETURNS SETOF RECORD` clause. Use the `GPPC_SRF_RESULT_DESC()` macro to get the output tuple descriptor of a function that uses the `RETURNS TABLE( ... )` clause.

Refer to the GPPC Set-Returning Function Example for a set-returning function code and deployment example.

Table Functions

The GPPC API provides the `GppcAnyTable` type to pass a table to a function as an input argument, or to return a table as a function result.

Table-related functions and macros provided in the GPPC API include:

Function/Macro Name	Description
GPPC_GETARG_ANYTABLE()	Fetch an anytable function argument.
GPPC_RETURN_ANYTABLE()	Return the table.
GppcAnyTableGetTupleDesc()	Fetch the tuple descriptor for the table.
GppcAnyTableGetNextTuple()	Fetch the next row in the table.

You can use the `GPPC_GETARG_ANYTABLE()` macro to retrieve a table input argument. When you have access to the table, you can examine the tuple descriptor for the table using the `GppcAnyTableGetTupleDesc()` function. The signature of this function is:

```
GppcTupleDesc GppcAnyTableGetTupleDesc(GppcAnyTable t);
```

For example, to retrieve the tuple descriptor of a table that is the first input argument to a function:

```
GppcAnyTable     intbl;
GppcTupleDesc    in_desc;

intbl = GPPC_GETARG_ANYTABLE(0);
in_desc = GppcAnyTableGetTupleDesc(intbl);
```

The `GppcAnyTableGetNextTuple()` function fetches the next row from the table. Similarly, to retrieve the next tuple from the table above:

```
GppcHeapTuple    ntuple;

ntuple = GppcAnyTableGetNextTuple(intbl);
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Limitations

The GPPC API does not support the following operators with WarehousePG version 5.0.x:

- integer || integer
- integer = text
- text < integer

Sample Code

The gppc test directory in the WarehousePG github repository includes sample GPPC code:

- `gppc_demo/` - sample code exercising GPPC SPI functions, error reporting, data type argument and return macros, set-returning functions, and encoding functions
- `tabfunc_gppc_demo/` - sample code exercising GPPC table and set-returning functions

Building a GPPC Shared Library with PGXS

You compile functions that you write with the GPPC API into one or more shared libraries that the WarehousePG server loads on demand.

You can use the PostgreSQL build extension infrastructure (PGXS) to build the source code for your GPPC functions against a WarehousePG installation. This framework automates common build rules for simple modules. If you have a more complicated use case, you will need to write your own build system.

To use the PGXS infrastructure to generate a shared library for functions that you create with the GPPC API, create a simple `Makefile` that sets PGXS-specific variables.

> **Note** Refer to Extension Building Infrastructure in the PostgreSQL documentation for information about the `Makefile` variables supported by PGXS.

For example, the following `Makefile` generates a shared library named `sharedlib_name.so` from two C source files named `src1.c` and `src2.c`:

```
MODULE_big = sharedlib_name
OBJS = src1.o src2.o
PG_CPPFLAGS = -I$(shell $(PG_CONFIG) --includedir)
SHLIB_LINK = -L$(shell $(PG_CONFIG) --libdir) -lgppc

PG_CONFIG = pg_config
PGXS := $(shell $(PG_CONFIG) --pgxs)
include $(PGXS)
```

`MODULE_big` identifes the base name of the shared library generated by the `Makefile`.

`PG_CPPFLAGS` adds the WarehousePG installation include directory to the compiler header file search path.

`SHLIB_LINK` adds the WarehousePG installation library directory to the linker search path. This variable also adds the GPPC library (`-lgppc`) to the link command.

The `PG_CONFIG` and `PGXS` variable settings and the `include` statement are required and typically reside in the last three lines of the `Makefile`.

Registering a GPPC Function with WarehousePG

Before users can invoke a GPPC function from SQL, you must register the function with WarehousePG.

Registering a GPPC function involves mapping the GPPC function signature to a SQL user-defined function. You define this mapping with the `CREATE FUNCTION .. AS` command specifying the GPPC shared library name. You may choose to use the same name or differing names for the GPPC and SQL functions.

Sample `CREATE FUNCTION ... AS` syntax follows:

```
CREATE FUNCTION <sql_function_name>(<arg>[, ...]) RETURNS <return_type>
  AS '<shared_library_path>'[, '<gppc_function_name>']
LANGUAGE C STRICT [WITH (DESCRIBE=<describe_function>)];
```

You may omit the shared library `.so` extension when you specify `shared\_library\_path`.

The following command registers the example `add_int4s()` function referenced earlier in this topic to a SQL UDF named `add_two_int4s_gppc()` if the GPPC function was compiled and linked in a shared library named `gppc_try.so`:

```
CREATE FUNCTION add_two_int4s_gppc(int4, int4) RETURNS int8
  AS 'gppc_try.so', 'add_int4s'
LANGUAGE C STRICT;
```

About Dynamic Loading

You specify the name of the GPPC shared library in the SQL `CREATE FUNCTION ... AS` command to register a GPPC function in the shared library with WarehousePG. The WarehousePG dynamic loader loads a GPPC shared library file into memory the first time that a user invokes a user-defined function linked in that shared library. If you do not provide an absolute path to the shared library in the `CREATE FUNCTION ... AS` command, WarehousePG attempts to locate the library using these ordered steps:

1. If the shared library file path begins with the string `$libdir`, WarehousePG looks for the file in the PostgreSQL package library directory. Run the `pg_config --pkglibdir` command to determine the location of this directory.
2. If the shared library file name is specified without a directory prefix, WarehousePG searches for the file in the directory identified by the `dynamic_library_path` server configuration parameter value.
3. The current working directory.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Packaging and Deployment Considerations

You must package the GPPC shared library and SQL function registration script in a form suitable for deployment by the WarehousePG administrator in the WarehousePG cluster. Provide specific deployment instructions for your GPPC package.

When you construct the package and deployment instructions, take into account the following:

- Consider providing a shell script or program that the WarehousePG administrator runs to both install the shared library to the desired file system location and register the GPPC functions.
- The GPPC shared library must be installed to the same file system location on the coordinator host and on every segment host in the WarehousePG cluster.
- The `gpadmin` user must have permission to traverse the complete file system path to the GPPC shared library file.
- The file system location of your GPPC shared library after it is installed in the WarehousePG deployment determines how you reference the shared library when you register a function in the library with the `CREATE FUNCTION ... AS` command.
- Create a `.sql` script file that registers a SQL UDF for each GPPC function in your GPPC shared library. The functions that you create in the `.sql` registration script must reference the deployment location of the GPPC shared library. Include this script in your GPPC deployment package.
- Document the instructions for running your GPPC package deployment script, if you provide one.
- Document the instructions for installing the GPPC shared library if you do not include this task in a package deployment script.
- Document the instructions for installing and running the function registration script if you do not include this task in a package deployment script.

GPPC Text Function Example

In this example, you develop, build, and deploy a GPPC shared library and register and run a GPPC function named `concat_two_strings`. This function uses the GPPC API to concatenate two string arguments and return the result.

You will develop the GPPC function on your WarehousePG coordinator host. Deploying the GPPC shared library that you create in this example requires administrative access to your WarehousePG cluster.

Perform the following procedure to run the example:

1. Log in to the WarehousePG coordinator host and set up your environment. For example:

   ```
   $ ssh gpadmin@<gpcoordinator>
   gpadmin@gpcoordinator$ . /usr/edb/whpg7/greenplum_path.sh
   ```

2. Create a work directory and navigate to the new directory. For example:

   ```
   gpadmin@gpcoordinator$ mkdir gppc_work
   gpadmin@gpcoordinator$ cd gppc_work
   ```

3. Prepare a file for GPPC source code by opening the file in the editor of your choice. For example, to open a file named `gppc_concat.c` using `vi`:

   ```
   gpadmin@gpcoordinator$ vi gppc_concat.c
   ```

4. Copy/paste the following code into the file:

   ```
   #include <stdio.h>
   #include <string.h>
   #include "gppc.h"

   // make the function SQL-invokable
   GPPC_FUNCTION_INFO(concat_two_strings);

   // declare the function
   GppcDatum concat_two_strings(GPPC_FUNCTION_ARGS);

   GppcDatum
   concat_two_strings(GPPC_FUNCTION_ARGS)
   {
       // retrieve the text input arguments
       GppcText arg0 = GPPC_GETARG_TEXT(0);
       GppcText arg1 = GPPC_GETARG_TEXT(1);

       // determine the size of the concatenated string and allocate
       // text memory of this size
       size_t arg0_len = GppcGetTextLength(arg0);
       size_t arg1_len = GppcGetTextLength(arg1);
       GppcText retstring = GppcAllocText(arg0_len + arg1_len);

       // construct the concatenated return string
       memcpy(GppcGetTextPointer(retstring), GppcGetTextPointer(arg0), arg0_len);
       memcpy(GppcGetTextPointer(retstring) + arg0_len, GppcGetTextPointer(arg1), arg1_len);

       GPPC_RETURN_TEXT( retstring );
   }
   ```

   The code declares and implements the `concat_two_strings()` function. It uses GPPC data types, macros, and functions to get the function arguments, allocate memory for the concatenated string, copy the arguments into the new string, and return the result.

5. Save the file and exit the editor.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

6. Open a file named `Makefile` in the editor of your choice. Copy/paste the following text into the file:

```
MODULE_big = gppc_concat
OBJS = gppc_concat.o

PG_CONFIG = pg_config
PGXS := $(shell $(PG_CONFIG) --pgxs)

PG_CPPFLAGS = -I$(shell $(PG_CONFIG) --includedir)
SHLIB_LINK = -L$(shell $(PG_CONFIG) --libdir) -lgppc
include $(PGXS)
```

7. Save the file and exit the editor.

8. Build a GPPC shared library for the `concat_two_strings()` function. For example:

```
gpadmin@gpcoordinator$ make all
```

   The `make` command generates a shared library file named `gppc_concat.so` in the current working directory.

9. Copy the shared library to your WarehousePG installation. You must have WarehousePG administrative privileges to copy the file. For example:

```
gpadmin@gpcoordinator$ cp gppc_concat.so /usr/edb/whpg7/lib/postgresql/
```

10. Copy the shared library to every host in your WarehousePG installation. For example, if `seghostfile` contains a list, one-host-per-line, of the segment hosts in your WarehousePG cluster:

```
gpadmin@gpcoordinator$ gpsync -v -f seghostfile /usr/edb/whpg7/lib/postgresql/gppc_concat.so =:/usr/edb/whpg7/lib/postgresql/gppc_concat.so
```

11. Open a `psql` session. For example:

```
gpadmin@gpcoordinator$ psql -d testdb
```

12. Register the GPPC function named `concat_two_strings()` with WarehousePG, For example, to map the WarehousePG function `concat_with_gppc()` to the GPPC `concat_two_strings()` function:

```
testdb=# CREATE FUNCTION concat_with_gppc(text, text) RETURNS text
  AS 'gppc_concat', 'concat_two_strings'
LANGUAGE C STRICT;
```

13. Run the `concat_with_gppc()` function. For example:

```
testdb=# SELECT concat_with_gppc( 'happy', 'monday' );
 concat_with_gppc
------------------
 happymonday
(1 row)
```

GPPC Set-Returning Function Example

In this example, you develop, build, and deploy a GPPC shared library. You also create and run a `.sql` registration script for a GPPC function named `return_tbl()`. This function uses the GPPC API to take an input table with an integer and a text column, determine if the integer column is greater than 13, and returns a result table with the input integer column and a boolean column identifying whether or not the integer is greater than 13. `return_tbl()` utilizes GPPC API reporting and SRF functions and macros.

You will develop the GPPC function on your WarehousePG coordinator host. Deploying the GPPC shared library that you create in this example requires administrative access to your WarehousePG cluster.

Perform the following procedure to run the example:

1. Log in to the WarehousePG coordinator host and set up your environment. For example:

```
$ ssh gpadmin@<gpcoordinator>
gpadmin@gpcoordinator$ . /usr/edb/whpg7/greenplum_path.sh
```

2. Create a work directory and navigate to the new directory. For example:

```
gpadmin@gpcoordinator$ mkdir gppc_work
gpadmin@gpcoordinator$ cd gppc_work
```

3. Prepare a source file for GPPC code by opening the file in the editor of your choice. For example, to open a file named `gppc_concat.c` using `vi`:

```
gpadmin@gpcoordinator$ vi gppc_rettbl.c
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4. Copy/paste the following code into the file:

```
#include <stdio.h>
#include <string.h>
#include "gppc.h"

// initialize the logging level
GppcReportLevel level = GPPC_INFO;

// make the function SQL-invokable and declare the function
GPPC_FUNCTION_INFO(return_tbl);
GppcDatum return_tbl(GPPC_FUNCTION_ARGS);

GppcDatum
return_tbl(GPPC_FUNCTION_ARGS)
{
    GppcFuncCallContext fctx;
    GppcAnyTable    intbl;
    GppcHeapTuple   intuple;
    GppcTupleDesc   in_tupdesc, out_tupdesc;
    GppcBool        resbool = false;
    GppcDatum       result, boolres, values[2];
    bool        nulls[2] = {false, false};

    // single input argument - the table
    intbl = GPPC_GETARG_ANYTABLE(0);

    // set the function context
    if (GPPC_SRF_IS_FIRSTCALL()) {
        fctx = GPPC_SRF_FIRSTCALL_INIT();
    }
    fctx = GPPC_SRF_PERCALL_SETUP();

    // get the tuple descriptor for the input table
    in_tupdesc  = GppcAnyTableGetTupleDesc(intbl);

    // retrieve the next tuple
    intuple = GppcAnyTableGetNextTuple(intbl);
    if( intuple == NULL ) {
      // no more tuples, conclude
      GPPC_SRF_RETURN_DONE(fctx);
    }

    // get the output tuple descriptor and verify that it is
    // defined as we expect
    out_tupdesc = GPPC_SRF_RESULT_DESC();
    if (GppcTupleDescNattrs(out_tupdesc) != 2                ||
        GppcTupleDescAttrType(out_tupdesc, 0) != GppcOidInt4 ||
        GppcTupleDescAttrType(out_tupdesc, 1) != GppcOidBool) {
        GppcReport(GPPC_ERROR, "INVALID out_tupdesc tuple");
    }

    // log the attribute names of the output tuple descriptor
    GppcReport(level, "output tuple descriptor attr0 name: %s", GppcTupleDescAttrName(out_tupdesc, 0));
    GppcReport(level, "output tuple descriptor attr1 name: %s", GppcTupleDescAttrName(out_tupdesc, 1));

    // retrieve the attribute values by name from the tuple
    bool text_isnull, int_isnull;
    GppcDatum intdat = GppcGetAttributeByName(intuple, "id", &int_isnull);
    GppcDatum textdat = GppcGetAttributeByName(intuple, "msg", &text_isnull);

    // convert datum to specific type
    GppcInt4 intarg = GppcDatumGetInt4(intdat);
    GppcReport(level, "id: %d", intarg);
    GppcReport(level, "msg: %s", GppcTextGetCString(GppcDatumGetText(textdat)));

    // perform the >13 check on the integer
    if( !int_isnull && (intarg > 13) ) {
        // greater than 13?
        resbool = true;
        GppcReport(level, "id is greater than 13!");
    }

    // values are datums; use integer from the tuple and
    // construct the datum for the boolean return
    values[0] = intdat;
    boolres = GppcBoolGetDatum(resbool);
    values[1] = boolres;

    // build a datum tuple and return
    result = GppcBuildHeapTupleDatum(out_tupdesc, values, nulls);
    GPPC_SRF_RETURN_NEXT(fctx, result);

}
```

The code declares and implements the `return_tbl()` function. It uses GPPC data types, macros, and functions to fetch the function arguments, examine tuple descriptors, build the return tuple, and return the result. The function also uses the SRF macros to keep track of the tuple context across function calls.

5. Save the file and exit the editor.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

6. Open a file named `Makefile` in the editor of your choice. Copy/paste the following text into the file:

```
MODULE_big = gppc_rettbl
OBJS = gppc_rettbl.o

PG_CONFIG = pg_config
PGXS := $(shell $(PG_CONFIG) --pgxs)

PG_CPPFLAGS = -I$(shell $(PG_CONFIG) --includedir)
SHLIB_LINK = -L$(shell $(PG_CONFIG) --libdir) -lgppc
include $(PGXS)
```

7. Save the file and exit the editor.

8. Build a GPPC shared library for the `return_tbl()` function. For example:

```
gpadmin@gpcoordinator$ make all
```

   The `make` command generates a shared library file named `gppc_rettbl.so` in the current working directory.

9. Copy the shared library to your WarehousePG installation. You must have WarehousePG administrative privileges to copy the file. For example:

```
gpadmin@gpcoordinator$ cp gppc_rettbl.so /usr/edb/whpg7/lib/postgresql/
```

   This command copies the shared library to `$libdir`

10. Copy the shared library to every host in your WarehousePG installation. For example, if `seghostfile` contains a list, one-host-per-line, of the segment hosts in your WarehousePG cluster:

```
gpadmin@gpcoordinator$ gpsync -v -f seghostfile /usr/edb/whpg7/lib/postgresql/gppc_rettbl.so =:/usr/edb/whpg7/lib/postgresql/gppc_rettbl.so
```

11. Create a `.sql` file to register the GPPC `return_tbl()` function. Open a file named `gppc_rettbl_reg.sql` in the editor of your choice.

12. Copy/paste the following text into the file:

```
CREATE FUNCTION rettbl_gppc(anytable) RETURNS TABLE(id int4, thirteen bool)
  AS 'gppc_rettbl', 'return_tbl'
LANGUAGE C STRICT;
```

13. Register the GPPC function by running the script you just created. For example, to register the function in a database named `testdb`:

```
gpadmin@gpcoordinator$ psql -d testdb -f gppc_rettbl_reg.sql
```

14. Open a `psql` session. For example:

```
gpadmin@gpcoordinator$ psql -d testdb
```

15. Create a table with some test data. For example:

```
CREATE TABLE gppc_testtbl( id int, msg text );
INSERT INTO gppc_testtbl VALUES (1, 'f1');
INSERT INTO gppc_testtbl VALUES (7, 'f7');
INSERT INTO gppc_testtbl VALUES (10, 'f10');
INSERT INTO gppc_testtbl VALUES (13, 'f13');
INSERT INTO gppc_testtbl VALUES (15, 'f15');
INSERT INTO gppc_testtbl VALUES (17, 'f17');
```

16. Run the `rettbl_gppc()` function. For example:

```
testdb=# SELECT * FROM rettbl_gppc(TABLE(SELECT * FROM gppc_testtbl));
 id | thirteen
----+----------
  1 | f
  7 | f
 13 | f
 15 | t
 17 | t
 10 | f
(6 rows)
```

7.14.2 Developing a Background Worker Process

WarehousePG can be extended to run user-supplied code in separate processes. Such processes are started, stopped, and monitored by `postgres`, which permits them to have a lifetime closely linked to the server's status. These processes have the option to attach to WarehousePG's shared memory area and to connect to databases internally; they can also run multiple transactions serially, just like a regular client-connected server process. Also, by linking to `libpq` they can connect to the server and behave like a regular client application.

> **Caution** There are considerable robustness and security risks in using background worker processes because, being written in the `C` language, they have unrestricted access to data. Administrators wishing to enable modules that include background worker processes should exercise extreme caution. Only carefully audited modules should be permitted to run background worker processes.

Background workers can be initialized at the time that WarehousePG is started by including the module name in the shared_preload_libraries server configuration parameter. A module wishing to run a background worker can register it by calling `RegisterBackgroundWorker(BackgroundWorker *worker)` from its `_PG_init()`. Background workers can also be started after the system is up and running by calling the function `RegisterDynamicBackgroundWorker(BackgroundWorker *worker, BackgroundWorkerHandle **handle)`. Unlike `RegisterBackgroundWorker`, which can only be called from within the `postmaster`, `RegisterDynamicBackgroundWorker` must be called from a regular backend.

The structure `BackgroundWorker` is defined thus:

```
typedef void (*bgworker_main_type)(Datum main_arg);
typedef struct BackgroundWorker
{
    char        bgw_name[BGW_MAXLEN];
    int         bgw_flags;
    BgWorkerStartTime bgw_start_time;
    int         bgw_restart_time;       /* in seconds, or BGW_NEVER_RESTART */
    bgworker_main_type bgw_main;
    char        bgw_library_name[BGW_MAXLEN];   /* only if bgw_main is NULL */
    char        bgw_function_name[BGW_MAXLEN];  /* only if bgw_main is NULL */
    Datum       bgw_main_arg;
    int         bgw_notify_pid;
} BackgroundWorker;
```

`bgw_name` is a string to be used in log messages, process listings and similar contexts.

`bgw_flags` is a bitwise-or'd bit mask indicating the capabilities that the module wants. Possible values are `BGWORKER_SHMEM_ACCESS` (requesting shared memory access) and `BGWORKER_BACKEND_DATABASE_CONNECTION` (requesting the ability to establish a database connection, through which it can later run transactions and queries). A background worker using `BGWORKER_BACKEND_DATABASE_CONNECTION` to connect to a database must also attach shared memory using `BGWORKER_SHMEM_ACCESS`, or worker start-up will fail.

`bgw_start_time` is the server state during which `postgres` should start the process; it can be one of `BgWorkerStart_PostmasterStart` (start as soon as `postgres` itself has finished its own initialization; processes requesting this are not eligible for database connections), `BgWorkerStart_ConsistentState` (start as soon as a consistent state has been reached in a hot standby, allowing processes to connect to databases and run read-only queries), and `BgWorkerStart_RecoveryFinished` (start as soon as the system has entered normal read-write state). Note the last two values are equivalent in a server that's not a hot standby. Note that this setting only indicates when the processes are to be started; they do not stop when a different state is reached.

`bgw_restart_time` is the interval, in seconds, that `postgres` should wait before restarting the process, in case it crashes. It can be any positive value, or `BGW_NEVER_RESTART`, indicating not to restart the process in case of a crash.

`bgw_main` is a pointer to the function to run when the process is started. This function must take a single argument of type `Datum` and return `void`. `bgw_main_arg` will be passed to it as its only argument. Note that the global variable `MyBgworkerEntry` points to a copy of the `BackgroundWorker` structure passed at registration time. `bgw_main` may be NULL; in that case, `bgw_library_name` and `bgw_function_name` will be used to determine the entry point. This is useful for background workers launched after postmaster startup, where the postmaster does not have the requisite library loaded.

`bgw_library_name` is the name of a library in which the initial entry point for the background worker should be sought. It is ignored unless `bgw_main` is NULL. But if `bgw_main` is NULL, then the named library will be dynamically loaded by the worker process and `bgw_function_name` will be used to identify the function to be called.

`bgw_function_name` is the name of a function in a dynamically loaded library which should be used as the initial entry point for a new background worker. It is ignored unless `bgw_main` is NULL.

`bgw_notify_pid` is the PID of a WarehousePG backend process to which the postmaster should send `SIGUSR1` when the process is started or exits. It should be 0 for workers registered at postmaster startup time, or when the backend registering the worker does not wish to wait for the worker to start up. Otherwise, it should be initialized to `MyProcPid`.

Once running, the process can connect to a database by calling `BackgroundWorkerInitializeConnection(` char *dbname `,` char *username `)`. This allows the process to run transactions and queries using the `SPI` interface. If dbname is NULL, the session is not connected to any particular database, but shared catalogs can be accessed. If username is NULL, the process will run as the superuser created during `initdb`. BackgroundWorkerInitializeConnection can only be called once per background process, it is not possible to switch databases.

Signals are initially blocked when control reaches the `bgw_main` function, and must be unblocked by it; this is to allow the process to customize its signal handlers, if necessary. Signals can be unblocked in the new process by calling `BackgroundWorkerUnblockSignals` and blocked by calling `BackgroundWorkerBlockSignals`.

If `bgw_restart_time` for a background worker is configured as `BGW_NEVER_RESTART`, or if it exits with an exit code of 0 or is terminated by `TerminateBackgroundWorker`, it will be automatically unregistered by the postmaster on exit. Otherwise, it will be restarted after the time period configured via `bgw_restart_time`, or immediately if the postmaster reinitializes the cluster due to a backend failure. Backends which need to suspend execution only temporarily should use an interruptible sleep rather than exiting; this can be achieved by calling `WaitLatch()`. Make sure the `WL_POSTMASTER_DEATH` flag is set when calling that function, and verify the return code for a prompt exit in the emergency case that `postgres` itself has terminated.

When a background worker is registered using the `RegisterDynamicBackgroundWorker` function, it is possible for the backend performing the registration to obtain information regarding the status of the worker. Backends wishing to do this should pass the address of a `BackgroundWorkerHandle *` as the second argument to `RegisterDynamicBackgroundWorker`. If the worker is successfully registered, this pointer will be initialized with an opaque handle that can subsequently be passed to `GetBackgroundWorkerPid(` BackgroundWorkerHandle * `,` pid_t * `)` or `TerminateBackgroundWorker(` BackgroundWorkerHandle * `)`. `GetBackgroundWorkerPid` can be used to poll the status of the worker: a return value of `BGWH_NOT_YET_STARTED` indicates that the worker has not yet been started by the postmaster; `BGWH_STOPPED` indicates that it has been started but is no longer running; and `BGWH_STARTED` indicates that it is currently running. In this last case, the PID will also be returned via the second argument. `TerminateBackgroundWorker` causes the postmaster to send `SIGTERM` to the worker if it is running, and to unregister it as soon as it is not.

In some cases, a process which registers a background worker may wish to wait for the worker to start up. This can be accomplished by initializing `bgw_notify_pid` to `MyProcPid` and then passing the `BackgroundWorkerHandle *` obtained at registration time to `WaitForBackgroundWorkerStartup(` BackgroundWorkerHandle *handle `,` pid_t * `)` function. This function will block until the postmaster has attempted to start the background worker, or until the postmaster dies. If the background runner is running, the return value will `BGWH_STARTED`, and the PID will be written to the provided address. Otherwise, the return value will be `BGWH_STOPPED` or `BGWH_POSTMASTER_DIED`.

The `worker_spi` contrib module contains a working example, which demonstrates some useful techniques.

The maximum number of registered background workers is limited by the `max_worker_processes` server configuration parameter.

8 About this Documentation

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

9 Migrating gphdfs External Tables to PXF

You may be using the `gphdfs` external table protocol in a WarehousePG version 4 or 5 cluster to access data stored in Hadoop. WarehousePG version 6 removes support for the `gphdfs` protocol. To maintain access to Hadoop data in WarehousePG 6, you must migrate your `gphdfs` external tables to use the WarehousePG Platform Extension Framework (PXF). This involves setting up PXF and creating new external tables that use the `pxf` external table protocol.

To migrate your `gphdfs` external tables to use the `pxf` external table protocol, you:

1. Prepare for the migration.
2. Map configuration properties, and then [set up PXF] (#id_cfg_prop).
3. Create a new `pxf` external table to replace each `gphdfs` external table.
4. Verify access to Hadoop files with the `pxf` external tables.
5. Remove the `gphdfs` external tables.
6. Revoke privileges to the `gphdfs` protocol.
7. Migrate data to WarehousePG 6.

> **Note: Note:** If you are migrating `gphdfs` from a WarehousePG 5 installation, you perform the migration in the order above in your WarehousePG 5 cluster before you migrate data to WarehousePG 6.

> **Note: Note:** If you are migrating `gphdfs` from a WarehousePG 4 installation, you perform the migration in a similar order. However, since PXF is not available in WarehousePG 4, you must perform certain actions in the WarehousePG 6 installation before you migrate the data:
>
> 1. WarehousePG 4: Prepare for the migration.
> 2. WarehousePG 6:
>   1. Install and configure the WarehousePG 6 software.
>   2. Map configuration properties, and then install and set up PXF.
>   3. Create a new `pxf` external table to replace each `gphdfs` external table.
>   4. Verify access to Hadoop files with the `pxf` external tables.
> 3. WarehousePG 4:
>   1. Remove the `gphdfs` external tables.
>   2. Revoke privileges to the `gphdfs` protocol.
> 4. Migrate WarehousePG 4 data to WarehousePG 6.

Preparing for the Migration

As you prepare for migrating from `gphdfs` to PXF:

1. Determine which `gphdfs` tables you want to migrate.

   You can run the following query to list the `gphdfs` external tables in a database:

   ```
   SELECT n.nspname, d.objid::regclass as
   tablename
     FROM pg_depend d
     JOIN pg_exttable x ON ( d.objid = x.reloid )
     JOIN pg_extprotocol p ON ( p.oid = d.refobjid )
     JOIN pg_class c ON ( c.oid = d.objid )
     JOIN pg_namespace n ON ( c.relnamespace = n.oid )
   WHERE d.refclassid = 'pg_extprotocol'::regclass AND p.ptcname = 'gphdfs';
   ```

2. For each table that you choose to migrate, identify the format of the external data and the column definitions. Also identify the options with which the `gphdfs` table was created. You can use the `\dt+` SQL meta-command to obtain this information. For example:

   ```
   \d+ public.gphdfs_writable_parquet
        External table
   "public.gphdfs_writable_parquet"
    Column |  Type   | Modifiers | Storage  | Description
   --------+---------+-----------+----------+-------------
    id     | integer |           | plain    |
    msg    | text    |           | extended |
   Type:
   writable
   Encoding: UTF8
   Format type: parquet
   Format options: formatter 'gphdfs_export'
   External options:
   {}
   External location: gphdfs://hdfshost:8020/data/dir1/gphdfs_writepq?codec=GZIP
   Execute on: all
   segments
   ```

3. Save the information that you gathered above.

Setting Up PXF

PXF does not use the following `gphdfs` configuration options:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

gphdfs Configuration Option	Description	pxf Consideration
HADOOP_HOME	Environment variable that identifies the Hadoop installation directory	Not applicable; PXF is bundled with the required dependent Hadoop libraries and JARs
CLASSPATH	Environment variable that identifies the locations of Hadoop JAR and configuration files	Not applicable, PXF automatically includes the Hadoop libraries, JARs, and configuration files that it bundles in the `CLASSPATH`. PXF also automatically includes in the `CLASSPATH` user-registered dependencies found in the `$PXF_CONF/lib` (PXF 5.x) or `$PXF_BASE/lib` (PXF 6.x) directory.
gp_hadoop_target_version	Server configuration parameter that identifies the Hadoop distribution	Not applicable, PXF works out-of-the-box with the different Hadoop distributions
gp_hadoop_home	Server configuration parameter that identifies the Hadoop installation directory	Not applicable, PXF works out-of-the-box with the different Hadoop distributions

Configuration properties required by PXF, and the `gphdfs` equivalent, if applicable, include:

Configuration Item	Description	gphdfs Config	pxf Config
JAVA_HOME	Environment variable that identifies the Java installation directory	Set `JAVA_HOME` on each segment host	Set `JAVA_HOME` in the `$PXF_CONF/conf/pxf-env.sh` (PXF 5.x) or `$PXF_BASE/conf/pxf-env.sh` (PXF 6.x) configuration file.
JVM option settings	Options with which to start the JVM	Set options in the `GP_JAVA_OPT` environment variable in `hadoop_env.sh`	Set options in the `PXF_JVM_OPTS` environment variable in `$PXF_CONF/conf/pxf-env.sh` (PXF 5.x) or `$PXF_BASE/conf/pxf-env.sh` (PXF 6.x).
PXF Server	PXF server configuration for Hadoop	Not applicable	Configure a PXF server for Hadoop
Privileges	The WarehousePG privileges required to create external tables in the given protocol	Grant `SELECT` and `INSERT` privileges on the `gphdfs` protocol to appropriate users	Grant `SELECT` and `INSERT` privileges on the `pxf` protocol to appropriate users

After you determine the equivalent PXF configuration properties, you will:

1. Update the Java version installed on each WarehousePG host, if necessary. PXF supports Java version 8 and 11. If your WarehousePG cluster hosts are running Java 7, upgrade to Java version 8 or 11 as described in Installing Java for PXF. Note the `$JAVA_HOME` setting.
2. If you are migrating from WarehousePG 4, *or* you have not previously used PXF in your WarehousePG 5 installation:
    1. Install the newest version of the independent PXF distribution on your WarehousePG hosts.
    2. Inform PXF of the $JAVA_HOME setting by specifying its value in the `pxf-env.sh` configuration file.
        - Edit the `pxf-env.sh` file on the WarehousePG coordinator node.

          ```
          gpadmin@gpcoordinator$ vi /usr/local/pxf-gp7/conf/pxf-env.sh
          ```

        - Locate the `JAVA_HOME` setting in the `pxf-env.sh` file, uncomment if necessary, and set it to your `$JAVA_HOME` value. For example:

          ```
          export JAVA_HOME=/usr/lib/jvm/java-1.8.0-openjdk/jre/
          ```

    3. Register the PXF extension with WarehousePG:

       ```
       gpadmin@gpcoordinator$ pxf cluster register
       ```

    4. Enable the PXF extension and grant users access to PXF.
3. Configure the PXF Hadoop Connectors. This procedure creates a PXF server configuration that provides PXF the information that it requires to access Hadoop. This procedure also synchronizes the configuration changes to all hosts in your WarehousePG cluster.
4. Start or restart PXF in your WarehousePG cluster:

   ```
   gpadmin@gpcoordinator$ pxf cluster start
   ```

Creating a PXF External Table

`gphdfs` and `pxf` are both external table protocols. Creating an external table using these protocols is similar. You specify the external table name and its column definitions. You also specify `LOCATION` and `FORMAT` clauses. `gphdfs` and `pxf` use information in these clauses to determine the location and type of the external data.

Mapping the LOCATION Clause

The `LOCATION` clause of an external table identifies the external table protocol, location of the external data, and protocol- and operation-specific custom options.

The format of `gphdfs`'s `LOCATION` clause is as follows:

```
LOCATION('gphdfs://<hdfs_host>:<hdfs_port>/<path-to-data>?[&<custom-option>=<value>[...]]')
```

PXF's `LOCATION` clause takes the following format when you access data stored on Hadoop:

```
LOCATION('pxf://<path-to-data>?PROFILE=<profile_name>[&SERVER=<server_name>][&<custom-option>=<value>[...]]')
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

You are not required to specify the HDFS host and port number when you create a PXF external table. PXF obtains this information from the `default` server configuration, or from the server configuration name that you specify in `<server_name>`.

Refer to Creating an External Table in the PXF documentation for more information about the PXF `CREATE EXTERNAL TABLE` syntax and keywords.

When you create an external table specifying the `gphdfs` protocol, you identify the format of the external data in the `FORMAT` clause (discussed in the next section). PXF uses a `PROFILE` option in the `LOCATION` clause to identify the source and type of the external data.

Data Format	pxf PROFILE
Avro	hdfs:avro
Parquet	hdfs:parquet
Text	hdfs:text

Refer to Connectors, Data Formats, and Profiles in the PXF documentation for more information about the PXF profiles supported for Hadoop.

Both `gphdfs` and `pxf` utilize custom options in the `LOCATION` clause to identify data-format-, operation-, or profile-specific options supported by the protocol. For example, both `gphdfs` and `pxf` support parquet and compression options on `INSERT` operations.

Should you need to migrate a `gphdfs` writable external table that references an HDFS file to PXF, map `gphdfs` to PXF writable external table compression options as follows:

Description	gphdfs LOCATION Option	pxf LOCATION Option
Use of Compression	compress	Not applicable; depends on the profile - may be uncompressed by default or specified via COMPRESSION_CODEC
Type of compression	compression_type	COMPRESSION_TYPE
Compression codec	codec	COMPRESSION_CODEC
Level of Compression[1]	codec_level	CODEC_LEVEL (supported in PXF 5.14.0 and newer versions)

[1] Avro format `deflate` codec only.

If the HDFS file is a Parquet-format file, map these additional parquet options as follows:

Description	gphdfs LOCATION Option	pxf LOCATION Option
Parquet schema	schema	SCHEMA
Page size	pagesize	PAGE_SIZE
Row group size	rowgroupsize	ROWGROUP_SIZE
Parquet version	parquetversion *or* pqversion	PARQUET_VERSION
Enable a dictionary	dictionaryenable	The dictionary is always enabled when writing Parquet data with PXF
Dictionary page size	dictionarypagesize	DICTIONARY_PAGE_SIZE

Mapping the FORMAT Options

The `gphdfs` protocol uses the `FORMAT` clause to determine the format of the external data. For Avro- and Parquet-format data, the PXF `FORMAT` clause must identify the name of a custom formatter.

Data Format	gphdfs FORMAT Option	pxf FORMAT Option
Avro	FORMAT 'AVRO'	FORMAT 'CUSTOM' (FORMATTER='pxfwritable_import') (read) FORMAT 'CUSTOM' (FORMATTER='pxfwritable_export') (write)
Parquet	FORMAT 'PARQUET'	FORMAT 'CUSTOM' (FORMATTER='pxfwritable_import') (read) FORMAT 'CUSTOM' (FORMATTER='pxfwritable_export') (write)
Text	FORMAT 'TEXT' (DELIMITER ',')	FORMAT 'TEXT' (DELIMITER ',')

For text data, the `FORMAT` clause may identify a delimiter or other formatting option as described on the CREATE EXTERNAL TABLE command reference page.

Example gphdfs to pxf External Table Mapping for an HDFS Text File

Example `gphdfs` `CREATE EXTERNAL TABLE` command to read a text file on HDFS:

```
CREATE EXTERNAL TABLE ext_expenses (
        name text,
        date date,
        amount
float4,
        category text,
        desc1 text
)
   LOCATION ('gphdfs://hdfshost-1:8081/dir/filename.txt')
   FORMAT 'TEXT' (DELIMITER
',');
```

Equivalent `pxf` `CREATE EXTERNAL TABLE` command, providing that the `default` PXF server contains the Hadoop configuration:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
CREATE EXTERNAL TABLE ext_expenses_pxf (
        name text,
        date date,
        amount
float4,
        category text,
        desc1 text
)
   LOCATION ('pxf://dir/filename.txt?PROFILE=hdfs:text')
   FORMAT 'TEXT' (DELIMITER
',');
```

Verifying Access with PXF

Ensure that you can read from, or write to, each `pxf` external table that you have created.

Removing the gphdfs External Tables

You must remove all `gphdfs` external tables before you can successfully migrate a WarehousePG 4 or 5 database to WarehousePG 6.

Drop an external table as follows:

```
DROP EXTERNAL TABLE
<schema_name>.<external_table_name>;
```

Revoking Privileges to the gphdfs Protocol

Before you migrate, you must revoke privileges to the `gphdfs` protocol from each WarehousePG role to which you assigned the privileges.

Revoke the privilege as follows:

```
ALTER ROLE <role_name> NOCREATEEXTTABLE(protocol='gphdfs',type='readable');
ALTER ROLE <role_name> NOCREATEEXTTABLE(protocol='gphdfs',type='writable');
```

9.1 PXF Upgrade and Migration

When you upgrade your WarehousePG cluster, you must perform some additional steps in order to bring your PXF configuration up to date.

1. *WarehousePG 6.x to 6.newer upgrade*: You may be required to perform PXF upgrade actions when you upgrade from a previous WarehousePG 6.x version. Note that different steps are outlined based on your PXF installation source: a manually installed `rpm` or `deb` or the PXF version included with the WarehousePG Server installer in versions 6.18.x and older.

If you are upgrading a PXF `rpm` or `deb` installation independent of a WarehousePG upgrade, refer to the PXF upgrade documentation.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

9.2 Upgrading PXF When You Upgrade from a Previous WarehousePG 6.x Version

> **Note: Note:** Starting in WarehousePG version 6.19.0, the PXF software is no longer bundled in the WarehousePG Server distribution. You may be required to download and install the PXF `rpm` or `deb` package to use PXF in your WarehousePG cluster as described in the procedures below.

If you are using PXF in your current WarehousePG 6.x installation, you must perform some PXF upgrade actions when you upgrade to a newer version of WarehousePG 6.x. This procedure uses*PXF.from* to refer to your currently-installed PXF version.

> **Note** if you are planning to upgrade a PXF `rpm` or `deb` installation, refer to the PXF upgrade documentation.

The PXF upgrade procedure has two parts. You perform one procedure before, and one procedure after, you upgrade to a new version of WarehousePG:

- Step 1: PXF Pre-Upgrade Actions
- Upgrade to a new WarehousePG version
- Step 2: Upgrading PXF

Step 1: PXF Pre-Upgrade Actions

Perform this procedure before you upgrade to a new version of WarehousePG:

1. Log in to the WarehousePG coordinator node. For example:

   ```
   $ ssh gpadmin@<gpcoordinator>
   ```

2. Identify and note the *PXF.from* version number. For example:

   ```
   gpadmin@gpcoordinator$ pxf version
   ```

3. Determine if *PXF.from* is a PXF `rpm` or `deb` installation (`/usr/local/pxf-gp<greenplum-major-version>`), or if you are running *PXF.from* from the WarehousePG server installation (`$GPHOME/pxf`), and note the answer.

4. If the *PXF.from* version is 5.x, identify the file system location of the `$PXF_CONF` setting in your PXF 5.x PXF installation; you might need this later. If you are unsure of the location, you can find the value in `pxf-env-default.sh` .

5. Stop PXF on each segment host as described in Stopping PXF.

6. Upgrade to the new version of WarehousePG and then continue your PXF upgrade with Step 2: Upgrading PXF.

Step 2: Registering or Upgrading PXF

After you upgrade to the new version of WarehousePG, perform the following procedure to configure the PXF software; you may be required to install the standalone PXF distribution:

1. Log in to the WarehousePG coordinator node. For example:

   ```
   $ ssh gpadmin@<gpcoordinator>
   ```

2. If you previously installed the PXF `rpm` or `deb` on your WarehousePG 6.x hosts, you must register it to continue using PXF:

   1. Copy the PXF extension files from the PXF installation directory to the new WarehousePG 6.x install directory:

      ```
      gpadmin@gpcoordinator pxf cluster register
      ```

   2. Start PXF on each segment host as described in Starting PXF.

   3. Skip the following steps and exit this procedure.

3. Starting in WarehousePG version 6.19.0, PXF is removed from the WarehousePG Server distribution. You must download and install the standalone PXF `rpm` or `deb` package as described in Installing PXF.

4. Synchronize the PXF configuration from the coordinator host to the standby coordinator and each WarehousePG segment host. For example:

   ```
   gpadmin@gpcoordinator$ $GPHOME/pxf/bin/pxf cluster sync
   ```

5. Start PXF on each segment host:

   ```
   gpadmin@gpcoordinator$ $GPHOME/pxf/bin/pxf cluster start
   ```

Your WarehousePG cluster is now running the same version of PXF, but running it from the PXF installation directory (`/usr/local/pxf-gp<greenplum-major-version>`). Should you wish to upgrade PXF in the future, consult the PXF upgrade documentation.
