1 EDB Postgres AI for WarehousePG 16
2 WarehousePG 7.x release notes 17
3 Installing and upgrading WarehousePG 21
3.1 Platform Requirements 22
3.2 Estimating Storage Capacity 28
3.3 Configure Operating System 30
3.4 Installing EDB Postgres AI for WarehousePG 39
3.5 Creating the Data Storage Areas 42
3.6 Validating the WHPG Cluster 43
3.7 Initializing WarehousePG 45
3.8 Installing Optional Extensions 49
3.8.1 Procedural Language, Machine Learning, and Geospatial Extensions 50
3.8.2 WarehousePG Platform Extension Framework (PXF) 51
3.8.3 Data Science Package for Python 52
3.8.4 R Data Science Library Package 56
3.9 Installing Extensions 59
3.10 Configuring Timezone and Localization Settings 60
3.11 Important Changes Between WHPG 6 and WHPG 7 64
3.12 Performing a minor upgrade 65
3.13 Upgrading from WarehousePG 6 to WarehousePG 7 69
3.14 >- 71
3.15 Enabling iptables (Optional) 77
3.16 Installation Utilities Reference 79
3.17 WarehousePG Environment Variables 80
3.18 Example Ansible Playbook 82
4 WarehousePG administrator guide 84
4.1 WarehousePG Concepts 85
4.1.1 About the WarehousePG Architecture 86
4.1.2 About Management and Monitoring Utilities 95
4.1.3 About Concurrency Control in WarehousePG 96
4.1.3.1 Example of Managing Transaction IDs 100
4.1.4 About Parallel Data Loading 102
4.1.5 About Redundancy and Failover in WarehousePG 103
4.1.6 About Database Statistics in WarehousePG 105
4.1.7 Introduction to WarehousePG 109
4.2 Managing a WarehousePG Cluster 119
4.2.1 About the WarehousePG Release Version Number 120
4.2.2 Starting and Stopping WarehousePG 121
4.2.3 Accessing the Database 123
4.2.3.1 Establishing a Database Session 124
4.2.3.2 Supported Client Applications 125
4.2.3.3 WarehousePG Client Applications 126
4.2.3.4 Connecting with psql 127
4.2.3.5 Using the PgBouncer Connection Pooler 128
4.2.3.6 Database Application Interfaces 133
4.2.3.7 Troubleshooting Connection Problems 134
4.2.4 Configuring the WarehousePG cluster 135
4.2.4.1 About WarehousePG Coordinator and Local Parameters 136

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.2.4.2 Setting Configuration Parameters 137
4.2.4.2.1 Setting a Local Configuration Parameter 138
4.2.4.2.2 Setting a Coordinator Configuration Parameter 139
4.2.4.2.2.1 Setting Parameters at the System Level 140
4.2.4.2.2.2 Setting Parameters at the Database Level 141
4.2.4.2.2.3 Setting Parameters at the Role Level 142
4.2.4.2.2.4 Setting Parameters in a Session 143
4.2.4.3 Viewing Server Configuration Parameter Settings 144
4.2.4.4 Configuration Parameter Categories 145
4.2.5 Enabling Compression 146
4.2.6 Configuring Proxies for the WarehousePG Interconnect 147
4.2.7 Enabling High Availability and Data Consistency Features 150
4.2.7.1 Overview of WarehousePG High Availability 151
4.2.7.2 Enabling Mirroring in WarehousePG 153
4.2.7.2.1 Enabling Segment Mirroring 154
4.2.7.2.2 Enabling Coordinator Mirroring 155
4.2.7.3 How WarehousePG Detects a Failed Segment 156
4.2.7.4 Understanding Segment Recovery 157
4.2.7.5 Recovering from Segment Failures 159
4.2.7.6 Recovering a Failed Coordinator 162
4.2.7.7 Checking for Failed Segments 163
4.2.7.8 Overview of Coordinator Mirroring 164
4.2.7.9 Overview of Segment Mirroring 165
4.2.7.10 Restoring Coordinator Mirroring After a Recovery 168
4.2.8 Backing Up and Restoring Databases 170
4.2.9 Expanding a WarehousePG cluster 172
4.2.9.1 System Expansion Overview 173
4.2.9.2 Planning WarehousePG cluster Expansion 175
4.2.9.3 Preparing and Adding Hosts 178
4.2.9.4 Initializing New Segments 180
4.2.9.5 Redistributing Tables 183
4.2.9.6 Post Expansion Tasks 185
4.2.10 Monitoring a WarehousePG cluster 186
4.2.11 Monitoring Long-Running Operations 196
4.2.12 Routine System Maintenance Tasks 199
4.2.13 Recommended Monitoring and Maintenance Tasks 202
4.3 Managing WarehousePG Access 205
4.3.1 Configuring Client Authentication 206
4.3.1.1 Using LDAP Authentication with TLS/SSL 209
4.3.1.2 Using Kerberos Authentication 211
4.3.1.3 Configuring Kerberos for Linux Clients 215
4.3.1.4 Configuring Kerberos For Windows Clients 217
4.3.2 Managing Roles and Privileges 220
4.3.3 About Configuring Row-Level Security Policies 225
4.4 DDL: Defining Database Objects 229
4.4.1 Creating and Managing Databases 230
4.4.2 Creating and Managing Tablespaces 232
4.4.3 Creating and Managing Schemas 234

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.4.4 About Table Definition Basics 236
4.4.5 Creating and Managing Tables 238
4.4.6 Choosing the Table Storage Model 242
4.4.7 Partitioning Large Tables 249
4.4.7.1 About Changes to Table Partitioning in WarehousePG 7 259
4.4.7.2 Examples Using the Classic Partitioning Syntax 261
4.4.8 Creating and Using Sequences 267
4.4.9 Using Indexes in WarehousePG 269
4.4.9.1 BRIN Indexes 275
4.4.10 Creating and Managing Views 277
4.4.10.1 Best Practices when Creating Views 278
4.4.10.2 Working with View Dependencies 279
4.4.10.3 About View Storage in WarehousePG 283
4.4.11 Creating and Managing Materialized Views 284
4.5 DML: Inserting, Updating and Deleting 285
4.6 Querying Data 290
4.6.1 About WarehousePG Query Processing 291
4.6.2 About GPORCA 295
4.6.2.1 Overview of GPORCA 296
4.6.2.2 Activating and Deactivating GPORCA 297
4.6.2.3 Collecting Root Partition Statistics 298
4.6.2.4 Considerations when Using GPORCA 299
4.6.2.5 GPORCA Features and Enhancements 300
4.6.2.6 Changed Behavior with GPORCA 303
4.6.2.7 GPORCA Limitations 304
4.6.2.8 Determining the Query Optimizer that is Used 306
4.6.3 Defining Queries 307
4.6.4 WITH Queries (Common Table Expressions) 316
4.6.5 Using Functions and Operators 320
4.6.6 Working with JSON Data 325
4.6.7 Working with XML Data 331
4.6.8 Using Full Text Search 339
4.6.8.1 About Full Text Search 340
4.6.8.2 Searching Text in Database Tables 343
4.6.8.3 Controlling Text Search 345
4.6.8.4 Additional Text Search Features 350
4.6.8.5 Text Search Parsers 353
4.6.8.6 Text Search Dictionaries 354
4.6.8.7 Text Search Configuration Example 360
4.6.8.8 Testing and Debugging Text Search 361
4.6.8.9 Preferred Index Types for Text Search 364
4.6.8.10 psql Support 365
4.6.8.11 Limitations 367
4.6.9 Query Performance 368
4.6.10 Managing Spill Files Generated by Queries 369
4.6.11 Query Profiling 370
4.6.12 Just-in-Time Compilation (JIT) 373
4.7 Overview of WarehousePG integrated analytics 375

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.7.1 Machine Learning and Deep Learning using MADlib 377
4.7.2 Graph Analytics 384
4.7.3 Geospatial Analytics 388
4.7.4 Geospatial Indexing with H3 and H3-PG 393
4.7.5 Procedural Languages 395
4.7.5.1 PL/Java Language 396
4.7.5.2 PL/Perl Language 406
4.7.5.3 PL/Python Language 410
4.7.5.4 PL/R Language 418
4.7.5.5 PL/pgSQL Language 423
4.8 Working with External Data 429
4.8.1 Accessing External Data with Foreign Tables 430
4.8.1.1 Writing a Foreign Data Wrapper 431
4.8.2 Accessing External Data with External Tables 436
4.8.2.1 Understanding the External Table to Foreign Table Mapping 438
4.8.2.2 About Changes to External Tables in WarehousePG 7 440
4.8.2.3 file:// Protocol 442
4.8.2.4 gpfdist:// Protocol 443
4.8.2.5 gpfdists:// Protocol 444
4.8.2.6 pxf:// Protocol 445
4.8.2.7 s3:// Protocol 446
4.8.2.8 Creating a Custom Protocol 452
4.8.2.9 Handling Errors in External Table Data 453
4.8.2.10 Creating and Using External Web Tables 454
4.8.2.11 Examples for Creating External Tables 455
4.8.2.11.1 Example 1—Single gpfdist instance on single-NIC machine 456
4.8.2.11.2 Example 2—Multiple gpfdist instances 457
4.8.2.11.3 Example 3—Multiple gpfdists instances 458
4.8.2.11.4 Example 4—Single gpfdist instance with error logging 459
4.8.2.11.5 Example 5—TEXT Format on a Hadoop Distributed File Server 460
4.8.2.11.6 Example 6—Multiple files in CSV format with header rows 461
4.8.2.11.7 Example 7—Readable External Web Table with Script 462
4.8.2.11.8 Example 8—Writable External Table with gpfdist 463
4.8.2.11.9 Example 9—Writable External Web Table with Script 464
4.8.2.11.10 Example 10—Readable and Writable External Tables with XML Transformations 465
4.8.3 Accessing External Data with PXF 466
4.8.4 Using the WarehousePG Parallel File Server (gpfdist) 467
4.9 Loading and Unloading Data 470
4.9.1 Loading Data Using an External Table 471
4.9.2 Loading and Writing Non-HDFS Custom Data 472
4.9.2.1 Using a Custom Format 473
4.9.2.1.1 Importing and Exporting Fixed Width Data 474
4.9.2.1.2 Examples of Reading Fixed-Width Data 475
4.9.2.2 Using a Custom Protocol 476
4.9.3 Handling Load Errors 477
4.9.3.1 Define an External Table with Single Row Error Isolation 478
4.9.3.2 Capture Row Formatting Errors and Declare a Reject Limit 479
4.9.3.3 Viewing Bad Rows in the Error Log 480

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.9.3.4 Moving Data between Tables 481
4.9.4 Loading Data with gpload 482
4.9.5 Transforming External Data with gpfdist and gpload 483
4.9.6 Loading Data with COPY 490
4.9.7 Running COPY in Single Row Error Isolation Mode 491
4.9.8 Optimizing Data Load and Query Performance 492
4.9.9 Unloading Data from WarehousePG 493
4.9.9.1 Defining a File-Based Writable External Table 494
4.9.9.1.1 Example 1—WarehousePG file server (gpfdist) 495
4.9.9.1.2 Example 2—Hadoop file server (pxf) 496
4.9.9.2 Defining a Command-Based Writable External Web Table 497
4.9.9.2.1 Deactivating EXECUTE for Web or Writable External Tables 498
4.9.9.3 Unloading Data Using a Writable External Table 499
4.9.9.4 Unloading Data Using COPY 500
4.9.10 Formatting Data Files 501
4.9.10.1 Formatting Rows 502
4.9.10.2 Formatting Columns 503
4.9.10.3 Representing NULL Values 504
4.9.10.4 Escaping 505
4.9.10.4.1 Escaping in Text Formatted Files 506
4.9.10.4.2 Escaping in CSV Formatted Files 507
4.9.10.5 Character Encoding 508
4.9.11 Example Custom Data Access Protocol 509
4.9.11.1 Installing the External Table Protocol 510
4.9.11.1.1 gpextprotocal.c 511
4.10 Managing Performance 515
4.10.1 Defining Database Performance 516
4.10.2 Distribution and Skew 517
4.10.3 Common Causes of Performance Issues 518
4.10.4 WarehousePG Memory Overview 520
4.10.5 WarehousePG memory calculator 522
4.10.6 Managing Resources 523
4.10.6.1 About Changes to Resource Groups in WarehousePG 7 524
4.10.6.2 Using Resource Groups 526
4.10.6.3 Using Resource Queues 535
4.10.7 Investigating a Performance Problem 543
4.11 Retrieving Query Results with a Parallel Retrieve Cursor 545
4.12 Backing up WarehousePG with gpbackup and gprestore 550
4.12.1 Incremental Backups using gpbackup and gprestore 563
5 WarehousePG security configuration guide 567
5.1 Securing the Database 568
5.2 WarehousePG Ports and Protocols 569
5.3 Configuring Client Authentication 571
5.4 Configuring Database Authorization 578
5.5 Auditing 581
5.6 Encrypting Data and Database Connections 583
5.7 Security Best Practices 590
6 WarehousePG best practices 593

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

6.1 Best Practices Summary 594
6.2 System Configuration 598
6.3 Schema Design 601
6.4 Memory and Resource Management with Resource Groups 605
6.5 Memory and Resource Management with Resource Queues 607
6.6 System Monitoring and Maintenance 609
6.6.1 Updating Statistics with ANALYZE 611
6.6.2 Managing Bloat in a Database 612
6.6.3 Monitoring WarehousePG Log Files 614
6.7 Loading Data 615
6.8 Identifying and Mitigating Heap Table Performance Issues 617
6.9 Security 618
6.10 Encrypting Data and Database Connections 620
6.11 Tuning SQL Queries 625
6.12 High Availability 627
7 WarehousePG reference guide 634

1 EDB Postgres AI for WarehousePG

Introducing WarehousePG

WarehousePG is a new Apache 2-licensed fork of the formerly open source Greenplum Database. It offers binary compatibility with the legacy Greenplum versions most widely deployed by customers (6.x and 7.x) — plus net-new functionality and integrations.

Key features

- Petabytes scale with high-speed /-concurrency performance, via MPP Cluster topology with a Postgres fork based on PG 12.12.
- A Master (coordinator) for query optimization and parallel plan and distribution
- Multiple segments (workers) for parallel execution of queries with each segment being a Postgres instance.
- High availability with standbys for the Master and mirrors for the segments.
- High-speed interconnections for continuous data processing pipelining.

Support

For business-critical workloads, EDB Postgres AI provides support for WarehousePG. See the EDB Postgres AI support for Greenplum workloads page for more information.

Documentation

This section is adapted from the WarehousePG v7.x documentation.

2 WarehousePG 7.x release notes

The WarehousePG documentation describes the latest version of WarehousePG 7.

Version	Release date
7.5.0-WHPG	8 June 2026
7.4.0-WHPG	7 April 2026
7.3.1-WHPG	30 January 2026
7.3.0-WHPG	14 November 2025
7.2.2-WHPG	17 November 2025
7.2.1-WHPG	15 May 2025

WarehousePG 7.5.0-WHPG

Released: 8 June 2026

WarehousePG 7.5.0-WHPG includes the following new features, enhancements, bug fixes, and other changes:

Upgrade considerations

Python 3.11 requirement for PL/Python

WarehousePG 7.5.0 upgrades PL/Python from Python 3.9 to Python 3.11. The PL/Python interpreter now links against `/usr/bin/python3.11` and requires the following packages on every node in the cluster:

- `python3.11`
- `python3.11-psycopg2`
- `python3.11-pyyaml`

On internet-connected clusters, the package manager installs these dependencies automatically when upgrading. On air-gapped clusters, install them manually on all nodes before upgrading. See Performing a minor upgrade for details.

New features

- Added support for renaming resource groups with the new `ALTER RESOURCE GROUP <name> SET NAME <new_name>` syntax.

Enhancements

- Bundled the LLVM 21 library (`libLLVM.so`) with the WarehousePG package. LLVM and Clang no longer need to be installed separately on cluster nodes for JIT compilation.
- Improved performance of AO/AOCS table sampling by using an adaptive tuples-per-block estimation algorithm.
- Optimized the `gp_toolkit.gp_resgroup_config` view for improved query performance.

Bug fixes

- Fixed `gpconfig` to correctly respect the `gp_resource_group_cgroup_parent` configuration parameter when verifying the `cgroup` root.
- Fixed a buffer over-read in `TranslateDXLDatumGenericToScalar()` that could cause instability in the ORCA optimizer.
- Fixed incorrect distinct qualified aggregate (DQA) type classification under `HAVING` clauses that could produce incorrect query results.
- Fixed an issue where `RelabelType` was not stripped when pulling up distribution keys through binary-compatible casts in partitioned table scans, which could produce incorrect query plans.

Security

- Hardened multiple modules against integer overflow vulnerabilities for CVE-2026-6473, including ltree, `ts_headline`, intarray, the regex engine, `unicode_normalize`, `formatting.c`, `array_agg`, and the hstore PL/Perl and PL/Python extensions.
- Fixed a format-string vulnerability in `timeofday()` for CVE-2026-6474 where a crafted time zone setting could abuse the `pg_strftime()` `%Z` format specifier to cause crashes or disclose server memory.
- Fixed a path traversal vulnerability in `pg_rewind` for CVE-2026-6475 where paths received from a rogue endpoint could overwrite files outside the target directory.
- Fixed a buffer overrun in the frontend large object interface (`libpq`) for CVE-2026-6477 where `PQfn()` could write beyond the end of the result buffer when the server returned more data than requested.
- Added timing-safe comparisons for secret material in all authentication paths for CVE-2026-6478, covering SCRAM, MD5, RADIUS, and plain authentication methods.
- Fixed a stack overflow vulnerability in `ProcessStartupPacket()` for CVE-2026-6479 where a malicious client could alternate SSL and GSS negotiation requests indefinitely to exhaust server stack space.
- Fixed an SQL injection and buffer overrun vulnerability in the `refint` contrib module for CVE-2026-6637.

WarehousePG 7.4.0-WHPG

Released: 7 April 2026

WarehousePG 7.4.0-WHPG includes the following new features, enhancements, bug fixes, and other changes:

New features

- Introduced `pg_stat_statements` for WarehousePG, extending standard PostgreSQL statistics collection to include all segment nodes.
- Implemented `DISTRIBUTED COORDINATOR ONLY` tables to allow metadata to reside exclusively on the coordinator node, supporting specialized use cases where extensions must access data during early-stage query processing before distributed execution begins.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Enhancements

- Added automatic fallback to the Postgres planner when `vchord` indexes are present.
- Simplified the `gp_stat_progress_copy_summary` view and corrected issues where `NULL` values were improperly handled.
- Enabled the `get_ao_compression_ratio()` function to execute in query executors.
- Optimized internal cluster communications by improving the performance of Interconnect (IC) UDP processes and eliminating stale file descriptor warnings, resulting in more stable and faster data exchange between nodes.

Bug fixes

- Improved query planner accuracy for anti-joins and left anti-semi joins by resolving a double-calculation error in join selectivity. This fix resolves issues where underestimated join costs led to inefficient query plans, resulting in significantly faster performance for complex analytical workloads.
- Resolved critical stability issues in the ORCA optimizer, including fixes for segmentation faults, infinite recursion, and improper motion creation on QE slices.
- Fixed ORCA `regr_count` scalar subquery decorrelation to prevent planning errors during complex aggregations.
- Resolved an issue where ORCA failed to handle views with unused CTEs after changes were made to underlying table structures.
- Improved DXL translation by fixing the handling of required but unused columns.
- Fixed `gpcheckcat` inconsistencies encountered when using the SCRAM-SHA-256 authentication algorithm.
- Ensured `initdb` only evaluates `errno` when a system call explicitly fails, preventing successful directory operations from being incorrectly reported as errors due to residual error codes from previous tasks.
- Ensured `isolation2` test compatibility for Python 3.14 by explicitly setting the subprocess start method to `fork`, preventing `cannot pickle TextIOWrapper` errors caused by the change in Python's default process spawning behavior on Linux.

Security

- Mitigated SQL injection risks in `pg_dump` and `pg_dumpall` for CVE-2025-8715 by ensuring object names containing newlines are properly sanitized before being written as comments in backup files, preventing a vulnerability where maliciously crafted names could execute arbitrary SQL during the restore process.
- Fixed a heap buffer overflow vulnerability in libpq for CVE-2025-12818 by hardening memory allocation against integer overflows. This change implements stricter `size_t` calculations for large, untrusted inputs to ensure allocated buffers are sufficient for their contents.

WarehousePG 7.3.1-WHPG

Released: 30 January 2026

WarehousePG 7.3.1-WHPG includes the following new features, enhancements, bug fixes, and other changes:

Enhancements

- Allowed parallel workers to retrieve combo command ids and distributed snapshots directly from Dynamic Shared Memory (DSM).
- Implemented pipes instead of sockets to terminate `poll()` blocking immediately for faster process signaling.
- Added native support for executing `customscans` within the engine.
- Made the `rescanforeignscan` callback optional for foreign data wrappers to improve FDW compatibility.
- Configured GDD to push transaction ids into waitgxids so the query dispatcher can wait on them effectively.
- Appended the WarehousePG name to the end of the version string for better identification.
- Replaced `spinlocks` with `lwlocks` at the instrumentation header to reduce CPU contention.
- Implemented pipes instead of sockets to terminate `poll()` blocking immediately for faster process signaling.
- Updated the build instructions for RHEL8 and RHEL9 systems.
- Updated regression test outputs to reflect recent FDW rescan changes.

Bug fixes

- Fixed a critical issue with shared snapshots in DSM to prevent potential data loss.
- Resolved a crash in ORCA when processing percentile aggregates.
- Fixed a crash and incorrect results when using distinct qualified aggregates (DQA) with a filter clause.
- Initialized missing `plannedstmt` fields in ORCA to prevent execution errors.
- Corrected the handling of required but unused columns during DXL translation.
- Fixed an incorrect join type assignment when pulling up expression sub-links.
- Adjusted the severity level to warning in `ftsprobe.c` under specific conditions to reduce log noise.
- Removed the `guc_no_show_all` flag for the `archive_timeout` setting.
- Fixed an invalid escape sequence in the `recoveryinfo.py` script.
- Resolved an intermittent failure case in the `pg_waldump` tests.
- Corrected the return type of `gddctxgetmaxvid()` to use `DistributedTransactionId(uint64)`.
- Removed the deprecated `pkg_resources` dependency from the Python environment.

WarehousePG 7.3.0-WHPG

Released: 14 November 2025

WarehousePG 7.3.0-WHPG includes the following new features, enhancements, bug fixes, and other changes:

Enhancements

- Enabled parallel workers context for index builds to improve creation speed.
- Merged Postgres 12 `llvm` changes and implemented explicit `llvmcontextref` for JIT inlining.
- Configured the system to insert WAL records uncompressed if compression fails, ensuring write continuity.
- Updated the copy utility to print the specific `errno` for program pipes.
- Prevented the sorting of in-memory tuples when a process has already been interrupted.
- Enabled builds for the `intarray` and `unaccent` extensions.
- Updated `waitgxids` to use `int64` for better handling of transaction ids.
- Added support for PL/Python2 testing.
- Improved the reliability of error detection in status_check cases.
- Updated the PR template and `.editorconfig` settings.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Bug fixes

- **High availability:** Fixed mirror promotion failures related to WAL segment renaming.
- Resolved a `VACUUM` issue on `AOCS` tables following an aborted `ADD COLUMN` transaction.
- Corrected `pg_exttable` view outputs specifically for ARM systems.
- Implemented recursive calls in the plan walker for `MergeAppend` to ensure plan integrity.
- Fixed a logic error involving `SubPlan PlaceHolderVar`.
- Removed extra blank lines in `EXPLAIN` output.
- Silenced harmless `fsync` errors when parent directories are removed.
- Fixed a `NULL` pointer error during `COPY (SELECT) TO` option validation.
- Dispatched ICU collation comments correctly.
- Stopped reporting `compresstype`, `zlib`, or `zstd` errors when not in the validation phase.
- Fixed inconsistent test cases for `REINDEX TABLE`, `REINDEX INDEX`, and `EXPLAIN FORMAT`.
- Fixed the `gpcheckcat mix_distribution_policy` test.
- Replaced the deprecated Python pipes module.
- Removed `gsutil` from developer requirements.

Security

- Included a fix for CVE-2025-1094.

WarehousePG 7.2.2-WHPG

Released: 17 November 2025

WarehousePG 7.2.2-WHPG includes the following new features, enhancements, bug fixes, and other changes:

Enhancements

- Enabled parallel workers context for index builds to reduce execution time.
- Optimized resource usage by skipping the sorting of in-memory tuples when a process is interrupted.
- Configured WAL records to be inserted uncompressed as a fallback if compression fails.
- Enhanced diagnostic output by printing the specific `errno` for copy program pipes.
- Improved concurrency handling by using `int64` for `waitgxids`.
- Enabled the `unaccent` extension by default.
- Added PL/Python2 testing support for WarehousePG 7 environments.
- Improved the reliability of error detection for `status_check` operations.

Bug fixes

- Fixed a failure in mirror promotion caused by WAL segment renaming.
- Resolved a vacuuming issue on `AOCS` tables that occurred after aborted add column transactions.
- Corrected `pg_exttable` view data for ARM-based architectures.
- Implemented recursive calls in the plan walker for `mergeappend` to ensure correct plan traversal.
- Fixed a sub-plan bug related to placeholder variables.
- Suppressed unnecessary blank lines in `EXPLAIN` output.
- Prevented harmless `fsync` errors from being reported when parent directories are missing.
- Ensured ICU collation comments are dispatched correctly to maintain metadata.
- Stopped reporting `compresstype` errors during the non-validation phase.
- Silenced `zlib` and `zstd` `reloption` errors during the non-validation phase.
- Reverted the fault tolerance service (FTS) enablement for mirror-less clusters.
- Resolved intermittent test failures in `REINDEX TABLE` and `REINDEX INDEX` cases.
- Fixed an intermittent failure in the `explain_format` test case.
- Fixed the `gpcheckcat mix_distribution_policy` test.
- Removed the `gsutil` dependency from development requirements.

Security

- Included a fix for CVE-2025-1094.

WarehousePG 7.2.1-WHPG

Released: 15 May 2025 WarehousePG 7.2.1-WHPG includes the following new features, enhancements, bug fixes, and other changes:

Enhancements

- Fixed a `work_mem` reference in hash aggregates to ensure planned memory is fully utilized and reduce unnecessary disk spills.

Bug fixes

- Resolved a `gpstart` failure caused by a `double free or corruption` error when using OpenSSL 3.2.2.
- Fixed a bug in the Postgres planner where correlated subqueries returned incorrect results due to improper `placeholdervar` handling.
- Resolved an `unexpected gang size` error occasionally encountered in the Postgres planner.
- Initialized `attnumswithentries` to prevent failures during concurrent-only (CO) table rewrites.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Security

- Included a fix for CVE-2023-5869.
- Included a fix for CVE-2024-7348.
- Included a fix for CVE-2024-10979.
- Included a fix for CVE-2024-10976.
- Included a fix for CVE-2022-41862.
- Included a fix for CVE-2023-39417.
- Included a fix for CVE-2024-10978.
- Included a fix for CVE-2024-0978.
- Included a fix for CVE-2024-10977.
- Included a fix for CVE-2023-5870.
- Included a fix for CVE-2023-5868.
- Included a fix for CVE-2024-0985.

3 Installing and upgrading WarehousePG

Information about installing, configuring, and upgrading WarehousePG software and configuring WarehousePG host machines.

- Platform Requirements
  This topic describes the WarehousePG 7 platform and operating system software requirements.
- Estimating Storage Capacity
  To estimate how much data your WarehousePG cluster can accommodate, use these measurements as guidelines. Also keep in mind that you may want to have extra space for landing backup files and data load files on each segment host.
- Configure Operating System
  Describes how to prepare your operating system environment for WarehousePG software installation.
- Installing WarehousePG
  Describes how to install the WarehousePG software binaries on all of the hosts that will comprise your WarehousePG cluster, how to enable passwordless SSH for the `gpadmin` user, and how to verify the installation.
- Creating the Data Storage Areas
  Describes how to create the directory locations where WarehousePG data is stored for each coordinator, standby, and segment instance.
- Validating the WHPG Cluster
  Validate your hardware and network performance.
- Initializing WarehousePG
  Describes how to initialize a WarehousePG database system.
- Installing Optional Extensions
  Information about installing optional WarehousePG extensions and packages, such as the Procedural Language extensions and the Python and R Data Science Packages.
- Installing Extensions
  The WarehousePG distribution includes several PostgreSQL- and WarehousePG-sourced `contrib` modules that you have the option to install.
- Configuring Timezone and Localization Settings
  Describes the available timezone and localization features of WarehousePG.
- Important Changes Between WHPG 6 and WHPG 7 Describes the changes between WarehousePG 6 and WarehousePG 7 that could potentially affect your existing 6 application when you move to 7.
- Performing a minor upgrade
  Explains how to upgrade to a newer version of WarehousePG 7.x.
- Upgrading from whpg 6 to whpg 7
  Explains how to upgrade from WarehousePG 6 to WarehousePG 7.
- Migrating Partition Maintenance Scripts to the New WarehousePG 7 Partitioning Catalogs Provides guidance on migrating partition maintenance scripts that you may have written for WarehousePG 6 to use the new partitioning system catalogs in WarehousePG 7.
- Enabling iptables (Optional)
  On Linux systems, you can configure and enable the `iptables` firewall to work with WarehousePG.
- Installation Utilities Reference
  References for the command-line management utilities used to install and initialize a WarehousePG cluster.
- WarehousePG Environment Variables
  Reference of the environment variables to set for WarehousePG.
- Example Ansible Playbook A sample Ansible playbook to install a Greenplum Database software release onto the hosts that will comprise a Greenplum Database system.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

3.1 Platform Requirements

This topic describes the WarehousePG 7 platform and operating system software requirements for deploying the software to on-premise hardware, or to public cloud services such as AWS, GCP, or Azure.

Operating System Requirements

WarehousePG 7 runs on the following operating system platforms:

- Red Hat Enterprise Linux 64-bit 8.7 or later
- Oracle Linux 64-bit 8.7 or later, using the Red Hat Compatible Kernel (RHCK)
- Rocky Linux 8.7 or later

> **Note** If you use endpoint security software on your WarehousePG hosts, it may affect your database performance and stability. See About Endpoint Security Sofware for more information.

> **Caution** A kernel issue in Red Hat Enterprise Linux 8.5 and 8.6 can cause I/O freezes and synchronization problems with XFS filesystems. This issue is fixed in RHEL 8.7. See RHEL8: xfs_buf deadlock between inode deletion and block allocation.

WarehousePG server supports TLS version 1.2 on RHEL/CentOS systems, and TLS version 1.3 on Ubuntu systems.

Software Dependencies

WarehousePG 7 requires the following software packages on RHEL systems. The packages are installed automatically as dependencies when you install the WarehousePG RPM package):

- apr
- apr-util
- bash
- bzip2
- curl
- iproute
- krb5-devel
- libcgroup-tools
- libcurl
- libevent
- libuuid
- libuv
- libxml2
- libyaml
- libzstd
- openldap
- openssh
- openssh-client
- openssh-server
- openssl
- openssl-libs
- perl
- python3
- python3-psycopg2
- python3-psutil
- python3-pyyaml
- python3.11
- python3.11-devel
- readline
- rsync
- sed
- tar
- which
- zip
- zlib

WarehousePG 7 client software requires these operating system packages:

- apr
- bzip2
- libedit
- libyaml
- libevent
- libzstd
- openssh
- python3
- python3-psycopg2
- python3-psutil
- python3-pyyaml
- zlib

> **Important** SSL is supported only on the WarehousePG coordinator host system. It cannot be used on the segment host systems.

> **Important** For all WarehousePG host systems, if SELinux is enabled in `Enforcing` mode then the WarehousePG process and users can operate successfully in the default `Unconfined` context. If increased confinement is required, then you must configure SELinux contexts, policies, and domains based on your security requirements, and test your configuration to ensure there is no functionality or performance impact to WarehousePG. Similarly, you should either deactivate or configure firewall software as needed to allow communication between WarehousePG hosts. See Deactivate or Configure SELinux.

Java

WarehousePGd 7 supports these Java versions for PL/Java and PXF:

- Open JDK 8 or Open JDK 11, available from AdoptOpenJDK
- Oracle JDK 8 or Oracle JDK 11

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Python

WarehousePG uses the system default `python3` for the WarehousePG management utilities, and `python3.11` for the PL/Python module. For most of the supported OS versions, the system default `python3` is `python3.9`. If you are installing WarehousePG on Rocky Linux 8, the default `python3` version included is `python3.6`. You may want to unify the `python3` versions to `python3.11` by running the following commands:

```
sudo yum install python3.11 python3.11-devel python3.11-psycopg2 python3.11-pyyaml python3.11-psutil
sudo update-alternatives set python3 /usr/bin/python3.11
sudo update-alternatives set python /usr/bin/python3.11
```

WarehousePG Tools and Extensions Compatibility

Client Tools

The WarehousePG 7 Clients tool package is supported on the following platforms:

- Red Hat Enterprise Linux x86_64 8.x (RHEL 8)
- Oracle Linux 64-bit 8, using the Red Hat Compatible Kernel (RHCK)
- Rocky Linux 8
- Windows 10 (64-bit)
- Windows 8 (64-bit)
- Windows Server 2012 (64-bit)
- Windows Server 2012 R2 (64-bit)
- Windows Server 2008 R2 (64-bit)

The WarehousePG 7 Clients package includes the client and loader programs plus database/role/language commands. Refer to WarehousePG Client and Loader Tools Package for installation and usage details of the WarehousePG 7 Client tools.

Extensions

This table lists the versions of the WarehousePG Extensions that are compatible with this release of WarehousePG 7.

Component	Package Version	Additional Information
PL/Java	2.0.7	Supports Java 8 and 11.
Python 3.11 Data Science Module Package	1.2	
PL/R	3.1.1	(CentOS) R 3.3.3 (Ubuntu) You install R 3.5.1+.
R Data Science Library Package	2.0.2	
PL/Container Image for R	2.1.2	R 3.6.3
PL/Container Images for Python	2.1.2	Python 2.7.12 Python 3.7
MADlib Machine Learning	2.1.0	Support matrix at MADlib FAQ.
PostGIS Spatial and Geographic Objects	3.3.2	

For information about the Oracle Compatibility Functions, see Oracle Compatibility Functions.

These WarehousePG extensions are installed with WarehousePG

- Fuzzy String Match Extension
- PL/Python Extension
- pgcrypto Extension

Hardware Requirements

The following table lists minimum recommended specifications for hardware servers intended to support WarehousePG on Linux systems in a production environment. All host servers in your WarehousePG cluster must have the same hardware and software configuration. WarehousePG also provides hardware build guides for its certified hardware platforms. Work with a WarehousePG clusters Engineer to review your anticipated environment to ensure an appropriate hardware configuration for WarehousePG.

Requirement	Specification
Minimum CPU	Any x86_64 compatible CPU
Minimum Memory	16 GB RAM per server
Disk Space Requirements	• 150MB per host for WarehousePG installation • Approximately 300MB per segment instance for metadata • Cap disk capacity at 70% full to accommodate temporary files and prevent performance degradation
Network Requirements	• 10 Gigabit Ethernet within the array • NIC bonding is recommended when multiple interfaces are present • WarehousePG can use either IPV4 or IPV6 protocols.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Hyperthreading

Resource Groups - one of the key WarehousePG features - can control transaction concurrency, CPU and memory resources, workload isolation, and dynamic bursting.

When using resource groups to control resource allocation on Intel based systems, consider switching off Hyper-Threading (HT) in the server BIOS (for Intel cores the default is ON). Switching off HT might cause a small throughput reduction (less than 15%), but can achieve greater isolation between resource groups, and higher query performance with lower concurrency workloads.

Storage

The only file system supported for running WarehousePG is the XFS file system. All other file systems are explicitly *not* supported by WarehousePG.

WarehousePG is supported on network or shared storage if the shared storage is presented as a block device to the servers running WarehousePG and the XFS file system is mounted on the block device. Network file systems are*not* supported. When using network or shared storage, WarehousePG mirroring must be used in the same way as with local storage, and no modifications may be made to the mirroring scheme or the recovery scheme of the segments.

Other features of the shared storage such as de-duplication and/or replication are not directly supported by WarehousePG, but may be used with support of the storage vendor as long as they do not interfere with the expected operation of WarehousePG.

WarehousePG can be deployed to virtualized systems only if the storage is presented as block devices and the XFS file system is mounted for the storage of the segment directories.

WarehousePG is supported on Amazon Web Services (AWS) servers using either Amazon instance store (Amazon uses the volume names `ephemeral[0-23]`) or Amazon Elastic Block Store (Amazon EBS) storage. If using Amazon EBS storage the storage should be RAID of Amazon EBS volumes and mounted with the XFS file system for it to be a supported configuration.

Hadoop Distributions

WarehousePG provides access to HDFS with the WarehousePG Platform Extension Framework PXF

PXF can use Cloudera and generic Apache Hadoop distributions. PXF bundles all of the JAR files on which it depends, including the following Hadoop libraries:

PXF Version	Hadoop Version	Hive Server Version	HBase Server Version
6.x, 5.15.x, 5.14.0, 5.13.0, 5.12.0, 5.11.1, 5.10.1	2.x, 3.1+	1.x, 2.x, 3.1+	1.3.2
5.8.2	2.x	1.x	1.3.2
5.8.1	2.x	1.x	1.3.2

> **Note** If you plan to access JSON format data stored in a Cloudera Hadoop cluster, PXF requires a Cloudera version 5.8 or later Hadoop distribution.

Public Cloud Requirements

Operating System

The operating system parameters for cloud deployments are the same as on-premise with a few modifications. Use the WarehousePG Installation Guide for reference. Additional changes are as follows:

Add the following line to `sysctl.conf`:

```
net.ipv4.ip_local_reserved_ports=65330
```

AWS requires loading network drivers and also altering the Amazon Machine Image (AMI) to use the faster networking capabilities. More information on this is provided in the AWS documentation.

Storage

The disk settings for cloud deployments are the same as on-premise with a few modifications. Use the WarehousePG Installation Guide for reference. Additional changes are as follows:

- Mount options:

  ```
  rw,noatime,nobarrier,nodev,inode64
  ```

  > **Note** The `nobarrier` option is not supported on RHEL 8 or Ubuntu nodes.

- Use mq-deadline instead of the deadline scheduler for the R5 series instance type in AWS
- Use a swap disk per VM (32GB size works well)

Amazon Web Services (AWS)

Virtual Machine Type

AWS provides a wide variety of virtual machine types and sizes to address virtually every use case. Testing in AWS has found that the optimal instance types for WarehousePG are "Memory Optimized". These provide the ideal balance of Price, Memory, Network, and Storage throughput, and Compute capabilities.

Price, Memory, and number of cores typically increase in a linear fashion, but the network speed and disk throughput limits do not. You may be tempted to use the largest instance type to get the highest network and disk speed possible per VM, but better overall performance for the same spend on compute resources can be obtained by using more VMs that are smaller in size.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Compute

AWS uses Hyperthreading when reporting the number of vCPUs, therefore 2 vCPUs equates to 1 Core. The processor types are frequently getting faster so using the latest instance type will be not only faster, but usually less expensive. For example, the R5 series provides faster cores at a lower cost compared to R4.

Memory

This variable is pretty simple. WarehousePG needs at least 8GB of RAM per segment process to work optimally. More RAM per segment helps with concurrency and also helps hide disk performance deficiencies.

Network

AWS provides 25Gbit network performance on the largest instance types, but the network is typically not the bottleneck in AWS. The "up to 10Gbit" network is sufficient in AWS.

Installing network drivers in the VM is also required in AWS, and depends on the instance type. Some instance types use an Intel driver while others use an Amazon ENA driver. Loading the driver requires modifying the machine image (AMI) to take advantage of the driver.

Storage

Elastic Block Storage (EBS)

The AWS default disk type is General Performance (GP2) which is ideal for IOP dependent applications. GP2 uses SSD disks and relative to other disk types in AWS, is expensive. The operating system and swap volumes are ideal for GP2 disks because of the size and higher random I/O needs.

Throughput Optimized Disks (ST1) are a disk type designed for high throughput needs such as WarehousePG. These disks are based on HDD rather than SSD, and are less expensive than GP2. Use this disk type for the optimal performance of loading and SQL: Querying Data in AWS.

Cold Storage (SC1) provides the best value for EBS storage in AWS. Using multiple 2TB or larger disks provides enough disk throughput to reach the throughput limit of many different instance types. Therefore, it is possible to reach the throughput limit of a VM by using SC1 disks.

EBS storage is durable so data is not lost when a virtual machine is stopped. EBS also provides infrastructure snapshot capabilities that can be used to create volume backups. These snapshots can be copied to different regions to provide a disaster recovery solution. The WarehousePG Cloud utility `gpsnap`, available in the AWS Cloud Marketplace, automates backup, restore, delete, and copy functions using EBS snapshots.

Storage can be grown in AWS with "gpgrow". This tool is included with the WarehousePG on AWS deployment and allows you to grow the storage independently of compute. This is an online operation in AWS too.

Ephemeral

Ephemeral Storage is directly attached to VMs, but has many drawbacks:

- Data loss when stopping a VM with ephemeral storage
- Encryption is not supported
- No Snapshots
- Same speed can be achieved with EBS storage
- Not recommended

AWS Recommendations

####### Coordinator

Instance Type	Memory	vCPUs	Data Disks
r5.xlarge	32	4	1
r5.2xlarge	64	8	1
r5.4xlarge	128	16	1

####### Segments

Instance Type	Memory	vCPUs	Data Disks
r5.4xlarge	128	16	3

Performance testing has indicated that the Coordinator node can be deployed on the smallest r5.xlarge instance type to save money without a measurable difference in performance. Testing was performed using the TPC-DS benchmark.

The Segment instances run optimally on the r5.4xlarge instance type. This provides the highest performance given the cost of the AWS resources.

Google Compute Platform (GCP)

Virtual Machine Type

The two most common instance types in GCP are "Standard" or "HighMem" instance types. The only difference is the ratio of Memory to Cores. Each offer 1 to 64 vCPUs per VM.

Compute

Like AWS, GCP uses Hyperthreading, so 2 vCPUs equates to 1 Core. The CPU clock speed is determined by the region in which you deploy.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Memory

Instance type n1-standard-8 has 8 vCPUs with 30GB of RAM while n1-highmem-8 also has 8 vCPUs with 52GB of RAM. There is also a HighCPU instance type that generally isn't ideal for WarehousePG. Like AWS and Azure, the machines with more vCPUs will have more RAM.

Network

GCP network speeds are dependent on the instance type but the maximum network performance is possible (10Gbit) with a virtual machine as small as only 8 vCPUs.

Storage

Standard (HDD) and SSD disks are available in GCP. SSD is slightly faster in terms of throughput but comes at a premium. The size of the disk does not impact performance.

The biggest obstacle to maximizing storage performance is the throughput limit placed on every virtual machine. Unlike AWS and Azure, the storage throughput limit is relatively low, consistent across all instance types, and only a single disk is needed to reach the VM limit.

GCP Recommendations

Testing has revealed that *while using the same number of vCPUs*, a cluster using a large instance type like n1-highmem-64 (64 vCPUs) will have lower performance than a cluster using more of the smaller instance types like n1-highmem-8 (8 vCPUs). In general, use 8x more nodes in GCP than you would in another environment like AWS while using the 8 vCPU instance types.

The HighMem instance type is slightly faster for higher concurrency. Furthermore, SSD disks are slightly faster also but come at a cost.

####### Coordinator and Segment Instances

Instance Type	Memory	vCPUs	Data Disks
n1-standard-8	30	8	1
n1-highmem-8	52	8	1

Azure

> **Note** On the Azure platform, in addition to bandwidth, the number of network connections present on a VM at any given moment can affect the VM's network performance. The Azure networking stack maintains the state for each direction of a TCP/UDP connection in a data structures called a *flow*. A typical TCP/UDP connection will have 2 flows created: one for the inbound direction and another for the outbound direction. The number of network flows on Azure is limited to an upper bound. See Virtual machine network bandwidth in the Azure documentation for more details. In practice this can present scalability challenges for workloads based on the number of concurrent queries, and on the complexity of those queries. Always test your workload on Azure to validate that you are within the Azure limits, and be advised that if your workload increases you may hit Azure flow count boundaries at which point your workload may fail. It is recomended to use the UDP interconnect, and not the TCP interconnect, when using Azure. A connection pooler and resource group settings can also be used to help keep flow counts at a lower level.

Virtual Machine Type

Each VM type has limits on disk throughput so picking a VM that doesn't have a limit that is too low is essential. Most of Azure is designed for OLTP or Application workloads, which limits the choices for databases like WarehousePG where throughput is more important. Disk type also plays a part in the throughput cap, so that needs to be considered too.

Compute

Most instance types in Azure have hyperthreading enabled, which means 1 vCPU equates to 2 cores. However, not all instance types have this feature, so for these others, 1 vCPU equates to 1 core.

The High Performance Compute (HPC) instance types have the fastest cores in Azure.

Memory

In general, the larger the virtual machine type, the more memory the VM will have.

Network

The Accelerated Networking option offloads CPU cycles for networking to "FPGA-based SmartNICs". Virtual machine types either support this or do not, but most do support it. Testing of WarehousePG hasn't shown much difference and this is probably because of Azure's preference for TCP over UDP. Despite this, UDPIFC interconnect is the ideal protocol to use in Azure.

There is an undocumented process in Azure that periodically runs on the host machines on UDP port 65330. When a query runs using UDP port 65330 and this undocumented process runs, the query will fail after one hour with an interconnect timeout error. This is fixed by reserving port 65330 so that WarehousePG doesn't use it.

Storage

Storage in Azure is either Premium (SSD) or Regular Storage (HDD). The available sizes are the same and max out at 4TB. Instance types either do or do not support Premium but, interestingly, the instance types that do support Premium storage, have a *lower* throughput limit. For example:

- Standard_E32s_v3 has a limit of 768 MB/s.
- Standard_E32_v3 was tested with `gpcheckperf` to have 1424 write and 1557 read MB/s performance.

To get the maximum throughput from a VM in Azure, you have to use multiple disks. For larger instance types, you have to use upwards of 32 disks to reach the limit of a VM. Unfortunately, the memory and CPU constraints on these machines means that you have to run fewer segments than you have disks, so you have to use software RAID to utilize all of these disks. Performance takes a hit with software RAID, too, so you have to try multiple configurations to optimize.

The size of the disk also impacts performance, but not by much.

Software RAID not only is a little bit slower, but it also requires `umount` to take a snapshot. This greatly lengthens the time it takes to take a snapshot backup.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Disks use the same network as the VMs so you start running into the Azure limits in bigger clusters when using big virtual machines with 32 disks on each one. The overall throughput drops as you hit this limit and is most noticeable during concurrency testing.

Azure Recommendations

The best instance type to use in Azure is "Standard_H8" which is one of the High Performance Compute instance types. This instance series is the only one utilizing InfiniBand, but this does not include IP traffic. Because this instance type is n0t available in all regions, the "Standard_D13_v2" is also available.

####### Coordinator

Instance Type	Memory	vCPUs	Data Disks
D13_v2	56	8	1
H8	56	8	1

####### Segments

Instance Type	Memory	vCPUs	Data Disks
D13_v2	56	8	2
H8	56	8	2

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

3.2 Estimating Storage Capacity

To estimate how much data your WarehousePG cluster can accommodate, use these measurements as guidelines. Also keep in mind that you may want to have extra space for landing backup files and data load files on each segment host.

- Calculating Usable Disk Capacity
- Calculating User Data Size
- Calculating Space Requirements for Metadata and Logs

Parent topic: Installing and Upgrading WarehousePG

Calculating Usable Disk Capacity

To calculate how much data a WarehousePG cluster can hold, you have to calculate the usable disk capacity per segment host and then multiply that by the number of segment hosts in your WarehousePG cluster. Start with the raw capacity of the physical disks on a segment host that are available for data storage (raw_capacity), which is:

```
disk_size * number_of_disks
```

Account for file system formatting overhead (roughly 10 percent) and the RAID level you are using. For example, if using RAID-10, the calculation would be:

```
(raw_capacity * 0.9) / 2 = formatted_disk_space
```

For optimal performance, do not completely fill your disks to capacity, but run at 70% or lower. So with this in mind, calculate the usable disk space as follows:

```
formatted_disk_space * 0.7 = usable_disk_space
```

Using only 70% of your disk space allows WarehousePG to use the other 30% for temporary and transaction files on the same disks. If your host systems have a separate disk system that can be used for temporary and transaction files, you can specify a tablespace that WarehousePG uses for the files. Moving the location of the files might improve performance depending on the performance of the disk system.

Once you have formatted RAID disk arrays and accounted for the maximum recommended capacity (usable_disk_space), you will need to calculate how much storage is actually available for user data (`U`). If using WarehousePG mirrors for data redundancy, this would then double the size of your user data (`2 * U`). WarehousePG also requires some space be reserved as a working area for active queries. The work space should be approximately one third the size of your user data (work space = `U/3`):

```
With mirrors: (2 * U) + U/3 = usable_disk_space

Without mirrors: U + U/3 = usable_disk_space
```

Guidelines for temporary file space and user data space assume a typical analytic workload. Highly concurrent workloads or workloads with queries that require very large amounts of temporary space can benefit from reserving a larger working area. Typically, overall system throughput can be increased while decreasing work area usage through proper workload management. Additionally, temporary space and user space can be isolated from each other by specifying that they reside on different tablespaces.

In the *WarehousePG Administrator Guide*, see these topics:

- Managing Performance for information about workload management
- Creating and Managing Tablespaces for information about moving the location of temporary and transaction files
- Monitoring System State for information about monitoring WarehousePG disk space usage

Parent topic: Estimating Storage Capacity

Calculating User Data Size

As with all databases, the size of your raw data will be slightly larger once it is loaded into the database. On average, raw data will be about 1.4 times larger on disk after it is loaded into the database, but could be smaller or larger depending on the data types you are using, table storage type, in-database compression, and so on.

- Page Overhead - When your data is loaded into WarehousePG, it is divided into pages of 32KB each. Each page has 20 bytes of page overhead.
- Row Overhead - In a regular 'heap' storage table, each row of data has 24 bytes of row overhead. An 'append-optimized' storage table has only 4 bytes of row overhead.
- Attribute Overhead - For the data values itself, the size associated with each attribute value is dependent upon the data type chosen. As a general rule, you want to use the smallest data type possible to store your data (assuming you know the possible values a column will have).
- Indexes - In WarehousePG, indexes are distributed across the segment hosts as is table data. The default index type in WarehousePG is B-tree. Because index size depends on the number of unique values in the index and the data to be inserted, precalculating the exact size of an index is impossible. However, you can roughly estimate the size of an index using these formulas.

  ```
  B-tree: unique_values * (data_type_size + 24 bytes)

  Bitmap: (unique_values * =number_of_rows * 1 bit * compression_ratio / 8) + (unique_values * 32)
  ```

Parent topic: Estimating Storage Capacity

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Calculating Space Requirements for Metadata and Logs

On each segment host, you will also want to account for space for WarehousePG log files and metadata:

- **System Metadata** — For each WarehousePG segment instance (primary or mirror) or coordinator instance running on a host, estimate approximately 20 MB for the system catalogs and metadata.
- **Write Ahead Log** — For each WarehousePG segment (primary or mirror) or coordinator instance running on a host, allocate space for the write ahead log (WAL). The WAL is divided into segment files of 64 MB each. At most, the maximum number of WAL files will be:

  ```
  max_wal_size / 64MB
  ```

  You can use this to estimate space requirements for WAL. The default checkpoint_segments setting for a WarehousePG instance is 8, meaning 1088 MB WAL space allocated for each segment or coordinator instance on a host.
- **WarehousePG Log Files** — Each segment instance and the coordinator instance generates database log files, which will grow over time. Sufficient space should be allocated for these log files, and some type of log rotation facility should be used to ensure that to log files do not grow too large.

Parent topic: Estimating Storage Capacity

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

3.3 Configure Operating System

Describes how to prepare your operating system environment for WarehousePG software installation.

Perform the following tasks in order:

1. Make sure your host systems meet the requirements described in On-Premise Hardware Requirements.
2. Deactivate or configure SELinux.
3. Deactivate or configure firewall software.
4. Set the required operating system parameters.
5. Synchronize system clocks.
6. Create the gpadmin account.

Unless noted, these tasks should be performed for *all* hosts in your WarehousePG cluster (coordinator, standby coordinator, and segment hosts).

The WarehousePG host naming convention for the coordinator host is `cdw` and for the standby coordinator host is `scdw`.

The segment host naming convention is sdwN where sdw is a prefix and N is an integer. For example, segment host names would be `sdw1`, `sdw2` and so on. NIC bonding is recommended for hosts with multiple interfaces, but when the interfaces are not bonded, the convention is to append a dash (`-`) and number to the host name. For example, `sdw1-1` and `sdw1-2` are the two interface names for host `sdw1`.

> **Important** When data loss is not acceptable for a WarehousePG cluster, WarehousePG coordinator and segment mirroring is recommended. If mirroring is not enabled then WarehousePG stores only one copy of the data, so the underlying storage media provides the only guarantee for data availability and correctness in the event of a hardware failure.

> **Note** For information about upgrading WarehousePG from a previous version, see the *WarehousePG Release Notes* for the release that you are installing.

> **Note** Automating the configuration steps described in this topic and Installing WarehousePG with a system provisioning tool, such as Ansible, Chef, or Puppet, can save time and ensure a reliable and repeatable WarehousePG installation.

Parent topic: Installing and Upgrading WarehousePG

Deactivate or Configure SELinux

For all WarehousePG host systems running RHEL/Oracle/Rocky Linux, SELinux must either be `Disabled` or configured to allow unconfined access to WarehousePG processes, directories, and the gpadmin user.

If you choose to deactivate SELinux:

1. As the root user, check the status of SELinux:

   ```
   # sestatus
   SELinuxstatus: disabled
   ```

2. If SELinux is not deactivated, deactivate it by editing the `/etc/selinux/config` file. As root, change the value of the `SELINUX` parameter in the `config` file as follows:

   ```
   SELINUX=disabled
   ```

3. If the System Security Services Daemon (SSSD) is installed on your systems, edit the SSSD configuration file and set the `selinux_provider` parameter to `none` to prevent SELinux-related SSH authentication denials that could occur even with SELinux deactivated. As root, edit `/etc/sssd/sssd.conf` and add this parameter:

   ```
   selinux_provider=none
   ```

4. Reboot the system to apply any changes that you made and verify that SELinux is deactivated.

If you choose to enable SELinux in `Enforcing` mode, then WarehousePG processes and users can operate successfully in the default `Unconfined` context. If you require increased SELinux confinement for WarehousePG processes and users, you must test your configuration to ensure that there are no functionality or performance impacts to WarehousePG. See the SELinux User's and Administrator's Guide for detailed information about configuring SELinux and SELinux users.

Deactivate or Configure Firewall Software

You should also deactivate firewall software such as `firewalld` (on systems such as RHEL). If firewall software is not deactivated, you must instead configure your software to allow required communication between WarehousePG hosts.

1. Check the status of `firewalld` with the command:

   ```
   # systemctl status firewalld
   ```

   If `firewalld` is deactivated, the command output is:

   ```
   * firewalld.service - firewalld - dynamic firewall daemon
      Loaded: loaded (/usr/lib/systemd/system/firewalld.service; disabled; vendor preset: enabled)
      Active: inactive (dead)
   ```

2. If necessary, run these commands as root to deactivate `firewalld`:

   ```
   # systemctl stop firewalld.service
   # systemctl disable firewalld.service
   ```

See the documentation for the firewall or your operating system for additional information.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Recommended OS Parameters Settings

WarehousePG requires that certain Linux operating system (OS) parameters be set on all hosts in your WarehousePG cluster (coordinators and segments).

In general, the following categories of system parameters need to be altered:

- **Shared Memory** - A WarehousePG instance will not work unless the shared memory segment for your kernel is properly sized. Most default OS installations have the shared memory values set too low for WarehousePG. On Linux systems, you must also deactivate the OOM (out of memory) killer. For information about WarehousePG shared memory requirements, see the WarehousePG server configuration parameter shared_buffers in the *WarehousePG Reference Guide*.
- **Network** - On high-volume WarehousePG clusters, certain network-related tuning parameters must be set to optimize network connections made by the WarehousePG interconnect.
- **User Limits** - User limits control the resources available to processes started by a user's shell. WarehousePG requires a higher limit on the allowed number of file descriptors that a single process can have open. The default settings may cause some WarehousePG queries to fail because they will run out of file descriptors needed to process the query.

More specifically, you need to edit the following Linux configuration settings:

- The hosts File
- The sysctl.conf File
- System Resources Limits
- Core Dump
- XFS Mount Options
- Disk I/O Settings
  - Read ahead values
  - Disk I/O scheduler disk access

- Networking
- Transparent Huge Pages (THP)
- IPC Object Removal
- SSH Connection Threshold

The hosts File

Edit the `/etc/hosts` file and make sure that it includes the host names and all interface address names for every machine participating in your WarehousePG cluster.

The sysctl.conf File

The `sysctl.conf` parameters listed in this topic are for performance, optimization, and consistency in a wide variety of environments. Change these settings according to your specific situation and setup.

Set the parameters in the `/etc/sysctl.conf` file and reload with `sysctl -p`:

```
# kernel.shmall = _PHYS_PAGES / 2 # See Shared Memory Pages

vm.dirty_bytes = 4294967296
```

Shared Memory Pages

WarehousePG uses shared memory to communicate between `postgres` processes that are part of the same `postgres` instance. `kernel.shmall` sets the total amount of shared memory, in pages, that can be used system wide. `kernel.shmmax` sets the maximum size of a single shared memory segment in bytes.

Set `kernel.shmall` and `kernel.shmmax` values based on your system's physical memory and page size. In general, the value for both parameters should be one half of the system physical memory.

Use the operating system variables `_PHYS_PAGES` and `PAGE_SIZE` to set the parameters.

```
kernel.shmall = ( _PHYS_PAGES / 2)
kernel.shmmax = ( _PHYS_PAGES / 2) * PAGE_SIZE
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

To calculate the values for `kernel.shmall` and `kernel.shmmax`, run the following commands using the `getconf` command, which returns the value of an operating system variable.

```
$ echo $(expr $(getconf _PHYS_PAGES) / 2)
$ echo $(expr $(getconf _PHYS_PAGES) / 2 \* $(getconf PAGE_SIZE))
```

As best practice, we recommend you set the following values in the `/etc/sysctl.conf` file using calculated values. For example, a host system has 1583 GB of memory installed and returns these values: _PHYS_PAGES = 395903676 and PAGE_SIZE = 4096. These would be the `kernel.shmall` and `kernel.shmmax` values:

```
kernel.shmall = 197951838
kernel.shmmax = 810810728448
```

If the WarehousePG coordinator has a different shared memory configuration than the segment hosts, the _PHYS_PAGES and PAGE_SIZE values might differ, and the `kernel.shmall` and `kernel.shmmax` values on the coordinator host will differ from those on the segment hosts.

Segment Host Memory

The `vm.overcommit_memory` Linux kernel parameter is used by the OS to determine how much memory can be allocated to processes. For WarehousePG, this parameter should always be set to 2.

`vm.overcommit_ratio` is the percent of RAM that is used for application processes and the remainder is reserved for the operating system. The default is 50 on Red Hat Enterprise Linux.

For `vm.overcommit_ratio` tuning and calculation recommendations with resource group-based resource management or resource queue-based resource management, refer to Options for Configuring Segment Host Memory in the *WarehousePG Administrator Guide*.

Port Settings

To avoid port conflicts between WarehousePG and other applications during WarehousePG initialization, make a note of the port range specified by the operating system parameter `net.ipv4.ip_local_port_range`. When initializing WarehousePG using the `gpinitsystem` cluster configuration file, do not specify WarehousePG ports in that range. For example, if `net.ipv4.ip_local_port_range = 10000 65535`, set the WarehousePG base port numbers to these values.

```
PORT_BASE = 6000
MIRROR_PORT_BASE = 7000
```

For information about the `gpinitsystem` cluster configuration file, see Initializing WarehousePG.

For Azure deployments with WarehousePG avoid using port 65330; add the following line to sysctl.conf:

```
net.ipv4.ip_local_reserved_ports=65330
```

For additional requirements and recommendations for cloud deployments, see Public Cloud Requirements.

IP Fragmentation Settings

When the WarehousePG interconnect uses UDP (the default), the network interface card controls IP packet fragmentation and reassemblies.

If the UDP message size is larger than the size of the maximum transmission unit (MTU) of a network, the IP layer fragments the message. (Refer to Networking later in this topic for more information about MTU sizes for WarehousePG.) The receiver must store the fragments in a buffer before it can reorganize and reassemble the message.

The following `sysctl.conf` operating system parameters control the reassembly process:

OS Parameter	Description
net.ipv4.ipfrag_high_thresh	The maximum amount of memory used to reassemble IP fragments before the kernel starts to remove fragments to free up resources. The default value is 4194304 bytes (4MB).
net.ipv4.ipfrag_low_thresh	The minimum amount of memory used to reassemble IP fragments. The default value is 3145728 bytes (3MB). (Deprecated after kernel version 4.17.)
net.ipv4.ipfrag_time	The maximum amount of time (in seconds) to keep an IP fragment in memory. The default value is 30.

The recommended settings for these parameters for WarehousePG follow:

```
net.ipv4.ipfrag_high_thresh = 41943040
net.ipv4.ipfrag_low_thresh = 31457280
net.ipv4.ipfrag_time = 60
```

System Memory

For host systems with more than 64GB of memory, these settings are recommended:

```
vm.dirty_background_ratio = 0
vm.dirty_ratio = 0
vm.dirty_background_bytes = 1610612736 # 1.5GB
vm.dirty_bytes = 4294967296 # 4GB
```

For host systems with 64GB of memory or less, remove `vm.dirty_background_bytes` and `vm.dirty_bytes` and set the two `ratio` parameters to these values:

```
vm.dirty_background_ratio = 3
vm.dirty_ratio = 10
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Increase `vm.min_free_kbytes` to ensure `PF_MEMALLOC` requests from network and storage drivers are easily satisfied. This is especially critical on systems with large amounts of system memory. The default value is often far too low on these systems. Use this awk command to set `vm.min_free_kbytes` to a recommended 3% of system physical memory:

```
awk 'BEGIN {OFMT = "%.0f";} /MemTotal/ {print "vm.min_free_kbytes =", $2 * .03;}'
              /proc/meminfo >> /etc/sysctl.conf
```

Do not set `vm.min_free_kbytes` to higher than 5% of system memory as doing so might cause out of memory conditions.

System Resources Limits

Set the following parameters in the `/etc/security/limits.conf` file:

```
* soft nofile 524288
* hard nofile 524288
* soft nproc 131072
* hard nproc 131072
```

For Red Hat Enterprise Linux (RHEL) systems, parameter values in the `/etc/security/limits.d/20-nproc.conf` file override the values in the `limits.conf` file. Ensure that any parameters in the override file are set to the required value. The Linux module `pam_limits` sets user limits by reading the values from the `limits.conf` file and then from the override file. For information about PAM and user limits, see the documentation on PAM and `pam_limits`.

Run the `ulimit -u` command on each segment host to display the maximum number of processes that are available to each user. Validate that the return value is `131072`.

Core Dump

Enable core file generation to a known location by adding the following line to `/etc/sysctl.conf`:

```
kernel.core_pattern = /var/crash/core-%e-%s-%u-%g-%p-%t
```

Add the following line to `/etc/security/limits.conf`:

```
* soft  core unlimited
```

To apply the changes to the live kernel, run the following command:

```
# sysctl -p
```

XFS Mount Options

XFS is the preferred data storage file system on Linux platforms. Use the `mount` command with the following recommended XFS mount options for RHEL systems:

```
rw,nodev,noatime,inode64
```

See the `mount` manual page (`man mount` opens the man page) for more information about using this command.

The XFS options can also be set in the `/etc/fstab` file. This example entry from an `fstab` file specifies the XFS options.

```
/dev/data /data xfs nodev,noatime,inode64 0 0
```

> **Note** You must have root permission to edit the `/etc/fstab` file.

Disk I/O Settings

- Read-ahead value

  Each disk device file should have a read-ahead (`blockdev`) value of `16384`. To verify the read-ahead value of a disk device:

  ```
  # sudo /sbin/blockdev --getra <devname>
  ```

  For example:

  ```
  # sudo /sbin/blockdev --getra /dev/sdb
  ```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

To set blockdev (read-ahead) on a device:

```
# sudo /sbin/blockdev --setra <bytes> <devname>
```

For example:

```
# sudo /sbin/blockdev --setra 16384 /dev/sdb
```

See the manual page (man) for the `blockdev` command for more information about using that command (`man blockdev` opens the man page).

> **Note** The `blockdev --setra` command is not persistent. You must ensure the read-ahead value is set whenever the system restarts. How to set the value will vary based on your system.

One method to set the `blockdev` value at system startup is by adding the `/sbin/blockdev --setra` command in the `rc.local` file. For example, add this line to the `rc.local` file to set the read-ahead value for the disk `sdb`.

```
/sbin/blockdev --setra 16384 /dev/sdb
```

On systems that use systemd, you must also set the execute permissions on the `rc.local` file to enable it to run at startup. For example, on a RHEL system, this command sets execute permissions on the file.

```
# chmod +x /etc/rc.d/rc.local
```

Restart the system to have the setting take effect.

- Disk I/O scheduler

  The Linux disk scheduler orders the I/O requests submitted to a storage device, controlling the way the kernel commits reads and writes to disk.

  A typical Linux disk I/O scheduler supports multiple access policies. The optimal policy selection depends on the underlying storage infrastructure. The recommended scheduler policy settings for WarehousePG clusters for specific OSs and storage device types follow:

Storage Device Type	OS	Recommended Scheduler Policy
Non-Volatile Memory Express (NVMe)	RHEL 7 RHEL 8 RHEL 9 Ubuntu	`none`
Solid-State Drives (SSD)	RHEL 7	`noop`
Solid-State Drives (SSD)	RHEL 8 RHEL 9 Ubuntu	`none`
Other	RHEL 7	`deadline`
Other	RHEL 8 RHEL 9 Ubuntu	`mq-deadline`

  To specify a scheduler until the next system reboot, run the following:

```
# echo schedulername > /sys/block/<devname>/queue/scheduler
```

  For example:

```
# echo deadline > /sys/block/sbd/queue/scheduler
```

> **Note** Using the `echo` command to set the disk I/O scheduler policy is not persistent; you must ensure that you run the command whenever the system reboots. How to run the command will vary based on your system.

  To specify the I/O scheduler at boot time on systems that use `grub2`, use the system utility `grubby`. This command adds the parameter when run as `root`:

```
# grubby --update-kernel=ALL --args="elevator=deadline"
```

  After adding the parameter, reboot the system.

  This `grubby` command displays kernel parameter settings:

```
# grubby --info=ALL
```

  Refer to your operating system documentation for more information about the `grubby` utility. If you used the `grubby` command to configure the disk scheduler on a RHEL system and it does not update the kernels, see the Note at the end of the section.

  For additional information about configuring the disk scheduler, refer to the RedHat Enterprise Linux documentation forRHEL 8.

Networking

The maximum transmission unit (MTU) of a network specifies the size (in bytes) of the largest data packet/frame accepted by a network-connected device. A jumbo frame is a frame that contains more than the standard MTU of 1500 bytes.

WarehousePG utilizes 3 distinct MTU settings:

- The WarehousePG gp_max_packet_size server configuration parameter. The default max packet size is 8192. This default assumes a jumbo frame MTU.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

- The operating system MTU setting.
- The rack switch MTU setting.

These settings are connected, in that they should always be either the same, or close to the same, value, or otherwise in the order of WarehousePG < OS < switch for MTU size.

9000 is a common supported setting for switches, and is the recommended OS and rack switch MTU setting for your WarehousePG hosts.

Transparent Huge Pages (THP)

Deactivate Transparent Huge Pages (THP) as it degrades WarehousePG performance. RHEL 6.0 or higher enables THP by default. One way to deactivate THP on RHEL 6.x is by adding the parameter `transparent_hugepage=never` to the kernel command in the file `/boot/grub/grub.conf`, the GRUB boot loader configuration file. This is an example kernel command from a `grub.conf` file. The command is on multiple lines for readability:

```
kernel /vmlinuz-2.6.18-274.3.1.el5 ro root=LABEL=/
          elevator=deadline crashkernel=128M@16M  quiet console=tty1
          console=ttyS1,115200 panic=30 transparent_hugepage=never
          initrd /initrd-2.6.18-274.3.1.el5.img
```

On systems that use `grub2`, use the system utility `grubby`. This command adds the parameter when run as root.

```
# grubby --update-kernel=ALL --args="transparent_hugepage=never"
```

After adding the parameter, reboot the system.

For Ubuntu systems, install the `hugepages` package and run this command as root:

```
# hugeadm --thp-never
```

This cat command checks the state of THP. The output indicates that THP is deactivated.

```
$ cat /sys/kernel/mm/*transparent_hugepage/enabled
always [never]
```

For more information about Transparent Huge Pages or the `grubby` utility, see your operating system documentation. If the `grubby` command does not update the kernels, see the Note at the end of the section.

IPC Object Removal

Deactivate IPC object removal. The default `systemd` setting `RemoveIPC=yes` removes IPC connections when non-system user accounts log out. This causes the WarehousePG utility `gpinitsystem` to fail with semaphore errors. Perform one of the following to avoid this issue.

- When you add the `gpadmin` operating system user account to the coordinator node in Creating the WarehousePG Administrative User, create the user as a system account.
- Deactivate `RemoveIPC`. Set this parameter in `/etc/systemd/logind.conf` on the WarehousePG host systems.

  ```
  RemoveIPC=no
  ```

  The setting takes effect after restarting the `systemd-login` service or rebooting the system. To restart the service, run this command as the root user.

  ```
  service systemd-logind restart
  ```

SSH Connection Threshold

Certain WarehousePG management utilities including `gpexpand`, `gpinitsystem`, and `gpaddmirrors`, use secure shell (SSH) connections between systems to perform their tasks. In large WarehousePG deployments, cloud deployments, or deployments with a large number of segments per host, these utilities may exceed the host's maximum threshold for unauthenticated connections. When this occurs, you receive errors such as: `ssh_exchange_identification: Connection closed by remote host`.

To increase this connection threshold for your WarehousePG cluster, update the SSH `MaxStartups` and `MaxSessions` configuration parameters in one of the `/etc/ssh/sshd_config` or `/etc/sshd_config` SSH daemon configuration files.

> **Note** You must have root permission to edit these two files.

If you specify `MaxStartups` and `MaxSessions` using a single integer value, you identify the maximum number of concurrent unauthenticated connections (`MaxStartups`) and maximum number of open shell, login, or subsystem sessions permitted per network connection (`MaxSessions`). For example:

```
MaxStartups 200
MaxSessions 200
```

If you specify `MaxStartups` using the "start:rate:full" syntax, you enable random early connection drop by the SSH daemon. start identifies the maximum number of unauthenticated SSH connection attempts allowed. Once start number of unauthenticated connection attempts is reached, the SSH daemon refuses rate percent of subsequent connection attempts. full identifies the maximum number of unauthenticated connection attempts after which all attempts are refused. For example:

```
Max Startups 10:30:200
MaxSessions 200
```

Restart the SSH daemon after you update `MaxStartups` and `MaxSessions`. For example, on a CentOS 6 system, run the following command as the `root` user:

```
# service sshd restart
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

For detailed information about SSH configuration options, refer to the SSH documentation for your Linux distribution.

> **Note** If the `grubby` command does not update the kernels of a RHEL 7.x or CentOS 7.x system, you can manually update all kernels on the system. For example, to add the parameter `transparent_hugepage=never` to all kernels on a system.

1. Add the parameter to the `GRUB_CMDLINE_LINUX` line in the file parameter in `/etc/default/grub`.

   ```
   GRUB_TIMEOUT=5
   GRUB_DISTRIBUTOR="$(sed 's, release .*$,,g' /etc/system-release)"
   GRUB_DEFAULT=saved
   GRUB_DISABLE_SUBMENU=true
   GRUB_TERMINAL_OUTPUT="console"
   GRUB_CMDLINE_LINUX="crashkernel=auto rd.lvm.lv=cl/root rd.lvm.lv=cl/swap rhgb quiet transparent_hugepage=never"
                GRUB_DISABLE_RECOVERY="true"
   ```

   > **Note** You must have root permission to edit the `/etc/default/grub` file.

2. As root, run the `grub2-mkconfig` command to update the kernels.

   ```
   # grub2-mkconfig -o /boot/grub2/grub.cfg
   ```

3. Reboot the system.

Synchronizing System Clocks

You must use NTP (Network Time Protocol) to synchronize the system clocks on all hosts that comprise your WarehousePG cluster. Accurate time keeping is essential to ensure reliable operations on the database and data integrity.

There are many different architectures you may choose from to implement NTP. We recommend you use one of the following:

- Configure coordinator as the NTP primary source and the other hosts in the cluster connect to it.
- Configure an external NTP primary source and all hosts in the cluster connect to it.

Depending on your operating system version, the NTP protocol may be implemented by the `ntpd` daemon, the `chronyd` daemon, or other. Refer to your preferred NTP protocol documentation for more details.

Option 1: Configure System Clocks with the Coordinator as the Primary Source

1. On the coordinator host, log in as root and edit your NTP daemon configuration file. Set the `server` parameter to point to your data center's NTP time server. For example (if `10.6.220.20` was the IP address of your data center's NTP server):

   ```
   server 10.6.220.20
   ```

2. On each segment host, log in as root and edit your NTP daemon configuration file. Set the first `server` parameter to point to the coordinator host, and the second server parameter to point to the standby coordinator host. For example:

   ```
   server cdw prefer
   server scdw
   ```

3. On the standby coordinator host, log in as root and edit your NTP daemon configuration file. Set the first `server` parameter to point to the primary coordinator host, and the second server parameter to point to your data center's NTP time server. For example:

   ```
   server cdw prefer
   server 10.6.220.20
   ```

4. Synchronize the system clocks on all WarehousePG hosts as root.

   If you are using the `ntpd` daemon:

   ```
   systemctl restart ntp
   ```

   If you are using the `chronyd` daemon:

   ```
   systemctl restart chronyd
   ```

Option 2: Configure System Clocks with an External Primary Source

1. On each host, including coordinator, standby coordinator, and segments, log in as root and edit your NTP daemon configuration file. Set the first `server` parameter to point to your data center's NTP time server. For example (if `10.6.220.20` was the IP address of your data center's NTP server):

   ```
   server 10.6.220.20
   ```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

2. On the coordinator host, use your NTP daemon to synchronize the system clocks on all WarehousePG hosts. For example, usinggpssh:

   If you are using the `ntpd` daemon:

   ```
   gpssh -f hostfile_gpssh_allhosts -v -e 'ntpd'
   ```

   If you are using the `chronyd` daemon:

   ```
   gpssh -f hostfile_gpssh_allhosts -v -e 'chronyd'
   ```

Creating the WarehousePG Administrative User

Create a dedicated operating system user account on each node to run and administer WarehousePG. This user account is named `gpadmin` by convention.

> **Important** You cannot run the WarehousePG server as `root`.

The `gpadmin` user must have permission to access the services and directories required to install and run WarehousePG.

The `gpadmin` user on each WarehousePG host must have an SSH key pair installed and be able to SSH from any host in the cluster to any other host in the cluster without entering a password or passphrase (called "passwordless SSH"). If you enable passwordless SSH from the coordinator host to every other host in the cluster ("1-*n* passwordless SSH"), you can use the WarehousePG `gpssh-exkeys` command-line utility later to enable passwordless SSH from every host to every other host ("*n*-*n* passwordless SSH").

You can optionally give the `gpadmin` user sudo privilege, so that you can easily administer all hosts in the WarehousePG cluster as `gpadmin` using the `sudo`, `ssh/rsync`, and `gpssh/gpsync` commands.

The following steps show how to set up the `gpadmin` user on a host, set a password, create an SSH key pair, and (optionally) enable sudo capability. These steps must be performed as root on every WarehousePG cluster host. (For a large WarehousePG cluster you will want to automate these steps using your system provisioning tools.)

1. Create the `gpadmin` group and user.

   > **Note** If you are installing WarehousePG on RHEL 7.2 or CentOS 7.2 and want to deactivate IPC object removal by creating the `gpadmin` user as a system account, provide both the `-r` option (create the user as a system account) and the `-m` option (create a home directory) to the `useradd` command. On Ubuntu systems, you must use the `-m` option with the `useradd` command to create a home directory for a user.

   This example creates the `gpadmin` group, creates the `gpadmin` user as a system account with a home directory and as a member of the `gpadmin` group, and creates a password for the user.

   ```
   # groupadd gpadmin
   # useradd gpadmin -r -m -g gpadmin
   # passwd gpadmin
   New password: <changeme>
   Retype new password: <changeme>
   ```

   > **Note** You must have root permission to create the `gpadmin` group and user.

   > **Note** Make sure the `gpadmin` user has the same user id (uid) and group id (gid) numbers on each host to prevent problems with scripts or services that use them for identity or permissions. For example, backing up WarehousePGs to some networked filesy stems or storage appliances could fail if the `gpadmin` user has different uid or gid numbers on different segment hosts. When you create the `gpadmin` group and user, you can use the `groupadd -g` option to specify a gid number and the `useradd -u` option to specify the uid number. Use the command `id gpadmin` to see the uid and gid for the `gpadmin` user on the current host.

2. Switch to the `gpadmin` user and generate an SSH key pair for the `gpadmin` user.

   ```
   $ su gpadmin
   $ ssh-keygen -t rsa -b 4096
   Generating public/private rsa key pair.
   Enter file in which to save the key (/home/gpadmin/.ssh/id_rsa):
   Created directory '/home/gpadmin/.ssh'.
   Enter passphrase (empty for no passphrase):
   Enter same passphrase again:
   ```

   At the passphrase prompts, press Enter so that SSH connections will not require entry of a passphrase.

3. Grant sudo access to the `gpadmin` user.

   On Red Hat or CentOS, run `visudo` and uncomment the `%wheel` group entry.

   ```
   %wheel        ALL=(ALL)       NOPASSWD: ALL
   ```

   Make sure you uncomment the line that has the `NOPASSWD` keyword.

   Add the `gpadmin` user to the `wheel` group with this command.

   ```
   # usermod -aG wheel gpadmin
   ```

Next Steps

- Installing WarehousePG Software
- Validating the WHPG Cluster
- Initializing WarehousePG

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

3.4 Installing EDB Postgres AI for WarehousePG

WarehousePG software is a downloadable package that you install on each host system using your operating system's package management system. You must install WarehousePG on each host machine of the WarehousePG cluster.

Perform the following tasks in order:

1. Install EDB Postgres AI for WarehousePG
2. Enable passwordless SSH
3. Verify your installation

> **Note**
>
> Starting from WarehousePG 7.4, the default installation directory is `/usr/edb/whpg7`. For backward compatibility, symlinks are provided at `/usr/local/greenplum-db` and `/usr/local/greenplum-db-clients`.

Before you begin installing WarehousePG, be sure you have completed the steps inConfigure operating system to configure each of the coordinator, standby coordinator, and segment host machines for WarehousePG.

> **Important**
>
> You require sudo or root user access to install from a pre-built RPM file.

Installing EDB Postgres AI for WarehousePG

To install, you will need an EDB Repos 2.0 token to gain access to the EDB private software repositories. For instructions on obtaining this token, see:Get your token.

Save the EDB Subscription token in an environment variable:

```
export EDB_SUBSCRIPTION_TOKEN=<your-token>
```

Run the following command to add the EDB repository to your system:

```
curl -1sSLf "https://downloads.enterprisedb.com/$EDB_SUBSCRIPTION_TOKEN/gpsupp/setup.rpm.sh" | sudo -E bash
```

> **Important**
>
> Starting with WarehousePG 7.4, the `warehouse-pg-7-clients` package is mandatory and must be installed alongside the server package.

Install the EPEL repository and Warehouse-pg packages according to your operating system:

```
sudo dnf -y install https://dl.fedoraproject.org/pub/epel/epel-release-latest-
8.noarch.rpm
sudo dnf install -y warehouse-pg-7 warehouse-pg-7-
clients
```

```
sudo dnf -y install https://dl.fedoraproject.org/pub/epel/epel-release-latest-
9.noarch.rpm
sudo dnf install -y warehouse-pg-7 warehouse-pg-7-
clients
```

Change the owner and group of the installed files to `gpadmin`:

```
sudo chown -R gpadmin:gpadmin /usr/edb/whpg*
```

Enabling passwordless SSH

The `gpadmin` user on each WarehousePG host must be able to connect from any host in the cluster to any other host in the cluster without entering a password or passphrase (called "passwordless SSH"). If you enable passwordless SSH from the coordinator host to every other host in the cluster ("1-*n* passwordless SSH"), you can use the WarehousePG `gpssh-exkeys` command-line utility to enable passwordless SSH from every host to every other host ("*n*-*n* passwordless SSH").

1. Log in to the coordinator host as the `gpadmin` user.

2. Source the `path` file in the WarehousePG installation directory.

   ```
   source /usr/edb/whpg7/greenplum_path.sh
   source /usr/edb/whpg7/greenplum_clients_path.sh
   ```

   > **Note**
   >
   > Add the above `source` command to the `gpadmin` user's `.bashrc` or other shell startup file so that the WarehousePG path and environment variables are set whenever you log in as `gpadmin`.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

3. Use the `ssh-copy-id` command to add the `gpadmin` user's public key to the `authorized_hosts` SSH file on every other host in the cluster.

```
ssh-copy-id scdw
ssh-copy-id sdw1
ssh-copy-id sdw2
ssh-copy-id sdw3
. .
.
```

   This enables 1-*n* passwordless SSH. You will be prompted to enter the `gpadmin` user's password for each host. If you have the `sshpass` command on your system, you can use a command like the following to avoid the prompt.

```
SSHPASS=<password> sshpass -e ssh-copy-id scdw
```

4. In the `gpadmin` home directory, create a file named `hostfile_exkeys` that has the machine configured host names and host addresses (interface names) for each host in your WarehousePG cluster (coordinator, standby coordinator, and segment hosts). Make sure there are no blank lines or extra spaces. Check the `/etc/hosts` file on your systems for the correct host names to use for your environment. For example, if you have a coordinator, standby coordinator, and three segment hosts with two unbonded network interfaces per host, your file would look something like this:

```
cdw
cdw-1
cdw-2
scdw
scdw-1
scdw-2
sdw1
sdw1-1
sdw1-2
sdw2
sdw2-1
sdw2-2
sdw3
sdw3-1
sdw3-2
```

5. Run the `gpssh-exkeys` utility with your `hostfile_exkeys` file to enable *n*-*n* passwordless SSH for the `gpadmin` user.

```
gpssh-exkeys -f hostfile_exkeys
```

Verifying your installation

To make sure the WarehousePG software was installed and configured correctly, run the following confirmation steps from your WarehousePG coordinator host. If necessary, correct any problems before continuing on to the next task.

1. Log in to the coordinator host as `gpadmin`:

```
su - gpadmin
```

2. Use the `gpssh` utility to see if you can log in to all hosts without a password prompt, and to confirm that the WarehousePG software was installed on all hosts. Use the `hostfile_exkeys` file you used to set up passwordless SSH. For example:

```
gpssh -f hostfile_exkeys -e 'ls -l
/usr/edb/whpg7'
```

   If the installation was successful, you should be able to log in to all hosts without a password prompt. All hosts should show that they have the same contents in their installation directories, and that the directories are owned by the `gpadmin` user.

   If you are prompted for a password, run the following command to redo the ssh key exchange:

```
gpssh-exkeys -f hostfile_exkeys
```

WarehousePG installation files and directories

The following files and directories are included with your WarehousePG installation:

- `greenplum_path.sh` — This file contains the environment variables for WarehousePG. See Setting WarehousePG environment variables.
- **bin** — This directory contains the WarehousePG management utilities. This directory also contains the PostgreSQL client and server programs, most of which are also used in WarehousePG.
- **docs/cli_help** — This directory contains help files for WarehousePG command-line utilities.
- **docs/cli_help/gpconfigs** — This directory contains sample `gpinitsystem` configuration files and host files that can be modified and used when installing and initializing WarehousePG.
- **ext** — Bundled programs (such as Python) used by some WarehousePG utilities.
- **include** — The C header files for WarehousePG.
- **lib** — WarehousePG and PostgreSQL library files.
- **sbin** — Supporting/Internal scripts and programs.
- **share** — Shared files for WarehousePG.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Next steps

Perform the following steps once your installation of WarehousePG is complete:

- Create the data storage areas
- Validate the WHPG cluster
- Initialize WarehousePG

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

3.5 Creating the Data Storage Areas

Describes how to create the directory locations where WarehousePG data is stored for each coordinator, standby, and segment instance.

Parent topic: Installing and Upgrading WarehousePG

Creating Data Storage Areas on the Coordinator and Standby Coordinator Hosts

A data storage area is required on the WarehousePG coordinator and standby coordinator hosts to store WarehousePG cluster data such as catalog data and other system metadata.

To create the data directory location on the coordinator

The data directory location on the coordinator is different than those on the segments. The coordinator does not store any user data, only the system catalog tables and system metadata are stored on the coordinator instance, therefore you do not need to designate as much storage space as on the segments.

1. Create or choose a directory that will serve as your coordinator data storage area. This directory should have sufficient disk space for your data and be owned by the `gpadmin` user and group. For example, run the following commands as `root`:

   ```
   # mkdir -p /data/coordinator
   ```

2. Change ownership of this directory to the `gpadmin` user. For example:

   ```
   # chown gpadmin:gpadmin /data/coordinator
   ```

3. Using gpssh, create the coordinator data directory location on your standby coordinator as well. For example:

   ```
   # source /usr/edb/whpg7/greenplum_path.sh
   # gpssh -h scdw -e 'mkdir -p /data/coordinator'
   # gpssh -h scdw -e 'chown gpadmin:gpadmin /data/coordinator'
   ```

Creating Data Storage Areas on Segment Hosts

Data storage areas are required on the WarehousePG segment hosts for primary segments. Separate storage areas are required for mirror segments.

To create the data directory locations on all segment hosts

1. On the coordinator host, log in as `root`:

   ```
   # su
   ```

2. Create a file called `hostfile_gpssh_segonly`. This file should have only one machine configured host name for each segment host. For example, if you have three segment hosts:

   ```
   sdw1
   sdw2
   sdw3
   ```

3. Using gpssh, create the primary and mirror data directory locations on all segment hosts at once using the `hostfile_gpssh_segonly` file you just created. For example:

   ```
   # source /usr/edb/whpg7/greenplum_path.sh
   # gpssh -f hostfile_gpssh_segonly -e 'mkdir -p /data1/primary'
   # gpssh -f hostfile_gpssh_segonly -e 'mkdir -p /data2/primary'
   # gpssh -f hostfile_gpssh_segonly -e 'mkdir -p /data1/mirror'
   # gpssh -f hostfile_gpssh_segonly -e 'mkdir -p /data2/mirror'
   # gpssh -f hostfile_gpssh_segonly -e 'chown -R gpadmin /data*/*'
   ```

Next Steps

- Validating the WHPG Cluster
- Initializing WarehousePG

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

3.6 Validating the WHPG Cluster

Validate your hardware and network performance.

WarehousePG provides a management utility called gpcheckperf, which can be used to identify hardware and system-level issues on the machines in your WarehousePG cluster. gpcheckperf starts a session on the specified hosts and runs the following performance tests:

- Network Performance (`gpnetbench*`)
- Disk I/O Performance (`dd` test)
- Memory Bandwidth (`stream` test)

Before using `gpcheckperf` , you must have a trusted host setup between the hosts involved in the performance test. You can use the utility gpssh-exkeys to update the known host files and exchange public keys between hosts if you have not done so already. Note that `gpcheckperf` calls to gpssh and gpsync, so these WarehousePG utilities must be in your `$PATH` .

- **Validating Network Performance**
- **Validating Disk I/O and Memory Bandwidth**

Parent topic: Installing and Upgrading WarehousePG

Validating Network Performance

To test network performance, run gpcheckperf with one of the network test run options: parallel pair test (`-r N`), serial pair test (`-r n`), or full matrix test (`-r M`). The utility runs a network benchmark program that transfers a 5 second stream of data from the current host to each remote host included in the test. By default, the data is transferred in parallel to each remote host and the minimum, maximum, average and median network transfer rates are reported in megabytes (MB) per second. If the summary transfer rate is slower than expected (less than 100 MB/s), you can run the network test serially using the `-r n` option to obtain per-host results. To run a full-matrix bandwidth test, you can specify `-r M` which will cause every host to send and receive data from every other host specified. This test is best used to validate if the switch fabric can tolerate a full-matrix workload.

Most systems in a WarehousePG cluster are configured with multiple network interface cards (NICs), each NIC on its own subnet. When testing network performance, it is important to test each subnet individually. For example, considering the following network configuration of two NICs per host:

WarehousePG Host	Subnet1 NICs	Subnet2 NICs
Segment 1	sdw1-1	sdw1-2
Segment 2	sdw2-1	sdw2-2
Segment 3	sdw3-1	sdw3-2

You would create four distinct host files for use with the gpcheckperf network test:

hostfile_gpchecknet_ic1	hostfile_gpchecknet_ic2
sdw1-1	sdw1-2
sdw2-1	sdw2-2
sdw3-1	sdw3-2

You would then run gpcheckperf once per subnet. For example (if testing an *even* number of hosts, run in parallel pairs test mode):

```
$ gpcheckperf -f hostfile_gpchecknet_ic1 -r N -d /tmp > subnet1.out
$ gpcheckperf -f hostfile_gpchecknet_ic2 -r N -d /tmp > subnet2.out
```

If you have an *odd* number of hosts to test, you can run in serial test mode (`-r n`).

Parent topic: Validating the WHPG Cluster

Validating Disk I/O and Memory Bandwidth

To test disk and memory bandwidth performance, run gpcheckperf with the disk and stream test run options (`-r ds`). The disk test uses the `dd` command (a standard UNIX utility) to test the sequential throughput performance of a logical disk or file system. The memory test uses the STREAM benchmark program to measure sustainable memory bandwidth. Results are reported in MB per second (MB/s).

To run the disk and stream tests

1. Log in on the coordinator host as the `gpadmin` user.
2. Source the `greenplum_path.sh` path file from your WarehousePG installation. For example:

   ```
   $ source /usr/edb/whpg7/greenplum_path.sh
   ```

3. Create a host file named `hostfile_gpcheckperf` that has one host name per segment host. Do not include the coordinator host. For example:

   ```
   sdw1
   sdw2
   sdw3
   sdw4
   ```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4. Run the `gpcheckperf` utility using the `hostfile_gpcheckperf` file you just created. Use the `-d` option to specify the file systems you want to test on each host (you must have write access to these directories). You will want to test all primary and mirror segment data directory locations. For example:

```
$ gpcheckperf -f hostfile_gpcheckperf -r ds -D \
  -d /data1/primary -d  /data2/primary \
  -d /data1/mirror -d  /data2/mirror
```

5. The utility may take a while to perform the tests as it is copying very large files between the hosts. When it is finished you will see the summary results for the Disk Write, Disk Read, and Stream tests.

Parent topic: Validating the WHPG Cluster

3.7 Initializing WarehousePG

Describes how to initialize a WarehousePG database system.

The instructions in this chapter assume you have already prepared your hosts as described in Configure Operating System and installed the WarehousePG software on all of the hosts in the system according to the instructions in Installing WarehousePG.

This chapter contains the following topics:

- Overview
- Initializing WarehousePG
- Setting WarehousePG Environment Variables
- Next Steps

Parent topic: Installing and Upgrading WarehousePG

Overview

Because WarehousePG is distributed, the process for initializing a WarehousePG management system (DBMS) involves initializing several individual PostgreSQL database instances (called *segment instances* in WarehousePG).

Each database instance (the coordinator and all segments) must be initialized across all of the hosts in the system in such a way that they can all work together as a unified DBMS. WarehousePG provides its own version of `initdb` called gpinitsystem, which takes care of initializing the database on the coordinator and on each segment instance, and starting each instance in the correct order.

After the WarehousePG database system has been initialized and started, you can then create and manage databases as you would in a regular PostgreSQL DBMS by connecting to the WarehousePG coordinator.

Initializing WarehousePG

These are the high-level tasks for initializing WarehousePG:

1. Make sure you have completed all of the installation tasks described in Configure Operating System and Installing WarehousePG.
2. Create a host file that contains the host addresses of your segments. See Creating the Initialization Host File.
3. Create your WarehousePG cluster configuration file. See Creating the WarehousePG Configuration File.
4. By default, WarehousePG will be initialized using the locale of the coordinator host system. Make sure this is the correct locale you want to use, as some locale options cannot be changed after initialization. See Configuring Timezone and Localization Settings for more information.
5. Run the WarehousePG initialization utility on the coordinator host. See Running the Initialization Utility.
6. Set the WarehousePG timezone. See Setting the WarehousePG Timezone.
7. Set environment variables for the WarehousePG user. See Setting WarehousePG Environment Variables.

When performing the following initialization tasks, you must be logged into the coordinator host as the `gpadmin` user, and to run WarehousePG utilities, you must source the `greenplum_path.sh` file to set WarehousePG environment variables. For example, if you are logged into the coordinator, run these commands.

```
$ su - gpadmin
$ source /usr/edb/whpg7/greenplum_path.sh
```

Creating the Initialization Host File

The gpinitsystem utility requires a host file that contains the list of addresses for each segment host. The initialization utility determines the number of segment instances per host by the number host addresses listed per host times the number of data directory locations specified in the `gpinitsystem_config` file.

This file should only contain segment host addresses (not the coordinator or standby coordinator). For segment machines with multiple, unbonded network interfaces, this file should list the host address names for each interface — one per line.

> **Note** The WarehousePG segment host naming convention is sdwN where sdw is a prefix and N is an integer. For example, `sdw2` and so on. If hosts have multiple unbonded NICs, the convention is to append a dash (`-`) and number to the host name. For example, `sdw1-1` and `sdw1-2` are the two interface names for host `sdw1`. However, NIC bonding is recommended to create a load-balanced, fault-tolerant network.

To create the initialization host file

1. Create a file named `hostfile_gpinitsystem`. In this file add the host address name(s) of your *segment* host interfaces, one name per line, no extra lines or spaces. For example, if you have four segment hosts with two unbonded network interfaces each:

   ```
   sdw1-1
   sdw1-2
   sdw2-1
   sdw2-2
   sdw3-1
   sdw3-2
   sdw4-1
   sdw4-2
   ```

2. Save and close the file.

> **Note** If you are not sure of the host names and/or interface address names used by your machines, look in the `/etc/hosts` file.

Creating the WarehousePG Configuration File

Your WarehousePG configuration file tells the gpinitsystem utility how you want to configure your WarehousePG cluster. An example configuration file can be found in `$GPHOME/docs/cli_help/gpconfigs/gpinitsystem_config`.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

To create a gpinitsystem_config file

1. Make a copy of the `gpinitsystem_config` file to use as a starting point. For example:

```
$ cp $GPHOME/docs/cli_help/gpconfigs/gpinitsystem_config \
     /home/gpadmin/gpconfigs/gpinitsystem_config
```

2. Open the file you just copied in a text editor.

   Set all of the required parameters according to your environment. See gpinitsystem for more information. A WarehousePG cluster must contain a coordinator instance and at *least two* segment instances (even if setting up a single node system).

   The `DATA_DIRECTORY` parameter is what determines how many segments per host will be created. If your segment hosts have multiple network interfaces, and you used their interface address names in your host file, the number of segments will be evenly spread over the number of available interfaces.

   To specify `PORT_BASE`, review the port range specified in the `net.ipv4.ip_local_port_range` parameter in the `/etc/sysctl.conf` file. See Recommended OS Parameters Settings.

   Here is an example of the *required* parameters in the `gpinitsystem_config` file:

```
SEG_PREFIX=gpseg
PORT_BASE=6000
declare -a DATA_DIRECTORY=(/data1/primary /data1/primary /data1/primary /data2/primary /data2/primary /data2/primary)
COORDINATOR_HOSTNAME=cdw
COORDINATOR_DIRECTORY=/data/coordinator
COORDINATOR_PORT=5432
TRUSTED SHELL=ssh
CHECK_POINT_SEGMENTS=8
ENCODING=UNICODE
```

3. (Optional) If you want to deploy mirror segments, uncomment and set the mirroring parameters according to your environment. To specify `MIRROR_PORT_BASE`, review the port range specified under the `net.ipv4.ip_local_port_range` parameter in the `/etc/sysctl.conf` file. Here is an example of the *optional* mirror parameters in the `gpinitsystem_config` file:

```
MIRROR_PORT_BASE=7000
declare -a MIRROR_DATA_DIRECTORY=(/data1/mirror /data1/mirror /data1/mirror /data2/mirror /data2/mirror /data2/mirror)
```

   > **Note** You can initialize your WarehousePG cluster with primary segments only and deploy mirrors later using the gpaddmirrors utility.

4. Save and close the file.

Running the Initialization Utility

The gpinitsystem utility will create a WarehousePG cluster using the values defined in the configuration file.

These steps assume you are logged in as the `gpadmin` user and have sourced the `greenplum_path.sh` file to set WarehousePG environment variables.

To run the initialization utility

1. Run the following command referencing the path and file name of your initialization configuration file (`gpinitsystem_config`) and host file (`hostfile_gpinitsystem`). For example:

```
$ cd ~
$ gpinitsystem -c gpconfigs/gpinitsystem_config -h gpconfigs/hostfile_gpinitsystem
```

   For a fully redundant system (with a standby coordinator and a *spread* mirror configuration) include the `-s` and `--mirror-mode=spread` options. For example:

```
$ gpinitsystem -c gpconfigs/gpinitsystem_config -h gpconfigs/hostfile_gpinitsystem \
  -s <standby_coordinator_hostname> --mirror-mode=spread
```

   During a new cluster creation, you may use the `-O output\_configuration\_file` option to save the cluster configuration details in a file. For example:

```
$ gpinitsystem -c gpconfigs/gpinitsystem_config -O gpconfigs/config_template
```

   This output file can be edited and used at a later stage as the input file of the `-I` option, to create a new cluster or to recover from a backup. See gpinitsystem for further details.

   > **Note** Calling `gpinitsystem` with the `-O` option does not initialize the WarehousePG cluster; it merely generates and saves a file with cluster configuration details.

2. The utility will verify your setup information and make sure it can connect to each host and access the data directories specified in your configuration. If all of the pre-checks are successful, the utility will prompt you to confirm your configuration. For example:

```
=> Continue with WarehousePG creation? Yy/Nn
```

3. Press `y` to start the initialization.

4. The utility will then begin setup and initialization of the coordinator instance and each segment instance in the system. Each segment instance is set up in parallel. Depending on the number of segments, this process can take a while.

5. At the end of a successful setup, the utility will start your WarehousePG cluster. You should see:

```
=> WarehousePG instance successfully created.
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Troubleshooting Initialization Problems

If the utility encounters any errors while setting up an instance, the entire process will fail, and could possibly leave you with a partially created system. Refer to the error messages and logs to determine the cause of the failure and where in the process the failure occurred. Log files are created in `~/gpAdminLogs`.

Depending on when the error occurred in the process, you may need to clean up and then try the `gpinitsystem` utility again. For example, if some segment instances were created and some failed, you may need to stop `postgres` processes and remove any utility-created data directories from your data storage area(s). A backout script is created to help with this cleanup if necessary.

Using the Backout Script

If the gpinitsystem utility fails, it will create the following backout script if it has left your system in a partially installed state:

```
~/gpAdminLogs/backout_gpinitsystem_<user>_<timestamp>
```

You can use this script to clean up a partially created WarehousePG cluster. This backout script will remove any utility-created data directories, `postgres` processes, and log files. After correcting the error that caused `gpinitsystem` to fail and running the backout script, you should be ready to retry initializing your WarehousePG cluster.

The following example shows how to run the backout script:

```
$ bash ~/gpAdminLogs/backout_gpinitsystem_gpadmin_20071031_121053
```

Setting the WarehousePG Timezone

As a best practice, configure WarehousePG and the host systems to use a known, supported timezone. WarehousePG uses a timezone from a set of internally stored PostgreSQL timezones. Setting the WarehousePG timezone prevents WarehousePG from selecting a timezone each time the cluster is restarted and sets the timezone for the WarehousePG coordinator and segment instances.

Use the gpconfig utility to show and set the WarehousePG timezone. For example, these commands show the WarehousePG timezone and set the timezone to `US/Pacific`.

```
$ gpconfig -s TimeZone
$ gpconfig -c TimeZone -v 'US/Pacific'
```

You must restart WarehousePG after changing the timezone. The command `gpstop -ra` restarts WarehousePG. The catalog view `pg_timezone_names` provides WarehousePG timezone information.

For more information about the WarehousePG timezone, see Configuring Timezone and Localization Settings.

Setting WarehousePG Environment Variables

You must set environment variables in the WarehousePG user (`gpadmin`) environment that runs WarehousePG on the WarehousePG coordinator and standby coordinator hosts. A `greenplum_path.sh` file is provided in the WarehousePG installation directory with environment variable settings for WarehousePG.

The WarehousePG management utilities also require that the `COORDINATOR_DATA_DIRECTORY` environment variable be set. This should point to the directory created by the `gpinitsystem` utility in the coordinator data directory location.

> **Note** The `greenplum_path.sh` script changes the operating environment in order to support running the WarehousePG-specific utilities. These same changes to the environment can negatively affect the operation of other system-level utilities, such as `ps` or `yum`. Use separate accounts for performing system administration and database administration, instead of attempting to perform both functions as `gpadmin`.

These steps ensure that the environment variables are set for the `gpadmin` user after a system reboot.

To set up the gpadmin environment for WarehousePG

1. Open the `gpadmin` profile file (such as `.bashrc`) in a text editor. For example:

   ```
   $ vi ~/.bashrc
   ```

2. Add lines to this file to source the `greenplum_path.sh` file and set the `COORDINATOR_DATA_DIRECTORY` environment variable. For example:

   ```
   source /usr/edb/whpg7/greenplum_path.sh
   export COORDINATOR_DATA_DIRECTORY=/data/coordinator/gpseg-1
   ```

3. (Optional) You may also want to set some client session environment variables such as `PGPORT`, `PGUSER` and `PGDATABASE` for convenience. For example:

   ```
   export PGPORT=5432
   export PGUSER=gpadmin
   export PGDATABASE=gpadmin
   ```

4. (Optional) If you use RHEL/Oracle/Rocky Linux, add the following line to the end of the `.bashrc` file to enable using the `ps` command in the `greenplum_path.sh` environment:

   ```
   export LD_PRELOAD=/lib64/libz.so.1 ps
   ```

5. Save and close the file.

6. After editing the profile file, source it to make the changes active. For example:

   ```
   $ source ~/.bashrc
   ```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

7. If you have a standby coordinator host, copy your environment file to the standby coordinator as well. For example:

```
$ cd ~
$ scp .bashrc <standby_hostname>:`pwd`
```

Note The `.bashrc` file should not produce any output. If you wish to have a message display to users upon logging in, use the `.bash_profile` file instead.

Next Steps

After your system is up and running, the next steps are:

- Allowing Client Connections
- Creating Databases and Loading Data

Allowing Client Connections

After a WarehousePG is first initialized it will only allow local connections to the database from the `gpadmin` role (or whatever system user ran `gpinitsystem`). If you would like other users or client machines to be able to connect to WarehousePG, you must give them access. See the *WarehousePG Administrator Guide* for more information.

Creating Databases and Loading Data

After verifying your installation, you may want to begin creating databases and loading data. See DDL: Defining Database Objects and Loading and Unloading Data in the *WarehousePG Administrator Guide* for more information about creating databases, schemas, tables, and other database objects in WarehousePG and loading your data.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

3.8 Installing Optional Extensions

Information about installing optional WarehousePG extensions and packages, such as the Procedural Language extensions and the Python and R Data Science Packages.

- Procedural Language, Machine Learning, and Geospatial Extensions
- Python Data Science Module Package
- R Data Science Library Package
- WarehousePG Platform Extension Framework (PXF)

Parent topic: Installing and Upgrading WarehousePG

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

3.8.1 Procedural Language, Machine Learning, and Geospatial Extensions

The extension documentation in the *WarehousePG Reference Guide* contains information about installing extension packages and using extensions.

- WarehousePG PL/R Language Extension
- WarehousePG PL/Java Language Extension
- WarehousePG MADlib Extension for Analytics
- WarehousePG PostGIS Extension
- WarehousePG H3 Extension

Parent topic: Installing Optional Extensions (WarehousePG)

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

3.8.2 WarehousePG Platform Extension Framework (PXF)

Optional. If you do not plan to use PXF, no action is necessary.

If you plan to use PXF, refer to Accessing External Data with PXF for introductory PXF information.

Parent topic: Installing Optional Extensions (WarehousePG)

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

3.8.3 Data Science Package for Python

WarehousePG provides a collection of data science-related Python modules that can be used with the WarehousePG PL/Python language. This section contains the following information:

- Data Science Package for Python 3.11 Modules
- Installing a Data Science Package for Python
- Uninstalling a Data Science Package for Python

For information about the WarehousePG PL/Python Language, see WarehousePG PL/Python Language Extension.

Parent topic: Installing Optional Extensions (WarehousePG)

Data Science Package for Python 3.11 Modules

The following table lists the modules that are provided in the Data Science Package for Python 3.11.

Module Name	Description/Used For
absl-py	Abseil Python Common Libraries
arviz	Exploratory analysis of Bayesian models
astor	Read/rewrite/write Python ASTs
astunparse	An AST unparser for Python
autograd	Efficiently computes derivatives of numpy code
autograd-gamma	autograd compatible approximations to the derivatives of the Gamma-family of functions
backports.csv	Backport of Python 3 csv module
beautifulsoup4	Screen-scraping library
blis	The Blis BLAS-like linear algebra library, as a self-contained C-extension
cachetools	Extensible memoizing collections and decorators
catalogue	Super lightweight function registries for your library
catboost	A high-performance open source library for gradient boosting on decision trees
certifi	Python package for providing Mozilla's CA Bundle
cffi	Foreign Function Interface for Python calling C code
cftime	Time-handling functionality from netcdf4-python
charset-normalizer	The Real First Universal Charset Detector. Open, modern and actively maintained alternative to Chardet.
cheroot	Highly-optimized, pure-python HTTP server
CherryPy	Object-Oriented HTTP framework
click	Composable command line interface toolkit
convertdate	Converts between Gregorian dates and other calendar systems
cryptography	A set of functions useful in cryptography and linear algebra
cycler	Composable style cycles
cymem	Manage calls to calloc/free through Cython
Cython	The Cython compiler for writing C extensions for the Python language
datasets	HuggingFace community-driven open-source library of datasets
deprecat	Python @deprecat decorator to deprecate old python classes, functions or methods
dill	serialize all of python
fastprogress	A nested progress with plotting options for fastai
feedparser	Universal feed parser, handles RSS 0.9x, RSS 1.0, RSS 2.0, CDF, Atom 0.3, and Atom 1.0 feeds
filelock	A platform independent file lock
flatbuffers	The FlatBuffers serialization format for Python
fonttools	Tools to manipulate font files
formulaic	An implementation of Wilkinson formulas
funcy	A fancy and practical functional tools
future	Clean single-source support for Python 3 and 2
gast	Python AST that abstracts the underlying Python version
gensim	Python framework for fast Vector Space Modelling
gluonts	GluonTS is a Python toolkit for probabilistic time series modeling, built around MXNet
google-auth	Google Authentication Library
google-auth-oauthlib	Google Authentication Library
google-pasta	pasta is an AST-based Python refactoring library
graphviz	Simple Python interface for Graphviz
greenlet	Lightweight in-process concurrent programming
grpcio	HTTP/2-based RPC framework
h5py	Read and write HDF5 files from Python
hijri-converter	Accurate Hijri-Gregorian dates converter based on the Umm al-Qura calendar
holidays	Generate and work with holidays in Python
idna	Internationalized Domain Names in Applications (IDNA)
importlib-metadata	Read metadata from Python packages
InstructorEmbedding	Text embedding tool
interface-meta	Provides a convenient way to expose an extensible API with enforced method signatures and consistent documentation
jaraco.classes	Utility functions for Python class constructs
jaraco.collections	Collection objects similar to those in stdlib by jaraco

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Module Name	Description/Used For
jaraco.context	Context managers by jaraco
jaraco.functools	Functools like those found in stdlib
jaraco.text	Module for text manipulation
Jinja2	A very fast and expressive template engine
joblib	Lightweight pipelining with Python functions
keras	Deep learning for humans
Keras-Preprocessing	Easy data preprocessing and data augmentation for deep learning models
kiwisolver	A fast implementation of the Cassowary constraint solver
korean-lunar-calendar	Korean Lunar Calendar
langcodes	Tools for labeling human languages with IETF language tags
libclang	Clang Python Bindings, mirrored from the official LLVM repo
lifelines	Survival analysis in Python, including Kaplan Meier, Nelson Aalen and regression
lime	Local Interpretable Model-Agnostic Explanations for machine learning classifiers
llvmlite	lightweight wrapper around basic LLVM functionality
lxml	Powerful and Pythonic XML processing library combining libxml2/libxslt with the ElementTree API
Markdown	Python implementation of Markdown
MarkupSafe	Safely add untrusted strings to HTML/XML markup
matplotlib	Python plotting package
more-itertools	More routines for operating on iterables, beyond itertools
murmurhash	Cython bindings for MurmurHash
mxnet	An ultra-scalable deep learning framework
mysqlclient	Python interface to MySQL
netCDF4	Provides an object-oriented python interface to the netCDF version 4 library
nltk	Natural language toolkit
numba	Compiling Python code using LLVM
numexpr	Fast numerical expression evaluator for NumPy
numpy	Scientific computing
oauthlib	A generic, spec-compliant, thorough implementation of the OAuth request-signing logic
opt-einsum	Optimizing numpys einsum function
orjson	Fast, correct Python JSON library supporting dataclasses, datetimes, and numpy
packaging	Core utilities for Python packages
pandas	Data analysis
pathy	pathlib.Path subclasses for local and cloud bucket storage
patsy	Package for describing statistical models and for building design matrices
Pattern	Web mining module for Python
pdfminer.six	PDF parser and analyzer
Pillow	Python Imaging Library
pmdarima	Python's forecast::auto.arima equivalent
portend	TCP port monitoring and discovery
preshed	Cython hash table that trusts the keys are pre-hashed
prophet	Automatic Forecasting Procedure
protobuf	Protocol buffers
psycopg2	PostgreSQL database adapter for Python
pyasn1	ASN.1 types and codecs
pyasn1-modules	pyasn1-modules
pycparser	C parser in Python
pydantic	Data validation and settings management using python type hints
pyLDAvis	Interactive topic model visualization
pymc3	Statistical modeling and probabilistic machine learning
PyMeeus	Python implementation of Jean Meeus astronomical routines
pyparsing	Python parsing
python-dateutil	Extensions to the standard Python datetime module
python-docx	Create and update Microsoft Word .docx files
PyTorch	Tensors and Dynamic neural networks in Python with strong GPU acceleration
pytz	World timezone definitions, modern and historical
PyXB-X	To generate Python code for classes that correspond to data structures defined by XMLSchema
regex	Alternative regular expression module, to replace re
requests	HTTP library
requests-oauthlib	OAuthlib authentication support for Requests
rouge	Full Python ROUGE Score Implementation (not a wrapper)
rsa	OAuthlib authentication support for Requests
sacrebleu	Hassle-free computation of shareable, comparable, and reproducible BLEU, chrF, and TER scores
scikit-learn	Machine learning data mining and analysis
scipy	Scientific computing
semver	Python helper for Semantic Versioning
sentence_transformers	Multilingual Sentence, Paragraph, and Image Embeddings using BERT & Co.
sgmllib3k	Py3k port of sgmllib
shap	A unified approach to explain the output of any machine learning model

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Module Name	Description/Used For
six	Python 2 and 3 compatibility library
sklearn	A set of python modules for machine learning and data mining
smart-open	Utilities for streaming large files (S3, HDFS, gzip, bz2, and so forth)
soupsieve	A modern CSS selector implementation for Beautiful Soup
spacy	Large scale natural language processing
spacy-legacy	Legacy registered functions for spaCy backwards compatibility
spacy-loggers	Logging utilities for SpaCy
spectrum	Spectrum Analysis Tools
SQLAlchemy	Database Abstraction Library
srsly	Modern high-performance serialization utilities for Python
statsmodels	Statistical modeling
tempora	Objects and routines pertaining to date and time
tensorboard	TensorBoard lets you watch Tensors Flow
tensorboard-data-server	Fast data loading for TensorBoard
tensorboard-plugin-wit	What-If Tool TensorBoard plugin
tensorflow	Numerical computation using data flow graphs
tensorflow-estimator	What-If Tool TensorBoard plugin
tensorflow-io-gcs-filesystem	TensorFlow IO
termcolor	simple termcolor wrapper
Theano-PyMC	Theano-PyMC
thinc	Practical Machine Learning for NLP
threadpoolctl	Python helpers to limit the number of threads used in the threadpool-backed of common native libraries used for scientific computing and data science
toolz	List processing tools and functional utilities
tqdm	Fast, extensible progress meter
transformers	State-of-the-art Machine Learning for JAX, PyTorch and TensorFlow
tslearn	A machine learning toolkit dedicated to time-series data
typer	Typer, build great CLIs. Easy to code. Based on Python type hints
typing_extensions	Backported and Experimental Type Hints for Python 3.7+
urllib3	HTTP library with thread-safe connection pooling, file post, and more
wasabi	Lightweight console printing and formatting toolkit
Werkzeug	Comprehensive WSGI web application library
wrapt	Module for decorators, wrappers and monkey patching
xarray	N-D labeled arrays and datasets in Python
xarray-einstats	Stats, linear algebra and einops for xarray
xgboost	Gradient boosting, classifying, ranking
xmltodict	Makes working with XML feel like you are working with JSON
zc.lockfile	Basic inter-process locks
zipp	Backport of pathlib-compatible object wrapper for zip files
tensorflow	Numerical computation using data flow graphs
keras	An implementation of the Keras API that uses TensorFlow as a backend

Installing a Data Science Package for Python

Before you install a Data Science Package for Python, make sure that your WarehousePG is running, you have sourced `greenplum_path.sh`, and that the `$COORDINATOR_DATA_DIRECTORY` and `$GPHOME` environment variables are set.

> **Note** The `PyMC3` module depends on `Tk`. If you want to use `PyMC3`, you must install the `tk` OS package on every node in your cluster. For example:

```
$ sudo yum install tk
```

1. Locate the Data Science Package for Python that you built or downloaded.
2. Copy the package to the WarehousePG coordinator host.
3. Install the package.
4. Restart WarehousePG. You must re-source `greenplum_path.sh` before restarting your WarehousePG cluster:

   ```
   $ source /usr/edb/whpg7/greenplum_path.sh
   $ gpstop -r
   ```

The Data Science Package for Python modules are installed in the following directory:

```
$GPHOME/ext/DataSciencePython/lib/python3.11/site-packages/
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Uninstalling a Data Science Package for Python

The command removes the Data Science Package for Python modules from your WarehousePG cluster. It also updates the `PYTHONPATH`, `PATH`, and `LD_LIBRARY_PATH` environment variables in your `greenplum_path.sh` file to their pre-installation values.

Re-source `greenplum_path.sh` and restart WarehousePG after you remove the Python Data Science Module package:

```
$ . /usr/edb/whpg7/greenplum_path.sh
$ gpstop -r
```

> **Note** After you uninstall a Data Science Package for Python from your WarehousePG cluster, any UDFs that you have created that import Python modules installed with this package will return an error.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

3.8.4 R Data Science Library Package

R packages are modules that contain R functions and data sets. WarehousePG provides a collection of data science-related R libraries that can be used with the WarehousePG PL/R language.

This chapter contains the following information:

- R Data Science Libraries
- Installing the R Data Science Library Package

For information about the WarehousePG PL/R Language, see WarehousePG PL/R Language Extension.

Parent topic: Installing Optional Extensions (WarehousePG)

R Data Science Libraries

Libraries provided in the R Data Science package include:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

abind	gower	quantmod
adabag	gplots	quantreg

Installing the R Data Science Library Package

Before you install the R Data Science Library package, make sure that your WarehousePG is running, you have sourced `greenplum_path.sh`, and that the `COORDINATOR_DATA_DIRECTORY` and `$GPHOME` environment variables are set.

1. Locate the R Data Science library package that you built or downloaded.
2. Copy the package to the WarehousePG coordinator host.
3. Install the package.
4. Restart WarehousePG. You must re-source `greenplum_path.sh` before restarting your WarehousePG cluster:

```
$ source /usr/edb/whpg7/greenplum_path.sh
$ gpstop -r
```

The WarehousePG R Data Science Modules are installed in the following directory:

```
$GPHOME/ext/DataScienceR/library
```

> **Note** When you uninstall the R Data Science Library package from your WarehousePG cluster, any UDFs that you have created that use R libraries installed with this package will return an error.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

3.9 Installing Extensions

The WarehousePG distribution includes several PostgreSQL- and WarehousePG-sourced `contrib` modules that you have the option to install.

Each module is typically packaged as a WarehousePG extension. You must register these modules in each database in which you want to use it. For example, to register the `dblink` module in the database named `testdb`, use the command:

```
$ psql -d testdb -c 'CREATE EXTENSION dblink;'
```

To remove a module from a database, drop the associated extension. For example, to remove the `dblink` module from the `testdb` database:

```
$ psql -d testdb -c 'DROP EXTENSION dblink;'
```

> **Note** When you drop a module extension from a database, any user-defined function that you created in the database that references functions defined in the module will no longer work. If you created any database objects that use data types defined in the module, WarehousePG will notify you of these dependencies when you attempt to drop the module extension.

You can register the following modules in this manner:

• btree_gin • citext • dblink • diskquota • fuzzystrmatch • gp_sparse_vector • hstore • ip4r	• ltree • orafce (WarehousePG only) • pageinspect • pg_trgm • pgcrypto • postgres_fdw • postgresql-hll • sslinfo • tablefunc • timestamp9 • uuid-ossp

For additional information about the modules supplied with WarehousePG, refer toAdditional Supplied Modules in the *WarehousePG Reference Guide*.

Parent topic: Installing and Upgrading WarehousePG

3.10 Configuring Timezone and Localization Settings

Describes the available timezone and localization features of WarehousePG.

Parent topic: Installing and Upgrading WarehousePG

Configuring the Timezone

WarehousePG selects a timezone to use from a set of internally stored PostgreSQL timezones. The available PostgreSQL timezones are taken from the Internet Assigned Numbers Authority (IANA) Time Zone Database, and WarehousePG updates its list of available timezones as necessary when the IANA database changes for PostgreSQL.

WarehousePG selects the timezone by matching a PostgreSQL timezone with the value of the `TimeZone` server configuration parameter, or the host system time zone if `TimeZone` is not set. For example, when selecting a default timezone from the host system time zone, WarehousePG uses an algorithm to select a PostgreSQL timezone based on the host system timezone files. If the system timezone includes leap second information, WarehousePG cannot match the system timezone with a PostgreSQL timezone. In this case, WarehousePG calculates a "best match" with a PostgreSQL timezone based on information from the host system.

As a best practice, configure WarehousePG and the host systems to use a known, supported timezone. This sets the timezone for the WarehousePG coordinator and segment instances, and prevents WarehousePG from selecting a best match timezone each time the cluster is restarted, using the current system timezone and WarehousePG timezone files (which may have been updated from the IANA database since the last restart). Use the `gpconfig` utility to show and set the WarehousePG timezone. For example, these commands show the WarehousePG timezone and set the timezone to `US/Pacific`.

```
# gpconfig -s TimeZone
# gpconfig -c TimeZone -v 'US/Pacific'
```

You must restart WarehousePG after changing the timezone. The command `gpstop -ra` restarts WarehousePG. The catalog view `pg_timezone_names` provides WarehousePG timezone information.

About Locale Support in WarehousePG

WarehousePG supports localization with two approaches:

- Using the locale features of the operating system to provide locale-specific collation order, number formatting, and so on.
- Providing a number of different character sets defined in the WarehousePG server, including multiple-byte character sets, to support storing text in all kinds of languages, and providing character set translation between client and server.

Locale support refers to an application respecting cultural preferences regarding alphabets, sorting, number formatting, etc. WarehousePG uses the standard ISO C and POSIX locale facilities provided by the server operating system. For additional information refer to the documentation of your operating system.

Locale support is automatically initialized when a WarehousePG cluster is initialized. The initialization utility, gpinitsystem, will initialize the WarehousePG cluster with the locale setting of its execution environment by default, so if your system is already set to use the locale that you want in your WarehousePG cluster then there is nothing else you need to do.

When you are ready to initiate WarehousePG and you want to use a different locale (or you are not sure which locale your system is set to), you can instruct `gpinitsystem` exactly which locale to use by specifying the -n locale option. For example:

```
$ gpinitsystem -c gp_init_config -n sv_SE
```

See Initializing WarehousePG for information about the database initialization process.

The example above sets the locale to Swedish (sv) as spoken in Sweden (SE). Other possibilities might be `en_US` (U.S. English) and `fr_CA` (French Canadian). If more than one character set can be useful for a locale then the specifications look like this: `cs_CZ.ISO8859-2`. What locales are available under what names on your system depends on what was provided by the operating system vendor and what was installed. On most systems, the command `locale -a` will provide a list of available locales.

Occasionally it is useful to mix rules from several locales, for example use English collation rules but Spanish messages. To support that, a set of locale subcategories exist that control only a certain aspect of the localization rules:

- `LC_COLLATE` — String sort order
- `LC_CTYPE` — Character classification (What is a letter? Its upper-case equivalent?)
- `LC_MESSAGES` — Language of messages
- `LC_MONETARY` — Formatting of currency amounts
- `LC_NUMERIC` — Formatting of numbers
- `LC_TIME` — Formatting of dates and times

If you want the system to behave as if it had no locale support, use the special locale `C` or `POSIX`.

The nature of some locale categories is that their value has to be fixed for the lifetime of a WarehousePG cluster. That is, once `gpinitsystem` has run, you cannot change them anymore. `LC_COLLATE` and `LC_CTYPE` are those categories. They affect the sort order of indexes, so they must be kept fixed, or indexes on text columns will become corrupt. WarehousePG enforces this by recording the values of `LC_COLLATE` and `LC_CTYPE` that are seen by gpinitsystem. The server automatically adopts those two values based on the locale that was chosen at initialization time.

The other locale categories can be changed as desired whenever the server is running by setting the server configuration parameters that have the same name as the locale categories (see the*WarehousePG Reference Guide* for more information on setting server configuration parameters). The defaults that are chosen by gpinitsystem are written into the coordinator and segment `postgresql.conf` configuration files to serve as defaults when the WarehousePG cluster is started. If you delete these assignments from the coordinator and each segment `postgresql.conf` files then the server will inherit the settings from its execution environment.

Note that the locale behavior of the server is determined by the environment variables seen by the server, not by the environment of any client. Therefore, be careful to configure the correct locale settings on each WarehousePG host (coordinator and segments) before starting the system. A consequence of this is that if client and server are set up in different locales, messages may appear in different languages depending on where they originated.

Inheriting the locale from the execution environment means the following on most operating systems: For a given locale category, say the collation, the following environment variables are consulted in this order until one is found to be set: `LC_ALL`, `LC_COLLATE` (the variable corresponding to the respective category), `LANG`. If none of these environment variables are set then the locale defaults to `C`.

Some message localization libraries also look at the environment variable `LANGUAGE` which overrides all other locale settings for the purpose of setting the language of messages. If in doubt, please refer to the documentation for your operating system, in particular the documentation about `gettext`, for more information.

Native language support (NLS), which enables messages to be translated to the user's preferred language, is not enabled in WarehousePG for languages other than English. This is independent of the other locale support.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Locale Behavior

The locale settings influence the following SQL features:

- Sort order in queries using `ORDER BY` on textual data
- The ability to use indexes with `LIKE` clauses
- The `upper`, `lower`, and `initcap` functions
- The `to_char` family of functions

The drawback of using locales other than `C` or `POSIX` in WarehousePG is its performance impact. It slows character handling and prevents ordinary indexes from being used by `LIKE`. For this reason use locales only if you actually need them.

Troubleshooting Locales

If locale support does not work as expected, check that the locale support in your operating system is correctly configured. To check what locales are installed on your system, you may use the command `locale -a` if your operating system provides it.

Check that WarehousePG is actually using the locale that you think it is. `LC_COLLATE` and `LC_CTYPE` settings are determined at initialization time and cannot be changed without redoing gpinitsystem. Other locale settings including `LC_MESSAGES` and `LC_MONETARY` are initially determined by the operating system environment of the coordinator and/or segment host, but can be changed after initialization by editing the `postgresql.conf` file of each WarehousePG coordinator and segment instance. You can check the active locale settings of the coordinator host using the `SHOW` command. Note that every host in your WarehousePG cluster should be using identical locale settings.

Character Set Support

The character set support in WarehousePG allows you to store text in a variety of character sets, including single-byte character sets such as the ISO 8859 series and multiple-byte character sets such as EUC (Extended Unix Code), UTF-8, and Mule internal code. All supported character sets can be used transparently by clients, but a few are not supported for use within the server (that is, as a server-side encoding). The default character set is selected while initializing your WarehousePG cluster using `gpinitsystem`. It can be overridden when you create a database, so you can have multiple databases each with a different character set.

Name	Description	Language	Server?	Bytes/Char	Aliases
BIG5	Big Five	Traditional Chinese	No	1-2	WIN950, Windows950
EUC_CN	Extended UNIX Code-CN	Simplified Chinese	Yes	1-3	
EUC_JP	Extended UNIX Code-JP	Japanese	Yes	1-3	
EUC_KR	Extended UNIX Code-KR	Korean	Yes	1-3	
EUC_TW	Extended UNIX Code-TW	Traditional Chinese, Taiwanese	Yes	1-3	
GB18030	National Standard	Chinese	No	1-2	
GBK	Extended National Standard	Simplified Chinese	No	1-2	WIN936, Windows936
ISO_8859_5	ISO 8859-5, ECMA 113	Latin/Cyrillic	Yes	1	
ISO_8859_6	ISO 8859-6, ECMA 114	Latin/Arabic	Yes	1	
ISO_8859_7	ISO 8859-7, ECMA 118	Latin/Greek	Yes	1	
ISO_8859_8	ISO 8859-8, ECMA 121	Latin/Hebrew	Yes	1	
JOHAB	JOHA	Korean (Hangul)	Yes	1-3	
KOI8	KOI8-R(U)	Cyrillic	Yes	1	KOI8R
LATIN1	ISO 8859-1, ECMA 94	Western European	Yes	1	ISO88591
LATIN2	ISO 8859-2, ECMA 94	Central European	Yes	1	ISO88592
LATIN3	ISO 8859-3, ECMA 94	South European	Yes	1	ISO88593
LATIN4	ISO 8859-4, ECMA 94	North European	Yes	1	ISO88594
LATIN5	ISO 8859-9, ECMA 128	Turkish	Yes	1	ISO88599

Setting the Character Set

gpinitsystem defines the default character set for a WarehousePG cluster by reading the setting of the `ENCODING` parameter in the `gp_init_config` file at initialization time. The default character set is `UNICODE` or `UTF8`.

You can create a database with a different character set besides what is used as the system-wide default. For example:

```
=> CREATE DATABASE korean WITH ENCODING 'EUC_KR';
```

> **Important** Although you can specify any encoding you want for a database, it is unwise to choose an encoding that is not what is expected by the locale you have selected. The `LC_COLLATE` and `LC_CTYPE` settings imply a particular encoding, and locale-dependent operations (such as sorting) are likely to misinterpret data that is in an incompatible encoding.

Since these locale settings are frozen by gpinitsystem, the apparent flexibility to use different encodings in different databases is more theoretical than real.

One way to use multiple encodings safely is to set the locale to `C` or `POSIX` during initialization time, thus deactivating any real locale awareness.

Character Set Conversion Between Server and Client

WarehousePG supports automatic character set conversion between server and client for certain character set combinations. The conversion information is stored in the coordinator `pg_conversion` system catalog table. WarehousePG comes with some predefined conversions or you can create a new conversion using the SQL command `CREATE CONVERSION`.

Server Character Set	Available Client Character Sets
BIG5	not supported as a server encoding
EUC_CN	EUC_CN, MULE_INTERNAL, UTF8
EUC_JP	EUC_JP, MULE_INTERNAL, SJIS, UTF8
EUC_KR	EUC_KR, MULE_INTERNAL, UTF8
EUC_TW	EUC_TW, BIG5, MULE_INTERNAL, UTF8
GB18030	not supported as a server encoding
GBK	not supported as a server encoding
ISO_8859_5	ISO_8859_5, KOI8, MULE_INTERNAL, UTF8, WIN866, WIN1251
ISO_8859_6	ISO_8859_6, UTF8
ISO_8859_7	ISO_8859_7, UTF8
ISO_8859_8	ISO_8859_8, UTF8
JOHAB	JOHAB, UTF8
KOI8	KOI8, ISO_8859_5, MULE_INTERNAL, UTF8, WIN866, WIN1251
LATIN1	LATIN1, MULE_INTERNAL, UTF8
LATIN2	LATIN2, MULE_INTERNAL, UTF8, WIN1250
LATIN3	LATIN3, MULE_INTERNAL, UTF8
LATIN4	LATIN4, MULE_INTERNAL, UTF8
LATIN5	LATIN5, UTF8
LATIN6	LATIN6, UTF8
LATIN7	LATIN7, UTF8
LATIN8	LATIN8, UTF8
LATIN9	LATIN9, UTF8
LATIN10	LATIN10, UTF8
MULE_INTERNAL	MULE_INTERNAL, BIG5, EUC_CN, EUC_JP, EUC_KR, EUC_TW, ISO_8859_5, KOI8, LATIN1 to LATIN4, SJIS, WIN866, WIN1250, WIN1251
SJIS	not supported as a server encoding
SQL_ASCII	not supported as a server encoding
UHC	not supported as a server encoding
UTF8	all supported encodings
WIN866	WIN866
ISO_8859_5	KOI8, MULE_INTERNAL, UTF8, WIN1251
WIN874	WIN874, UTF8
WIN1250	WIN1250, LATIN2, MULE_INTERNAL, UTF8
WIN1251	WIN1251, ISO_8859_5, KOI8, MULE_INTERNAL, UTF8, WIN866
WIN1252	WIN1252, UTF8
WIN1253	WIN1253, UTF8
WIN1254	WIN1254, UTF8
WIN1255	WIN1255, UTF8
WIN1256	WIN1256, UTF8
WIN1257	WIN1257, UTF8
WIN1258	WIN1258, UTF8

To enable automatic character set conversion, you have to tell WarehousePG the character set (encoding) you would like to use in the client. There are several ways to accomplish this:

- Using the `\encoding` command in `psql`, which allows you to change client encoding on the fly.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

- Using `SET client_encoding TO`. Setting the client encoding can be done with this SQL command:

  ```
  => SET CLIENT_ENCODING TO '<value>';
  ```

  To query the current client encoding:

  ```
  => SHOW client_encoding;
  ```

  To return to the default encoding:

  ```
  => RESET client_encoding;
  ```

- Using the `PGCLIENTENCODING` environment variable. When `PGCLIENTENCODING` is defined in the client's environment, that client encoding is automatically selected when a connection to the server is made. (This can subsequently be overridden using any of the other methods mentioned above.)

- Setting the configuration parameter `client_encoding`. If `client_encoding` is set in the coordinator `postgresql.conf` file, that client encoding is automatically selected when a connection to WarehousePG is made. (This can subsequently be overridden using any of the other methods mentioned above.)

If the conversion of a particular character is not possible — suppose you chose `EUC_JP` for the server and `LATIN1` for the client, then some Japanese characters do not have a representation in `LATIN1` — then an error is reported.

If the client character set is defined as `SQL_ASCII`, encoding conversion is deactivated, regardless of the server's character set. The use of `SQL_ASCII` is unwise unless you are working with all-ASCII data. `SQL_ASCII` is not supported as a server encoding.

[^1]: Not all APIs support all the listed character sets. For example, the JDBC driver does not support MULE_INTERNAL, LATIN6, LATIN8, and LATIN10.

[^2]: The SQL_ASCII setting behaves considerably differently from the other settings. Byte values 0-127 are interpreted according to the ASCII standard, while byte values 128-255 are taken as uninterpreted characters. If you are working with any non-ASCII data, it is unwise to use the SQL_ASCII setting as a client encoding. SQL_ASCII is not supported as a server encoding.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

3.11 Important Changes Between WHPG 6 and WHPG 7

There are a substantial number of changes between WarehousePG 6 and WarehousePG 7 that could potentially affect your existing 6 application when you move to 7. This topic provides information about these changes.

Naming Changes

The following table summarizes naming changes in WarehousePG 7:

Old Name	New Name
master	coordinator
pg_log	log
pg_xlog	pg_wal
pg_clog	pg_xact
xlog (includes SQL functions, tools and options)	wal
pg_xlogdump	pg_waldump
pg_resetxlog	pg_resetwal

Deprecated Features

The following features have been deprecated in WarehousePG 7:

- The `gpreload` utility. Instead, use `ALTER TABLE...REPACK BY`.

Changes in Feature Behavior

The following feature behaviors have changed in WarehousePG 7:

- The `checkpoint_segments` parameter in the `postgresql.conf` file has been removed. Use the server configuration parameters `min_wal_size` and `max_wal_size`, instead.
- Autovacuum is now enabled by default for all databases.
- Pattern matching behavior of the `substring()` function has changed. In cases where the pattern can be matched in more than one way, the initial subpattern is now treated as matching the least possible amount of text rather than the greatest; for example, a pattern such as `%#"aa*#"%` now selects the first group of `a`'s from the input, rather than the last group.
- Multi-dimensional arrays can now be passed into PL/Python functions, and returned as nested Python lists - Previously, you could return an array of composite values by writing, for exmaple, `[[col1, col2], [col1, col2]]`. Now, this is interpreted as a two-dimensional array. Composite types in arrays must now be written as Python tuples, not lists, to resolve the ambiguity; that is, you must write `[(col1, col2), (col1, col2)]`, instead.
- When `x` is a table name or composite column, PostgreSQL has traditionally considered the syntactic forms `f(x)` and `x.f` to be equivalent, allowing tricks such as writing a function and then using it as though it were a computed-on-demand column. However, if both interpretations are feasible, the column interpretation was always chosen. Now, if there is ambiguity, the interpretation that matches the syntactic form is chosen.
- WarehousePG 7 now prevents the `to_number()` function from consuming characters when the template separator does not match. For example, `SELECT to_number('1234', '9,999')` used to return `134`. It will now return `1234`, instead. L and TH now only consume characters that are not digits, positive/negative signs, decimal points, or commas.
- The `fix to_date()`, `to_number()`, and `to_timestamp()` functions previously skipped one byte for each byte of template character, resulting in strange behavior if either string contained multibyte characters. Adjust the handling of backslashes inside double-quotes in template strings for to_char(), to_number(), and to_timestamp(). Such a backslash now escapes the character after it, particularly a double-quote or another backslash.

Other Important Changes in WarehousePG 7

WarehousePG 7 also:

- Removes some features and objects that were in Greeplum 6. See Features and Objects Removed in WarehousePG 7.
- Changes some server configuration parameters. See Server Configuration Parameter Changes from WarehousePG 6 to WarehousePG 7.
- Changes the partitioning system catalogs. See Changes in Partitioning and Migrating Partition Maintenance Scripts to the New WarehousePG 7 Partitioning Catalogs.
- Makes changes to external tables. See Changes to External Tables.
- Makes changes to resource groups. See Changes to Resource Groups.
- Makes changes to system views and system tables. See System Catalog Changes between WarehousePG 6 and WarehousePG 7.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

3.12 Performing a minor upgrade

Perform a minor version upgrade. Because minor versions are binary-compatible, this process replaces the software binaries without requiring a full data migration.

An upgrade involves stopping the WHPG cluster, updating the software binaries across all nodes, and restarting the services.

> **Note**
>
> Starting from WarehousePG 7.4, the installation directory has been consolidated to `/usr/edb/whpg7`. For backward compatibility, the system automatically maintains a symbolic link at `/usr/local/greenplum-db` and `/usr/local/greenplum-db-clients`.

In this guide:

- `7.origin` refers to your current version.
- `7.target` refers to the version you are upgrading to.

Process overview

The following high-level steps summarize the upgrade lifecycle:

1. Prepare for maintenance: Isolate the cluster and secure a full backup.
2. Clear automation: Disable scheduled tasks and coordinate infrastructure snapshots.
3. Validate baseline: Verify current software versions and run smoke tests.
4. Quiesce the database: Stop peripheral services and the WHPG cluster.
5. Replace binaries: Install the new software package across all cluster nodes.
6. Restore services: Restart the cluster and verify health.
7. Re-establish connectivity: Restore automation, connection pooling, and federation.
8. Hand back: Resume normal business operations and monitoring.

Preparing for maintenance

These steps isolate the cluster from external traffic and automated scripts before the system handover.

1. Stop all monitoring applications: Shut down all monitoring agents to prevent false alerts during the maintenance window.

2. Stop scheduled tasks: Disable external schedulers that trigger jobs against the database.

3. Stop applications: Notify users and shut down application servers, web services, and BI tools. Ensure no new connections are being initiated.

4. Perform a backup of all databases: Execute a full backup. This is your final safety point before modifying the environment.

   ```
   gpbackup --leaf-partition-data
   ```

Clearing automation and system handover

Once data is secure and traffic has ceased, prepare the operating system environment.

1. Hand over the for infrastructure maintenance: Coordinate with your Infrastructure or Platform team to perform any required pre-upgrade safety measures. This may include creating environment snapshots, initiating virtual machine checkpoints, or performing hardware-level health checks to ensure the underlying platform is stable.

2. Save and remove crontab entries: Perform these steps as the `root` user on coordinator and standby nodes to prevent maintenance scripts from firing during the binary swap.

   1. Back up your `gpadmin` tasks from both the coordinator and standby nodes:

      ```
      crontab -l -u gpadmin > /home/gpadmin/crontab_backup_$(date +%F)
      ```

   2. Check for other user crontabs:

      ```
      crontab -u <username> -
      l
      for user in $(cut -f1 -d: /etc/passwd); do echo $user; crontab -u $user -l; done >crontab_all
      2>crontab_all_no_cron
      ```

   3. Remove current entries:

      ```
      crontab -r
      ```

   4. Verify the list is empty (should return `no crontab for gpadmin`):

      ```
      crontab -l
      ```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Establishing a pre-upgrade baseline

Before beginning the update, capture the current state of your environment. This baseline serves as a reference point to ensure that all software versions, configurations, and connectivity are restored correctly once the update is complete.

1. Inventory installed packages: Document the exact versions of the WHPG packages currently running on the coordinator and segments.
    - For RHEL 8, RHEL 9: `sudo rpm -qa | grep whpg`
    - For RHEL 7: `sudo yum list installed | grep whpg`
2. Record component versions: Document the versions of any additionally installed components, such as PXF, or PgBouncer. For example:
    - Check PXF version: `pxf --version`
    - Check pgBouncer version: Connect to the admin console with `psql -p 6543 -U pgbouncer -d pgbouncer` and run `SHOW VERSION;`.
3. Perform a PXF smoke test: Ensure pre-upgrade connectivity is functional to confirm any connectivity issues found after the upgrade were not pre-existing. For example:

```
psql -x demo -c 'SELECT * FROM public.jsonb_events LIMIT
2;'
```

Quiescing the database

Perform a final cleanup of the running database instance.

1. Stop exernal services: Shut down the PXF service on all nodes and stop the PgBouncer connection pooler.
    - Stop PXF: `pxf cluster stop`
    - Stop pgBouncer: Connect to the admin console with `psql -p 6543 -U pgbouncer -d pgbouncer` and run `SHUTDOWN;`.
2. Terminate sessions and check queries: Ensure no active user queries remain. Forcefully terminate any remaining client backends.

```
# View active
queries
psql -d postgres -c "SELECT * FROM pg_stat_activity where backend_type = 'client backend' and state <>
'idle';"
# Terminate a specific
PID
psql -d postgres -c 'SELECT
pg_cancel_backend(<procpid>);'
```

3. Verify segment health: Run `gpstate -m`. All segments must be in `Synchronized` status. If not, run `gprecoverseg -a` and wait for completion.
4. Stop the WHPG cluster:

```
gpstop -a -M fast
```

Replacing binaries and restarting WHPG

Perform the following steps as the `gpadmin` user. When upgrading, the package manager will automatically remove old files in `/usr/local/greenplum-db-<version>` and install new files to `/usr/edb/whpg7`.

> **Upgrading to 7.5.0: Python 3.11 requirement**
>
> WarehousePG 7.5.0 upgrades PL/Python to Python 3.11. The PL/Python interpreter now links against `/usr/bin/python3.11` and requires the following packages on every node:
>
> - `python3.11`
> - `python3.11-psycopg2`
> - `python3.11-pyyaml`
>
> On internet-connected clusters, the package manager installs these dependencies automatically. On air-gapped clusters, install them manually on all nodes before upgrading:
>
> ```
> sudo rpm -ivh python3.11-<version>.rpm python3.11-psycopg2-<version>.rpm python3.11-
> pyyaml-<version>.rpm
> ```
>
> Verify the packages are available in your local repository before starting the upgrade. Without Python 3.11, the upgrade will fail.

1. On the coordinator, back up old WHPG binaries:

```
sudo cp -R /usr/local/greenplum-db-7.origin-WHPG /usr/local/greenplum-db-7.origin-
WHPG_save
sudo chown -R gpadmin /usr/local/greenplum-db-7.origin-
WHPG_save
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

2. Download your `7.target` package. See Downloading the WarehousePG Server Software for details on how to download the packages. From your jump host, copy the new package to the coordinator:

```
scp <warehouse-pg-7.target.rpm>
gpadmin@coordinator_host:/tmp
scp <warehouse-pg-7.target-clients.rpm>
gpadmin@coordinator_host:/tmp
```

   Where `<warehouse-pg-7.target.rpm>` is the package of the WarehousePG version to install.

3. On the coordinator, create a file `hostfile_without_coord` that lists all hosts in the cluster except the coordinator. For example:

```
scdw
sdw1
sdw2
sdw3
```

4. From the coordinator, create a directory for the binaries on all hosts and transfer the new package:

```
gpssh -f hostfile_without_coord -e "mkdir -p
/tmp/binary"
gpsync -f hostfile_without_coord <warehouse-pg-7.target.rpm> =:/tmp/binary
```

5. Install WHPG `7.target` on the coordinator:

   > **Important**
   >
   > Starting with WarehousePG 7.4, the `warehouse-pg-7-clients` package is mandatory and must be installed alongside the server package.

   - For RHEL 8, RHEL 9:

     ```
     sudo rpm -U <warehouse-pg-7.target.rpm> -
     v
     sudo chown -R gpadmin.
     /usr/edb/whpg7
     ```

   - For RHEL 7:

     ```
     sudo yum install -y <warehouse-pg-
     7.target.rpm>
     sudo chown -R gpadmin.
     /usr/edb/whpg7
     ```

6. Install WHPG `7.target` on segments: From the coordinator, run:

   - For RHEL 8, RHEL 9:

     ```
     source
     /home/gpadmin/.bashrc
     gpssh -f hostfile_without_coord -e "sudo rpm -U <warehouse-pg-7.target.rpm> -v"
     gpssh -f hostfile_without_coord -e "sudo chown -R gpadmin:gpadmin
     /usr/edb/whpg7"
     ```

   - For RHEL 7:

     ```
     source
     /home/gpadmin/.bashrc
     gpssh -f hostfile_without_coord -e "sudo yum install -y <warehouse-pg-7.target.rpm>"
     gpssh -f hostfile_without_coord -e "sudo chown -R gpadmin:gpadmin /usr/edb/whpg7"
     ```

7. Verify symbolic links: Ensure `/usr/local/greenplum-db` and `/usr/local/greenplum-db-clients` point to `/usr/edb/whpg7` across the cluster and that `gpadmin` is the owner of the installation directories:

```
ll /usr/local/'| grep 'greenplum-db ->' |
sort
gpssh -f hostfile_without_coord  -e "ll /usr/local/'| grep 'greenplum-db ->' |
sort"
```

Restoring services and finalizing the upgrade

Start the WHPG cluster on the target version. After the cluster is back online, restart the extension services and restore the operational environment.

1. Update environment: Ensure `/home/gpadmin/.bashrc` on coordinator and standby points to the new path, then reload:

```
source
/home/gpadmin/.bashrc
```

2. Start WHPG:

```
gpstart -a
```

3. Perform system health check: Run `gpstate -f` and `gpstate -m` to ensure all segments are up and mirrors are synchronized.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4. Verify the installed version:

```
psql -d postgres -c "select
version();"
psql -d postgres -c "select distinct  version() from
gp_dist_random('gp_id');"
```

Restoring automation and connectivity

Once the core database services are back online, re-establish the secondary layers to return the cluster to a full operational state.

1. Restore crontabs: Reload the saved files for `gpadmin` on coordinator and standby hosts. For example:

```
crontab -u gpadmin /home/gpadmin/crontab_backup_YYYY-MM-
DD
```

2. Start PXF and re-run the smoke test query:

```
pxf cluster start
psql -x demo -c 'SELECT * FROM public.jsonb_events LIMIT
2;'
```

3. Start PgBouncer: Restart the connection pooler and verify client connections.

```
pgbouncer -d /data/gpdata/pgbouncer/pgbouncer.ini
psql -p 6543 -U pgbouncer -d pgbouncer -c "SHOW CLIENTS;"
```

Handing back the system

With the upgrade verified and the infrastructure services restored, the final phase involves transitioning the environment back to the end-users and resuming normal business operations.

1. Applications: Re-enable application traffic and BI tools.
2. Schedules: Re-enable external schedulers.
3. Monitoring: Resume all monitoring agents.
4. Handover: Formally notify the Infrastructure or Platform teams that the cluster is stable on version `7.target`.

3.13 Upgrading from WarehousePG 6 to WarehousePG 7

This topic walks you through upgrading from WarehousePG 6 to WarehousePG 7.

> **WARNING** There are a substantial number of changes between WarehousePG 6 and WarehousePG 7 that could potentially affect your existing application when you move to WarehousePG 7. Before going any further, familiarize yourself with all of these changes Important Changes between WHPG 6 and WHPG 7 .

> **Note** You cannot upgrade to WarehousePG 7.0.0 using the `gpupgrade` utility.

Preparing to Upgrade

To prepare for upgrading from WarehousePG 6 to WarehousePG 7:

- Read carefully through Important Changes between WHPG 6 and WHPG 7 to identify changes you may need to make in your application before upgrading to WarehousePG 7.
- Before using `gpbackup` / `gprestore` to move your data, read carefully through Backup and Restore Caveats to avert problems that can arise.

Steps to Upgrade

Follow the steps in this section to upgrade from WarehousePG 6 to WarehousePG 7.

When upgrading, the `gpbackup/gprestore` utilities are the recomended tools for data loading.

Steps to Upgrade Using Backup/Restore

Review Backup and Restore Caveats before starting the upgrade.

To upgrade while moving data using `gpbackup/gprestore` :

1. If not already installed, install the latest release of the WarehousePG Backup and Restore utilities
2. Run the `gpbackup` utility to back up the data from your WarehousePG 6 cluster to an external data storage location, such as mounted directories, cloud storage, or Data Domain.
3. Initalize a WarehousePG 7 cluster on the destination hardware, by issuing the `gpinitsystem` command.
4. Install any external modules used in your WarehousePG 6 system in the WarehousePG 7 system before you restore the backup, for example MADlib or PostGIS. If versions of the external modules are not compatible, you may need to exclude tables that reference them when restoring the WarehousePG 6 backup to WarehousePG 7.
5. Run the `gprestore` utility to restore your data to the WarehousePG 7 cluster from the external data storage location.

Completing the Upgrade

Migrate any tables you skipped during the restore using other methods, for example using the `COPY TO` command to create an external file and then loading the data from the external file into WarehousePG 6 with the `COPY FROM` command.

Recreate any objects you dropped in the WarehousePG 6 database to enable migration, such as external tables, indexes, user-defined functions, or user-defined aggregates.

After migrating data you may need to modify SQL scripts, administration scripts, and user-defined functions as necessary to account for changes in WarehousePG version 7. Review the WarehousePG Release Notes and Important Changes between WHPG 6 and WHPG 7 for features and changes that may necessitate post-migration tasks.

Backup and Restore Caveats

There are a number of caveats with respect to backing up and restoring your data as part of upgrading from WarehousePG 6 to WarehousePG 7.

- Before you do an actual backup, use `gpbackup` to create a `--metadata-only` backup from the source WarehousePG and restore it to the WarehousePG 7 system. Review the `gprestore` log file for error messages and correct any remaining problems in the source WarehousePG.
- If you intend to install WarehousePG 7 on the same hardware as your 6 system, you will need enough disk space to accommodate over five times the original data set (two full copies of the primary and mirror data sets, plus the original backup data in ASCII format) in order to migrate data with `gpbackup` and `gprestore` . Keep in mind that the ASCII backup data will require more disk space than the original data, which may be stored in compressed binary format. Offline backup solutions such as Dell PowerProtect (Data Domain) can reduce the required disk space on each host.

  If you do not have the disk space, then:

  - Run `gpbackup` on your WarehousePG 6 cluster to back up your data
  - Run `gpdeletesystem` to remove the existing WarehousePG 6 cluster
  - Proceed with initializing the new cluster, as described above
- When restoring language-based user-defined functions, the shared object file must be in the location specified in the `CREATE FUNCTION` SQL command and must have been recompiled on the WarehousePG 7 system. This applies to user-defined functions, user-defined types, and any other objects that use custom functions, such as aggregates created with the `CREATE AGGREGATE` command.
- `gpbackup` saves the distribution policy and distribution key for each table in the backup so that data can be restored to the same segment. If a table's distribution key in the WarehousePG 6 database is incompatible with WarehousePG 7, `gprestore` cannot restore the table to the correct segment in the WarehousePG 6 database. This can happen if the distribution key in the older WarehousePG release has columns with data types not allowed in WarehousePG 7 distribution keys, or if the data representation for data types has changed or is insufficient for WarehousePG 7 to generate the same hash value for a distribution key. You should correct these kinds of problems by altering distribution keys in the tables before you back up the WarehousePG.

3.14 >-

This topic provides guidance on migrating partition maintenance scripts that you may have written for WarehousePG 6 to use the new partitioning system catalogs in WarehousePG 7.

About the WarehousePG 6 and 7 Partitioning Catalogs

The following partitioning-related catalog tables, views, and functions available in WarehousePG 6 are removed in WarehousePG 7:

- `pg_partition`
- `pg_partition_columns`
- `pg_partition_encoding`
- `pg_partition_rule`
- `pg_partition_templates`
- `pg_partitions`
- `pg_stat_partition_operations`
- `pg_partition_def()`

WarehousePG 7 adds the following new catalog table and functions:

- gp_partition_template
- pg_partitioned_table
- pg_partition_tree()
- pg_partition_ancestors()
- pg_partition_root()

Why are Migration Tasks Required?

Because partitioning-related system catalog, view, and function definitions have changed in WarehousePG 7, you must update any partition maintenance scripts that you have been using in WarehousePG 6.

The following sections identify, for each WarehousePG 6 partitioning catalog column, how to obtain similar information in WarehousePG 7. These mappings should help ease your partition maintenance migration effort.

In some cases, there is an equivalent field in, or query of, a WarehousePG 7 system catalog or view. In other cases, there may be no direct mapping because WarehousePG 7 no longer stores the information in the catalog.

pg_partitions

The WarehousePG 6 `pg_partitions` view displays all leaf partitions in the current database.

Column Name	WarehousePG 6 Description	WarehousePG 7 Equivalent
schemaname	The name of the schema in which the root partitioned table resides.	Use `pg_partition_root()` to obtain the root object identifier, and then query pg_namespace.
tablename	The name of the root partitioned table.	Use `pg_partition_root()` to obtain the root object identifier, and then query pg_class.
partitionschemaname	The namespace of the leaf partition.	pg_namespace
partitiontablename	The table name of the leaf partition (the table name you use to access the partition directly).	pg_class
partitionname	The partition name of the leaf partition (the name you use to refer to the partition in an `ALTER TABLE` command).	N/A
parentpartitiontablename	The table name of the parent table of this partition.	Get the parent object identifier via pg_inherits and then query pg_class.
parentpartitionname	The partition name of the parent table of this partition.	N/A
partitiontype	The type of partition (range or list).	Get the parent object identifier via pg_inherits and then query pg_partitioned_table.
partitionlevel	The level of this partition in the partition hierarchy.	Get the level from `pg_partition_tree()` using the root object identifier. Note that the level differs in WarehousePG 6 and 7. In WarehousePG 6, the level of the immediate child of a partitioned table is 0. In WarehousePG 7, the level of the partitioned table itself is 0, and the level of its immediate child is 1.
partitionrank	For range partitions, the rank of the partition compared to other partitions at the same level.	N/A
partitionposition	The rule order position of this partition.	N/A
partitionlistvalues	For list partitions, the list value(s) associated with this partition.	Get the partition boundary via `pg_get_expr()` and then filter the text.
partitionrangestart	For range partitions, the start value of this partition.	Get the partition boundary via `pg_get_expr()` and then filter the text.
partitionstartinclusive	Whether or not the start value is included in this partition. `true` if the start value is included.	always inclusive
partitionrangeend	For range partitions, the end value of this partition.	Get the partition boundary via `pg_get_expr()` and then filter the text.
partitionendinclusive	Whether or not the end value is included in this partition. `true` if the end value is included.	always exclusive
partitioneveryclause	The `EVERY` clause (interval) of this partition.	N/A
partitionisdefault	Whether or not this is a default partition. `true` if this is the default, otherwise `false`.	Get the partition boundary via `pg_get_expr()` and check if it is `DEFAULT`. Alternatively, use `pg_partitioned_table.partdefid`.
partitionboundary	The entire partition specification for this partition.	`pg_get_expr()`, but note that it is returned in modern syntax.
parenttablespace	The tablespace of the parent table of this partition.	Get the parent object identifier via pg_inherits and then query pg_tablespace.
partitiontablespace	The tablespace of this partition.	pg_tablespace

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Examples Retrieving Similar Information in WarehousePG 7

Some of the information is quite trivial to retrieve in WarehousePG 7, while other information is not. The following sections provide examples for specific WarehousePG 6 system catalog columns.

partitionname / parentpartitionname

The `partitionname` and `parentpartitionname` columns provide the WarehousePG 6 "partition name" in constrast to the actual table name. Because WarehousePG 7 no longer stores the partition name in the catalog (previously in `pg_partition_rule`), it cannot retrieve that information now. Use the table names directly to refer to the partitions. However, if you really need the partition name, you can achieve that via some text massaging:

```
SELECT
    c.relname AS table_name,
    split_part(substr(c.relname, position(inh.inhparent::regclass::text in c.relname) + length(inh.inhparent::regclass::text)), '_', 4) AS partition_name
FROM
    pg_class c
LEFT JOIN
    pg_inherits inh ON inh.inhrelid = c.oid
WHERE
    c.relname LIKE concat(inh.inhparent::regclass::text, '%')
    AND c.relname LIKE '<your_partition_name>';
```

This query is valid only if the table name is implicitly generated by WarehousePG from the partition name and is in the form of `<parent_tablename>_prt_<level>_<partition_name>`. This query will not work for a partitioned table created with modern syntax (where you always specify the table name when adding a partition) or for a partitioned table created with classic syntax where you explicitly specify the table name in a `WITH` clause for the partition.

partitionposition / partitionrank

The `partitionposition` and `partitionrank` columns in the WarehousePG 6 `pg_partitions` view are based on the "order" number for each partition in the `pg_partition_rule` catalog, but that catalog is removed in WarehousePG 7. However, if you are simply interested in retrieving the sorted order for range partitions, you can order the range value. For example, if the WarehousePG 6 query below provides the highest rank partition:

```
SELECT
    CASE
        WHEN partitionstartinclusive THEN partitionrangestart
        ELSE partitionrangeend
    END AS old_part_value
FROM
    pg_catalog.pg_partitions p
WHERE
    p.schemaname = '" + cfg.schema + "'
    AND p.tablename = '" + cfg.table + "'
    AND p.partitiontype = 'range'
    AND p.partitionlevel = " + str(cfg.partition_level) + "
    AND " + chk + "
ORDER BY
    partitionrank
LIMIT 1;
```

A similar query in WarehousePG 7 follows:

```
SELECT
   rank() OVER (
       PARTITION BY pc.oid
       ORDER BY CAST(
           (regexp_matches(pg_get_expr(c.relpartbound, c.oid), 'FOR VALUES FROM \(([0-9]+)\) TO \(([0-9]+)\)'))[1]
           AS INTEGER
       )
   ) AS rank,
    (regexp_matches(pg_get_expr(c.relpartbound, c.oid), 'FOR VALUES FROM \(([0-9]+)\) TO \(([0-9]+)\)'))[1] AS old_part_value
FROM
    pg_class c
LEFT JOIN
    pg_inherits inh ON inh.inhrelid = c.oid
LEFT JOIN
    pg_partitioned_table pt ON inh.inhparent = pt.partrelid
LEFT JOIN
    pg_class pc ON pc.oid = pt.partrelid
WHERE
    c.relispartition = 't' AND pc.relname LIKE ('<partition_root_schema>.<partition_root_name>')
ORDER BY
    rank
LIMIT 1;
```

Assuming that the partitioning method for the partitioned table is `RANGE`, the above query calculates the ranks for each child partition, and prints the range `START` value (which is always inclusive) with the highest rank.

You cannot retrieve the order number for list partitions with this query, however, because the order is based on the time the partition is added, and WarehousePG 7 does not store that information. A query for list partitions must not be dependent on order information.

partitioneveryclause

Because WarehousePG 7 does not store the use of the `EVERY` clause in the catalog, it can not discern if a partition was created with the clause. The main use of this column is to reconstruct a partition definition clause using the classic-syntax for display or `pg_dump` purposes. No mapping is provided at this time.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

partitionstartinclusive / partitionendinclusive

WarehousePG 7 supports the classic syntax `INCLUSIVE` and `EXCLUSIVE` clauses through the adjustment of `START` and `END` values. It dos not record whether a range `START` or `END` is inclusive or not, because the `START` is always inclusive and the `END` is always exclusive. So the `partitionstartinclusive` and `partitionendinclusive` columns are simply redundant.

partitionboundary

You can retrieve the partition boundary definition in WarehousePG 7 via the `pg_get_expr()` function:

```
SELECT
    pg_get_expr(relpartbound, oid)
FROM
    pg_class
WHERE
    relispartition = 't';
```

Composing a Similar View in WarehousePG 7

An approximate `pg_partitions` view follows. This view, given all limitations addressed above, prints the information that is possible to retrieve in WarehousePG 7.

> **Caution** This example is for illustrative purposes only, not for practical use.

```
SELECT
    (SELECT relnamespace::regnamespace FROM pg_class WHERE oid = pg_partition_root(c.oid)) AS schemaname,
    (SELECT pg_partition_root(c.oid)::regclass) AS tablename,
    n.nspname AS partitionschemaname,
    c.relname AS partitiontablename,
    -- assuming the table name is implicitly generated like <parent>_prt_<id>_<partition>
    split_part(
        substr(c.relname, position(pc.relname in c.relname) + length(pc.relname)),
        '_',
        4
    ) AS partitionname,
    pc.relname AS parentpartitiontablename,
    -- same assumption as above
    split_part(
        substr(pc.relname, position(ppc.relname in pc.relname) + length(ppc.relname)),
        '_',
        4
    ) AS parentpartitionname,
    CASE
        WHEN pt.partstrat = 'r' THEN 'range'
        ELSE 'list'
    END AS partitiontype,
    (SELECT level FROM pg_partition_tree(pg_partition_root(c.oid)) WHERE relid = c.oid) AS partitionlevel,
    -- can be calculated like a previous example
    NULL AS partitionrank,
    -- cannot be trusted because no real order for list partitions
    NULL AS partitionposition,
    (regexp_matches(pg_get_expr(c.relpartbound, c.oid), 'FOR VALUES IN \(\((.*?)\)'))[1] AS partitionlistvalues,
    -- assuming range values are normal integers instead of expressions which WarehousePG 7 supports
    (regexp_matches(pg_get_expr(c.relpartbound, c.oid), 'FOR VALUES FROM \(\([0-9]+)\) TO \(\([0-9]+)\)'))[1] AS partitionrangestart,
    't' AS partitionstartinclusive,
    (regexp_matches(pg_get_expr(c.relpartbound, c.oid), 'FOR VALUES FROM \(\([0-9]+)\) TO \(\([0-9]+)\)'))[2] AS partitionrangeend,
    'f' AS partitionendinclusive,
    -- information cannot be retrieved
    NULL AS partitioneveryclause,
    CASE
        WHEN pg_get_expr(c.relpartbound, c.oid) = 'DEFAULT' THEN 't'
        ELSE 'f'
    END AS partitionisdefault,
    (regexp_matches(pg_get_expr(c.relpartbound, c.oid), '.+'))[1] AS partitionboundary,
    CASE
        WHEN pc.reltablespace = 0 THEN 'pg_default'
        ELSE (SELECT spcname FROM pg_tablespace WHERE oid = pc.reltablespace)
    END AS parenttablespace,
    CASE
        WHEN c.reltablespace = 0 THEN 'pg_default'
        ELSE (SELECT spcname FROM pg_tablespace WHERE oid = c.reltablespace)
    END AS partitiontablespace
FROM
    pg_class c
LEFT JOIN
    pg_namespace n ON n.oid = c.relnamespace
LEFT JOIN
    pg_inherits inh ON inh.inhrelid = c.oid
LEFT JOIN
    pg_partitioned_table pt ON inh.inhparent = pt.partrelid
LEFT JOIN
    pg_class pc ON pc.oid = pt.partrelid
LEFT JOIN
    pg_inherits pinh ON pinh.inhrelid = pc.oid
LEFT JOIN
    pg_partitioned_table ppt ON pinh.inhparent = ppt.partrelid
LEFT JOIN
    pg_class ppc ON ppc.oid = ppt.partrelid
WHERE
    c.relispartition = 't';
```

pg_partition_columns

The WarehousePG 6 `pg_partition_columns` view displays the partition key columns of a partitioned table.

Column Name	WarehousePG 6 Description	WarehousePG 7 Equivalent
schemaname	The name of the schema in which the partitioned table resides.	Get the root partitioned table object identifier via `pg_partition_root()` and then query pg_namespace.
tablename	The table name of the partitioned table.	pg_class
columnname	The name of the partition key column.	pg_attribute
partitionlevel	The level of this subpartition in the partition hierarchy.	Get the level from `pg_partition_tree()` using the parent object identifier.
position_in_partition_key	List partitions can have a composite (multi-column) partition key. This attribute identifies the position of the column in a composite key.	always 1

The `position_in_partition_key` column is no longer relevant in WarehousePG 7. WarehousePG 7 supports a multi-column partition key via multi-column type, so the relative position of the column in the partition key will always be one. Another reason that this no longer holds true in WarehousePG 7: the `pg_partition_columnns` view assumes a homogenous partition structure, while WarehousePG 7 also supports heterogenous partition structures.

Composing a Similar View in WarehousePG 7

As long as these two assumptions hold:

1. The partitioned table does not have a multi-column partition key.
2. All partition structures are a homogeneous.

A query to generate a comparable view in WarehousePG 7 follows:

```
SELECT
    c.relnamespace::regnamespace AS schemaname,
    c.relname AS tablename,
    att.attname AS columnname,
    (
        SELECT level
        FROM pg_partition_tree(pg_partition_root(c.oid))
        WHERE relid = c.oid
    ) AS partitionlevel,
    1 AS position_in_partition_key
FROM
    pg_partitioned_table pt
LEFT JOIN
    pg_class c ON c.oid = pt.partrelid
JOIN
    pg_attribute att ON c.oid = att.attrelid AND att.attnum = pt.partattrs[0];
```

pg_partition_rule

The WarehousePG 6 `pg_partition_rule` table tracks partitioned tables, their check constraints, and their data containment rules.

Column Name	WarehousePG 6 Description	WarehousePG 7 Equivalent
paroid	The row identifier of the partitioning level (from `pg_partition`) to which this partition belongs. In the case of a branch partition, the corresponding table (identified by `pg_partition_rule`) is an empty container table. In the case of a leaf partition, the table contains the rows for that partition containment rule.	N/A (removed object)
parchildrelid	The table identifier of the partition.	pg_class
parparentrule	The row identifier of the rule associated with the parent table of this partition.	N/A (removed object)
parname	The given name of this partition.	pg_class
parisdefault	Specifies whether or not this partition is a default partition.	See pg_partitions.partitionisdefault.
parruleord	For range partitioned tables, the rank of this partition in this level of the partition hierarchy.	N/A (See the explanation for the `partitionposition` / `partitionrank` columns in pg_partitions.)
parrangestartincl	For range partitioned tables, specifies whether or not the starting value is inclusive.	always inclusive
parrangeendincl	For range partitioned tables, specifies whether or not the ending value is inclusive.	always exclusive
parrangestart	For range partitioned tables, the starting value of the range.	See pg_partitions.partitionrangestart.
parrangeend	For range partitioned tables, the ending value of the range.	See pg_partitions.partitionrangeend.
parrangeevery	For range partitioned tables, the interval value of the `EVERY` clause.	N/A (See pg_partitions.partitioneveryclause.)
parlistvalues	For list partitioned tables, the list of values assigned to this partition.	See pg_partitions.partitionlistvalues.
parreloptions	An array describing the storage characteristics of the particular partition.	pg_class.reloptions

pg_partition

The WarehousePG 6 `pg_partition` system catalog table tracks partitioned tables and their inheritance level relationships.

The majority of this information resides in pg_partitioned_table in WarehousePG 7.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Column Name	WarehousePG 6 Description	WarehousePG 7 Equivalent
parrelid	The object identifier of the table.	pg_partitioned_table.partrelid
parkind	The partition type - R for range or L for list.	pg_partitioned_table.partstrat
parlevel	The partition level of this row: 0 for the top-level parent table, 1 for the first level under the parent table, 2 for the second level, and so on.	Cross-check pg_partitioned_table and `pg_partition_root()/pg_partition_tree()`, similar to how you retrieve pg_partitions.partitionlevel.
paristemplate	Whether or not this row represents a subpartition template definition (`true`) or an actual partitioning level (`false`).	Cross-check pg_partitioned_table.partrelid with gp_partition_template.
parnatts	The number of attributes that define this level.	pg_partitioned_table.partnatts
paratts	An array of the attribute numbers (as in `pg_attribute.attnum`) of the attributes that participate in defining this level.	pg_partitioned_table.partattrs
parclass	The operator class identifier(s) of the partition columns.	pg_partitioned_table.partclass

pg_partition_templates

The WarehousePG 6 `pg_partition_templates` view displays the subpartitions that were created using a subpartition template.

While the information is same as that of the `pg_partitions` view, `pg_partition_templates` displays only those subpartitions created by a subpartition template (cross-check with `pg_partition.paristemplate` of the root partitioned table).

> **Note** WarehousePG 6 assumes that if the root partitioned table has a subpartition template, then all of its subpartitions are created by this subpartition template. In WarehousePG 7 this assumption no longer holds true - you can add any table to a partitioned table with `ATTACH PARTITION`. Ensure that you take this into account when you rewrite your scripts.

Column Name	WarehousePG 6 Description	WarehousePG 7 Equivalent
schemaname	The name of the schema in which the partitioned table resides.	See pg_partitions.schemaname.
tablename	The table name of the top-level parent table.	See pg_partitions.tablename.
partitionname	The name of the subpartition (this is the name to use if referring to the partition in an `ALTER TABLE` command). NULL if the partition was not given a name at create time or generated by an `EVERY` clause.	See pg_partitions.partitionname.
partitiontype	The type of subpartition (range or list).	See pg_partitions.partitiontype.
partitionlevel	The level of this subpartition in the hierarchy.	See pg_partitions.partitionlevel.
partitionrank	For range partitions, the rank of the partition compared to other partitions of the same level.	See pg_partitions.partitionrank.
partitionposition	The rule order position of this subpartition.	See pg_partitions.partitionposition.
partitionlistvalues	For list partitions, the list value(s) associated with this subpartition.	See pg_partitions.partitionlistvalues.
partitionrangestart	For range partitions, the start value of this subpartition.	See pg_partitions.partitionrangestart.
partitionstartinclusive	Whether or not the start value is included in this partition. `true` if the start value is included. `false` if it is excluded.	See pg_partitions.partitionstartinclusive.
partitionrangeend	For range partitions, the end value of this subpartition.	See pg_partitions.partitionrangend.
partitionendinclusive	Whether or not the end value is included in this partition. `true` if the end value is included. `false` if it is excluded.	See pg_partitions.partitionendinclusive.
partitioneveryclause	The `EVERY` clause (interval) of this subpartition.	See pg_partitions.partitioneveryclause.
partitionisdefault	Whether or not this is a default subpartition. `true` if this is the default, otherwise `false`.	See pg_partitions.partitionisdefault.
partitionboundary	The entire partition specification for this subpartition.	See pg_partitions.partitionboundary.

pg_partition_encoding

The WarehousePG 6 `pg_partition_encoding` table describes the available column compression options for a subpartition template. This information is stored in gp_partition_template in WarehousePG 7.

You must perform some text filtering to retrieve the per-column encoding information in WarehousePG 7 in the same format as that of `pg_partition_encoding`.

Column Name	WarehousePG 6 Description	WarehousePG 7 Equivalent
parencoid	The object identifier of the parent partition of this subpartition template.	`gp_partition_template`
parencattnum	The attribute number of the column for which the encoding option applies.	`pg_get_expr(template, <root_partition_oid>)`
parencattoptions	The storage option of this column.	`pg_get_expr(template, <root_partition_oid>)`

Composing a Similar View in WarehousePG 7

You can retrieve a one-line definition of the template using `pg_get_expr()` as follows:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
SELECT level, pg_get_expr(template, relid) from gp_partition_template where relid::regclass::text = '<tablename>';
 level |                                                
```

3.15 Enabling iptables (Optional)

On Linux systems, you can configure and enable the `iptables` firewall to work with WarehousePG.

> **Note** WarehousePG performance might be impacted when `iptables` is enabled. You should test the performance of your application with `iptables` enabled to ensure that performance is acceptable.

For more information about `iptables` see the `iptables` and firewall documentation for your operating system. See also Deactivating SELinux and Firewall Software.

How to Enable iptables

1. As `gpadmin`, run this command on the WarehousePG coordinator host to stop WarehousePG:

   ```
   $ gpstop -a
   ```

2. On the WarehousePG hosts:

   1. Update the file `/etc/sysconfig/iptables` based on the Example iptables Rules.

   2. As root user, run these commands to enable `iptables`:

      ```
      # chkconfig iptables on
      # service iptables start
      ```

3. As gpadmin, run this command on the WarehousePG coordinator host to start WarehousePG:

   ```
   $ gpstart -a
   ```

> **Caution** After enabling `iptables`, this error in the `/var/log/messages` file indicates that the setting for the `iptables` table is too low and needs to be increased.

```
ip_conntrack: table full, dropping packet.
```

As root, run this command to view the `iptables` table value:

```
# sysctl net.ipv4.netfilter.ip_conntrack_max
```

To ensure that the WarehousePG workload does not overflow the `iptables` table, as root, set it to the following value:

```
# sysctl net.ipv4.netfilter.ip_conntrack_max=6553600
```

The value might need to be adjusted for your hosts. To maintain the value after reboot, you can update the `/etc/sysctl.conf` file as discussed in Setting the WarehousePG Recommended OS Parameters.

Parent topic: Installing and Upgrading WarehousePG

Example iptables Rules

When `iptables` is enabled, `iptables` manages the IP communication on the host system based on configuration settings (rules). The example rules are used to configure `iptables` for WarehousePG coordinator host, standby coordinator host, and segment hosts.

- Example Coordinator and Standby Coordinator iptables Rules
- Example Segment Host iptables Rules

The two sets of rules account for the different types of communication WarehousePG expects on the coordinator (primary and standby) and segment hosts. The rules should be added to the `/etc/sysconfig/iptables` file of the WarehousePG hosts. For WarehousePG, `iptables` rules should allow the following communication:

- For customer facing communication with the WarehousePG coordinator, allow at least `postgres` and `28080` (`eth1` interface in the example).
- For WarehousePG cluster interconnect, allow communication using `tcp`, `udp`, and `icmp` protocols (`eth4` and `eth5` interfaces in the example).

  The network interfaces that you specify in the `iptables` settings are the interfaces for the WarehousePG hosts that you list in the hostfile_gpinitsystem file. You specify the file when you run the `gpinitsystem` command to initialize a WarehousePG cluster. See Initializing WarehousePG for information about the hostfile_gpinitsystem file and the `gpinitsystem` command.

- For the administration network on a WarehousePG DCA, allow communication using `ssh`, `ntp`, and `icmp` protocols. (`eth0` interface in the example).

In the `iptables` file, each append rule command (lines starting with `-A`) is a single line.

The example rules should be adjusted for your configuration. For example:

- The append command, the `-A` lines and connection parameter `-i` should match the connectors for your hosts.
- the CIDR network mask information for the source parameter `-s` should match the IP addresses for your network.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Example Coordinator and Standby Coordinator iptables Rules

Example `iptables` rules with comments for the `/etc/sysconfig/iptables` file on the WarehousePG coordinator host and standby coordinator host.

```
*filter
# Following 3 are default rules. If the packet passes through
# the rule set it gets these rule.
# Drop all inbound packets by default.
# Drop all forwarded (routed) packets.
# Let anything outbound go through.
:INPUT DROP [0:0]
:FORWARD DROP [0:0]
:OUTPUT ACCEPT [0:0]
# Accept anything on the loopback interface.
-A INPUT -i lo -j ACCEPT
# If a connection has already been established allow the
# remote host packets for the connection to pass through.
-A INPUT -m state --state ESTABLISHED,RELATED -j ACCEPT
# These rules let all tcp and udp through on the standard
# interconnect IP addresses and on the interconnect interfaces.
# NOTE: gpsyncmaster uses random tcp ports in the range 1025 to 65535
# and WarehousePG uses random udp ports in the range 1025 to 65535.
-A INPUT -i eth4 -p udp -s 192.0.2.0/22 -j ACCEPT
-A INPUT -i eth5 -p udp -s 198.51.100.0/22 -j ACCEPT
-A INPUT -i eth4 -p tcp -s 192.0.2.0/22 -j ACCEPT --syn -m state --state NEW
-A INPUT -i eth5 -p tcp -s 198.51.100.0/22 -j ACCEPT --syn -m state --state NEW
\# Allow udp/tcp ntp connections on the admin network on WarehousePG DCA.
-A INPUT -i eth0 -p udp --dport ntp -s 203.0.113.0/21 -j ACCEPT
-A INPUT -i eth0 -p tcp --dport ntp -s 203.0.113.0/21 -j ACCEPT --syn -m state --state NEW
# Allow ssh on all networks (This rule can be more strict).
-A INPUT -p tcp --dport ssh -j ACCEPT --syn -m state --state NEW
# Allow WarehousePG on all networks.
-A INPUT -p tcp --dport postgres -j ACCEPT --syn -m state --state NEW
# Allow ping and any other icmp traffic on the interconnect networks.
-A INPUT -i eth4 -p icmp -s 192.0.2.0/22 -j ACCEPT
-A INPUT -i eth5 -p icmp -s 198.51.100.0/22 -j ACCEPT
\# Allow ping only on the admin network on WarehousePG DCA.
-A INPUT -i eth0 -p icmp --icmp-type echo-request -s 203.0.113.0/21 -j ACCEPT
# Log an error if a packet passes through the rules to the default
# INPUT rule (a DROP).
-A INPUT -m limit --limit 5/min -j LOG --log-prefix "iptables denied: " --log-level 7
COMMIT
```

Example Segment Host iptables Rules

Example `iptables` rules for the `/etc/sysconfig/iptables` file on the WarehousePG segment hosts. The rules for segment hosts are similar to the coordinator rules with fewer interfaces and fewer `udp` and `tcp` services.

```
*filter
:INPUT DROP
:FORWARD DROP
:OUTPUT ACCEPT
-A INPUT -i lo -j ACCEPT
-A INPUT -m state --state ESTABLISHED,RELATED -j ACCEPT
-A INPUT -i eth2 -p udp -s 192.0.2.0/22 -j ACCEPT
-A INPUT -i eth3 -p udp -s 198.51.100.0/22 -j ACCEPT
-A INPUT -i eth2 -p tcp -s 192.0.2.0/22 -j ACCEPT --syn -m state --state NEW
-A INPUT -i eth3 -p tcp -s 198.51.100.0/22 -j ACCEPT --syn -m state --state NEW
-A INPUT -p tcp --dport ssh -j ACCEPT --syn -m state --state NEW
-A INPUT -i eth2 -p icmp -s 192.0.2.0/22 -j ACCEPT
-A INPUT -i eth3 -p icmp -s 198.51.100.0/22 -j ACCEPT
-A INPUT -i eth0 -p icmp --icmp-type echo-request -s 203.0.113.0/21 -j ACCEPT
-A INPUT -m limit --limit 5/min -j LOG --log-prefix "iptables denied: " --log-level 7
COMMIT
```

3.16 Installation Utilities Reference

References for the command-line management utilities used to install and initialize a WarehousePG cluster.

For a full reference of all WarehousePG utilities, see the WarehousePG Utility Guide.

The following WarehousePG management utilities are located in `$GPHOME/bin`.

- gpactivatestandby
- gpaddmirrors
- gpcheckperf
- gpdeletesystem
- gpinitstandby
- gpinitsystem
- gpssh
- gpssh-exkeys
- gpstart
- gpstop
- gpsync

3.17 WarehousePG Environment Variables

Reference of the environment variables to set for WarehousePG.

Set these in your user's startup shell profile (such as `~/.bashrc` or `~/.bash_profile`), or in `/etc/profile` if you want to set them for all users.

- Required Environment Variables
- Optional Environment Variables

Parent topic: Installing and Upgrading WarehousePG

Required Environment Variables

> **Note** `GPHOME`, `PATH` and `LD_LIBRARY_PATH` can be set by sourcing the `greenplum_path.sh` file from your WarehousePG installation directory

Parent topic: WarehousePG Environment Variables

GPHOME

This is the installed location of your WarehousePG software. For example:

```
GPHOME=/usr/edb/whpg7
export GPHOME
```

PATH

Your `PATH` environment variable should point to the location of the WarehousePG `bin` directory. For example:

```
PATH=$GPHOME/bin:$PATH
export PATH
```

LD_LIBRARY_PATH

The `LD_LIBRARY_PATH` environment variable should point to the location of the WarehousePG/PostgreSQL library files. For example:

```
LD_LIBRARY_PATH=$GPHOME/lib
export LD_LIBRARY_PATH
```

COORDINATOR_DATA_DIRECTORY

This should point to the directory created by the gpinitsystem utility in the coordinator data directory location. For example:

```
COORDINATOR_DATA_DIRECTORY=/data/coordinator/gpseg-1
export COORDINATOR_DATA_DIRECTORY
```

Optional Environment Variables

The following are standard PostgreSQL environment variables, which are also recognized in WarehousePG. You may want to add the connection-related environment variables to your profile for convenience, so you do not have to type so many options on the command line for client connections. Note that these environment variables should be set on the WarehousePG coordinator host only.

Parent topic: WarehousePG Environment Variables

PGAPPNAME

The name of the application that is usually set by an application when it connects to the server. This name is displayed in the activity view and in log entries. The `PGAPPNAME` environmental variable behaves the same as the `application_name` connection parameter. The default value for `application_name` is `psql`. The name cannot be longer than 63 characters.

PGDATABASE

The name of the default database to use when connecting.

PGHOST

The WarehousePG coordinator host name.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

PGHOSTADDR

The numeric IP address of the coordinator host. This can be set instead of or in addition to `PGHOST` to avoid DNS lookup overhead.

PGPASSWORD

The password used if the server demands password authentication. Use of this environment variable is not recommended for security reasons (some operating systems allow non-root users to see process environment variables via `ps`). Instead consider using the `~/.pgpass` file.

PGPASSFILE

The name of the password file to use for lookups. If not set, it defaults to `~/.pgpass`. See the topic about The Password File in the PostgreSQL documentation for more information.

PGOPTIONS

Sets additional configuration parameters for the WarehousePG coordinator server.

PGPORT

The port number of the WarehousePG server on the coordinator host. The default port is 5432.

PGUSER

The WarehousePG user name used to connect.

PGDATESTYLE

Sets the default style of date/time representation for a session. (Equivalent to `SET datestyle TO...`)

PGTZ

Sets the default time zone for a session. (Equivalent to `SET timezone TO...`)

PGCLIENTENCODING

Sets the default client character set encoding for a session. (Equivalent to `SET client_encoding TO...`)

3.18 Example Ansible Playbook

A sample Ansible playbook to install a WarehousePG software release onto the hosts that will comprise a WarehousePG cluster.

This Ansible playbook shows how tasks described in [Installing WarehousePG]() might be automated using Ansible.

> **Important** This playbook is provided as an *example only* to illustrate how WarehousePG cluster configuration and software installation tasks can be automated using provisioning tools such as Ansible, Chef, or Puppet. Presented as an example.

The example playbook is designed for use with RedHat. It creates the `gpadmin` user, installs the WarehousePG software release, sets the owner and group of the installed software to `gpadmin`, and sets the Pam security limits for the `gpadmin` user.

You can revise the script to work with your operating system platform and to perform additional host configuration tasks.

Following are steps to use this Ansible playbook.

1. Install Ansible on the control node using your package manager. See the Ansible documentation for help with installation.
2. Set up passwordless SSH from the control node to all hosts that will be a part of the WarehousePG cluster. You can use the `ssh-copy-id` command to install your public SSH key on each host in the cluster. Alternatively, your provisioning software may provide more convenient ways to securely install public keys on multiple hosts.
3. Create an Ansible inventory by creating a file called `hosts` with a list of the hosts that will comprise your WarehousePG cluster. For example:

   ```
   cdw
   sdw1
   sdw2
   ...
   ```

   This file can be edited and used with the WarehousePG `gpssh-exkeys` and `gpinitsystem` utilities later on.
4. Copy the playbook code below to a file `ansible-playbook.yml` on your Ansible control node.
5. Edit the playbook variables at the top of the playbook, such as the `gpadmin` administrative user and password to create, and the version of WarehousePG you are installing.
6. Run the playbook, passing the package to be installed to the `package_path` parameter.

   ```
   ansible-playbook ansible-playbook.yml -i hosts -e package_path=./greenplum-db-7.0.0-rhel8-x86_64.rpm
   ```

4 WarehousePG administrator guide

Information about configuring, managing and monitoring WarehousePG installations, and administering, monitoring, and working with databases. The guide also contains information about WarehousePG architecture and concepts such as parallel processing.

- WarehousePG Concepts
  This section provides an overview of WarehousePG components and features such as high availability, parallel data loading features, and management utilities.
- Managing a WarehousePG cluster
  This section describes basic system administration tasks performed by a WarehousePG cluster administrator.
- Managing WarehousePG Access
  Securing WarehousePG includes protecting access to the database through network configuration, database user authentication, and encryption.
- Data Distribution and Skew
  WarehousePG relies on even distribution of data across segments.
- DDL: Defining Database Objects
  This section covers data definition language (DDL) in WarehousePG and how to create and manage database objects.
- DML: Inserting, Updating and Deleting
  This section provides information about manipulating data and concurrent access in WarehousePG.
- Querying Data
  This topic provides information about using SQL in WarehousePGs.
- Analytics guide Advanced data analytics
- External Data Sources
  Both external and foreign tables provide access to data stored in data sources outside of WarehousePG as if the data were stored in regular database tables. You can read data from and write data to external and foreign tables.
- Loading and Unloading Data
  The topics in this section describe methods for loading and writing data into and out of a WarehousePG, and how to format data files.
- Managing Performance
  The topics in this section cover WarehousePG performance management, including how to monitor performance and how to configure workloads to prioritize resource utilization.
- Retrieving Query Results with a Parallel Retrieve Cursor A *parallel retrieve cursor*is an enhanced cursor implementation that you can use to create a special kind of cursor on the WarehousePG coordinator node, and retrieve query results, on demand and in parallel, directly from the WarehousePG segments.

4.1.1 About the WarehousePG Architecture

WarehousePG is a massively parallel processing (MPP) database server with an architecture specially designed to manage large-scale analytic data warehouses and business intelligence workloads.

MPP (also known as a *shared nothing* architecture) refers to systems with two or more processors that cooperate to carry out an operation, each processor with its own memory, operating system and disks. WarehousePG uses this high-performance system architecture to distribute the load of multi-terabyte data warehouses, and can use all of a system's resources in parallel to process a query.

WarehousePG is based on PostgreSQL open-source technology. It is essentially several PostgreSQL disk-oriented database instances acting together as one cohesive database management system (DBMS). It is based on PostgreSQL 12, and in most cases is very similar to PostgreSQL with regard to SQL support, features, configuration options, and end-user functionality. Database users interact with WarehousePG as they would with a regular PostgreSQL DBMS.

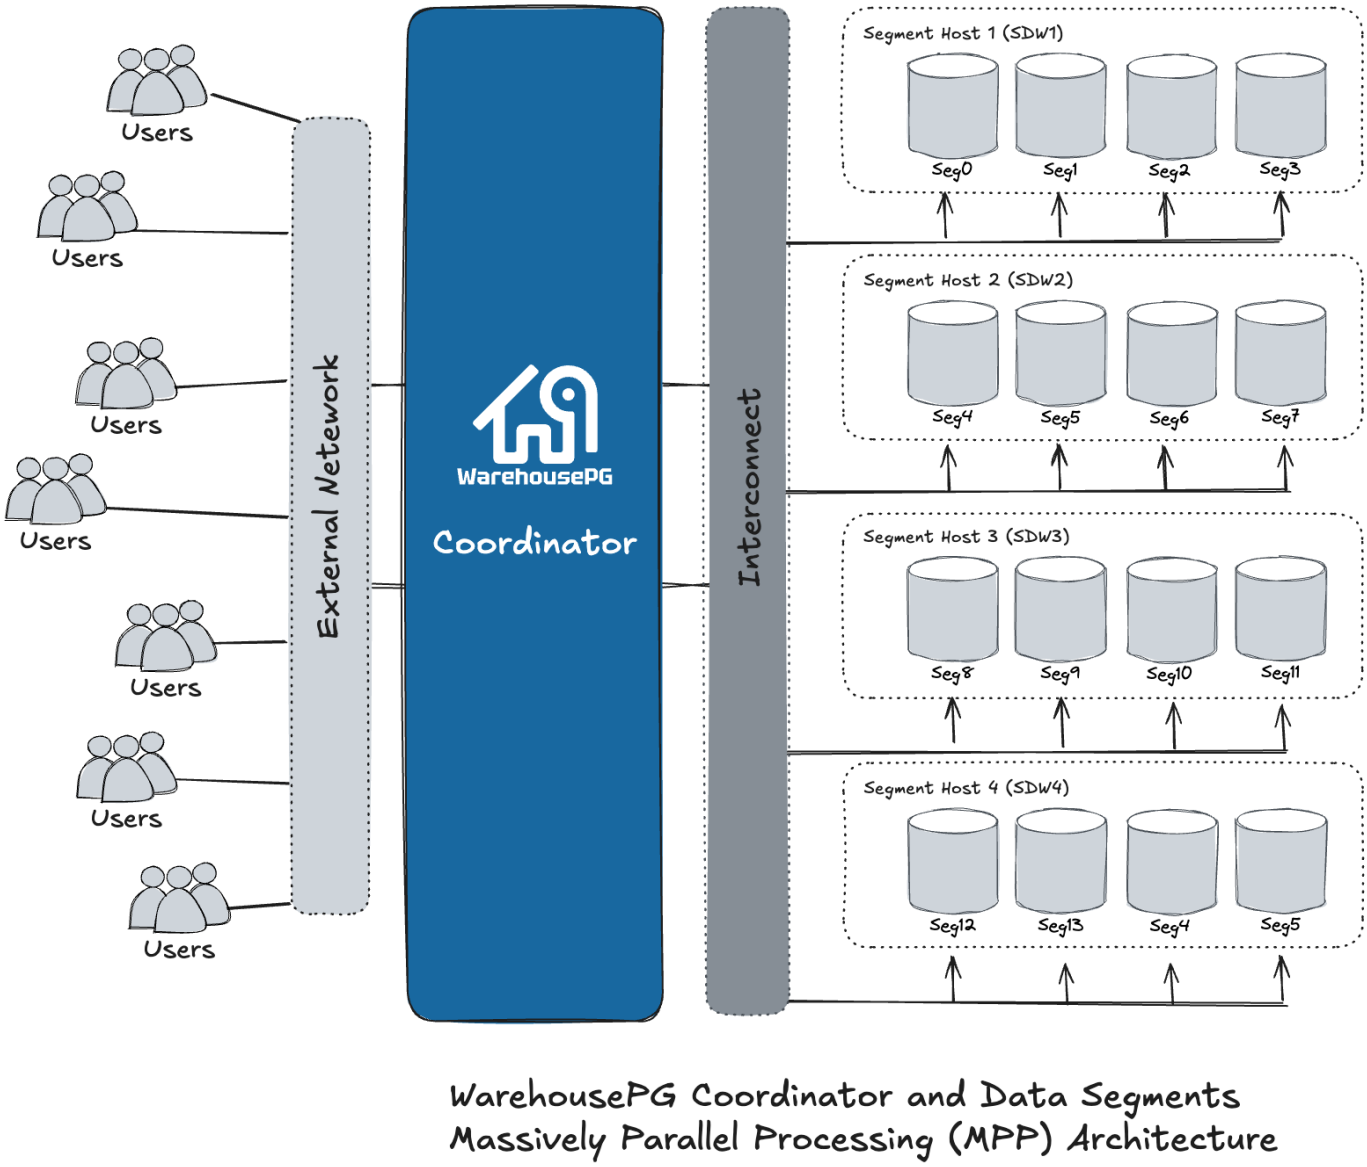
WarehousePG can use the append-optimized (AO) storage format for bulk loading and reading of data, and provides performance advantages over HEAP tables. Append-optimized storage provides checksums for data protection, compression and row/column orientation. Both row-oriented or column-oriented append-optimized tables can be compressed.

The main differences between WarehousePG and PostgreSQL are as follows:

- GPORCA is leveraged for query planning, in addition to the Postgres-based planner.
- WarehousePG can use append-optimized storage.
- WarehousePG has the option to use column storage, data that is logically organized as a table, using rows and columns that are physically stored in a column-oriented format, rather than as rows. Column storage can only be used with append-optimized tables. Column storage is compressible. It also can provide performance improvements as you only need to return the columns of interest to you. All compression algorithms can be used with either row or column-oriented tables, but Run-Length Encoded (RLE) compression can only be used with column-oriented tables. WarehousePG provides compression on all Append-Optimized tables that use column storage.

The internals of PostgreSQL have been modified or supplemented to support the parallel structure of WarehousePG. For example, the system catalog, optimizer, query executor, and transaction manager components have been modified and enhanced to be able to run queries simultaneously across all of the parallel PostgreSQL database instances. The WarehousePG *interconnect* (the networking layer) enables communication between the distinct PostgreSQL instances and allows the system to behave as one logical database.

WarehousePG also can use declarative partitions and sub-partitions to implicitly generate partition constraints.



WarehousePG also includes features designed to optimize PostgreSQL for business intelligence (BI) workloads. For example, WarehousePG has added parallel data loading (external tables), resource management, query optimizations, and storage enhancements, which are not found in standard PostgreSQL. Many features and optimizations developed by WarehousePG make their way into the PostgreSQL community. For example, table partitioning is a feature first developed by WarehousePG, and it is now in standard PostgreSQL.

WarehousePG queries use a Volcano-style query engine model, where the execution engine takes an execution plan and uses it to generate a tree of physical operators, evaluates tables through physical operators, and delivers results in a query response.

WarehousePG stores and processes large amounts of data by distributing the data and processing workload across several servers or *hosts*. WarehousePG is an *array* of individual databases based upon PostgreSQL 12 working together to present a single database image. The *coordinator* is the entry point to the WarehousePG cluster. It is the database instance to which clients connect and submit SQL statements. The coordinator coordinates its work with the other database instances in the system, called *segments*, which store and process the data.

WarehousePG Architecture

WarehousePG Coordinator and Data Segments
Massively Parallel Processing (MPP) Architecture

The following topics describe the components that make up a WarehousePG cluster and how they work together.

- About the WarehousePG Coordinator
- About the WarehousePG Segments
- About the WarehousePG Interconnect
- About ETL Hosts for Data Loading

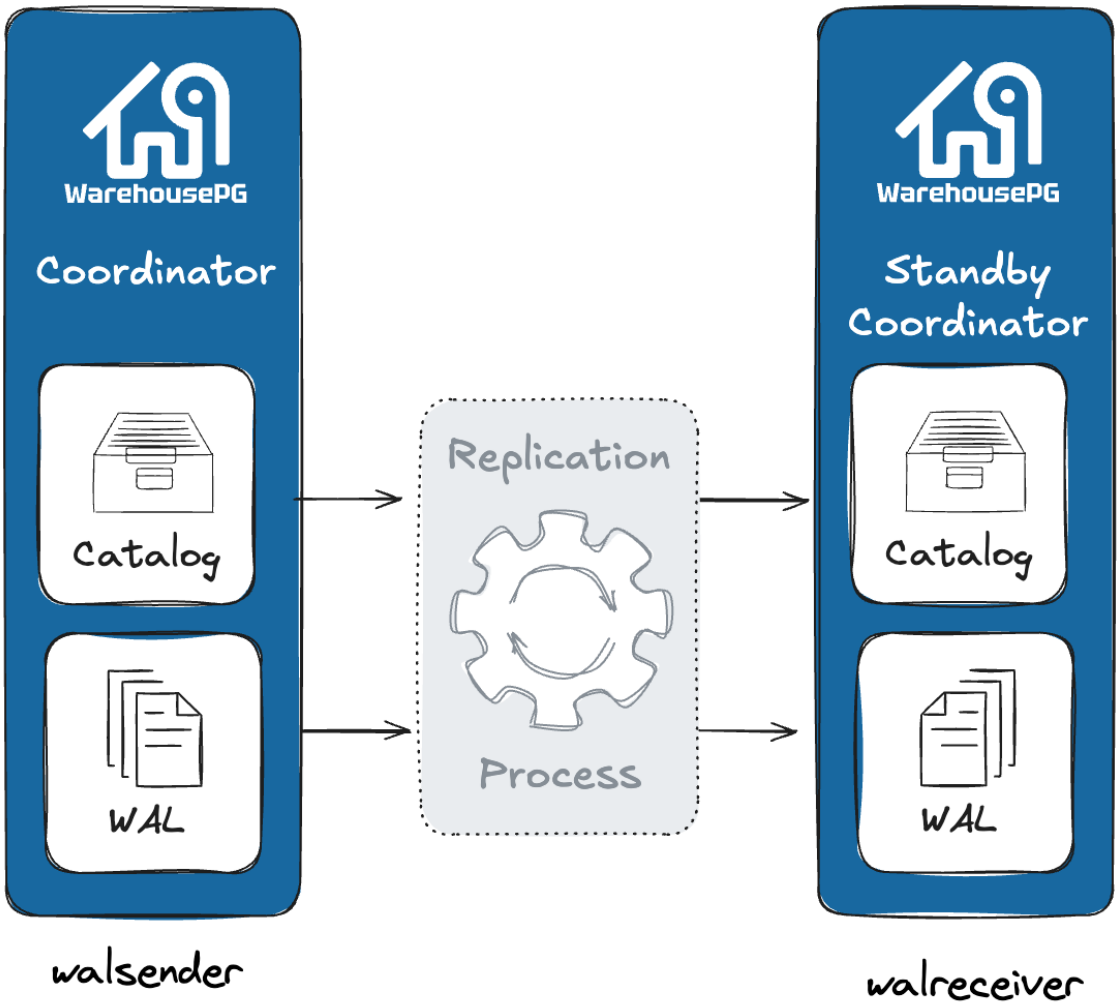
About the WarehousePG Coordinator

The WarehousePG coordinator is the entry to the WarehousePG cluster, accepting client connections and SQL queries, and distributing work to the segment instances.

WarehousePG end-users interact with WarehousePG (through the coordinator) as they would with a typical PostgreSQL database. They connect to the database using client programs such as `psql` or application programming interfaces (APIs) such as JDBC, ODBC or libpq (the PostgreSQL C API).

The coordinator is where the *global system catalog* resides. The global system catalog is the set of system tables that contain metadata about the WarehousePG cluster itself. The coordinator does not contain any user data; data resides only on the *segments*. The coordinator authenticates client connections, processes incoming SQL commands, distributes workloads among segments, coordinates the results returned by each segment, and presents the final results to the client program.

WarehousePG uses Write-Ahead Logging (WAL) for coordinator/standby coordinator mirroring. In WAL-based logging, all modifications are written to the log before being applied, to ensure data integrity for any in-process operations.



Coordinator Redundancy

You may optionally deploy a *backup* or *mirror* of the coordinator instance. A backup coordinator host serves as a *warm standby* if the primary coordinator host becomes nonoperational. You can deploy the standby coordinator on a designated redundant coordinator host or on one of the segment hosts.

The standby coordinator is kept up to date by a transaction log replication process, which runs on the standby coordinator host and synchronizes the data between the primary and standby coordinator hosts. If the primary coordinator fails, the log replication process shuts down, and an administrator can activate the standby coordinator in its place. When the standby coordinator is active, the replicated logs are used to reconstruct the state of the coordinator host at the time of the last successfully committed transaction.

Since the coordinator does not contain any user data, only the system catalog tables need to be synchronized between the primary and backup copies. When these tables are updated, changes automatically copy over to the standby coordinator so it is always synchronized with the primary.

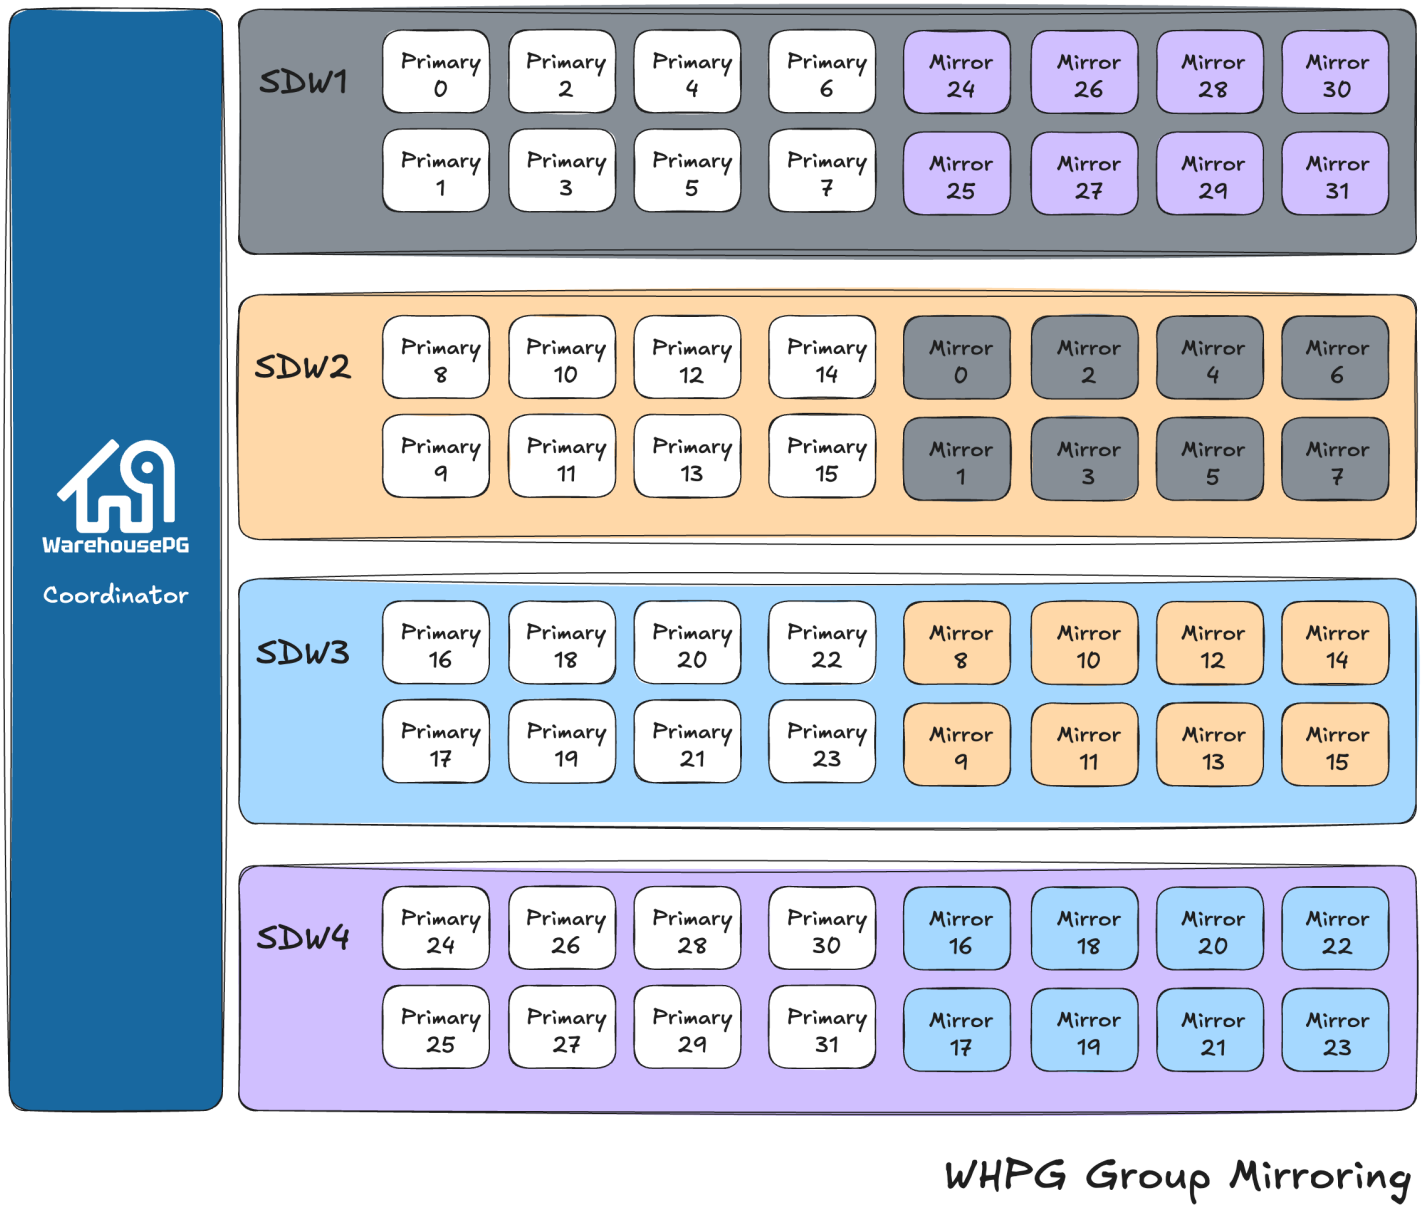
About the WarehousePG Segments

WarehousePG segment instances are independent PostgreSQL databases that each store a portion of the data and perform the majority of query processing.

When a user connects to the database via the WarehousePG coordinator and issues a query, processes are created in each segment database to handle the work of that query. For more information about query processes, seeAbout WarehousePG Query Processing.

User-defined tables and their indexes are distributed across the available segments in a WarehousePG cluster; each segment contains a distinct portion of data. The database server processes that serve segment data run under the corresponding segment instances. Users interact with segments in a WarehousePG cluster through the coordinator.



A server that runs a segment instance is called a *segment host*. A segment host typically runs from two to eight WarehousePG segments, depending on the CPU cores, RAM, storage, network interfaces, and workloads. Segment hosts are expected to be identically configured. The key to obtaining the best performance from WarehousePG is to distribute data and workloads *evenly* across a large number of equally capable segments so that all segments begin working on a task simultaneously and complete their work at the same time.

Segment Redundancy

When you deploy your WarehousePG cluster, you have the option to configure *mirror* segments. Mirror segments allow database queries to fail over to a backup segment if the primary segment becomes unavailable. Mirroring is a requirement for WarehousePG-supported production WarehousePG clusters.

A mirror segment must always reside on a different host than its primary segment. Mirror segments can be arranged across the hosts in the system in one of two standard configurations, or in a custom configuration you design. The default configuration, called *group* mirroring, places the mirror segments for all primary segments on one other host. Another option, called *spread* mirroring, spreads mirrors for each host's primary segments over the remaining hosts. Spread mirroring requires that there be more hosts in the system than there are primary segments on the host. On hosts with multiple network interfaces, the primary and mirror segments are distributed equally among the interfaces. The following figure shows how table data is distributed across the segments when the default group mirroring option is configured.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

WHPG Group Mirroring

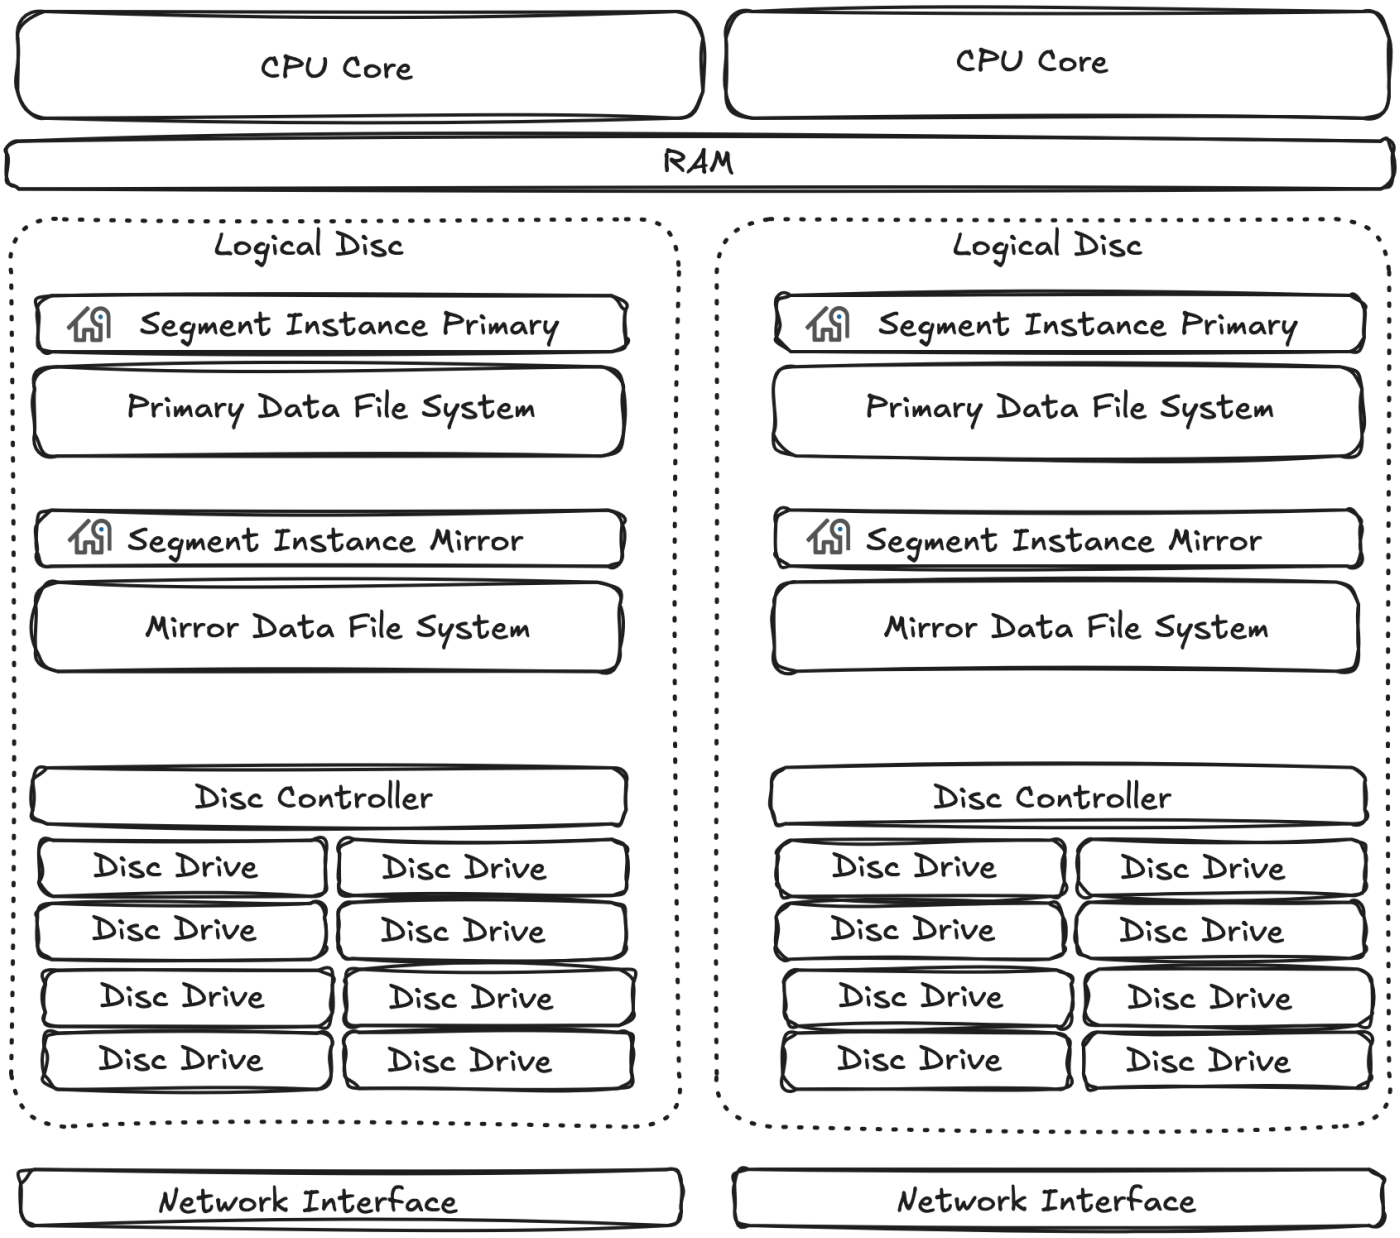
Segment Failover and Recovery

When mirroring is enabled in a WarehousePG cluster, the system automatically fails over to the mirror copy if a primary copy becomes unavailable. A WarehousePG cluster can remain operational if a segment instance or host goes down only if all portions of data are available on the remaining active segments.

If the coordinator cannot connect to a segment instance, it marks that segment instance as *invalid* in the WarehousePG cluster catalog. The segment instance remains invalid and out of operation until an administrator brings that segment back online. An administrator can recover a failed segment while the system is up and running. The recovery process copies over only the changes that were missed while the segment was nonoperational.

If you do not have mirroring enabled and a segment becomes invalid, the system automatically shuts down. An administrator must recover all failed segments before operations can continue.

Example Segment Host Hardware Stack

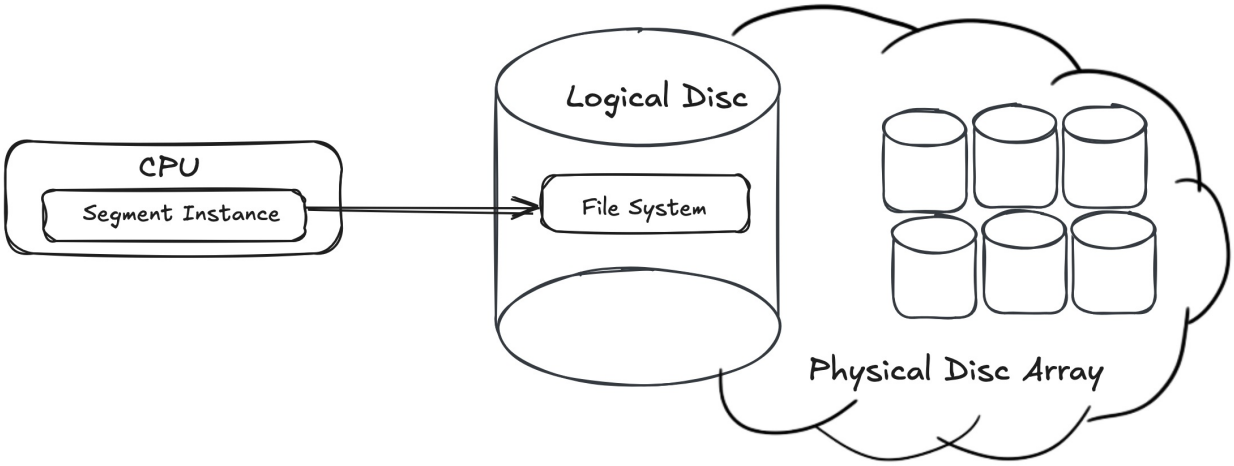


Regardless of the hardware platform you choose, a production WarehousePG processing node (a segment host) is typically configured as described in this section.

The segment hosts do the majority of database processing, so the segment host servers are configured in order to achieve the best performance possible from your WarehousePG cluster. WarehousePG's performance will be as fast as the slowest segment server in the array. Therefore, it is important to ensure that the underlying hardware and operating systems that are running WarehousePG are all running at their optimal performance level. It is also advised that all segment hosts in a WarehousePG cluster have identical hardware resources and configurations.

Segment hosts should also be dedicated to WarehousePG operations only. To get the best query performance, you do not want WarehousePG competing with other applications for machine or network resources.

The following diagram shows an example WarehousePG segment host hardware stack. The number of effective CPUs on a host is the basis for determining how many primary WarehousePG segment instances to deploy per segment host. This example shows a host with two effective CPUs (one dual-core CPU). Note that there is one primary segment instance (or primary/mirror pair if using mirroring) per CPU core.



Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Example Segment Disk Layout

Each CPU is typically mapped to a logical disk. A logical disk consists of one primary file system (and optionally a mirror file system) accessing a pool of physical disks through an I/O channel or disk controller. The logical disk and file system are provided by the operating system. Most operating systems provide the ability for a logical disk drive to use groups of physical disks arranged in RAID arrays.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Depending on the hardware platform you choose, different RAID configurations offer different performance and capacity levels. WarehousePG supports and certifies a number of reference hardware platforms and operating systems. Check with your sales account representative for the recommended configuration on your chosen platform.

About the WarehousePG Interconnect

The interconnect is the networking layer of the WarehousePG architecture.

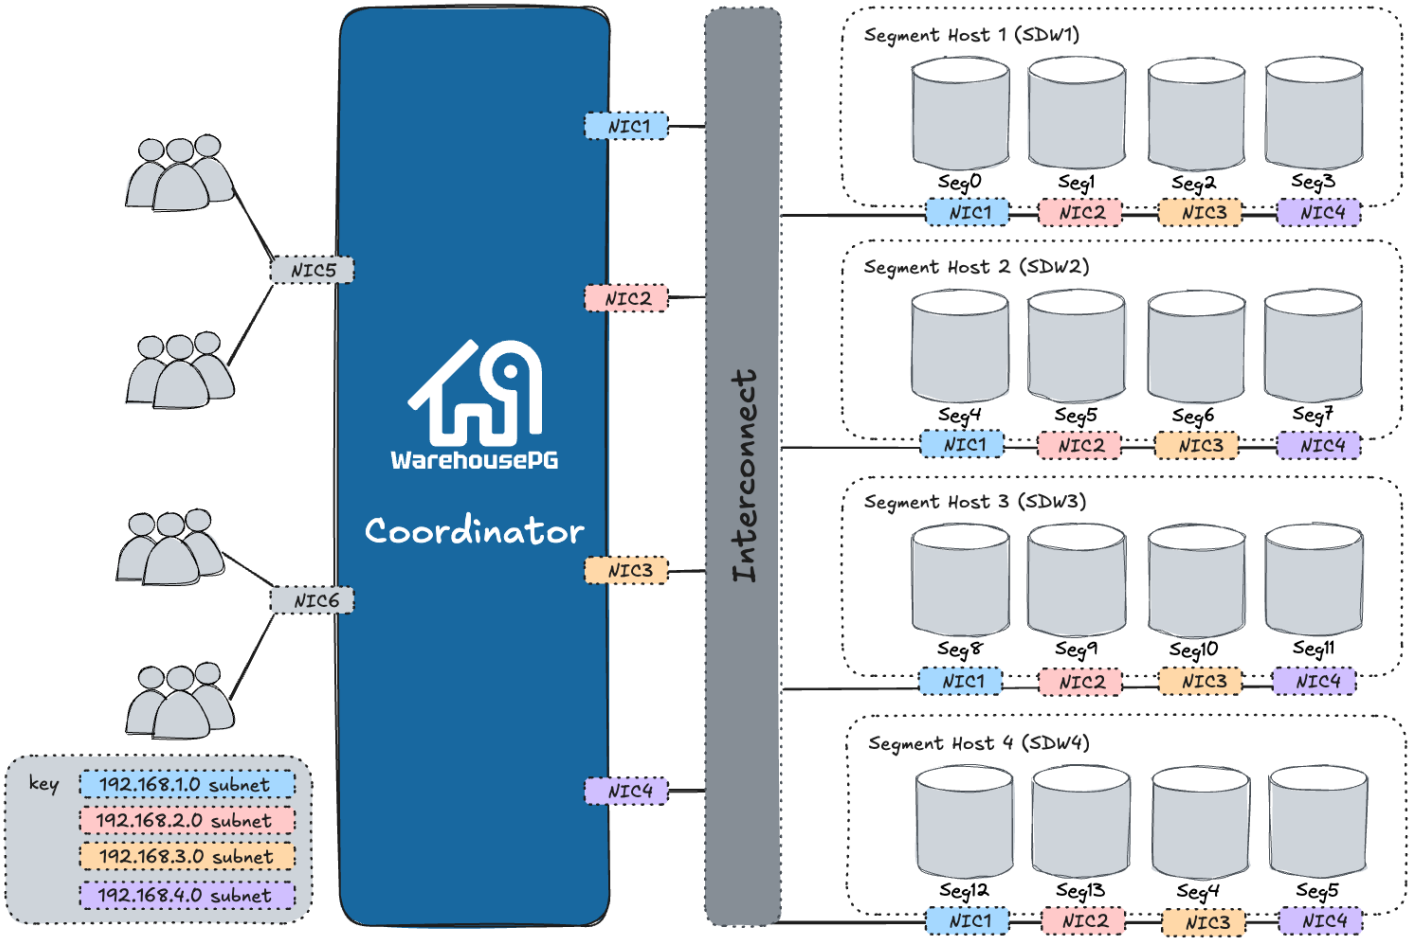
The *interconnect* refers to the inter-process communication between segments and the network infrastructure on which this communication relies. The WarehousePG interconnect uses a standard Ethernet switching fabric. For performance reasons, a 10-Gigabit system, or faster, is recommended.

By default, the interconnect uses User Datagram Protocol with flow control (UDPIFC) for interconnect traffic to send messages over the network. The WarehousePG software performs packet verification beyond what is provided by UDP. This means the reliability is equivalent to Transmission Control Protocol (TCP), and the performance and scalability exceeds TCP. If the interconnect is changed to TCP, WarehousePG has a scalability limit of 1000 segment instances. With UDPIFC as the default protocol for the interconnect, this limit is not applicable.

Interconnect Redundancy

A highly available interconnect can be achieved by deploying dual 10 Gigabit Ethernet switches on your network, and redundant 10 Gigabit connections to the WarehousePG coordinator and segment host servers.

Network Interface Configuration

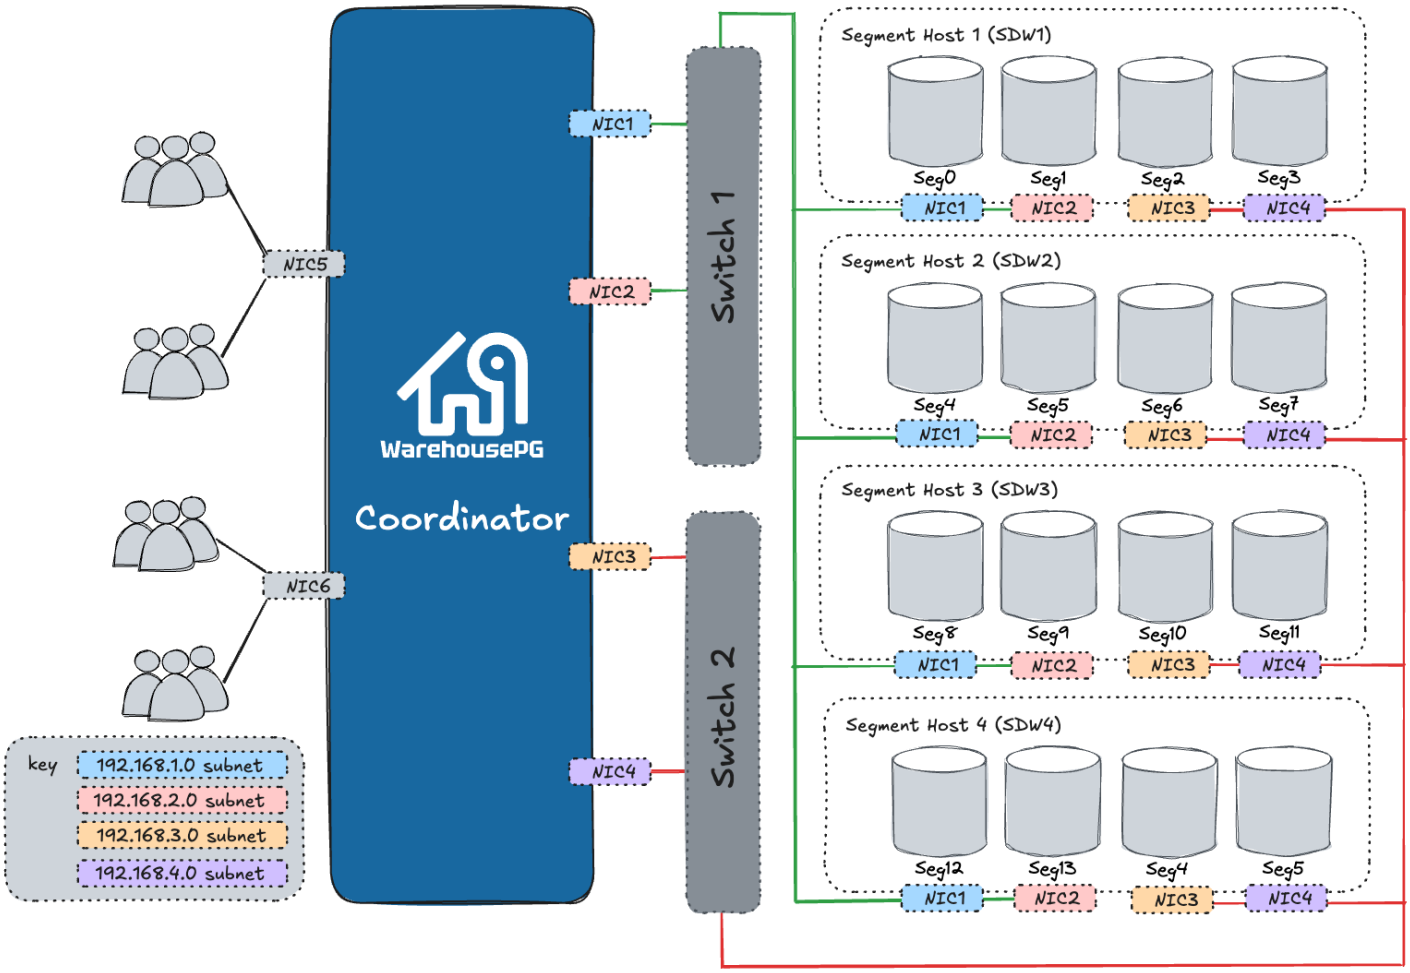


A segment host typically has multiple network interfaces designated to WarehousePG interconnect traffic. The coordinator host typically has additional external network interfaces in addition to the interfaces used for interconnect traffic.

Depending on the number of interfaces available, you will want to distribute interconnect network traffic across the number of available interfaces. This is done by assigning segment instances to a particular network interface and ensuring that the primary segments are evenly balanced over the number of available interfaces.

This is done by creating separate host address names for each network interface. For example, if a host has four network interfaces, then it would have four corresponding host addresses, each of which maps to one or more primary segment instances. The `/etc/hosts` file should be configured to contain not only the host name of each machine, but also all interface host addresses for all of the WarehousePG hosts (coordinator, standby coordinator, segments, and ETL hosts).

With this configuration, the operating system automatically selects the best path to the destination. WarehousePG automatically balances the network destinations to maximize parallelism.



Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Switch Configuration

When using multiple 10 Gigabit Ethernet switches within your WarehousePG cluster, evenly divide the number of subnets between each switch. In this example configuration, if we had two switches, NICs 1 and 2 on each host would use switch 1 and NICs 3 and 4 on each host would use switch 2. For the coordinator host, the host name bound to NIC 1 (and therefore using switch 1) is the effective coordinator host name for the array. Therefore, if deploying a warm standby coordinator for redundancy purposes, the standby coordinator should map to a NIC that uses a different switch than the primary coordinator.

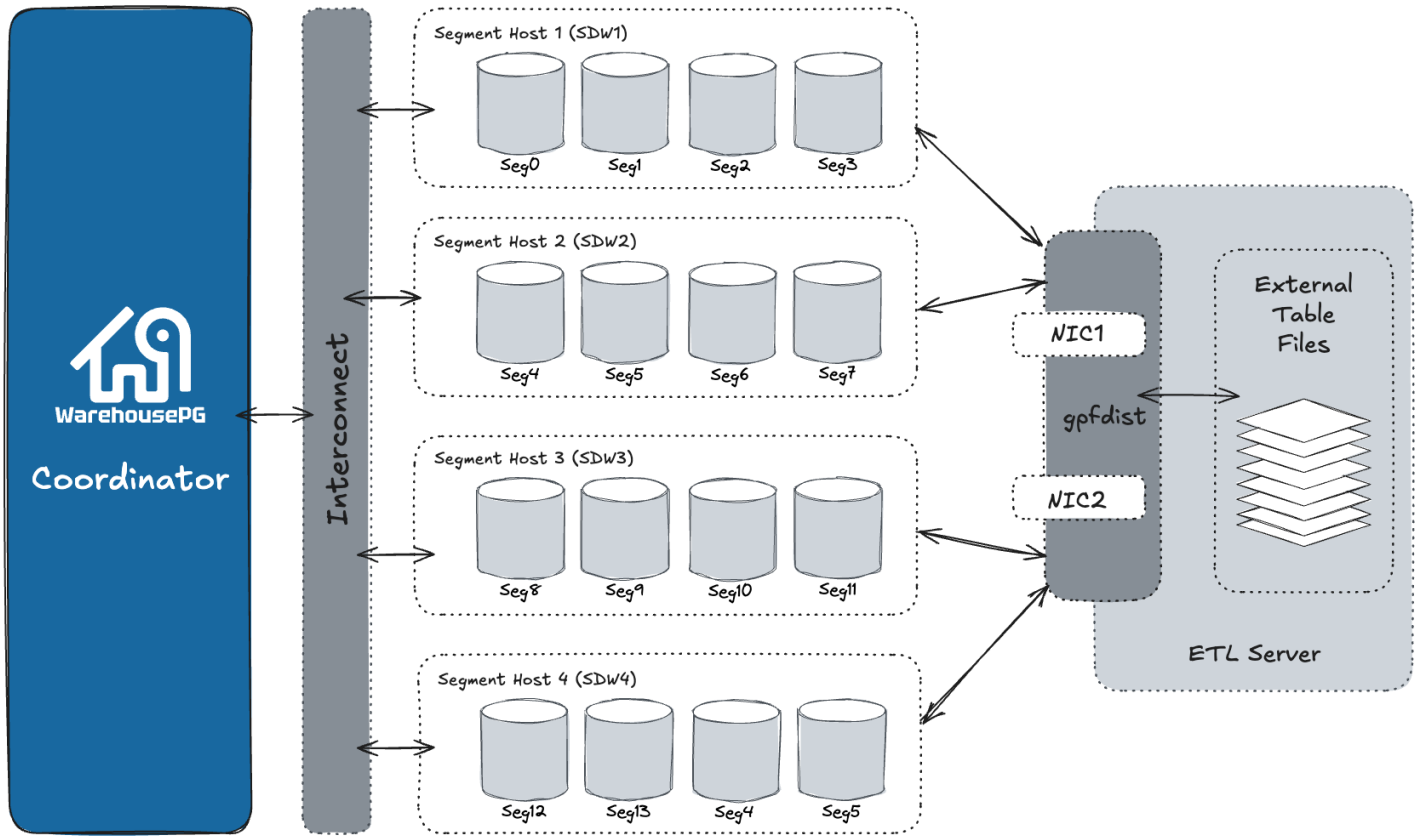
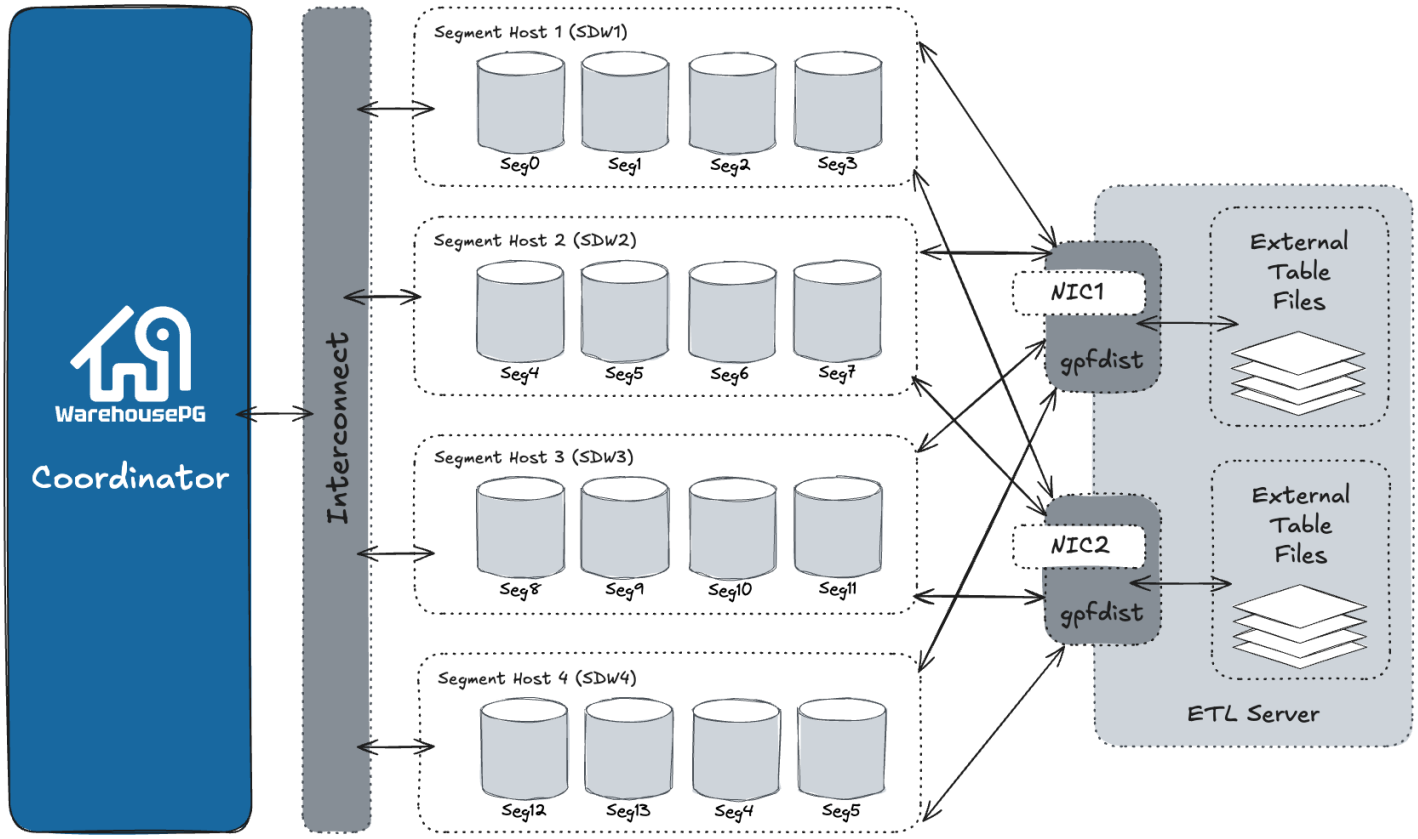
About ETL Hosts for Data Loading



WarehousePG supports fast, parallel data loading with its external tables feature. By using external tables in conjunction with WarehousePG's parallel file server (`gpfdist`), administrators can achieve maximum parallelism and load bandwidth from their WarehousePG cluster. Many production systems deploy designated ETL servers for data loading purposes. These machines run the WarehousePG parallel file server (`gpfdist`), but not WarehousePG instances.

One advantage of using the `gpfdist` file server program is that it ensures that all of the segments in your WarehousePG cluster are fully utilized when reading from external table data files.



The `gpfdist` program can serve data to the segment instances at an average rate of about 350 MB/s for delimited text formatted files and 200 MB/s for CSV formatted files. Therefore, you should consider the following options when running `gpfdist` in order to maximize the network bandwidth of your ETL systems:

- If your ETL machine is configured with multiple network interface cards (NICs) as described in Network Interface Configuration, run one instance of `gpfdist` on your ETL host and then define your external table definition so that the host name of each NIC is declared in the `LOCATION` clause (see `CREATE EXTERNAL TABLE` in the *WarehousePG Reference Guide*). This allows network traffic between your WarehousePG segment hosts and your ETL host to use all NICs simultaneously.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

- Run multiple `gpfdist` instances on your ETL host and divide your external data files equally between each instance. For example, if you have an ETL system with two network interface cards (NICs), then you could run two `gpfdist` instances on that machine to maximize your load performance. You would then divide the external table data files evenly between the two `gpfdist` programs.

4.1.2 About Management and Monitoring Utilities

WarehousePG provides standard command-line utilities for performing common monitoring and administration tasks.

WarehousePG command-line utilities are located in the $GPHOME/bin directory and are run on the coordinator host. WarehousePG provides utilities for the following administration tasks:

- Installing WarehousePG on an array
- Initializing WarehousePG
- Starting and stopping WarehousePG
- Adding or removing a host
- Expanding the array and redistributing tables among new segments
- Managing recovery for failed segment instances
- Managing failover and recovery for a failed coordinator instance
- Backing up and restoring a database (in parallel)
- Loading data in parallel
- Transferring data between WarehousePGs
- System state reporting

Parent topic: WarehousePG Concepts

4.1.3 About Concurrency Control in WarehousePG

WarehousePG uses the PostgreSQL Multiversion Concurrency Control (MVCC) model to manage concurrent transactions for heap tables.

Concurrency control in a database management system allows concurrent queries to complete with correct results while ensuring the integrity of the database. Traditional databases use a two-phase locking protocol that prevents a transaction from modifying data that has been read by another concurrent transaction and prevents any concurrent transaction from reading or writing data that another transaction has updated. The locks required to coordinate transactions add contention to the database, reducing overall transaction throughput.

WarehousePG uses the PostgreSQL Multiversion Concurrency Control (MVCC) model to manage concurrency for heap tables. With MVCC, each query operates on a snapshot of the database when the query starts. While it runs, a query cannot see changes made by other concurrent transactions. This ensures that a query sees a consistent view of the database. Queries that read rows can never block waiting for transactions that write rows. Conversely, queries that write rows cannot be blocked by transactions that read rows. This allows much greater concurrency than traditional database systems that employ locks to coordinate access between transactions that read and write data.

> **Note** Append-optimized tables are managed with a different concurrency control model than the MVCC model discussed in this topic. They are intended for "write-once, read-many" applications that never, or only very rarely, perform row-level updates.

Snapshots

The MVCC model depends on the system's ability to manage multiple versions of data rows. A query operates on a snapshot of the database at the start of the query. A snapshot is the set of rows that are visible at the beginning of a statement or transaction. The snapshot ensures the query has a consistent and valid view of the database for the duration of its execution.

Each transaction is assigned a unique *transaction ID* (XID), an incrementing 32-bit value. When a new transaction starts, it is assigned the next XID. An SQL statement that is not enclosed in a transaction is treated as a single-statement transaction—the `BEGIN` and `COMMIT` are added implicitly. This is similar to autocommit in some database systems.

> **Note** WarehousePG assigns XID values only to transactions that involve DDL or DML operations, which are typically the only transactions that require an XID.

When a transaction inserts a row, the XID is saved with the row in the `xmin` system column. When a transaction deletes a row, the XID is saved in the `xmax` system column. Updating a row is treated as a delete and an insert, so the XID is saved to the `xmax` of the current row and the `xmin` of the newly inserted row. The `xmin` and `xmax` columns, together with the transaction completion status, specify a range of transactions for which the version of the row is visible. A transaction can see the effects of all transactions less than `xmin`, which are guaranteed to be committed, but it cannot see the effects of any transaction greater than or equal to `xmax`.

Multi-statement transactions must also record which command within a transaction inserted a row (`cmin`) or deleted a row (`cmax`) so that the transaction can see changes made by previous commands in the transaction. The command sequence is only relevant during the transaction, so the sequence is reset to 0 at the beginning of a transaction.

XID is a property of the database. Each segment database has its own XID sequence that cannot be compared to the XIDs of other segment databases. The coordinator coordinates distributed transactions with the segments using a cluster-wide *session ID number*, called `gp_session_id`. The segments maintain a mapping of distributed transaction IDs with their local XIDs. The coordinator coordinates distributed transactions across all of the segment with the two-phase commit protocol. If a transaction fails on any one segment, it is rolled back on all segments.

You can see the `xmin`, `xmax`, `cmin`, and `cmax` columns for any row with a `SELECT` statement:

```
SELECT xmin, xmax, cmin, cmax, * FROM <tablename>;
```

Because you run the `SELECT` command on the coordinator, the XIDs are the distributed transactions IDs. If you could run the command in an individual segment database, the `xmin` and `xmax` values would be the segment's local XIDs.

> **Note** WarehousePG distributes all of a replicated table's rows to every segment, so each row is duplicated on every segment. Each segment instance maintains its own values for the system columns `xmin`, `xmax`, `cmin`, and `cmax`, as well as for the `gp_segment_id` and `ctid` system columns. WarehousePG does not permit user queries to access these system columns for replicated tables because they have no single, unambiguous value to evaluate in a query.

Transaction ID Wraparound

The MVCC model uses transaction IDs (XIDs) to determine which rows are visible at the beginning of a query or transaction. The XID is a 32-bit value, so a database could theoretically run over four billion transactions before the value overflows and wraps to zero. However, WarehousePG uses *modulo 232* arithmetic with XIDs, which allows the transaction IDs to wrap around, much as a clock wraps at twelve o'clock. For any given XID, there could be about two billion past XIDs and two billion future XIDs. This works until a version of a row persists through about two billion transactions, when it suddenly appears to be a new row. To prevent this, WarehousePG has a special XID, called `FrozenXID`, which is always considered older than any regular XID it is compared with. The `xmin` of a row must be replaced with `FrozenXID` within two billion transactions, and this is one of the functions the `VACUUM` command performs.

Vacuuming the database at least every two billion transactions prevents XID wraparound. WarehousePG monitors the transaction ID and warns if a `VACUUM` operation is required.

A warning is issued when a significant portion of the transaction IDs are no longer available and before transaction ID wraparound occurs:

```
WARNING: database "<database_name>" must be vacuumed within <number_of_transactions> transactions
```

When the warning is issued, a `VACUUM` operation is required. If a `VACUUM` operation is not performed, WarehousePG stops creating transactions to avoid possible data loss when it reaches a limit prior to when transaction ID wraparound occurs and issues this error:

```
FATAL: database is not accepting commands to avoid wraparound data loss in database "<database_name>"
```

See Recovering from a Transaction ID Limit Error for the procedure to recover from this error.

The server configuration parameters `xid_warn_limit` and `xid_stop_limit` control when the warning and error are displayed. The `xid_warn_limit` parameter specifies the number of transaction IDs before the `xid_stop_limit` when the warning is issued. The `xid_stop_limit` parameter specifies the number of transaction IDs before wraparound would occur when the error is issued and new transactions cannot be created.

Transaction Isolation Levels

The SQL standard defines four levels of transaction isolation. The most strict is Serializable, which the standard defines as any concurrent execution of a set of Serializable transactions is guaranteed to produce the same effect as running them one at a time in some order. The other three levels are defined in terms of phenomena, resulting from interaction between concurrent transactions, which must not occur at each level. The standard notes that due to the definition of Serializable, none of these phenomena are possible at that level.

The phenomena which are prohibited at various levels are:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

- *dirty read* – A transaction reads data written by a concurrent uncommitted transaction.
- *non-repeatable read* – A transaction re-reads data that it has previously read and finds that the data has been modified by another transaction (that committed since the initial read).
- *phantom read* – A transaction re-executes a query returning a set of rows that satisfy a search condition and finds that the set of rows satisfying the condition has changed due to another recently-committed transaction.
- *serialization anomaly* - The result of successfully committing a group of transactions is inconsistent with all possible orderings of running those transactions one at a time.

The four transaction isolation levels defined in the SQL standard and the corresponding behaviors are described in the table below.

Isolation Level	Dirty Read	Non-Repeatable	Phantom Read	Serialization Anomoly
`READ UNCOMMITTED`	Allowed, but not in WarehousePG	Possible	Possible	Possible
`READ COMMITTED`	Impossible	Possible	Possible	Possible
`REPEATABLE READ`	Impossible	Impossible	Allowed, but not in WarehousePG	Possible
`SERIALIZABLE`	Impossible	Impossible	Impossible	Impossible

WarehousePG implements only two distinct transaction isolation levels, although you can request any of the four described levels. The WarehousePG `READ UNCOMMITTED` level behaves like `READ COMMITTED`, and the `SERIALIZABLE` level falls back to `REPEATABLE READ`.

The table also shows that WarehousePG's `REPEATABLE READ` implementation does not allow phantom reads. This is acceptable under the SQL standard because the standard specifies which anomalies must not occur at certain isolation levels; higher guarantees are acceptable.

The following sections detail the behavior of the available isolation levels.

Important: Some WarehousePG data types and functions have special rules regarding transactional behavior. In particular, changes made to a sequence (and therefore the counter of a column declared using `serial`) are immediately visible to all other transactions, and are not rolled back if the transaction that made the changes aborts.

Read Committed Isolation Level

The default isolation level in WarehousePG is `READ COMMITTED`. When a transaction uses this isolation level, a `SELECT` query (without a `FOR UPDATE/SHARE` clause) sees only data committed before the query began; it never sees either uncommitted data or changes committed during query execution by concurrent transactions. In effect, a `SELECT` query sees a snapshot of the database at the instant the query begins to run. However, `SELECT` does see the effects of previous updates executed within its own transaction, even though they are not yet committed. Also note that two successive `SELECT` commands can see different data, even though they are within a single transaction, if other transactions commit changes after the first `SELECT` starts and before the second `SELECT` starts.

`UPDATE`, `DELETE`, `SELECT FOR UPDATE`, and `SELECT FOR SHARE` commands behave the same as `SELECT` in terms of searching for target rows: they find only the target rows that were committed as of the command start time. However, such a target row might have already been updated (or deleted or locked) by another concurrent transaction by the time it is found. In this case, the would-be updater waits for the first updating transaction to commit or roll back (if it is still in progress). If the first updater rolls back, then its effects are negated and the second updater can proceed with updating the originally found row. If the first updater commits, the second updater will ignore the row if the first updater deleted it, otherwise it will attempt to apply its operation to the updated version of the row. The search condition of the command (the `WHERE` clause) is re-evaluated to see if the updated version of the row still matches the search condition. If so, the second updater proceeds with its operation using the updated version of the row. In the case of `SELECT FOR UPDATE` and `SELECT FOR SHARE`, this means the updated version of the row is locked and returned to the client.

`INSERT` with an `ON CONFLICT DO UPDATE` clause behaves similarly. In `READ COMMITTED` mode, each row proposed for insertion will either insert or update. Unless there are unrelated errors, one of those two outcomes is guaranteed. If a conflict originates in another transaction whose effects are not yet visible to the `INSERT`, the `UPDATE` clause will affect that row, even though possibly no version of that row is conventionally visible to the command.

`INSERT` with an `ON CONFLICT DO NOTHING` clause may have insertion not proceed for a row due to the outcome of another transaction whose effects are not visible to the `INSERT` snapshot. Again, this is only the case in `READ COMMITTED` mode.

Because of the above rules, it is possible for an updating command to see an inconsistent snapshot: it can see the effects of concurrent updating commands on the same rows it is trying to update, but it does not see effects of those commands on other rows in the database. This behavior makes `READ COMMITTED` mode unsuitable for commands that involve complex search conditions; however, it is just right for simpler cases. For example, consider updating bank balances with transactions like:

```
BEGIN;
UPDATE accounts SET balance = balance + 100.00 WHERE acctnum =
12345;
UPDATE accounts SET balance = balance - 100.00 WHERE acctnum =
7534;
COMMIT;
```

If two such transactions concurrently try to change the balance of account `12345`, we clearly want the second transaction to start with the updated version of the account's row. Because each command is affecting only a predetermined row, letting it access the updated version of the row does not create any troublesome inconsistency.

More complex usage may produce undesirable results in `READ COMMITTED` mode. For example, consider a `DELETE` command operating on data that is being both added and removed from its restriction criteria by another command; assume `website` is a two-row table with `website.hits` equaling `9` and `10`:

```
BEGIN;
UPDATE website SET hits = hits + 1;
-- run from another session:  DELETE FROM website WHERE hits =
10;
COMMIT;
```

The `DELETE` will have no effect even though there is a `website.hits = 10` row before and after the `UPDATE`. This occurs because the pre-update row value `9` is skipped, and when the `UPDATE` completes and `DELETE` obtains a lock, the new row value is no longer `10` but `11`, which no longer matches the criteria.

Because `READ COMMITTED` mode starts each command with a new snapshot that includes all transactions committed up to that instant, subsequent commands in the same transaction will see the effects of the committed concurrent transaction in any case. The point at issue above is whether or not a single command sees an absolutely consistent view of the database.

The partial transaction isolation provided by `READ COMMITTED` mode is adequate for many applications, and this mode is fast and simple to use; however, it is not sufficient for all cases. Applications that do complex queries and updates might require a more rigorously consistent view of the database than `READ COMMITTED` mode provides.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Repeatable Read Isolation Level

The `REPEATABLE READ` isolation level only sees data committed before the transaction began; it never sees either uncommitted data or changes committed during transaction execution by concurrent transactions. (However, the query does see the effects of previous updates executed within its own transaction, even though they are not yet committed.) This is a stronger guarantee than is required by the SQL standard for this isolation level, and prevents all of the phenomena described in the table above. As mentioned previously, this is specifically allowed by the standard, which only describes the minimum protections each isolation level must provide.

The `REPEATABLE READ` isolation level is different from `READ COMMITTED` in that a query in a `REPEATABLE READ` transaction sees a snapshot as of the start of the first non-transaction-control statement in the transaction, not as of the start of the current statement within the transaction. Successive `SELECT` commands within a single transaction see the same data; they do not see changes made by other transactions that committed after their own transaction started.

Applications using this level must be prepared to retry transactions due to serialization failures.

`UPDATE`, `DELETE`, `SELECT FOR UPDATE`, and `SELECT FOR SHARE` commands behave the same as `SELECT` in terms of searching for target rows: they will only find target rows that were committed as of the transaction start time. However, such a target row might have already been updated (or deleted or locked) by another concurrent transaction by the time it is found. In this case, the `REPEATABLE READ` transaction will wait for the first updating transaction to commit or roll back (if it is still in progress). If the first updater rolls back, then its effects are negated and the `REPEATABLE READ` can proceed with updating the originally found row. But if the first updater commits (and actually updated or deleted the row, not just locked it), then WarehousePG rolls back the `REPEATABLE READ` transaction with the message:

```
ERROR:  could not serialize access due to concurrent update
```

because a `REPEATABLE READ` transaction cannot modify or lock rows changed by other transactions after the `REPEATABLE READ` transaction began.

When an application receives this error message, it should abort the current transaction and retry the whole transaction from the beginning. The second time through, the transaction will see the previously-committed change as part of its initial view of the database, so there is no logical conflict in using the new version of the row as the starting point for the new transaction's update.

Note that you may need to retry only updating transactions; read-only transactions will never have serialization conflicts.

The `REPEATABLE READ` mode provides a rigorous guarantee that each transaction sees a completely stable view of the database. However, this view will not necessarily always be consistent with some serial (one at a time) execution of concurrent transactions of the same level. For example, even a read-only transaction at this level may see a control record updated to show that a batch has been completed but not see one of the detail records which is logically part of the batch because it read an earlier revision of the control record. Attempts to enforce business rules by transactions running at this isolation level are not likely to work correctly without careful use of explicit locks to block conflicting transactions.

Serializable Isolation Level

The `SERIALIZABLE` level, which WarehousePG does not fully support, guarantees that a set of transactions run concurrently produces the same result as if the transactions ran sequentially one after the other. If `SERIALIZABLE` is specified, WarehousePG falls back to `REPEATABLE READ`. The MVCC Snapshot Isolation (SI) model prevents dirty reads, non-repeatable reads, and phantom reads without expensive locking, but there are other interactions that can occur between some `SERIALIZABLE` transactions in WarehousePG that prevent them from being truly serializable. These anomalies can often be attributed to the fact that WarehousePG does not perform *predicate locking*, which means that a write in one transaction can affect the result of a previous read in another concurrent transaction.

About Setting the Transaction Isolation Level

The default transaction isolation level for WarehousePG is specified by the default_transaction_isolation server configuration parameter, and is initially `READ COMMITTED`.

When you set `default_transaction_isolation` in a session, you specify the default transaction isolation level for all transactions in the session.

To set the isolation level for the current transaction, you can use the SET TRANSACTION SQL command. Be sure to set the isolation level before any `SELECT`, `INSERT`, `DELETE`, `UPDATE`, or `COPY` statement:

```
BEGIN;
SET TRANSACTION ISOLATION LEVEL REPEATABLE READ;
...
COMMIT;
```

You can also specify the isolation mode in a `BEGIN` statement:

```
BEGIN TRANSACTION ISOLATION LEVEL REPEATABLE READ;
```

Removing Dead Rows from Tables

Updating or deleting a row leaves an expired version of the row in the table. When an expired row is no longer referenced by any active transactions, it can be removed and the space it occupied can be reused. The `VACUUM` command marks the space used by expired rows for reuse.

When expired rows accumulate in a table, the disk files must be extended to accommodate new rows. Performance degrades due to the increased disk I/O required to run queries. This condition is called *bloat* and it should be managed by regularly vacuuming tables.

The `VACUUM` command (without `FULL`) can run concurrently with other queries. It marks the space previously used by the expired rows as free, and updates the free space map. When WarehousePG later needs space for new rows, it first consults the table's free space map to find pages with available space. If none are found, new pages will be appended to the file.

`VACUUM` (without `FULL`) does not consolidate pages or reduce the size of the table on disk. The space it recovers is only available through the free space map. To prevent disk files from growing, it is important to run `VACUUM` often enough. The frequency of required `VACUUM` runs depends on the frequency of updates and deletes in the table (inserts only ever add new rows). Heavily updated tables might require several `VACUUM` runs per day, to ensure that the available free space can be found through the free space map. It is also important to run `VACUUM` after running a transaction that updates or deletes a large number of rows.

The `VACUUM FULL` command rewrites the table without expired rows, reducing the table to its minimum size. Every page in the table is checked, and visible rows are moved up into pages which are not yet fully packed. Empty pages are discarded. The table is locked until `VACUUM FULL` completes. This is very expensive compared to the regular `VACUUM` command, and can be avoided or postponed by vacuuming regularly. It is best to run `VACUUM FULL` during a maintenance period. An alternative to `VACUUM FULL` is to recreate the table with a `CREATE TABLE AS` statement and then drop the old table.

You can run `VACUUM VERBOSE tablename` to get a report, by segment, of the number of dead rows removed, the number of pages affected, and the number of pages with usable free space.

Query the `pg_class` system table to find out how many pages a table is using across all segments. Be sure to `ANALYZE` the table first to get accurate data.

```
SELECT relname, relpages, reltuples FROM pg_class WHERE relname='<tablename>';
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Another useful tool is the `gp_bloat_diag` view in the `gp_toolkit` schema, which identifies bloat in tables by comparing the actual number of pages used by a table to the expected number. See "The gp_toolkit Administrative Schema" in the *WarehousePG Reference Guide* for more about `gp_bloat_diag`.

- **Example of Managing Transaction IDs**

Parent topic: WarehousePG Concepts

4.1.3.1 Example of Managing Transaction IDs

For WarehousePG, the transaction ID (XID) value an incrementing 32-bit (2^{32}) value. The maximum unsigned 32-bit value is 4,294,967,295, or about four billion. The XID values restart at 3 after the maximum is reached. WarehousePG handles the limit of XID values with two features:

- Calculations on XID values using modulo-2^{32} arithmetic that allow WarehousePG to reuse XID values. The modulo calculations determine the order of transactions, whether one transaction has occurred before or after another, based on the XID.

  Every XID value can have up to two billion (2^{31}) XID values that are considered previous transactions and two billion (231 -1) XID values that are considered newer transactions. The XID values can be considered a circular set of values with no endpoint similar to a 24 hour clock.

  Using the WarehousePG modulo calculations, as long as two XIDs are within 2^{31} transactions of each other, comparing them yields the correct result.

- A frozen XID value that WarehousePG uses as the XID for current (visible) data rows. Setting a row's XID to the frozen XID performs two functions.

  - When WarehousePG compares XIDs using the modulo calculations, the frozen XID is always smaller, earlier, when compared to any other XID. If a row's XID is not set to the frozen XID and 2^{31} new transactions are run, the row appears to be run in the future based on the modulo calculation.
  - When the row's XID is set to the frozen XID, the original XID can be used, without duplicating the XID. This keeps the number of data rows on disk with assigned XIDs below (2^{32}).

> **Note** WarehousePG assigns XID values only to transactions that involve DDL or DML operations, which are typically the only transactions that require an XID.

Parent topic: About Concurrency Control in WarehousePG

Simple MVCC Example

This is a simple example of the concepts of a MVCC database and how it manages data and transactions with transaction IDs. This simple MVCC database example consists of a single table:

- The table is a simple table with 2 columns and 4 rows of data.
- The valid transaction ID (XID) values are from 0 up to 9, after 9 the XID restarts at 0.
- The frozen XID is -2. This is different than the WarehousePG frozen XID.
- Transactions are performed on a single row.
- Only insert and update operations are performed.
- All updated rows remain on disk, no operations are performed to remove obsolete rows.

The example only updates the amount values. No other changes to the table.

The example shows these concepts.

- How transaction IDs are used to manage multiple, simultaneous transactions on a table.
- How transaction IDs are managed with the frozen XID
- How the modulo calculation determines the order of transactions based on transaction IDs

Managing Simultaneous Transactions

This table is the initial table data on disk with no updates. The table contains two database columns for transaction IDs, `xmin` (transaction that created the row) and `xmax` (transaction that updated the row). In the table, changes are added, in order, to the bottom of the table.

item	amount	xmin	xmax
widget	100	0	null
giblet	200	1	null
sprocket	300	2	null
gizmo	400	3	null

The next table shows the table data on disk after some updates on the amount values have been performed.

- xid = 4: `update tbl set amount=208 where item = 'widget'`
- xid = 5: `update tbl set amount=133 where item = 'sprocket'`
- xid = 6: `update tbl set amount=16 where item = 'widget'`

In the next table, the bold items are the current rows for the table. The other rows are obsolete rows, table data that on disk but is no longer current. Using the xmax value, you can determine the current rows of the table by selecting the rows with `null` value. WarehousePG uses a slightly different method to determine current table rows.

item	amount	xmin	xmax
widget	100	0	4
giblet	**200**	1	**null**
sprocket	300	2	5
gizmo	**400**	3	**null**
widget	208	4	6
sprocket	**133**	5	**null**
widget	**16**	6	**null**

The simple MVCC database works with XID values to determine the state of the table. For example, both these independent transactions run concurrently.

- `UPDATE` command changes the sprocket amount value to `133` (xmin value `5`)
- `SELECT` command returns the value of sprocket.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

During the `UPDATE` transaction, the database returns the value of sprocket `300`, until the `UPDATE` transaction completes.

Managing XIDs and the Frozen XID

For this simple example, the database is close to running out of available XID values. When WarehousePG is close to running out of available XID values, WarehousePG takes these actions.

- WarehousePG issues a warning stating that the database is running out of XID values.

  ```
  WARNING: database "<database_name>" must be vacuumed within <number_of_transactions> transactions
  ```

- Before the last XID is assigned, WarehousePG stops accepting transactions to prevent assigning an XID value twice and issues this message.

  ```
  FATAL: database is not accepting commands to avoid wraparound data loss in database "<database_name>"
  ```

To manage transaction IDs and table data that is stored on disk, WarehousePG provides the `VACUUM` command.

- A `VACUUM` operation frees up XID values so that a table can have more than 10 rows by changing the xmin values to the frozen XID.
- A `VACUUM` operation manages obsolete or deleted table rows on disk. This database's `VACUUM` command changes the XID values `obsolete` to indicate obsolete rows. A WarehousePG `VACUUM` operation, without the `FULL` option, deletes the data opportunistically to remove rows on disk with minimal impact to performance and data availability.

For the example table, a `VACUUM` operation has been performed on the table. The command updated table data on disk. This version of the `VACUUM` command performs slightly differently than the WarehousePG command, but the concepts are the same.

- For the widget and sprocket rows on disk that are no longer current, the rows have been marked as `obsolete`.

- For the giblet and gizmo rows that are current, the xmin has been changed to the frozen XID.

  The values are still current table values (the row's xmax value is `null`). However, the table row is visible to all transactions because the xmin value is frozen XID value that is older than all other XID values when modulo calculations are performed.

After the `VACUUM` operation, the XID values `0`, `1`, `2`, and `3` available for use.

item	amount	xmin	xmax
widget	100	obsolete	obsolete
giblet	**200**	-2	**null**
sprocket	300	obsolete	obsolete
gizmo	**400**	-2	**null**
widget	208	4	6
sprocket	**133**	5	**null**
widget	**16**	6	**null**

When a row disk with the xmin value of `-2` is updated, the xmax value is replaced with the transaction XID as usual, and the row on disk is considered obsolete after any concurrent transactions that access the row have completed.

Obsolete rows can be deleted from disk. For WarehousePG, the `VACUUM` command, with `FULL` option, does more extensive processing to reclaim disk space.

Example of XID Modulo Calculations

The next table shows the table data on disk after more `UPDATE` transactions. The XID values have rolled over and start over at `0`. No additional `VACUUM` operations have been performed.

item	amount	xmin	xmax
widget	100	obsolete	obsolete
giblet	200	-2	1
sprocket	300	obsolete	obsolete
gizmo	400	-2	9
widget	208	4	6
sprocket	**133**	5	**null**
widget	16	6	7
widget	**222**	7	**null**
giblet	233	8	0
gizmo	**18**	9	**null**
giblet	88	0	1
giblet	**44**	1	**null**

When performing the modulo calculations that compare XIDs, WarehousePG, considers the XIDs of the rows and the current range of available XIDs to determine if XID wrapping has occurred between row XIDs.

For the example table XID wrapping has occurred. The XID `1` for giblet row is a later transaction than the XID `7` for widget row based on the modulo calculations for XID values even though the XID value `7` is larger than `1`.

For the widget and sprocket rows, XID wrapping has not occurred and XID `7` is a later transaction than XID `5`.

4.1.4 About Parallel Data Loading

This topic provides a short introduction to WarehousePG data loading features.

In a large scale, multi-terabyte data warehouse, large amounts of data must be loaded within a relatively small maintenance window. WarehousePG supports fast, parallel data loading with its external tables feature. Administrators can also load external tables in single row error isolation mode to filter bad rows into a separate error log while continuing to load properly formatted rows. Administrators can specify an error threshold for a load operation to control how many improperly formatted rows cause WarehousePG to cancel the load operation.

By using external tables in conjunction with WarehousePG's parallel file server (`gpfdist`), administrators can achieve maximum parallelism and load bandwidth from their WarehousePG cluster.

Another WarehousePG utility, `gpload` , runs a load task that you specify in a YAML-formatted control file. You describe the source data locations, format, transformations required, participating hosts, database destinations, and other particulars in the control file and `gpload` runs the load. This allows you to describe a complex task and run it in a controlled, repeatable fashion.

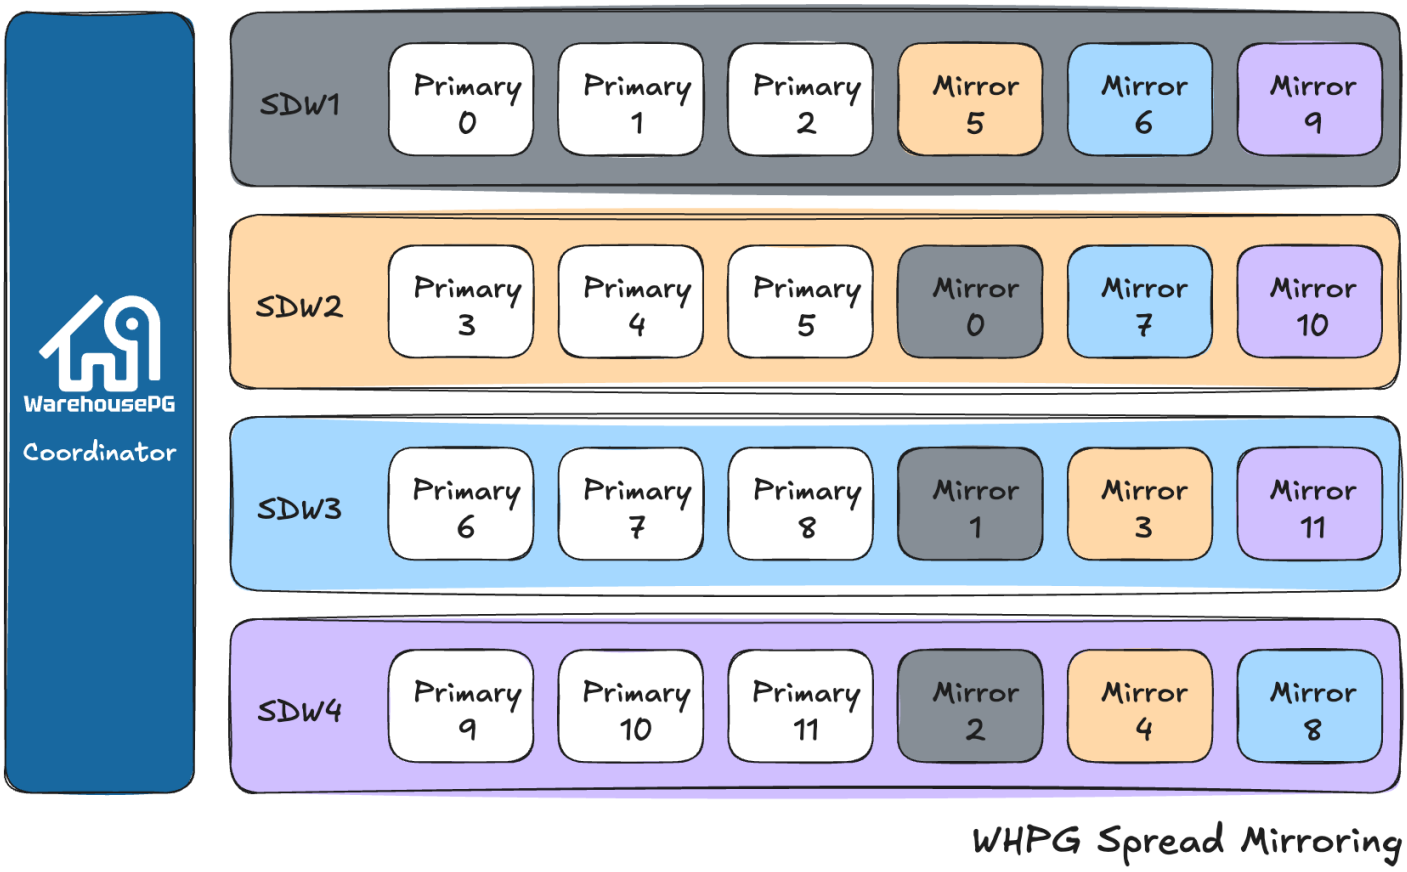
4.1.5 About Redundancy and Failover in WarehousePG

This topic provides a high-level overview of WarehousePG high availability features.

You can deploy WarehousePG without a single point of failure by mirroring components. The following sections describe the strategies for mirroring the main components of a WarehousePG cluster. For a more detailed overview of WarehousePG high availability features, see Overview of WarehousePG High Availability.

> **Important** When data loss is not acceptable for a WarehousePG cluster, WarehousePG coordinator and segment mirroring is recommended. If mirroring is not enabled then WarehousePG stores only one copy of the data, so the underlying storage media provides the only guarantee for data availability and correctness in the event of a hardware failure.



About Segment Mirroring

When you deploy your WarehousePG cluster, you can configure *mirror* segment instances. Mirror segments allow database queries to fail over to a backup segment if the primary segment becomes unavailable. The mirror segment is kept current by a transaction log replication process, which synchronizes the data between the primary and mirror instances. Mirroring is strongly recommended for production systems and required for WarehousePG support.

As a best practice, the secondary (mirror) segment instance must always reside on a different host than its primary segment instance to protect against a single host failure. In virtualized environments, the secondary (mirror) segment must always reside on a different storage system than the primary. Mirror segments can be arranged over the remaining hosts in the cluster in configurations designed to maximize availability, or minimize the performance degradation when hosts or multiple primary segments fail.

Two standard mirroring configurations are available when you initialize or expand a WarehousePG cluster. The default configuration, called *group mirroring*, places all the mirrors for a host's primary segments on one other host in the cluster. The other standard configuration, *spread mirroring*, can be selected with a command-line option. Spread mirroring spreads each host's mirrors over the remaining hosts and requires that there are more hosts in the cluster than primary segments per host.

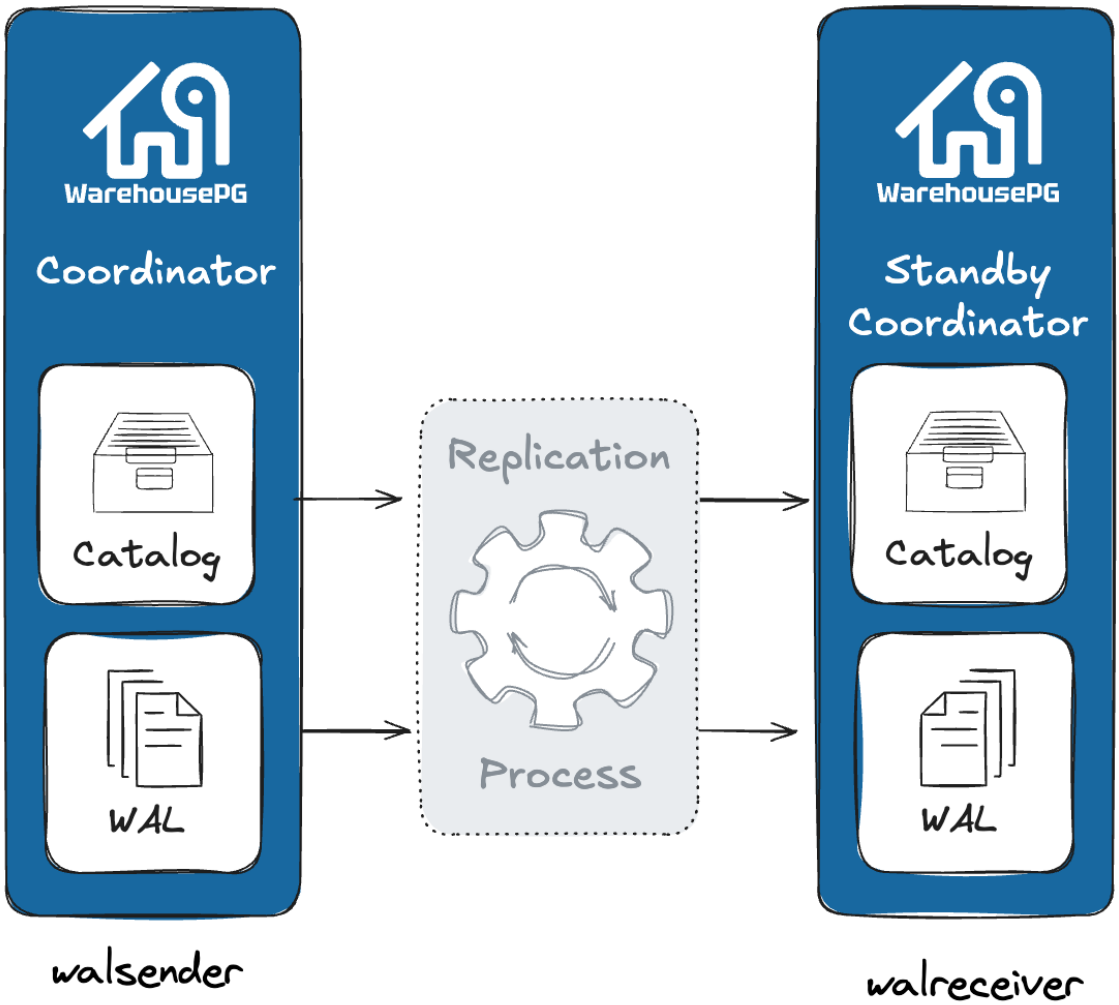
This figure shows how table data is distributed across segments when spread mirroring is configured.

Segment Failover and Recovery

When segment mirroring is enabled in a WarehousePG cluster, the system will automatically fail over to the *mirror segment* instance if a *primary segment* instance becomes unavailable. A WarehousePG cluster can remain operational if a segment instance or host goes down as long as all the data is available on the remaining active segment instances.

If the coordinator cannot connect to a segment instance, it marks that segment instance as down in the WarehousePG cluster catalog and brings up the mirror segment in its place. A failed segment instance will remain out of operation until an administrator takes steps to bring that segment back online. An administrator can recover a failed segment while the system is up and running. The recovery process copies over only the changes that were missed while the segment was out of operation.

If you do not have mirroring enabled, the system will automatically shut down if a segment instance becomes invalid. You must recover all failed segments before operations can continue.



Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

About Coordinator Mirroring

You can also optionally deploy a backup or mirror of the coordinator instance on a separate host from the coordinator host. The backup coordinator instance (the *standby coordinator*) serves as a *warm standby* in the event that the primary coordinator host becomes non-operational. The standby coordinator is kept current by a transaction log replication process, which synchronizes the data between the primary and standby coordinator.

If the primary coordinator fails, the log replication process stops, and the standby coordinator can be activated in its place. The switchover does not happen automatically, but must be triggered externally. Upon activation of the standby coordinator, the replicated logs are used to reconstruct the state of the coordinator host at the time of the last successfully committed transaction. The activated standby coordinator effectively becomes the WarehousePG coordinator, accepting client connections on the coordinator port (which must be set to the same port number on the coordinator host and the backup coordinator host).

Since the coordinator does not contain any user data, only the system catalog tables need to be synchronized between the primary and backup copies. When these tables are updated, changes are automatically copied over to the standby coordinator to ensure synchronization with the primary coordinator.

About Interconnect Redundancy

The *interconnect* refers to the inter-process communication between the segments and the network infrastructure on which this communication relies. You can achieve a highly available interconnect using by deploying dual Gigabit Ethernet switches on your network and redundant Gigabit connections to the WarehousePG host (coordinator and segment) servers. For performance reasons, 10-Gb Ethernet, or faster, is recommended.

Parent topic: WarehousePG Concepts

4.1.6 About Database Statistics in WarehousePG

An overview of statistics gathered by the ANALYZE command in WarehousePG.

Statistics are metadata that describe the data stored in the database. The query optimizer needs up-to-date statistics to choose the best execution plan for a query. For example, if a query joins two tables and one of them must be broadcast to all segments, the optimizer can choose the smaller of the two tables to minimize network traffic.

The statistics used by the optimizer are calculated and saved in the system catalog by the `ANALYZE` command. There are three ways to initiate an analyze operation:

- You can run the `ANALYZE` command directly.
- You can run the `analyzedb` management utility outside of the database, at the command line.
- An automatic analyze operation can be triggered when DML operations are performed on tables that have no statistics or when a DML operation modifies a number of rows greater than a specified threshold.

These methods are described in the following sections. The `VACUUM ANALYZE` command is another way to initiate an analyze operation, but its use is discouraged because vacuum and analyze are different operations with different purposes.

Calculating statistics consumes time and resources, so WarehousePG produces estimates by calculating statistics on samples of large tables. In most cases, the default settings provide the information needed to generate correct execution plans for queries. If the statistics produced are not producing optimal query execution plans, the administrator can tune configuration parameters to produce more accurate statistics by increasing the sample size or the granularity of statistics saved in the system catalog. Producing more accurate statistics has CPU and storage costs and may not produce better plans, so it is important to view explain plans and test query performance to ensure that the additional statistics-related costs result in better query performance.

Parent topic: WarehousePG Concepts

System Statistics

Table Size

The query planner seeks to minimize the disk I/O and network traffic required to run a query, using estimates of the number of rows that must be processed and the number of disk pages the query must access. The data from which these estimates are derived are the `pg_class` system table columns `reltuples` and `relpages`, which contain the number of rows and pages at the time a `VACUUM` or `ANALYZE` command was last run. As rows are added or deleted, the numbers become less accurate. However, an accurate count of disk pages is always available from the operating system, so as long as the ratio of `reltuples` to `relpages` does not change significantly, the optimizer can produce an estimate of the number of rows that is sufficiently accurate to choose the correct query execution plan.

When the `reltuples` column differs significantly from the row count returned by `SELECT COUNT(*)`, an analyze should be performed to update the statistics.

When a `REINDEX` command finishes recreating an index, the `relpages` and `reltuples` columns are set to zero. The `ANALYZE` command should be run on the base table to update these columns.

The pg_statistic System Table and pg_stats View

The `pg_statistic` system table holds the results of the last `ANALYZE` operation on each database table. There is a row for each column of every table. It has the following columns:

starelid The object ID of the table or index the column belongs to.

staattnum The number of the described column, beginning with 1.

stainherit If true, the statistics include inheritance child columns, not just the values in the specified relation.

stanullfrac The fraction of the column's entries that are null.

stawidth The average stored width, in bytes, of non-null entries.

stadistinct A positive number is an estimate of the number of distinct values in the column; the number is not expected to vary with the number of rows. A negative value is the number of distinct values divided by the number of rows, that is, the ratio of rows with distinct values for the column, negated. This form is used when the number of distinct values increases with the number of rows. A unique column, for example, has an `n_distinct` value of -1.0. Columns with an average width greater than 1024 are considered unique.

stakind*N* A code number indicating the kind of statistics stored in the *N*th slot of the `pg_statistic` row.

staop*N* An operator used to derive the statistics stored in the *N*th slot. For example, a histogram slot would show the < operator that defines the sort order of the data.

stanumbers*N* float4 array containing numerical statistics of the appropriate kind for the *N*th slot, or `NULL` if the slot kind does not involve numerical values.

stavalues*N* Column data values of the appropriate kind for the *N*th slot, or `NULL` if the slot kind does not store any data values. Each array's element values are actually of the specific column's data type, so there is no way to define these columns' types more specifically than *anyarray*.

The statistics collected for a column vary for different data types, so the `pg_statistic` table stores statistics that are appropriate for the data type in four *slots*, consisting of four columns per slot. For example, the first slot, which normally contains the most common values for a column, consists of the columns `stakind1`, `staop1`, `stanumbers1`, and `stavalues1`.

The `stakindN` columns each contain a numeric code to describe the type of statistics stored in their slot. The `stakind` code numbers from 1 to 99 are reserved for core PostgreSQL data types. WarehousePG uses code numbers 1, 2, 3, 4, 5, and 99. A value of 0 means the slot is unused. The following table describes the kinds of statistics stored for the three codes.

Table 1. Contents of pg_statistic "slots"

stakind Code	Description
1	*Most CommonValues (MCV) Slot* • `staop` contains the object ID of the "=" operator, used to decide whether values are the same or not. • `stavalues` contains an array of the *K* most common non-null values appearing in the column. • `stanumbers` contains the frequencies (fractions of total row count) of the values in the `stavalues` array. The values are ordered in decreasing frequency. Since the arrays are variable-size, *K* can be chosen by the statistics collector. Values must occur more than once to be added to the `stavalues` array; a unique column has no MCV slot.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

stakind Code	Description
2	*Histogram Slot* – describes the distribution of scalar data. • `staop` is the object ID of the "<" operator, which describes the sort ordering. • `stavalues` contains *M* (where *M*>=2) non-null values that divide the non-null column data values into *M*-1 bins of approximately equal population. The first `stavalues` item is the minimum value and the last is the maximum value. • `stanumbers` is not used and should be `NULL` . If a Most Common Values slot is also provided, then the histogram describes the data distribution after removing the values listed in the MCV array. (It is a *compressed histogram* in the technical parlance). This allows a more accurate representation of the distribution of a column with some very common values. In a column with only a few distinct values, it is possible that the MCV list describes the entire data population; in this case the histogram reduces to empty and should be omitted.
3	*Correlation Slot* – describes the correlation between the physical order of table tuples and the ordering of data values of this column. • `staop` is the object ID of the "<" operator. As with the histogram, more than one entry could theoretically appear. • `stavalues` is not used and should be `NULL` . • `stanumbers` contains a single entry, the correlation coefficient between the sequence of data values and the sequence of their actual tuple positions. The coefficient ranges from +1 to -1.
4	*Most Common Elements Slot* - is similar to a Most Common Values (MCV) Slot, except that it stores the most common non-null *elements* of the column values. This is useful when the column datatype is an array or some other type with identifiable elements (for instance, `tsvector`). • `staop` contains the equality operator appropriate to the element type. • `stavalues` contains the most common element values. • `stanumbers` contains common element frequencies. Frequencies are measured as the fraction of non-null rows the element value appears in, not the frequency of all rows. Also, the values are sorted into the element type's default order (to support binary search for a particular value). Since this puts the minimum and maximum frequencies at unpredictable spots in `stanumbers` , there are two extra members of `stanumbers` that hold copies of the minimum and maximum frequencies. Optionally, there can be a third extra member that holds the frequency of null elements (the frequency is expressed in the same terms: the fraction of non-null rows that contain at least one null element). If this member is omitted, the column is presumed to contain no `NULL` elements. Note: For `tsvector` columns, the `stavalues` elements are of type `text` , even though their representation within `tsvector` is not exactly `text` .
5	*Distinct Elements Count Histogram Slot* - describes the distribution of the number of distinct element values present in each row of an array-type column. Only non-null rows are considered, and only non-null elements. • `staop` contains the equality operator appropriate to the element type. • `stavalues` is not used and should be `NULL` . • `stanumbers` contains information about distinct elements. The last member of `stanumbers` is the average count of distinct element values over all non-null rows. The preceding *M* (where *M* >=2) members form a histogram that divides the population of distinct-elements counts into *M*-1 bins of approximately equal population. The first of these is the minimum observed count, and the last the maximum.
99	*Hyperloglog Slot* - for leaf partitions of a partitioned table, stores the `hyperloglog_counter` created for the sampled data. The `hyperloglog_counter` data structure is converted into a `bytea` and stored in a `stavalues5` slot of the `pg_statistic` catalog table.

The `pg_stats` view presents the contents of `pg_statistic` in a friendlier format. The `pg_stats` view has the following columns:

schemaname The name of the schema containing the table.

tablename The name of the table.

attname The name of the column this row describes.

inherited If true, the statistics include inheritance child columns.

null_frac The fraction of column entries that are null.

avg_width The average storage width in bytes of the column's entries, calculated as `avg(pg_column_size(column_name))` .

n_distinct A positive number is an estimate of the number of distinct values in the column; the number is not expected to vary with the number of rows. A negative value is the number of distinct values divided by the number of rows, that is, the ratio of rows with distinct values for the column, negated. This form is used when the number of distinct values increases with the number of rows. A unique column, for example, has an `n_distinct` value of -1.0. Columns with an average width greater than 1024 are considered unique.

most_common_vals An array containing the most common values in the column, or null if no values seem to be more common. If the `n_distinct` column is -1, `most_common_vals` is null. The length of the array is the lesser of the number of actual distinct column values or the value of the `default_statistics_target` configuration parameter. The number of values can be overridden for a column using `ALTER TABLE table SET COLUMN column SET STATISTICS N` .

most_common_freqs An array containing the frequencies of the values in the `most_common_vals` array. This is the number of occurrences of the value divided by the total number of rows. The array is the same length as the `most_common_vals` array. It is null if `most_common_vals` is null.

histogram_bounds An array of values that divide the column values into groups of approximately the same size. A histogram can be defined only if there is a `max()` aggregate function for the column. The number of groups in the histogram is the same as the `most_common_vals` array size.

correlation WarehousePG computes correlation statistics for both heap and AO/AOCO tables, but the Postgres-based planner uses these statistics only for heap tables.

most_common_elems An array that contains the most common element values.

most_common_elem_freqs An array that contains common element frequencies.

elem_count_histogram An array that describes the distribution of the number of distinct element values present in each row of an array-type column.

Newly created tables and indexes have no statistics. You can check for tables with missing statistics using the `gp_stats_missing` view, which is in the `gp_toolkit` schema:

```
SELECT * from gp_toolkit.gp_stats_missing;
```

Sampling

When calculating statistics for large tables, WarehousePG creates a smaller table by sampling the base table. If the table is partitioned, samples are taken from all partitions.

Updating Statistics

Running `ANALYZE` with no arguments updates statistics for all tables in the database. This could take a very long time, so it is better to analyze tables selectively after data has changed. You can also analyze a subset of the columns in a table, for example columns used in joins, `WHERE` clauses, `SORT` clauses, `GROUP BY` clauses, or `HAVING` clauses.

Analyzing a severely bloated table can generate poor statistics if the sample contains empty pages, so it is good practice to vacuum a bloated table before analyzing it.

See the *SQL Command Reference* in the *WarehousePG Reference Guide* for details of running the `ANALYZE` command.

Refer to the *WarehousePG Management Utility Reference* for details of running the `analyzedb` command.

Analyzing Partitioned Tables

When the `ANALYZE` command is run on a partitioned table, it analyzes each leaf partition, one at a time. You can run `ANALYZE` on just new or changed partitioned tables to avoid analyzing partitions that have not changed.

The `analyzedb` command-line utility skips unchanged partitions automatically. It also runs concurrent sessions so it can analyze several partitions concurrently. It runs five sessions by default, but the number of sessions can be set from 1 to 10 with the `-p` command-line option. Each time `analyzedb` runs, it saves state information for append-optimized tables and partitions in the `db_analyze` directory in the coordinator data directory. The next time it runs, `analyzedb` compares the current state of each table with the saved state and skips analyzing a table or partition if it is unchanged. Heap tables are always analyzed.

If GPORCA is enabled (the default), you also need to run `ANALYZE` or `ANALYZE ROOTPARTITION` on the root partitioned table (not a leaf partition) to refresh the root partition statistics. GPORCA requires statistics at the root level for partitioned tables. The Postgres-based planner does not use these statistics.

The time to analyze a partitioned table is similar to the time to analyze a non-partitioned table with the same data. When all the leaf partitions have statistics, performing `ANALYZE ROOTPARTITION` to generate root partition statistics should be quick (a few seconds depending on the number of partitions and table columns). If some of the leaf partitions do not have statistics, then all the table data is sampled to generate root partition statistics. Sampling table data takes longer and results in lower quality root partition statistics.

The WarehousePG server configuration parameter optimizer_analyze_root_partition affects when statistics are collected on the root partitioned table. If the parameter is `on` (the default), the `ROOTPARTITION` keyword is not required to collect statistics on the root partition when you run `ANALYZE`. Root partition statistics are collected when you run `ANALYZE` on the root partition, or when you run `ANALYZE` on a leaf partition of the partitioned table and the other leaf partitions have statistics. If the parameter is `off`, you must run `ANALYZE ROOTPARTITION` to collect root partition statistics.

If you do not intend to run queries on partitioned tables with GPORCA (setting the server configuration parameter optimizer to `off`), you can also set the server configuration parameter `optimizer_analyze_root_partition` to `off` to limit when `ANALYZE` updates the root partition statistics.

Configuring Statistics

There are several options for configuring WarehousePG statistics collection.

Statistics Target

The statistics target is the size of the `most_common_vals`, `most_common_freqs`, and `histogram_bounds` arrays for an individual column. By default, the target is 25. The default target can be changed by setting a server configuration parameter and the target can be set for any column using the `ALTER TABLE` command. Larger values increase the time needed to do `ANALYZE`, but may improve the quality of the Postgres-based planner estimates.

Set the system default statistics target to a different value by setting the `default_statistics_target` server configuration parameter. The default value is usually sufficient, and you should only raise or lower it if your tests demonstrate that query plans improve with the new target. For example, to raise the default statistics target from 100 to 150 you can use the `gpconfig` utility:

```
gpconfig -c default_statistics_target -v 150
```

The statistics target for individual columns can be set with the `ALTER TABLE` command. For example, some queries can be improved by increasing the target for certain columns, especially columns that have irregular distributions. You can set the target to zero for columns that never contribute to query optimization. When the target is 0, `ANALYZE` ignores the column. For example, the following `ALTER TABLE` command sets the statistics target for the `notes` column in the `emp` table to zero:

```
ALTER TABLE emp ALTER COLUMN notes SET STATISTICS 0;
```

The statistics target can be set in the range 0 to 1000, or set it to -1 to revert to using the system default statistics target.

Setting the statistics target on a parent partitioned table affects the child partitions. If you set statistics to 0 on some columns on the parent table, the statistics for the same columns are set to 0 for all children partitions. However, if you later add or exchange another child partition, the new child partition will use either the default statistics target or, in the case of an exchange, the previous statistics target. Therefore, if you add or exchange child partitions, you should set the statistics targets on the new child table.

Automatic Statistics Collection

WarehousePG can be set to automatically run `ANALYZE` on a table that either has no statistics or has changed significantly when certain operations are performed on the table. For partitioned tables, automatic statistics collection is only triggered when the operation is run directly on a leaf table, and then only the leaf table is analyzed.

Automatic statistics collection is governed by a server configuration parameter, and has three modes:

- `none` deactivates automatic statistics collection.
- `on_no_stats` triggers an analyze operation for a table with no existing statistics when any of the commands `CREATE TABLE AS SELECT`, `INSERT`, or `COPY` are run on the table by the table owner.
- `on_change` triggers an analyze operation when any of the commands `CREATE TABLE AS SELECT`, `UPDATE`, `DELETE`, `INSERT`, or `COPY` are run on the table by the table owner, and the number of rows affected exceeds the threshold defined by the `gp_autostats_on_change_threshold` configuration parameter.

The automatic statistics collection mode is set separately for commands that occur within a procedural language function and commands that run outside of a function:

- The `gp_autostats_mode` configuration parameter controls automatic statistics collection behavior outside of functions and is set to `on_no_stats` by default.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

- The `gp_autostats_mode_in_functions` parameter controls the behavior when table operations are performed within a procedural language function and is set to `none` by default.

With the `on_change` mode, `ANALYZE` is triggered only if the number of rows affected exceeds the threshold defined by the `gp_autostats_on_change_threshold` configuration parameter. The default value for this parameter is a very high value, 2147483647, which effectively deactivates automatic statistics collection; you must set the threshold to a lower number to enable it. The `on_change` mode could trigger large, unexpected analyze operations that could disrupt the system, so it is not recommended to set it globally. It could be useful in a session, for example to automatically analyze a table following a load.

Setting the `gp_autostats_allow_nonowner` server configuration parameter to `true` also instructs WarehousePG to trigger automatic statistics collection on a table when:

- `gp_autostats_mode=on_change` and the table is modified by a non-owner.
- `gp_autostats_mode=on_no_stats` and the first user to `INSERT` or `COPY` into the table is a non-owner.

To deactivate automatic statistics collection outside of functions, set the `gp_autostats_mode` parameter to `none`:

```
gpconfig -c gp_autostats_mode -v none
```

To enable automatic statistics collection in functions for tables that have no statistics, change `gp_autostats_mode_in_functions` to `on_no_stats`:

```
gpconfig -c gp_autostats_mode_in_functions -v on_no_stats
```

Set the `log_autostats` system configuration parameter to on if you want to log automatic statistics collection operations.

4.1.7 Introduction to WarehousePG

High-level overview of the WarehousePG cluster architecture.

WarehousePG stores and processes large amounts of data by distributing the load across several servers or *hosts*. A logical database in WarehousePG is an *array* of individual PostgreSQL databases working together to present a single database image. The *coordinator* is the entry point to the WarehousePG cluster. It is the database instance to which users connect and submit SQL statements. The coordinator coordinates the workload across the other database instances in the system, called *segments*, which handle data processing and storage. The segments communicate with each other and the coordinator over the *interconnect*, the networking layer of WarehousePG.

WarehousePG Architecture

WarehousePG is a software-only solution; the hardware and database software are not coupled. WarehousePG runs on a variety of commodity server platforms from WarehousePG-certified hardware vendors. Performance depends on the hardware on which it is installed. Because the database is distributed across multiple machines in a WarehousePG cluster, proper selection and configuration of hardware is vital to achieving the best possible performance.

This chapter describes the major components of a WarehousePG cluster and the hardware considerations and concepts associated with each component: The WarehousePG Coordinator, The Segments and The Interconnect. Additionally, a system may have optional ETL Hosts for Data Loading.

- The WarehousePG Coordinator
- The Segments
- The Interconnect
- ETL Hosts for Data Loading

Parent topic: Installing and Upgrading WarehousePG

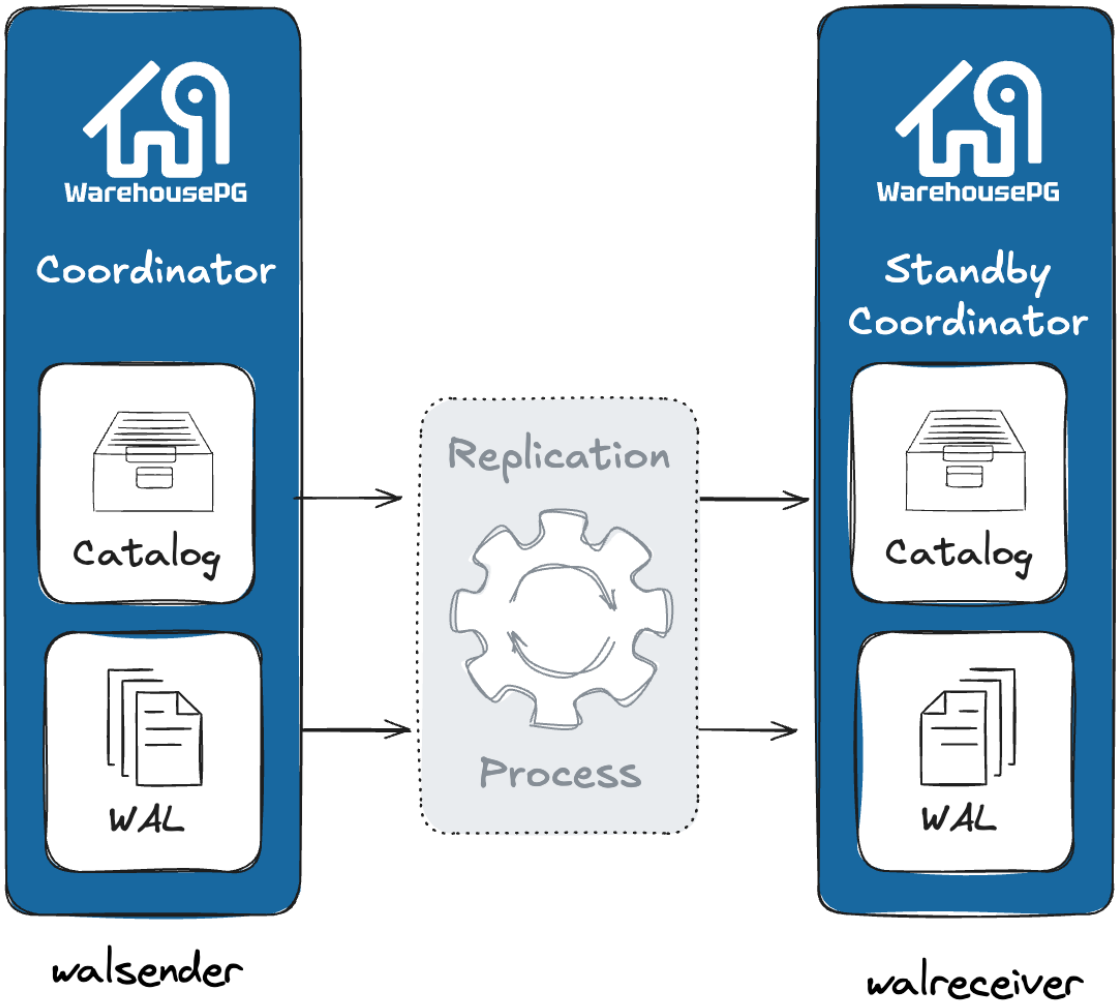
The WarehousePG Coordinator

The *coordinator* is the entry point to the WarehousePG cluster. It is the database server process that accepts client connections and processes the SQL commands that system users issue. Users connect to WarehousePG through the coordinator using a PostgreSQL-compatible client program such as `psql` or ODBC.

The coordinator maintains the *system catalog* (a set of system tables that contain metadata about the WarehousePG cluster itself), however the coordinator does not contain any user data. Data resides only on the *segments*. The coordinator authenticates client connections, processes incoming SQL commands, distributes the work load between segments, coordinates the results returned by each segment, and presents the final results to the client program.

Because the coordinator does not contain any user data, it has very little disk load. The coordinator needs a fast, dedicated CPU for data loading, connection handling, and query planning because extra space is often necessary for landing load files and backup files, especially in production environments. Customers may decide to also run ETL and reporting tools on the coordinator, which requires more disk space and processing power.



Parent topic: Introduction to WarehousePG

Coordinator Redundancy

You may optionally deploy a *backup* or *mirror* of the coordinator instance. A backup coordinator host serves as a *warm standby* if the primary coordinator host becomes nonoperational. You can deploy the standby coordinator on a designated redundant coordinator host or on one of the segment hosts.

The standby coordinator is kept up to date by a transaction log replication process, which runs on the standby coordinator host and synchronizes the data between the primary and standby coordinator hosts. If the primary coordinator fails, the log replication process shuts down, and an administrator can activate the standby coordinator in its place. When the standby coordinator is active, the replicated logs are used to reconstruct the state of the coordinator host at the time of the last successfully committed transaction.

Since the coordinator does not contain any user data, only the system catalog tables need to be synchronized between the primary and backup copies. When these tables are updated, changes automatically copy over to the standby coordinator so it is always synchronized with the primary.

The Segments

In WarehousePG, the *segments* are where data is stored and where most query processing occurs. User-defined tables and their indexes are distributed across the available segments in the WarehousePG cluster; each segment contains a distinct portion of the data. Segment instances are the database server processes that serve segments. Users do not interact directly with the segments in a WarehousePG cluster, but do so through the coordinator.

In the reference WarehousePG hardware configurations, the number of segment instances per segment host is determined by the number of effective CPUs or CPU core. For example, if your segment hosts have two dual-core processors, you may have two or four primary segments per host. If your segment hosts have three quad-core processors, you may have three, six or twelve segments per host. Performance testing will help decide the best number of segments for a chosen hardware platform.

Parent topic: Introduction to WarehousePG

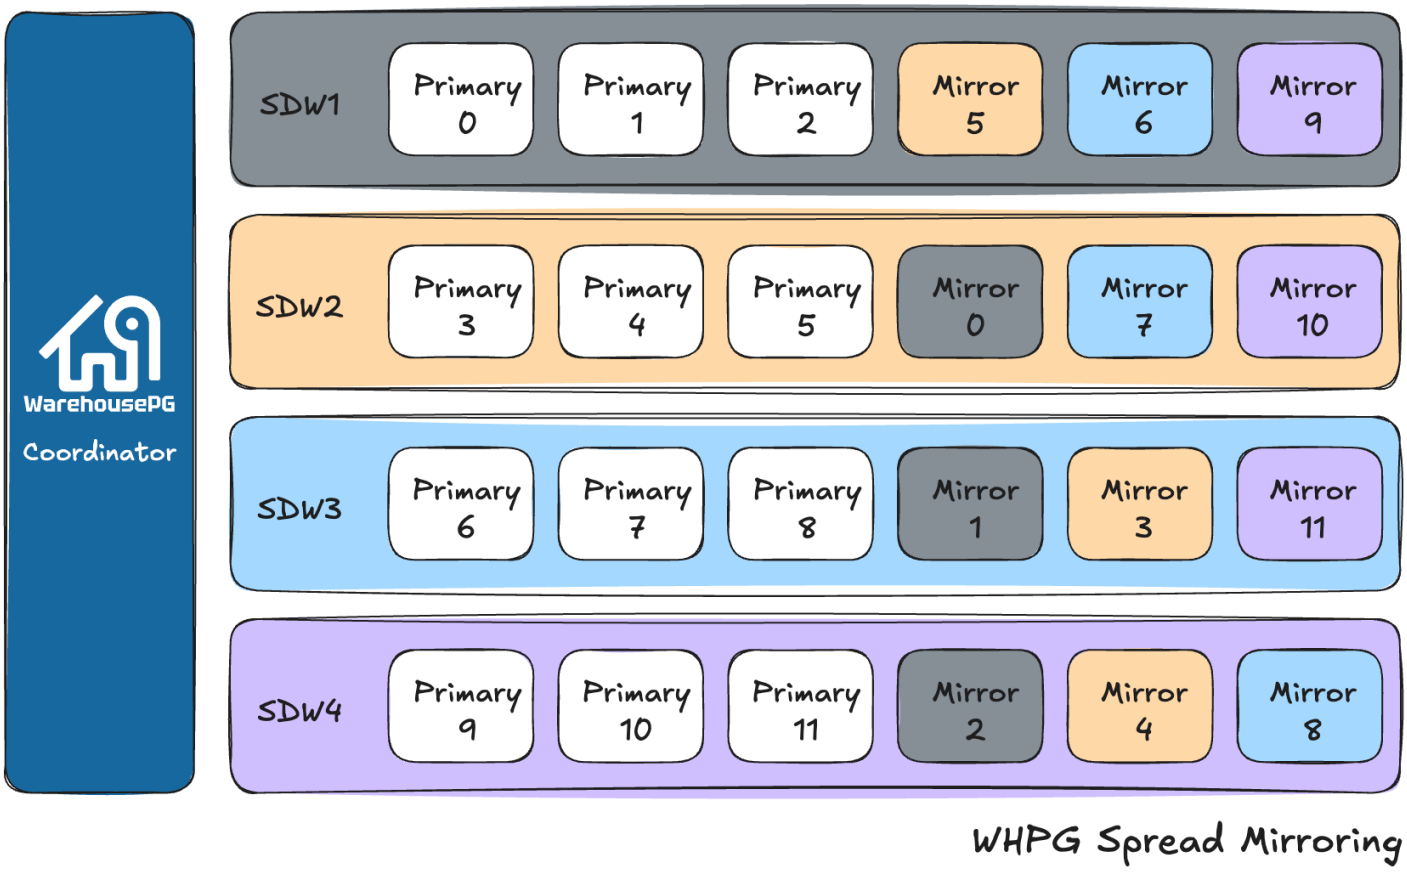
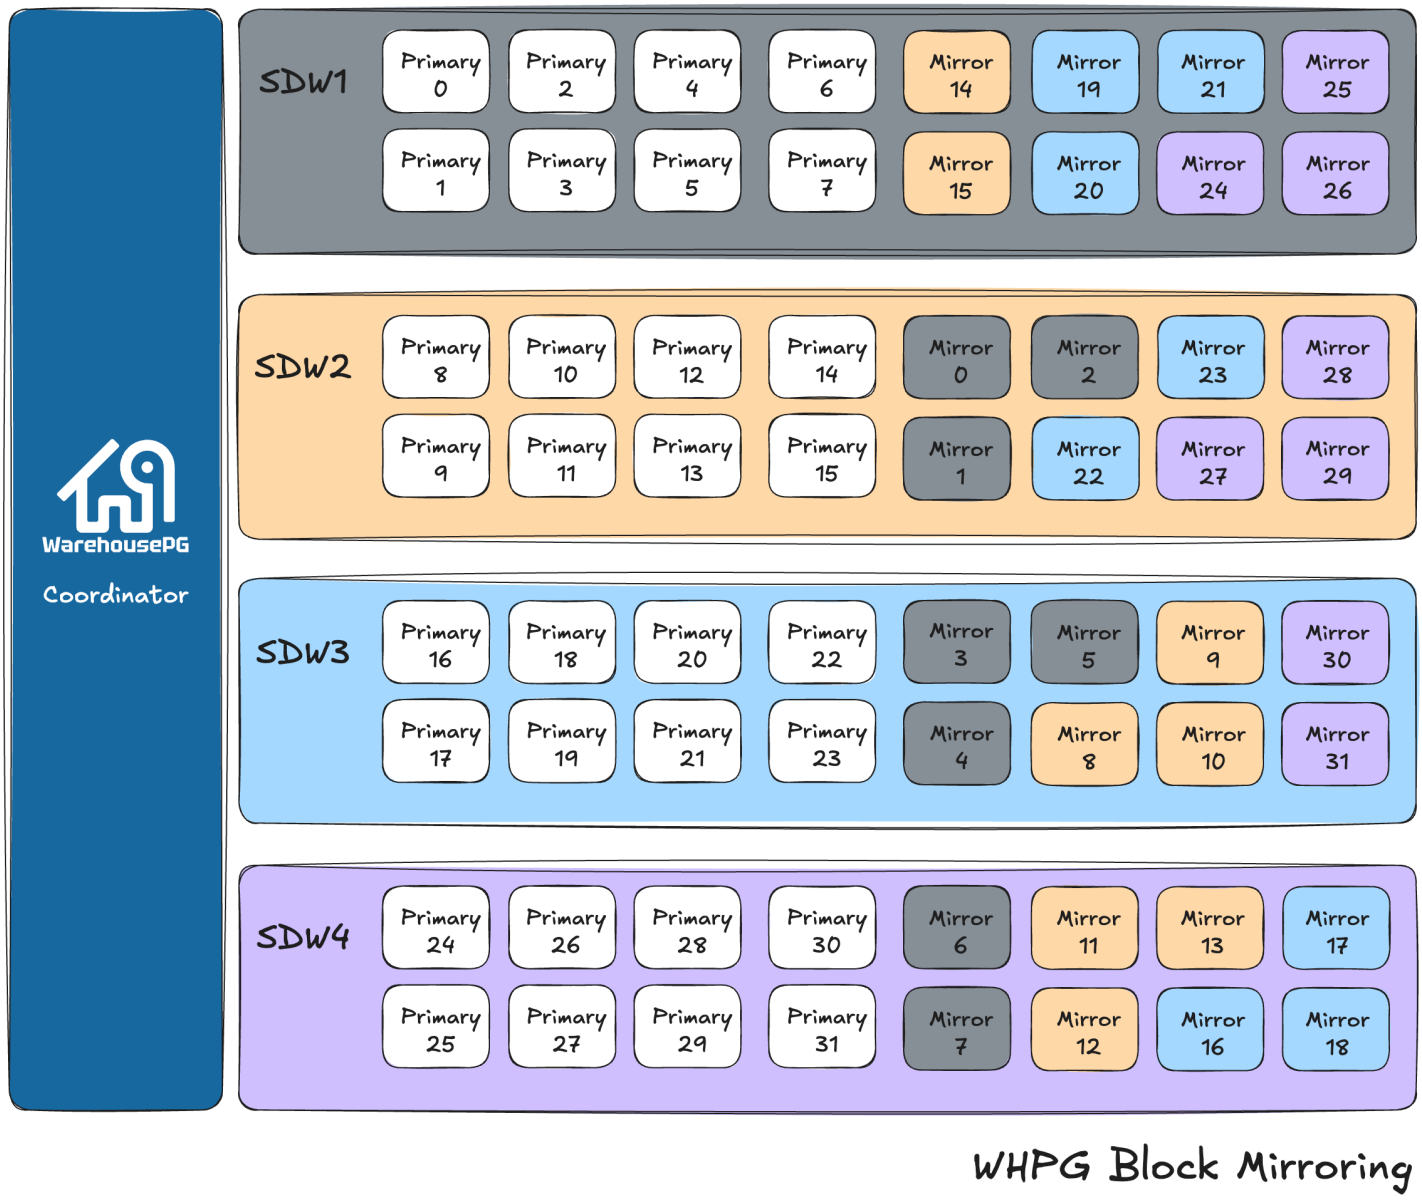
Segment Redundancy & Mirroring

When you deploy your WarehousePG cluster, you have the option to configure *mirror* segments. Mirror segments allow database queries to fail over to a backup segment if the primary segment becomes unavailable. Mirroring is a requirement for production WarehousePG clusters.



A mirror segment must always reside on a different host than its primary segment. Mirror segments can be arranged across the hosts in the system in one of two standard configurations, or in a custom configuration you design. The default configuration, called ***group*** mirroring, places the mirror segments for all primary segments on one other host. Another option, called ***spread*** mirroring, spreads mirrors for each host's primary segments over the remaining hosts. Spread mirroring requires that there be more hosts in the system than there are primary segments on the host. On hosts with multiple network interfaces, the primary and mirror segments are distributed equally among the interfaces. The following figure shows how table data is distributed across the segments when the default group mirroring option is configured.

Group Mirroring



Spread Mirroring

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Block Mirroring

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

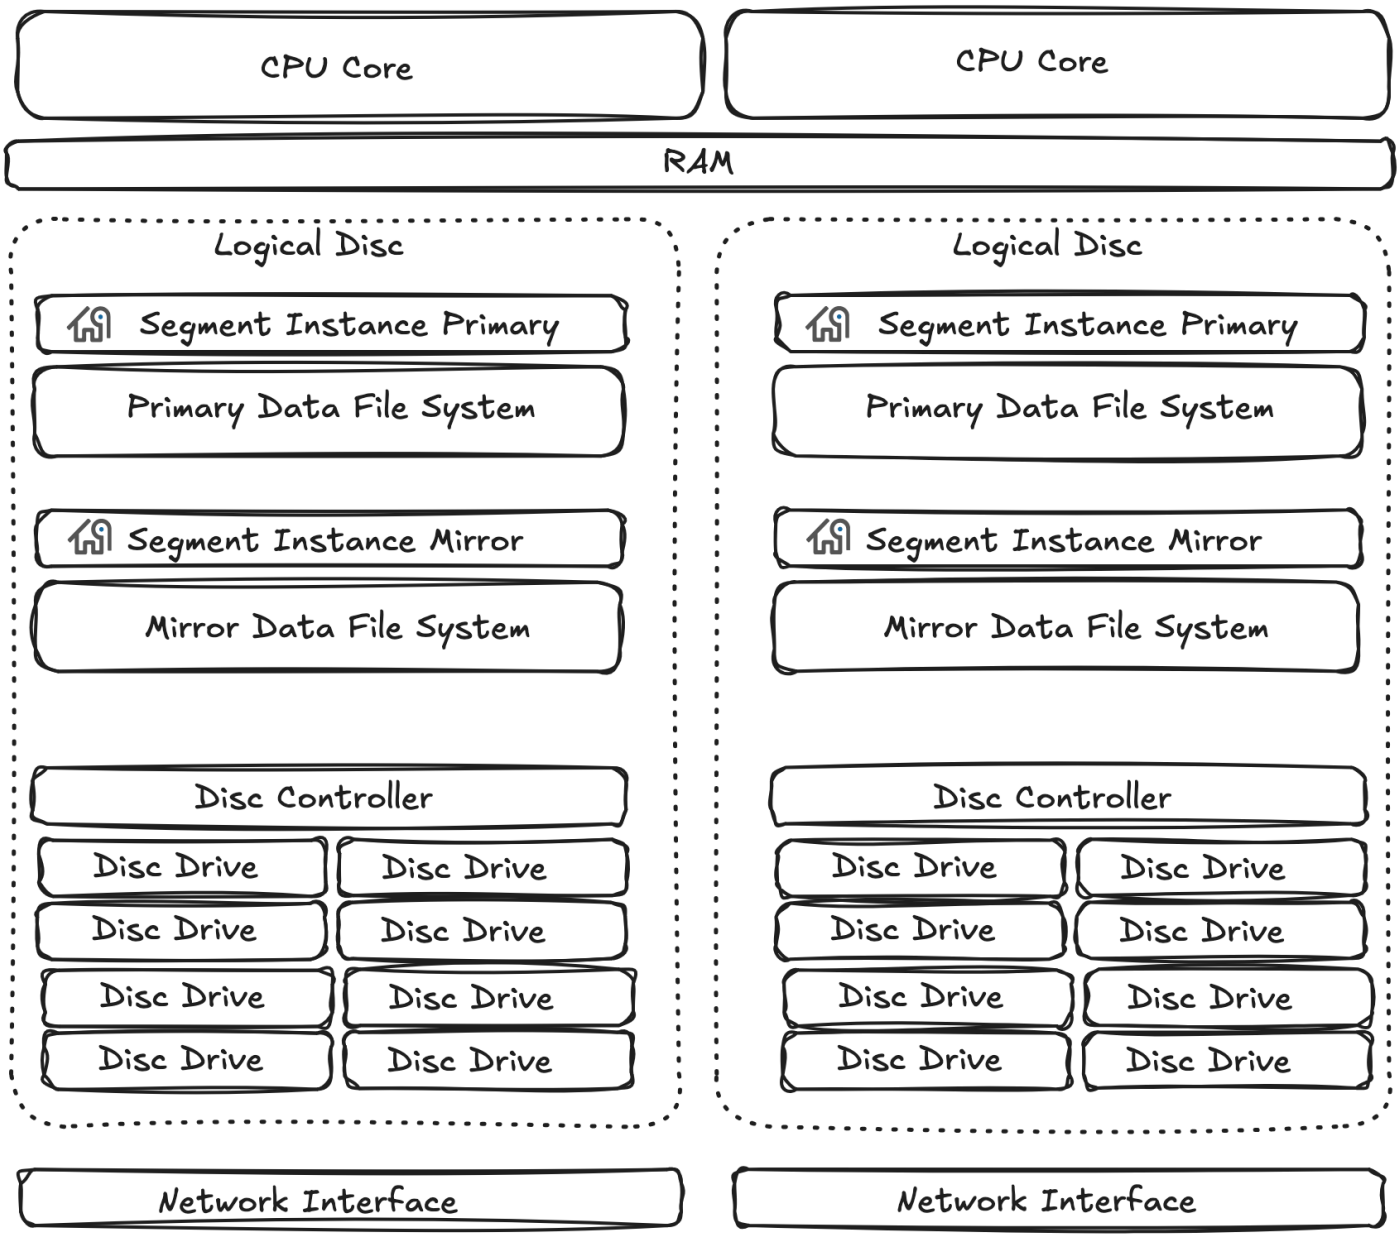
Segment Failover and Recovery

When mirroring is enabled in a WarehousePG cluster, the system automatically fails over to the mirror copy if a primary copy becomes unavailable. A WarehousePG cluster can remain operational if a segment instance or host goes down only if all portions of data are available on the remaining active segments.

If the coordinator cannot connect to a segment instance, it marks that segment instance as *invalid* in the WarehousePG cluster catalog. The segment instance remains invalid and out of operation until an administrator brings that segment back online. An administrator can recover a failed segment while the system is up and running. The recovery process copies over only the changes that were missed while the segment was nonoperational.

If you do not have mirroring enabled and a segment becomes invalid, the system automatically shuts down. An administrator must recover all failed segments before operations can continue.

Example Segment Host Hardware Stack

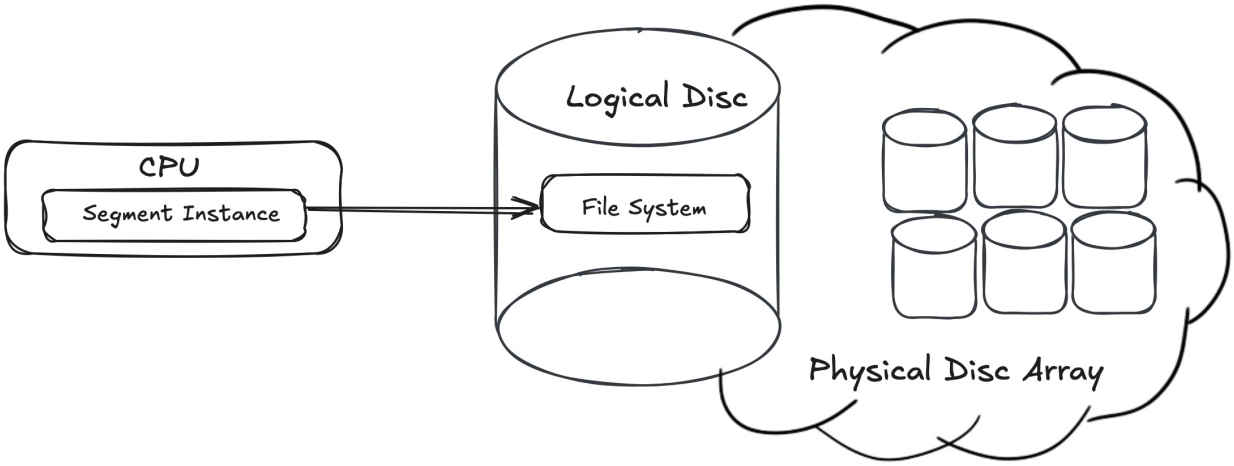


Regardless of the hardware platform you choose, a production WarehousePG processing node (a segment host) is typically configured as described in this section.

The segment hosts do the majority of database processing, so the segment host servers are configured in order to achieve the best performance possible from your WarehousePG cluster. WarehousePG's performance will be as fast as the slowest segment server in the array. Therefore, it is important to ensure that the underlying hardware and operating systems that are running WarehousePG are all running at their optimal performance level. It is also advised that all segment hosts in a WarehousePG cluster have identical hardware resources and configurations.

Segment hosts should also be dedicated to WarehousePG operations only. To get the best query performance, you do not want WarehousePG competing with other applications for machine or network resources.

The following diagram shows an example WarehousePG segment host hardware stack. The number of effective CPUs on a host is the basis for determining how many primary WarehousePG segment instances to deploy per segment host. This example shows a host with two effective CPUs (one dual-core CPU). Note that there is one primary segment instance (or primary/mirror pair if using mirroring) per CPU core.



Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Example Segment Disk Layout

Each CPU is typically mapped to a logical disk. A logical disk consists of one primary file system (and optionally a mirror file system) accessing a pool of physical disks through an I/O channel or disk controller. The logical disk and file system are provided by the operating system. Most operating systems provide the ability for a logical disk drive to use groups of physical disks arranged in RAID arrays.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Depending on the hardware platform you choose, different RAID configurations offer different performance and capacity levels. WarehousePG supports and certifies a number of reference hardware platforms and operating systems. Check with your sales account representative for the recommended configuration on your chosen platform.

The Interconnect

The *interconnect* is the networking layer of WarehousePG. When a user connects to a database and issues a query, processes are created on each of the segments to handle the work of that query. The *interconnect* refers to the inter-process communication between the segments, as well as the network infrastructure on which this communication relies. The interconnect uses a standard 10 Gigabit Ethernet switching fabric.

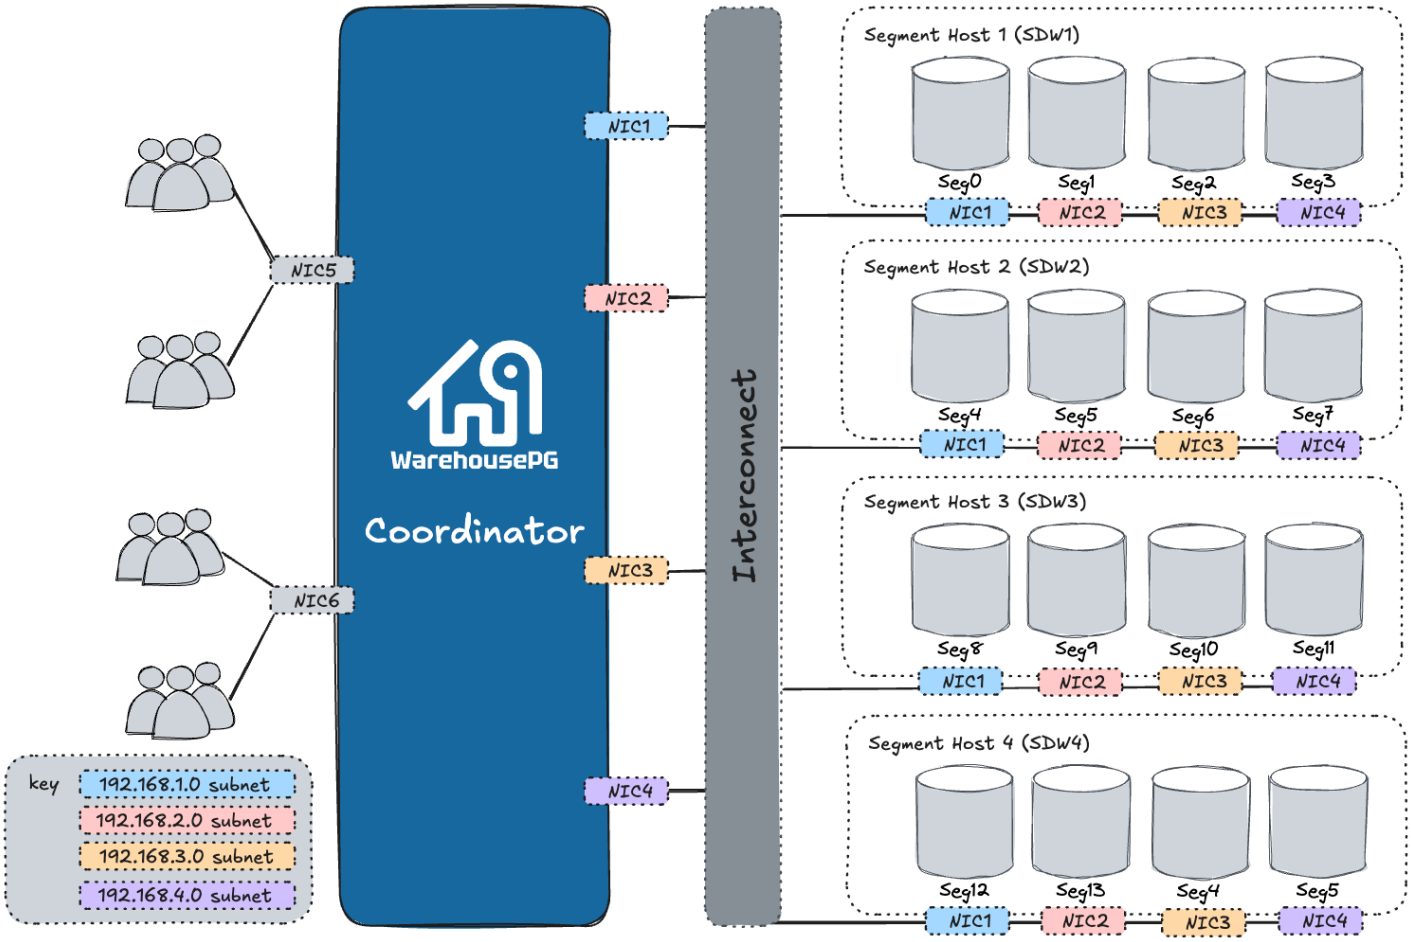
By default, WarehousePG interconnect uses UDP (User Datagram Protocol) with flow control for interconnect traffic to send messages over the network. The WarehousePG software does the additional packet verification and checking not performed by UDP, so the reliability is equivalent to TCP (Transmission Control Protocol), and the performance and scalability exceeds that of TCP. For information about the types of interconnect supported by WarehousePG, see server configuration parameter `gp_interconnect_type` in the *WarehousePG Reference Guide*.

Parent topic: Introduction to WarehousePG

Interconnect Redundancy

A highly available interconnect can be achieved by deploying dual 10 Gigabit Ethernet switches on your network, and redundant 10 Gigabit connections to the WarehousePG coordinator and segment host servers.

Network Interface Configuration

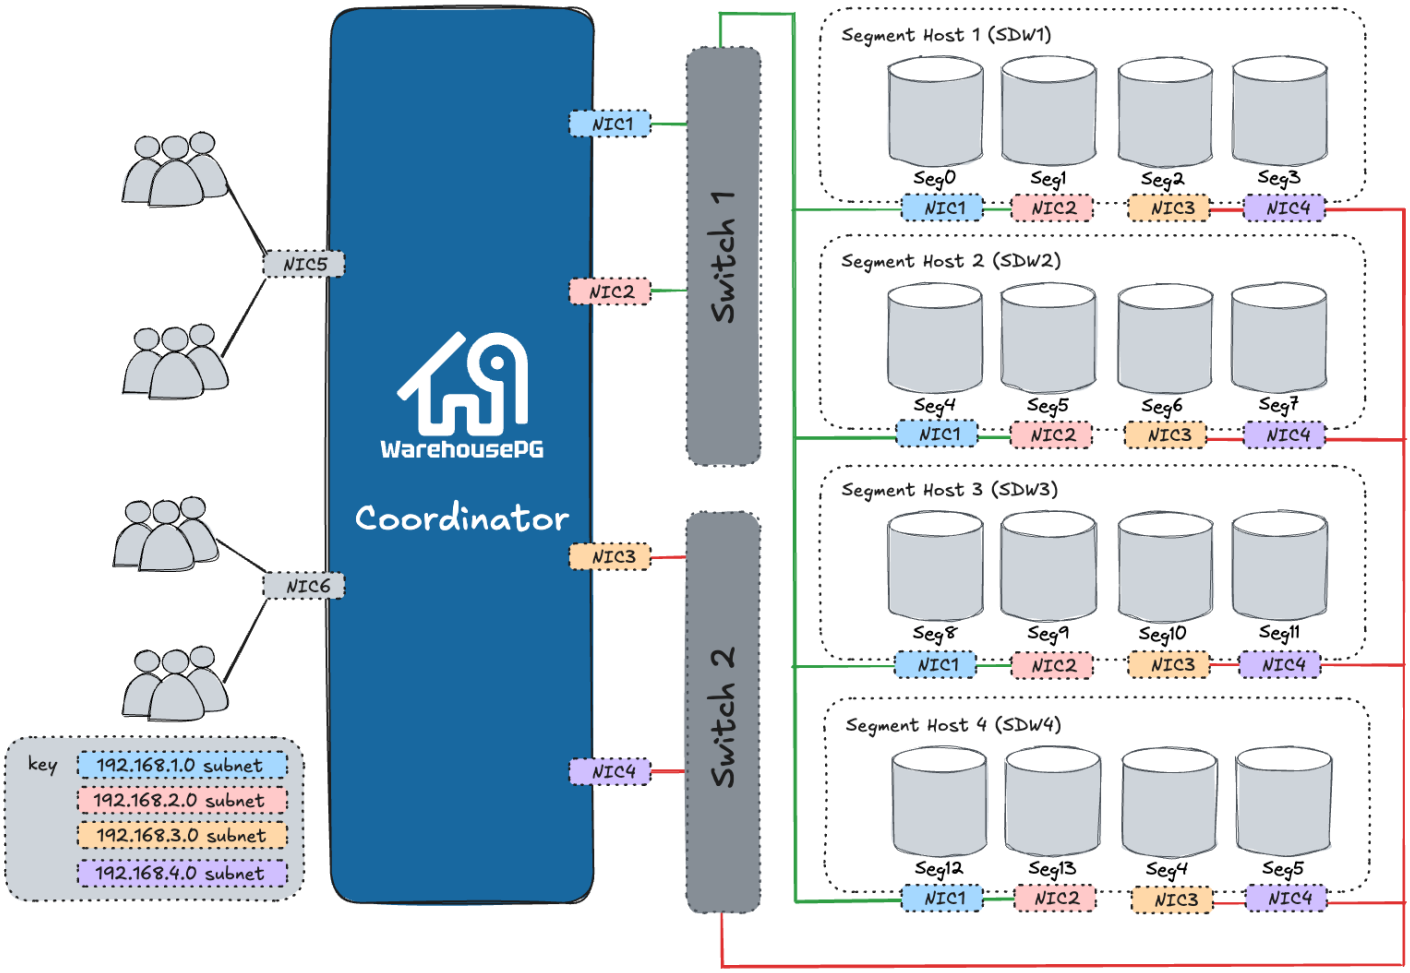


A segment host typically has multiple network interfaces designated to WarehousePG interconnect traffic. The coordinator host typically has additional external network interfaces in addition to the interfaces used for interconnect traffic.

Depending on the number of interfaces available, you will want to distribute interconnect network traffic across the number of available interfaces. This is done by assigning segment instances to a particular network interface and ensuring that the primary segments are evenly balanced over the number of available interfaces.

This is done by creating separate host address names for each network interface. For example, if a host has four network interfaces, then it would have four corresponding host addresses, each of which maps to one or more primary segment instances. The `/etc/hosts` file should be configured to contain not only the host name of each machine, but also all interface host addresses for all of the WarehousePG hosts (coordinator, standby coordinator, segments, and ETL hosts).

With this configuration, the operating system automatically selects the best path to the destination. WarehousePG automatically balances the network destinations to maximize parallelism.



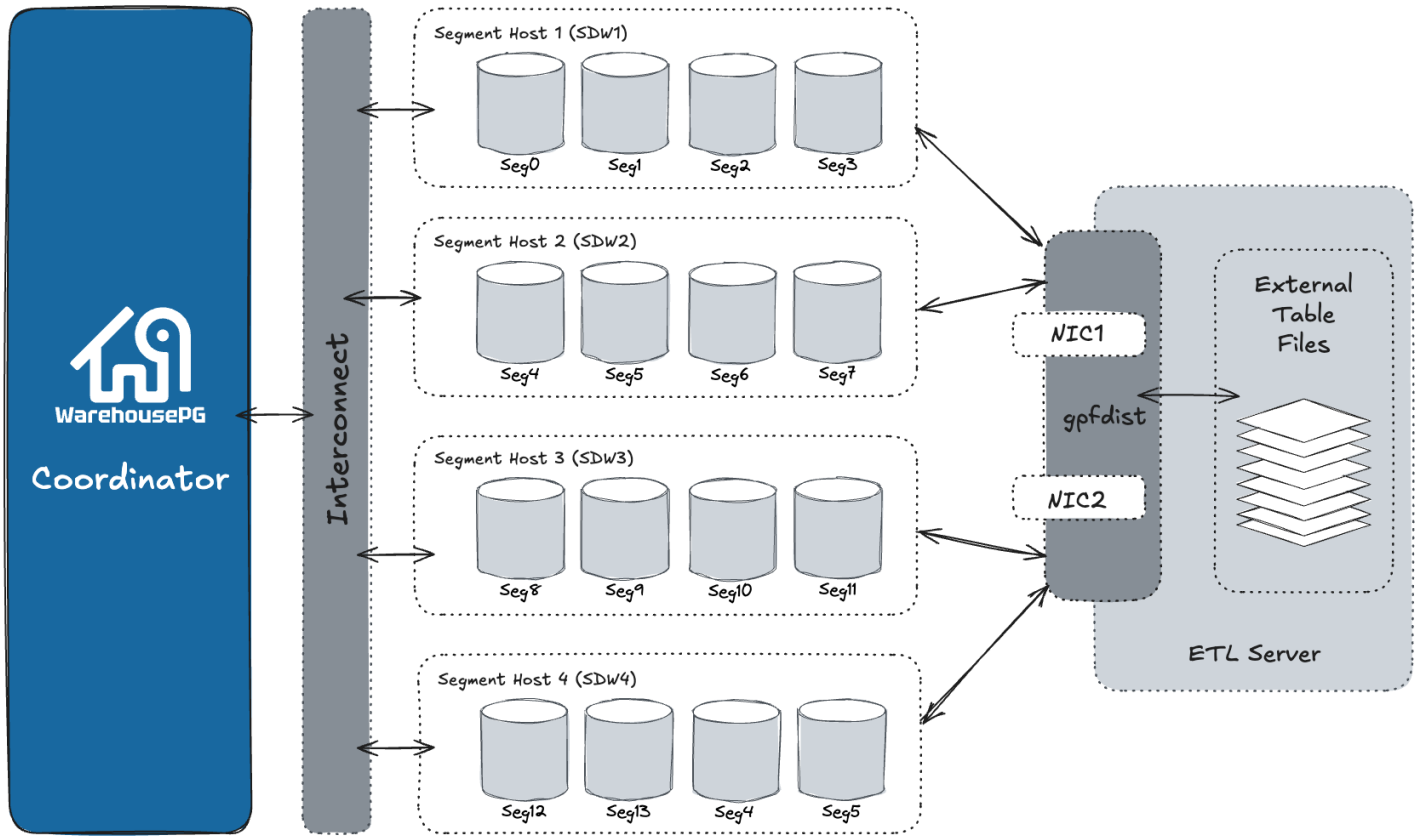
Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Switch Configuration

When using multiple 10 Gigabit Ethernet switches within your WarehousePG cluster, evenly divide the number of subnets between each switch. In this example configuration, if we had two switches, NICs 1 and 2 on each host would use switch 1 and NICs 3 and 4 on each host would use switch 2. For the coordinator host, the host name bound to NIC 1 (and therefore using switch 1) is the effective coordinator host name for the array. Therefore, if deploying a warm standby coordinator for redundancy purposes, the standby coordinator should map to a NIC that uses a different switch than the primary coordinator.

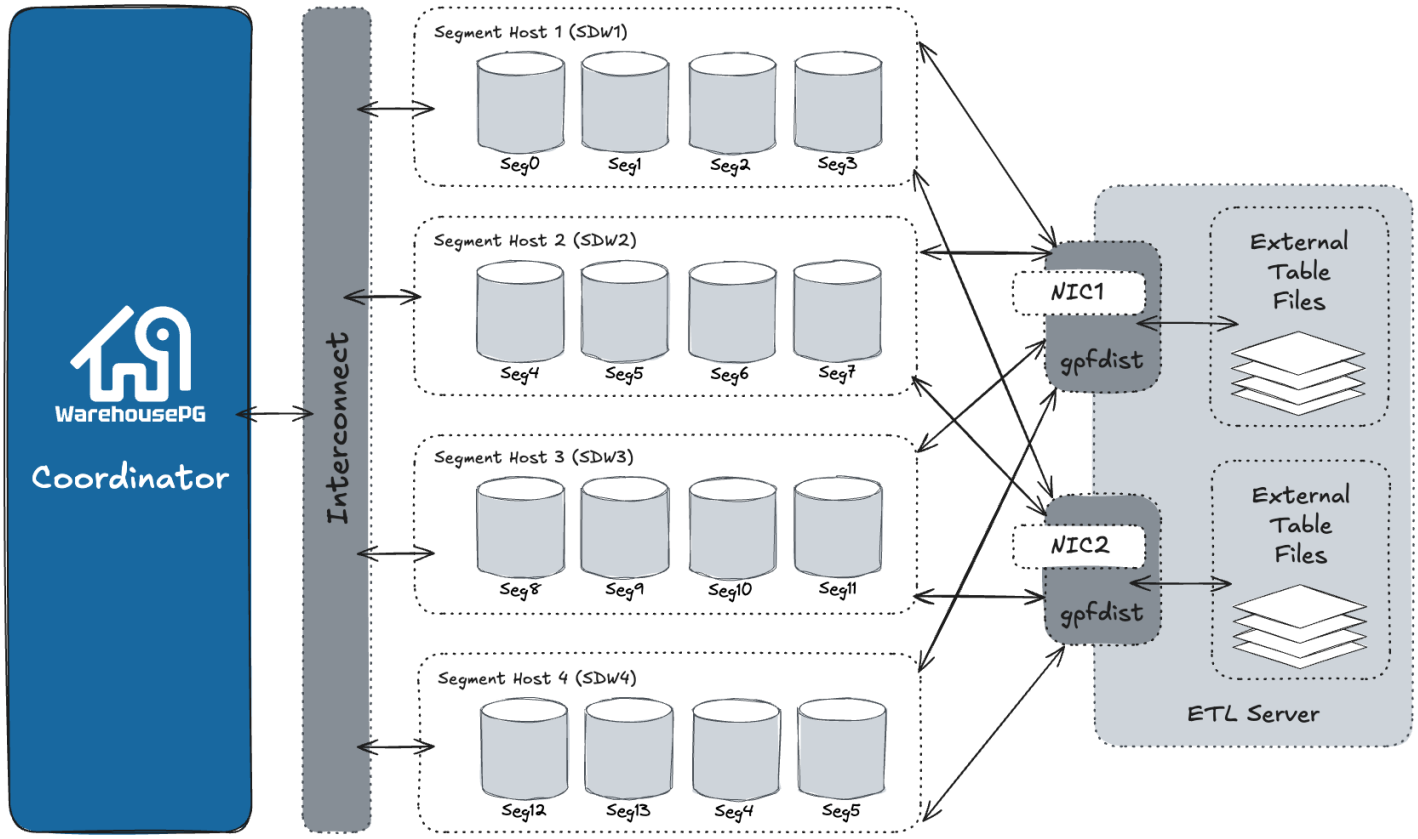
Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

ETL Hosts for Data Loading



WarehousePG supports fast, parallel data loading with its external tables feature. By using external tables in conjunction with WarehousePG's parallel file server (`gpfdist`), administrators can achieve maximum parallelism and load bandwidth from their WarehousePG cluster. Many production systems deploy designated ETL servers for data loading purposes. These machines run the WarehousePG parallel file server (`gpfdist`), but not WarehousePG instances.

One advantage of using the `gpfdist` file server program is that it ensures that all of the segments in your WarehousePG cluster are fully utilized when reading from external table data files.



The `gpfdist` program can serve data to the segment instances at an average rate of about 350 MB/s for delimited text formatted files and 200 MB/s for CSV formatted files. Therefore, you should consider the following options when running `gpfdist` in order to maximize the network bandwidth of your ETL systems:

- If your ETL machine is configured with multiple network interface cards (NICs) as described in Network Interface Configuration, run one instance of `gpfdist` on your ETL host and then define your external table definition so that the host name of each NIC is declared in the `LOCATION` clause (see `CREATE EXTERNAL TABLE` in the *WarehousePG Reference Guide*). This allows network traffic between your WarehousePG segment hosts and your ETL host to use all NICs simultaneously.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

- Run multiple `gpfdist` instances on your ETL host and divide your external data files equally between each instance. For example, if you have an ETL system with two network interface cards (NICs), then you could run two `gpfdist` instances on that machine to maximize your load performance. You would then divide the external table data files evenly between the two `gpfdist` programs.

4.2 Managing a WarehousePG Cluster

This section describes basic system administration tasks performed by a WarehousePG cluster administrator.

- About the WarehousePG Release Version Number
  WarehousePG version numbers and the way they change identify what has been modified from one WarehousePG release to the next.
- Starting and Stopping WarehousePG
  In a WarehousePG DBMS, the database server instances (the coordinator and all segments) are started or stopped across all of the hosts in the system in such a way that they can work together as a unified DBMS.
- Accessing the Database
  This topic describes the various client tools you can use to connect to WarehousePG, and how to establish a database session.
- Configuring the WarehousePG cluster
  Server configuration parameters affect the behavior of WarehousePG.
- Enabling Compression
  You can configure WarehousePG to use data compression with some database features and with some utilities.
- Configuring Proxies for the WarehousePG Interconnect
  You can configure a WarehousePG cluster to use proxies for interconnect communication to reduce the use of connections and ports during query processing.
- Enabling High Availability and Data Consistency Features
  The fault tolerance and the high-availability features of WarehousePG can be configured.
- Backing Up and Restoring Databases
  This topic describes how to use WarehousePG backup and restore features.
- Expanding a WarehousePG cluster
  To scale up performance and storage capacity, expand your WarehousePG cluster by adding hosts to the system. In general, adding nodes to a WarehousePG cluster achieves a linear scaling of performance and storage capacity.
- Monitoring a WarehousePG cluster
  You can monitor a WarehousePG cluster using a variety of tools included with the system or available as add-ons.
- Monitoring Long-Running Operations
  You can monitor, at run time, the progress of certain SQL and utility commands.
- Routine System Maintenance Tasks
  To keep a WarehousePG cluster running efficiently, the database must be regularly cleared of expired data and the table statistics must be updated so that the query optimizer has accurate information.
- Recommended Monitoring and Maintenance Tasks
  This section lists monitoring and maintenance activities recommended to ensure high availability and consistent performance of your WarehousePG cluster.

Parent topic: WarehousePG Administrator Guide

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.2.1 About the WarehousePG Release Version Number

WarehousePG version numbers and the way they change identify what has been modified from one WarehousePG release to the next.

A WarehousePG release version number takes the format x.y.z, where:

- x identifies the Major version number
- y identifies the Minor version number
- z identifies the Patch version number

WarehousePG releases that have the same Major release number are guaranteed to be backwards compatible. WarehousePG increments the Major release number when the catalog changes or when incompatible feature changes or new features are introduced. Previously deprecated functionality may be removed in a major release.

The Minor release number for a given Major release increments when backwards compatible new features are introduced or when a WarehousePG feature is deprecated. (Previously deprecated functionality will never be removed in a minor release.)

WarehousePG increments the Patch release number for a given Minor release for backwards-compatible bug fixes.

Parent topic: Managing a WarehousePG cluster

4.2.2 Starting and Stopping WarehousePG

In a WarehousePG DBMS, the database server instances (the coordinator and all segments) are started or stopped across all of the hosts in the system in such a way that they can work together as a unified DBMS.

Because a WarehousePG cluster is distributed across many machines, the process for starting and stopping a WarehousePG cluster is different than the process for starting and stopping a regular PostgreSQL DBMS.

Use the `gpstart` and `gpstop` utilities to start and stop WarehousePG, respectively. These utilities are located in the $GPHOME/bin directory on your WarehousePG coordinator host.

> **Important** Do not issue a `kill` command to end any Postgres process. Instead, use the database command `pg_cancel_backend()`.

Issuing a `kill -9` or `kill -11` can introduce database corruption and prevent root cause analysis from being performed.

For information about `gpstart` and `gpstop`, see the *WarehousePG Utility Guide*.

Parent topic: Managing a WarehousePG cluster

Starting WarehousePG

Start an initialized WarehousePG cluster by running the `gpstart` utility on the coordinator instance.

Use the `gpstart` utility to start a WarehousePG cluster that has already been initialized by the `gpinitsystem` utility, but has been stopped by the `gpstop` utility. The `gpstart` utility starts WarehousePG by starting all the Postgres database instances on the WarehousePG cluster. `gpstart` orchestrates this process and performs the process in parallel.

Run `gpstart` on the coordinator host to start WarehousePG:

```
$ gpstart
```

Restarting WarehousePG

Stop the WarehousePG cluster and then restart it.

The `gpstop` utility with the `-r` option can stop and then restart WarehousePG after the shutdown completes.

To restart WarehousePG, enter the following command on the coordinator host:

```
$ gpstop -r
```

Reloading Configuration File Changes Only

Reload changes to WarehousePG configuration files without interrupting the system.

The `gpstop` utility can reload changes to the pg_hba.conf configuration file and to *runtime* parameters in the coordinator postgresql.conf file without service interruption. Active sessions pick up changes when they reconnect to the database. Many server configuration parameters require a full system restart (`gpstop -r`) to activate. For information about server configuration parameters, see the *WarehousePG Reference Guide*.

Reload configuration file changes without shutting down the WarehousePG cluster using the `gpstop` utility:

```
$ gpstop -u
```

Starting the Coordinator in Maintenance Mode

Start only the coordinator to perform maintenance or administrative tasks without affecting data on the segments.

Maintenance mode should only be used with direction from WarehousePG Technical Support. For example, you could connect to a database only on the coordinator instance in maintenance mode and edit system catalog settings. For more information about system catalog tables, see the *WarehousePG Reference Guide*.

1. Run `gpstart` using the -m option:

   ```
   $ gpstart -m
   ```

2. Connect to the coordinator in maintenance mode to do catalog maintenance. For example:

   ```
   $ PGOPTIONS='-c gp_role=utility' psql postgres
   ```

3. After completing your administrative tasks, stop the coordinator in maintenance mode. Then, restart it in production mode.

   ```
   $ gpstop -m
   $ gpstart
   ```

   > **Caution** Incorrect use of maintenance mode connections can result in an inconsistent system state. Only Technical Support should perform this operation.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Stopping WarehousePG

The `gpstop` utility stops or restarts your WarehousePG cluster and always runs on the coordinator host. When activated, `gpstop` stops all `postgres` processes in the system, including the coordinator and all segment instances. The `gpstop` utility uses a default of up to 64 parallel worker threads to bring down the Postgres instances that make up the WarehousePG cluster. The system waits for any active transactions to finish before shutting down. If after two minutes there are still active connections, `gpstop` will prompt you to either continue waiting in smart mode, stop in fast mode, or stop in immediate mode. To stop WarehousePG immediately, use fast mode.

> **Important** Immediate shut down mode is not recommended. This mode stops all database processes without allowing the database server to complete transaction processing or clean up any temporary or in-process work files.

- To stop WarehousePG:

  ```
  $ gpstop
  ```

- To stop WarehousePG in fast mode:

  ```
  $ gpstop -M fast
  ```

  By default, you are not allowed to shut down WarehousePG if there are any client connections to the database. Use the `-M fast` option to roll back all in progress transactions and terminate any connections before shutting down.

Stopping Client Processes

WarehousePG launches a new backend process for each client connection. A WarehousePG user with `SUPERUSER` privileges can cancel and terminate these client backend processes.

Canceling a backend process with the `pg_cancel_backend()` function ends a specific queued or active client query. Terminating a backend process with the `pg_terminate_backend()` function terminates a client connection to a database.

The `pg_cancel_backend()` function has two signatures:

- `pg_cancel_backend( pid int4 )`
- `pg_cancel_backend( pid int4, msg text )`

The `pg_terminate_backend()` function has two similar signatures:

- `pg_terminate_backend( pid int4 )`
- `pg_terminate_backend( pid int4, msg text )`

If you provide a `msg`, WarehousePG includes the text in the cancel message returned to the client. `msg` is limited to 128 bytes; WarehousePG truncates anything longer.

The `pg_cancel_backend()` and `pg_terminate_backend()` functions return `true` if successful, and `false` otherwise.

To cancel or terminate a backend process, you must first identify the process ID of the backend. You can obtain the process ID from the `pid` column of the `pg_stat_activity` view. For example, to view the process information associated with all running and queued queries:

```
=# SELECT usename, pid, waiting, state, query, datname
     FROM pg_stat_activity;
```

Sample partial query output:

```
 usename |  pid     | waiting | state  |         query          | datname
---------+----------+---------+--------+------------------------+---------
  sammy  |   31861  |    f    | idle   | SELECT * FROM testtbl; | testdb
  billy  |   31905  |    t    | active | SELECT * FROM topten;  | testdb
```

Use the output to identify the process id (`pid`) of the query or client connection.

For example, to cancel the waiting query identified in the sample output above and include `'Admin canceled long-running query.'` as the message returned to the client:

```
=# SELECT pg_cancel_backend(31905 ,'Admin canceled long-running query.');
ERROR:  canceling statement due to user request: "Admin canceled long-running query."
```

4.2.3 Accessing the Database

This topic describes the various client tools you can use to connect to WarehousePG, and how to establish a database session.

- Establishing a Database Session
- Supported Client Applications
- WarehousePG Client Applications
- Connecting with psql
- Using the PgBouncer Connection Pooler
- Database Application Interfaces
- Troubleshooting Connection Problems

Parent topic: Managing a WarehousePG cluster

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.2.3.1 Establishing a Database Session

Users can connect to WarehousePG using a PostgreSQL-compatible client program, such as `psql`. Users and administrators *always* connect to WarehousePG through the *coordinator*; the segments cannot accept client connections.

In order to establish a connection to the WarehousePG coordinator, you will need to know the following connection information and configure your client program accordingly.

Connection Parameter	Description	Environment Variable
Application name	The application name that is connecting to the database. The default value, held in the `application_name` connection parameter is *psql*.	`$PGAPPNAME`
Database name	The name of the database to which you want to connect. For a newly initialized system, use the `postgres` database to connect for the first time.	`$PGDATABASE`
Host name	The host name of the WarehousePG coordinator. The default host is the local host.	`$PGHOST`
Port	The port number that the WarehousePG coordinator instance is running on. The default is 5432.	`$PGPORT`
User name	The database user (role) name to connect as. This is not necessarily the same as your OS user name. Check with your WarehousePG administrator if you are not sure what you database user name is. Note that every WarehousePG cluster has one superuser account that is created automatically at initialization time. This account has the same name as the OS name of the user who initialized the WarehousePG cluster (typically `gpadmin`).	`$PGUSER`

Connecting with psql provides example commands for connecting to WarehousePG.

Parent topic: Accessing the Database

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.2.3.2 Supported Client Applications

Users can connect to WarehousePG using various client applications:

- A number of WarehousePG Client Applications are provided with your WarehousePG installation. The `psql` client application provides an interactive command-line interface to WarehousePG.
- Using standard Database Application Interfaces, such as ODBC and JDBC, users can create their own client applications that interface to WarehousePG.
- Most client tools that use standard database interfaces, such as ODBC and JDBC, can be configured to connect to WarehousePG.

> **Note**
>
> While WarehousePG is compatible with community PostgreSQL drivers, EDB recommends using the EDB ODBC Connector or the EDB JDBC Connector for production environments. These drivers are specifically optimized for EDB-supported Postgres distributions, including WarehousePG, and ensure full compatibility with enterprise security and performance features.
>
> Download these drivers from the EDB Connectors page.

Parent topic: Accessing the Database

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.2.3.3 WarehousePG Client Applications

WarehousePG comes installed with a number of client utility applications located in the `$GPHOME/bin` directory of your WarehousePG coordinator host installation. The following are the most commonly used client utility applications:

Name	Usage
`createdb`	create a new database
`createuser`	define a new database role
`dropdb`	remove a database
`dropuser`	remove a role
`psql`	PostgreSQL interactive terminal
`reindexdb`	reindex a database
`vacuumdb`	garbage-collect and analyze a database

When using these client applications, you must connect to a database through the WarehousePG coordinator instance. You will need to know the name of your target database, the host name and port number of the coordinator, and what database user name to connect as. This information can be provided on the command-line using the options `-d`, `-h`, `-p`, and `-U` respectively. If an argument is found that does not belong to any option, it will be interpreted as the database name first.

All of these options have default values which will be used if the option is not specified. The default host is the local host. The default port number is 5432. The default user name is your OS system user name, as is the default database name. Note that OS user names and WarehousePG user names are not necessarily the same.

If the default values are not correct, you can set the environment variables `PGDATABASE`, `PGHOST`, `PGPORT`, and `PGUSER` to the appropriate values, or use a `psql` `~/.pgpass` file to contain frequently-used passwords.

For information about WarehousePG environment variables, see the *WarehousePG Reference Guide*. For information about psql, see the *WarehousePG Utility Guide*.

Parent topic: Accessing the Database

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.2.3.4 Connecting with psql

Depending on the default values used or the environment variables you have set, the following examples show how to access a database via `psql`:

```
$ psql -d gpdatabase -h coordinator_host -p 5432 -U `gpadmin`
```

```
$ psql gpdatabase
```

```
$ psql
```

If a user-defined database has not yet been created, you can access the system by connecting to the `postgres` database. For example:

```
$ psql postgres
```

After connecting to a database, `psql` provides a prompt with the name of the database to which `psql` is currently connected, followed by the string `=>` (or `=#` if you are the database superuser). For example:

```
gpdatabase=>
```

At the prompt, you may type in SQL commands. A SQL command must end with a `;` (semicolon) in order to be sent to the server and run. For example:

```
=> SELECT * FROM mytable;
```

See the *WarehousePG Reference Guide* for information about using the `psql` client application and SQL commands and syntax.

Parent topic: Accessing the Database

4.2.3.5 Using the PgBouncer Connection Pooler

The PgBouncer utility manages connection pools for PostgreSQL and WarehousePG connections.

The following topics describe how to set up and use PgBouncer with WarehousePG. Refer to the PgBouncer web site for information about using PgBouncer with PostgreSQL.

- Overview
- Migrating PgBouncer
- Configuring PgBouncer
- Starting PgBouncer
- Managing PgBouncer

Parent topic: Accessing the Database

Overview

A database connection pool is a cache of database connections. Once a pool of connections is established, connection pooling eliminates the overhead of creating new database connections, so clients connect much faster and the server load is reduced.

The PgBouncer connection pooler, from the PostgreSQL community, is included in your WarehousePG installation. PgBouncer is a light-weight connection pool manager for WarehousePG and PostgreSQL. PgBouncer maintains a pool for connections for each database and user combination. PgBouncer either creates a new database connection for a client or reuses an existing connection for the same user and database. When the client disconnects, PgBouncer returns the connection to the pool for re-use.

In order not to compromise transaction semantics for connection pooling, PgBouncer supports several types of pooling when rotating connections:

- *Session pooling* - Most polite method. When a client connects, a server connection will be assigned to it for the whole duration the client stays connected. When the client disconnects, the server connection will be put back into the pool. This is the default method.
- *Transaction pooling* - A server connection is assigned to a client only during a transaction. When PgBouncer notices that transaction is over, the server connection will be put back into the pool.
- *Statement pooling* - Most aggressive method. The server connection will be put back into the pool immediately after a query completes. Multi-statement transactions are disallowed in this mode as they would break.

You can set a default pool mode for the PgBouncer instance. You can override this mode for individual databases and users.

PgBouncer supports the standard connection interface shared by PostgreSQL and WarehousePG. The WarehousePG client application (for example, `psql`) connects to the host and port on which PgBouncer is running rather than the WarehousePG coordinator host and port.

PgBouncer includes a `psql`-like administration console. Authorized users can connect to a virtual database to monitor and manage PgBouncer. You can manage a PgBouncer daemon process via the admin console. You can also use the console to update and reload PgBouncer configuration at runtime without stopping and restarting the process.

PgBouncer natively supports TLS.

Migrating PgBouncer

When you migrate to a new WarehousePG version, you must migrate your PgBouncer instance to that in the new WarehousePG installation.

- **If you are migrating to a WarehousePG version 5.8.x or earlier**, you can migrate PgBouncer without dropping connections. Launch the new PgBouncer process with the `-R` option and the configuration file that you started the process with:

  ```
  $ pgbouncer -R -d pgbouncer.ini
  ```

  The `-R` (reboot) option causes the new process to connect to the console of the old process through a Unix socket and issue the following commands:

  ```
  SUSPEND;
  SHOW FDS;
  SHUTDOWN;
  ```

  When the new process detects that the old process is gone, it resumes the work with the old connections. This is possible because the `SHOW FDS` command sends actual file descriptors to the new process. If the transition fails for any reason, kill the new process and the old process will resume.

- **If you are migrating to a WarehousePG version 5.9.0 or later**, you must shut down the PgBouncer instance in your old installation and reconfigure and restart PgBouncer in your new installation.
- If you used stunnel to secure PgBouncer connections in your old installation, you must configure SSL/TLS in your new installation using the built-in TLS capabilities of PgBouncer 1.8.1 and later.
- If you currently use the built-in PAM LDAP integration, you may choose to migrate to the new native LDAP PgBouncer integration introduced in WarehousePG version 6.22; refer toConfiguring LDAP-based Authentication for PgBouncer for configuration information.

Configuring PgBouncer

You configure PgBouncer and its access to WarehousePG via a configuration file. This configuration file, commonly named `pgbouncer.ini`, provides location information for WarehousePGs. The `pgbouncer.ini` file also specifies process, connection pool, authorized users, and authentication configuration for PgBouncer.

Sample `pgbouncer.ini` file contents:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
[databases]
postgres = host=127.0.0.1 port=5432 dbname=postgres
pgb_mydb = host=127.0.0.1 port=5432 dbname=mydb

[pgbouncer]
pool_mode = session
listen_port = 6543
listen_addr = 127.0.0.1
auth_type = md5
auth_file = users.txt
logfile = pgbouncer.log
pidfile = pgbouncer.pid
admin_users = gpadmin
```

Refer to the pgbouncer.ini reference page for the PgBouncer configuration file format and the list of configuration properties it supports.

When a client connects to PgBouncer, the connection pooler looks up the the configuration for the requested database (which may be an alias for the actual database) that was specified in the `pgbouncer.ini` configuration file to find the host name, port, and database name for the database connection. The configuration file also identifies the authentication mode in effect for the database.

PgBouncer requires an authentication file, a text file that contains a list of WarehousePG users and passwords. The contents of the file are dependent on the `auth_type` you configure in the `pgbouncer.ini` file. Passwords may be either clear text or MD5-encoded strings. You can also configure PgBouncer to query the destination database to obtain password information for users that are not in the authentication file.

PgBouncer Authentication File Format

PgBouncer requires its own user authentication file. You specify the name of this file in the `auth_file` property of the `pgbouncer.ini` configuration file. `auth_file` is a text file in the following format:

```
"username1" "password" ...
"username2" "md5abcdef012342345" ...
"username2" "SCRAM-SHA-256$<iterations>:<salt>$<storedkey>:<serverkey>"
```

`auth_file` contains one line per user. Each line must have at least two fields, both of which are enclosed in double quotes (`" "`). The first field identifies the WarehousePG user name. The second field is either a plain-text password, an MD5-encoded password, or or a SCRAM secret. PgBouncer ignores the remainder of the line.

(The format of `auth_file` is similar to that of the `pg_auth` text file that WarehousePG uses for authentication information. PgBouncer can work directly with this WarehousePG authentication file.)

Use an MD5 encoded password. The format of an MD5 encoded password is:

```
"md5" + MD5_encoded(<password><username>)
```

You can also obtain the MD5-encoded passwords of all WarehousePG users from the `pg_shadow` view.

PostgreSQL SCRAM secret format:

```
SCRAM-SHA-256$<iterations>:<salt>$<storedkey>:<serverkey>
```

See the PostgreSQL documentation and RFC 5803 for details on this.

The passwords or secrets stored in the authentication file serve two purposes. First, they are used to verify the passwords of incoming client connections, if a password-based authentication method is configured. Second, they are used as the passwords for outgoing connections to the backend server, if the backend server requires password-based authentication (unless the password is specified directly in the database's connection string). The latter works if the password is stored in plain text or MD5-hashed.

SCRAM secrets can only be used for logging into a server if the client authentication also uses SCRAM, the PgBouncer database definition does not specify a user name, and the SCRAM secrets are identical in PgBouncer and the PostgreSQL server (same salt and iterations, not merely the same password). This is due to an inherent security property of SCRAM: The stored SCRAM secret cannot by itself be used for deriving login credentials.

The authentication file can be written by hand, but it's also useful to generate it from some other list of users and passwords. See `./etc/mkauth.py` for a sample script to generate the authentication file from the `pg_shadow` system table. Alternatively, use

```
auth_query
```

instead of `auth_file` to avoid having to maintain a separate authentication file.

Configuring HBA-based Authentication for PgBouncer

PgBouncer supports HBA-based authentication. To configure HBA-based authentication for PgBouncer, you set `auth_type=hba` in the `pgbouncer.ini` configuration file. You also provide the filename of the HBA-format file in the `auth_hba_file` parameter of the `pgbouncer.ini` file.

Contents of an example PgBouncer HBA file named `hba_bouncer.conf`:

```
local       all     bouncer             trust
host        all     bouncer      127.0.0.1/32       trust
```

Example excerpt from the related `pgbouncer.ini` configuration file:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
[databases]
p0 = port=15432 host=127.0.0.1 dbname=p0 user=bouncer pool_size=2
p1 = port=15432 host=127.0.0.1 dbname=p1 user=bouncer
...

[pgbouncer]
...
auth_type = hba
auth_file = userlist.txt
auth_hba_file = hba_bouncer.conf
...
```

Refer to the HBA file format discussion in the PgBouncer documentation for information about PgBouncer support of the HBA authentication file format.

Configuring LDAP-based Authentication for PgBouncer

Starting in WarehousePG version 6.22, PgBouncer supports native LDAP authentication between the `psql` client and the `pgbouncer` process. Configuring this LDAP-based authentication is similar to configuring HBA-based authentication for PgBouncer:

- Specify `auth-type=hba` in the `pgbouncer.ini` configuration file.
- Provide the file name of an HBA-format file in the `auth_hba_file` parameter of the `pgbouncer.ini` file, and specify the LDAP parameters (server address, base DN, bind DN, bind password, search attribute, etc.) in the file.

> **Note** You may, but are not required to, specify LDAP user names and passwords in the `auth-file`. When you do *not* specify these strings in the `auth-file`, LDAP user password changes require no PgBouncer configuration changes.

If you enable LDAP authentication between `psql` and `pgbouncer` and you use `md5`, `password`, or `scram-sha-256` for authentication between PgBouncer and WarehousePG, ensure that you configure the latter password independently.

Excerpt of an example PgBouncer HBA file named `hba_bouncer_for_ldap.conf` that specifies LDAP authentication follows:

```
host all user1 0.0.0.0/0 ldap ldapserver=<ldap-server-address> ldapbasedn="CN=Users,DC=greenplum,DC=org"
ldapbinddn="CN=Administrator,CN=Users,DC=greenplum,DC=org" ldapbindpasswd="ChangeMe1!!" ldapsearchattribute="SomeAttrName"
```

Refer to the WarehousePG LDAP Authentication discussion for more information on configuring an HBA file for LDAP.

Example excerpt from the related `pgbouncer.ini` configuration file:

```
[databases]
* = port = 6000 host=127.0.0.1

[pgbouncer]
listen_addr = 0.0.0.0
listen_port = 6432

auth_type = hba
auth_hba_file = hba_bouncer_for_ldap.conf
...
```

About Specifying an Encrypted LDAP Password

Starting in WarehousePG version 7.1, PgBouncer supports encrypted LDAP passwords. To utilize an encrypted LDAP password with PgBouncer, you must:

- Place the encrypted password in the `${HOME}/.ldapbindpass` file.
- Specify `ldapbindpasswd="$bindpasswd"` in the HBA-based authentication file for PgBouncer.
- Specify the file system path to the encryption key in the `auth_key_file` setting in the `pgbouncer.ini` configuration file.
- Specify the encryption cipher in the `auth_cipher` setting in the `pgbouncer.ini` configuration file.

The following example commands create an encrypted password and place it in `${HOME}/.ldapbindpass`:

```
# generate a key file named ldkeyfile
$ openssl rand -base64 256 | tr -d '\n' > ldkeyfile
# encrypt the password
$ encrypted_passwd=$(echo -n "your_secret_password_here" | openssl enc -aes-256-cbc -base64 -md sha256 -pass file:ldkeyfile
# copy the encrypted password to required location
$ echo -n $encrypted_passwd > "${HOME}/.ldapbindpass"
```

An excerpt of an example PgBouncer HBA file named `hba_bouncer_with_ldap_encrypted.conf` that specifies LDAP authentication with an encrypted password follows:

```
host all user2 0.0.0.0/0 ldap ldapserver=<ldap-server-address> ldapbindpasswd="$bindpasswd" ldapbasedn="CN=Users,DC=greenplum,DC=org"
ldapbinddn="CN=Administrator,CN=Users,DC=greenplum,DC=org" ldapsearchattribute="SomeAttrName"
```

Example excerpt from the related `pgbouncer.ini` configuration file:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
[databases]
* = port = 6000 host=127.0.0.1
[pgbouncer]
listen_addr = 0.0.0.0
listen_port = 6432
auth_type = hba
auth_hba_file = hba_bouncer_with_ldap_encrypted.conf
auth_key_file = /home/user2/ldkeyfile
auth_cipher = -aes-128-ecb
...
```

Starting PgBouncer

You can run PgBouncer on the WarehousePG coordinator or on another server. If you install PgBouncer on a separate server, you can easily switch clients to the standby coordinator by updating the PgBouncer configuration file and reloading the configuration using the PgBouncer Administration Console.

Follow these steps to set up PgBouncer.

1. Create a PgBouncer configuration file. For example, add the following text to a file named `pgbouncer.ini`:

   ```
   [databases]
   postgres = host=127.0.0.1 port=5432 dbname=postgres
   pgb_mydb = host=127.0.0.1 port=5432 dbname=mydb

   [pgbouncer]
   pool_mode = session
   listen_port = 6543
   listen_addr = 127.0.0.1
   auth_type = md5
   auth_file = users.txt
   logfile = pgbouncer.log
   pidfile = pgbouncer.pid
   admin_users = gpadmin
   ```

   The file lists databases and their connection details. The file also configures the PgBouncer instance. Refer to the pgbouncer.ini reference page for information about the format and content of a PgBouncer configuration file.

2. Create an authentication file. The filename should be the name you specified for the `auth_file` parameter of the `pgbouncer.ini` file, `users.txt`. Each line contains a user name and password. The format of the password string matches the `auth_type` you configured in the PgBouncer configuration file. If the `auth_type` parameter is `plain`, the password string is a clear text password, for example:

   ```
   "gpadmin" "gpadmin1234"
   ```

   If the `auth_type` in the following example is `md5`, the authentication field must be MD5-encoded. The format for an MD5-encoded password is:

   ```
   "md5" + MD5_encoded(<password><username>)
   ```

3. Launch `pgbouncer`:

   ```
   $ $GPHOME/bin/pgbouncer -d pgbouncer.ini
   ```

   The `-d` option runs PgBouncer as a background (daemon) process. Refer to the pgbouncer reference page for the `pgbouncer` command syntax and options.

4. Update your client applications to connect to `pgbouncer` instead of directly to WarehousePG server. For example, to connect to the WarehousePG named `mydb` configured above, run `psql` as follows:

   ```
   $ psql -p 6543 -U someuser pgb_mydb
   ```

   The `-p` option value is the `listen_port` that you configured for the PgBouncer instance.

Managing PgBouncer

PgBouncer provides a `psql`-like administration console. You log in to the PgBouncer Administration Console by specifying the PgBouncer port number and a virtual database named `pgbouncer`. The console accepts SQL-like commands that you can use to monitor, reconfigure, and manage PgBouncer.

For complete documentation of PgBouncer Administration Console commands, refer to the pgbouncer-admin command reference.

Follow these steps to get started with the PgBouncer Administration Console.

1. Use `psql` to log in to the `pgbouncer` virtual database:

   ```
   $ psql -p 6543 -U username pgbouncer
   ```

   The username that you specify must be listed in the `admin_users` parameter in the `pgbouncer.ini` configuration file. You can also log in to the PgBouncer Administration Console with the current Unix username if the `pgbouncer` process is running under that user's UID.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

2. To view the available PgBouncer Administration Console commands, run the `SHOW help` command:

```
pgbouncer=# SHOW help;
NOTICE:  Console usage
DETAIL:
    SHOW HELP|CONFIG|DATABASES|FDS|POOLS|CLIENTS|SERVERS|SOCKETS|LISTS|VERSION|...
    SET key = arg
    RELOAD
    PAUSE
    SUSPEND
    RESUME
    SHUTDOWN
    [...]
```

3. If you update PgBouncer configuration by editing the `pgbouncer.ini` configuration file, you use the `RELOAD` command to reload the file:

```
pgbouncer=# RELOAD;
```

Mapping PgBouncer Clients to WarehousePG Server Connections

To map a PgBouncer client to a WarehousePG server connection, use the PgBouncer Administration Console `SHOW CLIENTS` and `SHOW SERVERS` commands:

1. Use `ptr` and `link` to map the local client connection to the server connection.
2. Use the `addr` and the `port` of the client connection to identify the TCP connection from the client.
3. Use `local_addr` and `local_port` to identify the TCP connection to the server.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.2.3.6 Database Application Interfaces

You may want to develop your own client applications that interface to WarehousePG. PostgreSQL provides a number of database drivers for the most commonly used database application programming interfaces (APIs), which can also be used with WarehousePG. These drivers are available as a separate download. Each driver (except libpq, which comes with PostgreSQL) is an independent PostgreSQL development project and must be downloaded, installed and configured to connect to WarehousePG. The following drivers are available:

API	PostgreSQL Driver	Download Link
ODBC	EDB ODBC Connector	EDB Connectors page
JDBC	EDB JDBC Connector	EDB Connectors page
Perl DBI	pgperl	https://metacpan.org/release/DBD-Pg
Python DBI	pygresql	http://www.pygresql.org/
Python DBI	psycopg2	https://www.psycopg.org/
libpq C Library	libpq	https://www.postgresql.org/docs/12/libpq.html

> **Note**
>
> While WarehousePG is compatible with community PostgreSQL drivers, EDB recommends using the EDB ODBC Connector or the EDB JDBC Connector for production environments. These drivers are specifically optimized for EDB-supported Postgres distributions, including WarehousePG, and ensure full compatibility with enterprise security and performance features.

General instructions for accessing a WarehousePG with an API are:

1. Download your programming language platform and respective API from the appropriate source. For example, you can get the Java Development Kit (JDK) and JDBC API from Oracle.
2. Write your client application according to the API specifications. When programming your application, be aware of the SQL support in WarehousePG so you do not include any unsupported SQL syntax.

Download the appropriate driver and configure connectivity to your WarehousePG coordinator instance.

Parent topic: Accessing the Database

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.2.3.7 Troubleshooting Connection Problems

A number of things can prevent a client application from successfully connecting to WarehousePG. This topic explains some of the common causes of connection problems and how to correct them.

Problem	Solution
No `pg_hba.conf` entry for host or user	To enable WarehousePG to accept remote client connections, you must configure your WarehousePG coordinator instance so that connections are allowed from the client hosts and database users that will be connecting to WarehousePG. This is done by adding the appropriate entries to the `pg_hba.conf` configuration file (located in the coordinator instance's data directory). For more detailed information, see Allowing Connections to WarehousePG.
WarehousePG is not running	If the WarehousePG coordinator instance is down, users will not be able to connect. You can verify that the WarehousePG cluster is up by running the `gpstate` utility on the WarehousePG coordinator host.
Network problems Interconnect timeouts	If users connect to the WarehousePG coordinator host from a remote client, network problems can prevent a connection (for example, DNS host name resolution problems, the host system is down, and so on.). To ensure that network problems are not the cause, connect to the WarehousePG coordinator host from the remote client host. For example: `ping hostname` If the system cannot resolve the host names and IP addresses of the hosts involved in WarehousePG, queries and connections will fail. For some operations, connections to the WarehousePG coordinator use `localhost` and others use the actual host name, so you must be able to resolve both. If you encounter this error, first make sure you can connect to each host in your WarehousePG cluster from the coordinator host over the network. In the `/etc/hosts` file of the coordinator and all segments, make sure you have the correct host names and IP addresses for all hosts involved in the WarehousePG cluster. The `127.0.0.1` IP must resolve to `localhost`.
Too many clients already	By default, WarehousePG is configured to allow a maximum of 250 concurrent user connections on the coordinator and 750 on a segment. A connection attempt that causes that limit to be exceeded will be refused. This limit is controlled by the `max_connections` parameter in the `postgresql.conf` configuration file of the WarehousePG coordinator. If you change this setting for the coordinator, you must also make appropriate changes at the segments.

4.2.4 Configuring the WarehousePG cluster

Server configuration parameters affect the behavior of WarehousePG.They are part of the PostgreSQL "Grand Unified Configuration" system, so they are sometimes called "GUCs." Most of the WarehousePG server configuration parameters are the same as the PostgreSQL configuration parameters, but some are WarehousePG-specific.

- About WarehousePG Coordinator and Local Parameters
- Setting Configuration Parameters
- Viewing Server Configuration Parameter Settings
- Configuration Parameter Categories

Parent topic: Managing a WarehousePG cluster

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.2.4.1 About WarehousePG Coordinator and Local Parameters

Server configuration files contain parameters that configure server behavior. The WarehousePG configuration file, postgresql.conf, resides in the data directory of the database instance.

The coordinator and each segment instance have their own postgresql.conf file. Some parameters are *local*: each segment instance examines its postgresql.conf file to get the value of that parameter. Set local parameters on the coordinator and on each segment instance.

Other parameters are *coordinator* parameters that you set on the coordinator instance. The value is passed down to (or in some cases ignored by) the segment instances at query run time.

See the *WarehousePG Reference Guide* for information about *local* and *coordinator* server configuration parameters.

Parent topic: Configuring the WarehousePG cluster

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.2.4.2 Setting Configuration Parameters

Many configuration parameters limit who can change them and where or when they can be set. For example, to change certain parameters, you must be a WarehousePG superuser. Other parameters can be set only at the system level in the postgresql.conf file or require a system restart to take effect.

Many configuration parameters are *session* parameters. You can set session parameters at the system level, the database level, the role level or the session level. Database users can change most session parameters within their session, but some require superuser permissions.

See the *WarehousePG Reference Guide* for information about setting server configuration parameters.

- Setting a Local Configuration Parameter
- Setting a Coordinator Configuration Parameter

Parent topic: Configuring the WarehousePG cluster

4.2.4.2.1 Setting a Local Configuration Parameter

To change a local configuration parameter across multiple segments, update the parameter in the `postgresql.conf` file of each targeted segment, both primary and mirror. Use the `gpconfig` utility to set a parameter in all WarehousePG `postgresql.conf` files. For example:

```
$ gpconfig -c gp_vmem_protect_limit -v 4096
```

Restart WarehousePG to make the configuration changes effective:

```
$ gpstop -r
```

Parent topic: Setting Configuration Parameters

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.2.4.2.2 Setting a Coordinator Configuration Parameter

To set a coordinator configuration parameter, set it at the WarehousePG coordinator instance. If it is also a *session* parameter, you can set the parameter for a particular database, role or session. If a parameter is set at multiple levels, the most granular level takes precedence. For example, session overrides role, role overrides database, and database overrides system.

- Setting Parameters at the System Level
- Setting Parameters at the Database Level
- Setting Parameters at the Role Level
- Setting Parameters in a Session

Parent topic: Setting Configuration Parameters

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.2.4.2.2.1 Setting Parameters at the System Level

Coordinator parameter settings in the coordinator `postgresql.conf` file are the system-wide default. To set a coordinator parameter:

1. Edit the `$COORDINATOR_DATA_DIRECTORY/postgresql.conf` file.
2. Find the parameter to set, uncomment it (remove the preceding `#` character), and type the desired value.
3. Save and close the file.
4. For *session* parameters that do not require a server restart, upload the `postgresql.conf` changes as follows:

```
$ gpstop -u
```

5. For parameter changes that require a server restart, restart WarehousePG as follows:

```
$ gpstop -r
```

For details about the server configuration parameters, see the *WarehousePG Reference Guide*.

Parent topic: Setting a Coordinator Configuration Parameter

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.2.4.2.2.2 Setting Parameters at the Database Level

Use `ALTER DATABASE` to set parameters at the database level. For example:

```
=# ALTER DATABASE mydatabase SET search_path TO myschema;
```

When you set a session parameter at the database level, every session that connects to that database uses that parameter setting. Settings at the database level override settings at the system level.

Parent topic: Setting a Coordinator Configuration Parameter

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.2.4.2.2.3 Setting Parameters at the Role Level

Use `ALTER ROLE` to set a parameter at the role level. For example:

```
=# ALTER ROLE bob SET search_path TO bobschema;
```

When you set a session parameter at the role level, every session initiated by that role uses that parameter setting. Settings at the role level override settings at the database level.

Parent topic: Setting a Coordinator Configuration Parameter

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.2.4.2.2.4 Setting Parameters in a Session

Any session parameter can be set in an active database session using the `SET` command. For example:

```
=# SET statement_mem TO '200MB';
```

The parameter setting is valid for the rest of that session or until you issue a `RESET` command. For example:

```
=# RESET statement_mem;
```

Settings at the session level override those at the role level.

Parent topic: Setting a Coordinator Configuration Parameter

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.2.4.3 Viewing Server Configuration Parameter Settings

The SQL command `SHOW` allows you to see the current server configuration parameter settings. For example, to see the settings for all parameters:

```
$ psql -c 'SHOW ALL;'
```

`SHOW` lists the settings for the coordinator instance only. To see the value of a particular parameter across the entire system (and all segments), use the `gpconfig` utility. For example:

```
$ gpconfig --show max_connections
```

Parent topic: Configuring the WarehousePG cluster

4.2.4.4 Configuration Parameter Categories

Configuration parameters affect categories of server behaviors, such as resource consumption, query tuning, and authentication. Refer to Parameter Categories in the *WarehousePG Reference Guide* for a list of WarehousePG server configuration parameter categories.

Parent topic: Configuring the WarehousePG cluster

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.2.5 Enabling Compression

You can configure WarehousePG to use data compression with some database features and with some utilities.Compression reduces disk usage and improves I/O across the system, however, it adds some performance overhead when compressing and decompressing data.

You can configure support for data compression with these features and utilities. See the specific feature or utility for information about support for compression.

- Append-optimized tables support compressing table data. See CREATE TABLE.
- User-defined data types can be defined to compress data. SeeCREATE TYPE.
- The external table protocols gpfdist (gpfdists), s3, and pxf support compression when accessing external data. For information about external tables, see CREATE EXTERNAL TABLE.
- Workfiles (temporary spill files that are created when running a query that requires more memory than it is allocated) can be compressed. See the server configuration parametergp_workfile_compression.
- The WarehousePG utilities `gpbackup`, `gprestore`, `gpload`, `gplogfilter` support compression.

For some compression algorithms (such as zstd) WarehousePG requires software packages installed on the host system. For information about required software packages, see the *WarehousePG Installation Guide*.

Parent topic: Managing a WarehousePG cluster

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.2.6 Configuring Proxies for the WarehousePG Interconnect

You can configure a WarehousePG cluster to use proxies for interconnect communication to reduce the use of connections and ports during query processing.

The WarehousePG *interconnect* (the networking layer) refers to the inter-process communication between segments and the network infrastructure on which this communication relies. For information about the WarehousePG architecture and interconnect, see About the WarehousePG Architecture.

In general, when running a query, a QD (query dispatcher) on the WarehousePG coordinator creates connections to one or more QE (query executor) processes on segments, and a QE can create connections to other QEs. For a description of WarehousePG query processing and parallel query processing, see About WarehousePG Query Processing.

By default, connections between the QD on the coordinator and QEs on segment instances and between QEs on different segment instances require a separate network port. You can configure a WarehousePG cluster to use proxies when WarehousePG communicates between the QD and QEs and between QEs on different segment instances. The interconnect proxies require only one network connection for WarehousePG internal communication between two segment instances, so it consumes fewer connections and ports than `TCP` mode, and has better performance than `UDPIFC` mode in a high-latency network.

To enable interconnect proxies for the WarehousePG cluster, set these system configuration parameters.

- List the proxy ports with the parameter gp_interconnect_proxy_addresses. You must specify a proxy port for the coordinator, standby coordinator, and all segment instances.
- Set the parameter gp_interconnect_type to `proxy`.

> **Note** When expanding a WarehousePG cluster, you must deactivate interconnect proxies before adding new hosts and segment instances to the system, and you must update the `gp_interconnect_proxy_addresses` parameter with the newly-added segment instances before you re-enable interconnect proxies.

Parent topic: Managing a WarehousePG cluster

Example

This example sets up a WarehousePG cluster to use proxies for the WarehousePG interconnect when running queries. The example sets the gp_interconnect_proxy_addresses parameter and tests the proxies before setting the gp_interconnect_type parameter for the WarehousePG cluster.

- Setting the Interconnect Proxy Addresses
- Testing the Interconnect Proxies
- Setting Interconnect Proxies for the System

Setting the Interconnect Proxy Addresses

Set the `gp_interconnect_proxy_addresses` parameter to specify the proxy ports for the coordinator and segment instances. The syntax for the value has the following format and you must specify the parameter value as a single-quoted string.

```
<db_id>:<cont_id>:<seg_address>:<port>[, ... ]
```

For the coordinator, standby coordinator, and segment instance, the first three fields, db_id, cont_id, and seg_address can be found in the gp_segment_configuration catalog table. The fourth field, port, is the proxy port for the WarehousePG coordinator or a segment instance.

- db_id is the `dbid` column in the catalog table.
- cont_id is the `content` column in the catalog table.
- seg_address is the IP address or hostname corresponding to the `address` column in the catalog table.
- port is the TCP/IP port for the segment instance proxy that you specify.

> **Important** If a segment instance hostname is bound to a different IP address at runtime, you must run `gpstop -u` to re-load the `gp_interconnect_proxy_addresses` value.

This is an example PL/Python function that displays or sets the segment instance proxy port values for the `gp_interconnect_proxy_addresses` parameter. To create and run the function, you must enable PL/Python in the database with the `CREATE EXTENSION plpython3u` command.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
--
-- A PL/Python function to setup the interconnect proxy addresses.
-- Requires the Python modules os and socket.
--
-- Usage:
--   select my_setup_ic_proxy(-1000, '');              -- display IC proxy values for segments
--   select my_setup_ic_proxy(-1000, 'update proxy');  -- update the gp_interconnect_proxy_addresses parameter
--
-- The first argument, "delta", is used to calculate the proxy port with this formula:
--
--   proxy_port = postmaster_port + delta
--
-- The second argument, "action", is used to update the gp_interconnect_proxy_addresses parameter.
-- The parameter is not updated unless "action" is 'update proxy'.
-- Note that running  "gpstop -u" is required for the update to take effect.
-- A WarehousePG cluster restart will also work.
--
create or replace function my_setup_ic_proxy(delta int, action text)
returns table(dbid smallint, content smallint, address text, port int) as $$
    import os
    import socket

    results = []
    value = ''

    segs = plpy.execute('''SELECT dbid, content, port, address
                             FROM gp_segment_configuration
                            ORDER BY 1''')
    for seg in segs:
        dbid = seg['dbid']
        content = seg['content']
        port = seg['port']
        address = seg['address']

        # decide the proxy port
        port = port + delta

        # append to the result list
        results.append((dbid, content, address, port))

        # build the value for the GUC
        if value:
            value += ','
        value += '{}:{}:{}:{}'.format(dbid, content, address, port)

    if action.lower() == 'update proxy':
        os.system('''gpconfig --skipvalidation -c gp_interconnect_proxy_addresses -v "'{}'"'''.format(value))
        plpy.notice('''the settings are applied, please reload with 'gpstop -u' to take effect.''')
    else:
        plpy.notice('''if the settings are correct, re-run with 'update proxy' to apply.''')
    return results
$$ language plpython3u execute on coordinator;
```

> **Note** When you run the function, you should connect to the database using the WarehousePG interconnect type `UDPIFC` or `TCP`. This example uses `psql` to connect to the database `mytest` with the interconnect type `UDPIFC`.

```
PGOPTIONS="-c gp_interconnect_type=udpifc" psql -d mytest
```

Running this command lists the segment instance values for the `gp_interconnect_proxy_addresses` parameter.

```
select my_setup_ic_proxy(-1000, '');
```

This command runs the function to set the parameter.

```
select my_setup_ic_proxy(-1000, 'update proxy');
```

As an alternative, you can run the `gpconfig` utility to set the `gp_interconnect_proxy_addresses` parameter. To set the value as a string, the value is a single-quoted string that is enclosed in double quotes. The example WarehousePG cluster consists of a coordinator and a single segment instance.

```
gpconfig --skipvalidation -c gp_interconnect_proxy_addresses -v "'1:-1:192.168.180.50:35432,2:0:192.168.180.54:35000'"
```

After setting the `gp_interconnect_proxy_addresses` parameter, reload the `postgresql.conf` file with the `gpstop -u` command. This command does not stop and restart the WarehousePG cluster.

Testing the Interconnect Proxies

To test the proxy ports configured for the system, you can set the `PGOPTIONS` environment variable when you start a `psql` session in a command shell. This command sets the environment variable to enable interconnect proxies, starts `psql`, and logs into the database `mytest`.

```
PGOPTIONS="-c gp_interconnect_type=proxy" psql -d mytest
```

You can run queries in the shell to test the system. For example, you can run a query that accesses all the primary segment instances. This query displays the segment IDs and number of rows on the segment instance from the table `sales`.

```
# SELECT gp_segment_id, COUNT(*) FROM sales GROUP BY gp_segment_id ;
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Setting Interconnect Proxies for the System

After you have tested the interconnect proxies for the system, set the server configuration parameter for the system with the `gpconfig` utility.

```
gpconfig -c  gp_interconnect_type -v proxy
```

Reload the `postgresql.conf` file with the `gpstop -u` command. This command does not stop and restart the WarehousePG cluster.

4.2.7 Enabling High Availability and Data Consistency Features

The fault tolerance and the high-availability features of WarehousePG can be configured.

> **Important** When data loss is not acceptable for a WarehousePG cluster, WarehousePG coordinator and segment mirroring is recommended. If mirroring is not enabled then WarehousePG stores only one copy of the data, so the underlying storage media provides the only guarantee for data availability and correctness in the event of a hardware failure.

For information about the utilities that are used to enable high availability, see the *WarehousePG Utility Guide*.

- Overview of WarehousePG High Availability
- Enabling Mirroring in WarehousePG
- How WarehousePG Detects a Failed Segment
- Understanding Segment Recovery
- Recovering from Segment Failures
- Recovering a Failed Coordinator

Parent topic: Managing a WarehousePG cluster

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.2.7.1 Overview of WarehousePG High Availability

A WarehousePG cluster can be made highly available by providing a fault-tolerant hardware platform, by enabling WarehousePG high-availability features, and by performing regular monitoring and maintenance procedures to ensure the health of all system components.

Hardware components will eventually fail, whether due to normal wear or an unexpected circumstance. Loss of power can lead to temporarily unavailable components. A system can be made highly available by providing redundant standbys for components that can fail so that services can continue uninterrupted when a failure does occur. In some cases, the cost of redundancy is higher than users' tolerance for interruption in service. When this is the case, the goal is to ensure that full service is able to be restored, and can be restored within an expected timeframe.

With WarehousePG, fault tolerance and data availability is achieved with:

- Hardware level RAID storage protection
- Data storage checksums
- WarehousePG segment mirroring
- Coordinator mirroring
- Dual clusters
- Database backup and restore

Hardware level RAID

A best practice WarehousePG deployment uses hardware level RAID to provide high performance redundancy for single disk failure without having to go into the database level fault tolerance. This provides a lower level of redundancy at the disk level.

Data storage checksums

WarehousePG uses checksums to verify that data loaded from disk to memory has not been corrupted on the file system.

WarehousePG has two kinds of storage for user data: heap and append-optimized. Both storage models use checksums to verify data read from the file system and, with the default settings, they handle checksum verification errors in a similar way.

WarehousePG coordinator and segment database processes update data on pages in the memory they manage. When a memory page is updated and flushed to disk, checksums are computed and saved with the page. When a page is later retrieved from disk, the checksums are verified and the page is only permitted to enter managed memory if the verification succeeds. A failed checksum verification is an indication of corruption in the file system and causes WarehousePG to generate an error, cancelling the transaction.

The default checksum settings provide the best level of protection from undetected disk corruption propagating into the database and to mirror segments.

Heap checksum support is enabled by default when the WarehousePG cluster is initialized with the `gpinitsystem` management utility. Although it is strongly discouraged, a cluster can be initialized without heap checksum support by setting the `HEAP_CHECKSUM` parameter to off in the `gpinitsystem` cluster configuration file. See gpinitsystem.

Once initialized, it is not possible to change heap checksum support for a cluster without reinitializing the system and reloading databases.

You can check the read-only server configuration parameter data_checksums to see if heap checksums are enabled in a cluster:

```
$ gpconfig -s data_checksums
```

When a WarehousePG cluster starts up, the `gpstart` utility checks that heap checksums are consistently enabled or deactivated on the coordinator and all segments. If there are any differences, the cluster fails to start. Seegpstart.

In cases where it is necessary to ignore heap checksum verification errors so that data can be recovered, setting theignore_checksum_failure system configuration parameter to on causes WarehousePG to issue a warning when a heap checksum verification fails, but the page is then permitted to load into managed memory. If the page is updated and saved to disk, the corrupted data could be replicated to the mirror segment. Because this can lead to data loss, setting `ignore_checksum_failure` to on should only be done to enable data recovery.

For append-optimized storage, checksum support is one of several storage options set at the time an append-optimized table is created with the `CREATE TABLE` command. The default storage options are specified in the `gp_default_storage_options` server configuration parameter. The `checksum` storage option is activated by default and deactivating it is strongly discouraged.

If you choose to deactivate checksums for an append-optimized table, you can either

- change the `gp_default_storage_options` configuration parameter to include `checksum=false` before creating the table, or
- add the `checksum=false` option to the `WITH storage\_options` clause of the `CREATE TABLE` statement.

Note that the `CREATE TABLE` statement allows you to set storage options, including checksums, for individual partition files.

See the CREATE TABLE command reference and the gp_default_storage_options configuration parameter reference for syntax and examples.

Segment Mirroring

WarehousePG stores data in multiple segment instances, each of which is a WarehousePG PostgreSQL instance. The data for each table is spread between the segments based on the distribution policy that is defined for the table in the DDL at the time the table is created. When segment mirroring is enabled, for each segment instance there is a *primary* and *mirror* pair. The mirror segment is kept up to date with the primary segment using Write-Ahead Logging (WAL)-based streaming replication. See Overview of Segment Mirroring.

The mirror instance for each segment is usually initialized with the `gpinitsystem` utility or the `gpexpand` utility. As a best practice, the mirror runs on a different host than the primary instance to protect from a single machine failure. There are different strategies for assigning mirrors to hosts. When choosing the layout of the primaries and mirrors, it is important to consider the failure scenarios to ensure that processing skew is minimized in the case of a single machine failure.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Coordinator Mirroring

There are two coordinator instances in a highly available cluster, a *primary* and a *standby*. As with segments, the coordinator and standby should be deployed on different hosts so that the cluster can tolerate a single host failure. Clients connect to the primary coordinator and queries can be run only on the primary coordinator. The standby coordinator is kept up to date with the primary coordinator using Write-Ahead Logging (WAL)-based streaming replication. See Overview of Coordinator Mirroring.

If the coordinator fails, the administrator runs the `gpactivatestandby` utility to have the standby coordinator take over as the new primary coordinator. You can configure a virtual IP address for the coordinator and standby so that client programs do not have to switch to a different network address when the current coordinator changes. If the coordinator host fails, the virtual IP address can be swapped to the actual acting coordinator.

Dual Clusters

An additional level of redundancy can be provided by maintaining two WarehousePG clusters, both storing the same data.

Two methods for keeping data synchronized on dual clusters are "dual ETL" and "backup/restore."

Dual ETL provides a complete standby cluster with the same data as the primary cluster. ETL (extract, transform, and load) refers to the process of cleansing, transforming, validating, and loading incoming data into a data warehouse. With dual ETL, this process is run twice in parallel, once on each cluster, and is validated each time. It also allows data to be queried on both clusters, doubling the query throughput. Applications can take advantage of both clusters and also ensure that the ETL is successful and validated on both clusters.

To maintain a dual cluster with the backup/restore method, create backups of the primary cluster and restore them on the secondary cluster. This method takes longer to synchronize data on the secondary cluster than the dual ETL strategy, but requires less application logic to be developed. Populating a second cluster with backups is ideal in use cases where data modifications and ETL are performed daily or less frequently.

Backup and Restore

Making regular backups of the databases is recommended except in cases where the database can be easily regenerated from the source data. Backups should be taken to protect from operational, software, and hardware errors.

Use the `gpbackup` utility to backup WarehousePG. `gpbackup` performs the backup in parallel across segments, so backup performance scales up as hardware is added to the cluster.

When designing a backup strategy, a primary concern is where to store the backup data. The data each segment manages can be backed up on the segment's local storage, but should not be stored there permanently—the backup reduces disk space available to the segment and, more importantly, a hardware failure could simultaneously destroy the segment's live data and the backup. After performing a backup, the backup files should be moved from the primary cluster to separate, safe storage. Alternatively, the backup can be made directly to separate storage.

Using a WarehousePG storage plugin with the `gpbackup` and `gprestore` utilities, you can send a backup to, or retrieve a backup from a remote location or a storage appliance. WarehousePG storage plugins support connecting to locations including Amazon Simple Storage Service (Amazon S3) compatbile locations such as Cloudian and Minio.

Using the Backup/Restore Storage Plugin API you can create a custom plugin that the `gpbackup` and `gprestore` utilities can use to integrate a custom backup storage system with the WarehousePG.

For information about using `gpbackup` and `gprestore`, see the documentation.

- Overview of Segment Mirroring
- Overview of Coordinator Mirroring

Parent topic: Enabling High Availability and Data Consistency Features

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.2.7.2 Enabling Mirroring in WarehousePG

You can configure your WarehousePG cluster with mirroring at setup time using `gpinitsystem` or enable mirroring later using `gpaddmirrors` and `gpinitstandby`. This topic assumes you are adding mirrors to an existing system that was initialized without mirrors.

- Enabling Segment Mirroring
- Enabling Coordinator Mirroring

Parent topic: Enabling High Availability and Data Consistency Features

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.2.7.2.1 Enabling Segment Mirroring

Mirror segments allow database queries to fail over to a backup segment if the primary segment is unavailable. By default, mirrors are configured on the same array of hosts as the primary segments. You may choose a completely different set of hosts for your mirror segments so they do not share machines with any of your primary segments.

> **Important** During the online data replication process, WarehousePG should be in a quiescent state, workloads and other queries should not be running.

To add segment mirrors to an existing system (same hosts as primaries)

1. Allocate the data storage area for mirror data on all segment hosts. The data storage area must be different from your primary segments' file system location.
2. Use gpssh-exkeys to ensure that the segment hosts can SSH and remote sync to each other without a password prompt.
3. Run the gpaddmirrors utility to enable mirroring in your WarehousePG cluster. For example, to add 10000 to your primary segment port numbers to calculate the mirror segment port numbers:

   ```
   $ gpaddmirrors -p 10000
   ```

   Where `-p` specifies the number to add to your primary segment port numbers. Mirrors are added with the default group mirroring configuration.

To add segment mirrors to an existing system (different hosts from primaries)

1. Ensure the WarehousePG software is installed on all hosts. See the *WarehousePG Installation Guide* for detailed installation instructions.
2. Allocate the data storage area for mirror data, and tablespaces if needed, on all segment hosts.
3. Use `gpssh-exkeys` to ensure the segment hosts can SSH and remote sync to each other without a password prompt.
4. Create a configuration file that lists the host names, ports, and data directories on which to create mirrors. To create a sample configuration file to use as a starting point, run:

   ```
   $ gpaddmirrors -o <filename>
   ```

   The format of the mirror configuration file is:

   ```
   <row_id>=<contentID>|<address>|<port>|<data_dir>
   ```

   Where `row_id` is the row in the file, contentID is the segment instance content ID, address is the host name or IP address of the segment host, port is the communication port, and `data_dir` is the segment instance data directory.

   For example, this is contents of a mirror configuration file for two segment hosts and two segment instances per host:

   ```
   0=2|sdw1-1|41000|/data/mirror1/gp2
   1=3|sdw1-2|41001|/data/mirror2/gp3
   2=0|sdw2-1|41000|/data/mirror1/gp0
   3=1|sdw2-2|41001|/data/mirror2/gp1
   ```

5. Run the `gpaddmirrors` utility to enable mirroring in your WarehousePG cluster:

   ```
   $ gpaddmirrors -i <mirror_config_file>
   ```

   The `-i` option specifies the mirror configuration file you created.

Parent topic: Enabling Mirroring in WarehousePG

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.2.7.2.2 Enabling Coordinator Mirroring

You can configure a new WarehousePG cluster with a standby coordinator using `gpinitsystem` or enable it later using `gpinitstandby`. This topic assumes you are adding a standby coordinator to an existing system that was initialized without one.

For information about the utilities gpinitsystem and gpinitstandby, see the *WarehousePG Utility Guide*.

To add a standby coordinator to an existing system

1. Ensure the standby coordinator host is installed and configured: `gpadmin` system user created, WarehousePG binaries installed, environment variables set, SSH keys exchanged, and that the data directories and tablespace directories, if needed, are created.
2. Run the `gpinitstandby` utility on the currently active *primary* coordinator host to add a standby coordinator host to your WarehousePG cluster. For example:

   ```
   $ gpinitstandby -s scdw
   ```

   Where `-s` specifies the standby coordinator host name.

To switch operations to a standby coordinator, see Recovering a Failed Coordinator.

To check the status of the coordinator mirroring process (optional)

You can run the `gpstate` utility with the `-f` option to display details of the standby coordinator host.

```
$ gpstate -f
```

The standby coordinator status should be passive, and the WAL sender state should be streaming.

For information about the gpstate utility, see the *WarehousePG Utility Guide*.

Parent topic: Enabling Mirroring in WarehousePG

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.2.7.3 How WarehousePG Detects a Failed Segment

With segment mirroring enabled, WarehousePG automatically fails over to a mirror segment instance when a primary segment instance goes down. Provided one segment instance is online per portion of data, users may not realize a segment is down. If a transaction is in progress when a fault occurs, the in-progress transaction rolls back and restarts automatically on the reconfigured set of segments. The gpstate utility can be used to identify failed segments. The utility displays information from the catalog tables including gp_segment_configuration.

If the entire WarehousePG system becomes nonoperational due to a segment failure (for example, if mirroring is not enabled or not enough segments are online to access all user data), users will see errors when trying to connect to a database. The errors returned to the client program may indicate the failure. For example:

```
ERROR: All segment databases are unavailable
```

How a Segment Failure is Detected and Managed

On the WarehousePG coordinator host, the Postgres `postmaster` process forks a fault probe process, `ftsprobe`. This is also known as the FTS (Fault Tolerance Server) process. The `postmaster` process restarts the FTS if it fails.

The FTS runs in a loop with a sleep interval between each cycle. On each loop, the FTS probes each primary segment instance by making a TCP socket connection to the segment instance using the hostname and port registered in the `gp_segment_configuration` table. If the connection succeeds, the segment performs a few simple checks and reports back to the FTS. The checks include running a `stat` system call on critical segment directories and checking for internal faults in the segment instance. If no issues are detected, a positive reply is sent to the FTS and no action is taken for that segment instance.

If the connection cannot be made, or if a reply is not received in the timeout period, then a retry is attempted for the segment instance. If the configured maximum number of probe attempts fail, the FTS probes the segment's mirror to ensure that it is up, and then updates the `gp_segment_configuration` table, marking the primary segment "down" and setting the mirror to act as the primary. The FTS updates thegp_configuration_history table with the operations performed.

When there is only an active primary segment and the corresponding mirror is down, the primary goes into the *Not In Sync* state and continues logging database changes, so the mirror can be synchronized without performing a full copy of data from the primary to the mirror.

Configuring FTS Behavior

There is a set of server configuration parameters that affect FTS behavior:

gp_fts_probe_interval How often, in seconds, to begin a new FTS loop. For example if the setting is 60 and the probe loop takes 10 seconds, the FTS process sleeps 50 seconds. If the setting is 60 and probe loop takes 75 seconds, the process sleeps 0 seconds. The default is 60, and the maximum is 3600.

gp_fts_probe_timeout Probe timeout between coordinator and segment, in seconds. The default is 20, and the maximum is 3600.

gp_fts_probe_retries The number of attempts to probe a segment. For example if the setting is 5 there will be 4 retries after the first attempt fails. Default: 5

gp_log_fts Logging level for FTS. The value may be "off", "terse", "verbose", or "debug". The "verbose" setting can be used in production to provide useful data for troubleshooting. The "debug" setting should not be used in production. Default: "terse"

gp_segment_connect_timeout The maximum time (in seconds) allowed for a mirror to respond. Default: 180 (3 minutes)

In addition to the fault checking performed by the FTS, a primary segment that is unable to send data to its mirror can change the status of the mirror to down. The primary queues up the data and after `gp_segment_connect_timeout` seconds pass, indicates a mirror failure, causing the mirror to be marked down and the primary to go into `Not In Sync` mode.

4.2.7.4 Understanding Segment Recovery

This topic provides background information about concepts and principles of segment recovery. If you have down segments and need immediate help recovering them, see the instructions inRecovering from Segment Failures. For information on how WarehousePG detects that segments are down and an explanation of the Fault Tolerance Server (FTS) that manages down segment tracking, see How WarehousePG Detects a Failed Segment.

This topic is divided into the following sections:

- Segment Recovery Basics
- Segment Recovery: Flow of Events
- Simple Failover and Recovery Example
- The Three Types of Segment Recovery

Parent topic: Enabling High Availability and Data Consistency Features

Segment Recovery Basics

If the coordinator cannot connect to a segment instance, it marks that segment as down in the WarehousePG `gp_segment_configuration` table. The segment instance remains offline until an administrator takes steps to bring the segment back online. The process for recovering a down segment instance or host depends on the cause of the failure and on whether or not mirroring is enabled. A segment instance can be marked as down for a number of reasons:

- A segment host is unavailable; for example, due to network or hardware failures.
- A segment instance is not running; for example, there is no `postgres` database listener process.
- The data directory of the segment instance is corrupt or missing; for example, data is not accessible, the file system is corrupt, or there is a disk failure.

In order to bring the down segment instance back into operation again, you must correct the problem that made it fail in the first place, and then – if you have mirroring enabled – you can attempt to recover the segment instance from its mirror using the `gprecoverseg` utility. See The Three Types of Segment Recovery, below, for details on the three possible ways to recover a downed segment's data.

Segment Recovery: Flow of Events

When a Primary Segment Goes Down

The following summarizes the flow of events that follow a **primary** segment going down:

1. A primary segment goes down.
2. The Fault Tolerance Server (FTS) detects this and marks the segment as down in the `gp_segment_configuration` table.
3. The mirror segment is promoted to primary and starts functioning as primary. The previous primary is demoted to mirror.
4. The user fixes the underlying problem.
5. The user runs `gprecoverseg` to bring back the (formerly primary) mirror segment.
6. The WAL synchronization process ensures that the mirror segment data is synchronized with the primary segment data. Users can check the state of this synching with `gpstate -e`.
7. WarehousePG marks the segments as up (`u`) in the `gp_segment_configuration` table.
8. If segments are not in their preferred roles, user runs `gprecoverseg -r` to restore them to their preferred roles.

When a Mirror Segment Goes Down

The following summarizes the flow of events that follow a **mirror** segment going down:

1. A mirror segment goes down.
2. The Fault Tolerance Server (FTS) detects this and marks the segment as down in the `gp_segment_configuration` table.
3. The user fixes the underlying problem.
4. The user runs `gprecoverseg` to bring back the (formerly mirror) mirror segment.
5. The synching process occurs: the mirror comes into sync with its primary via WAL synching. You can check the state of this synching with `gpstate -e`.

Rebalancing After Recovery

After a segment instance has been recovered, the segments may not be in their preferred roles, which can cause processing to be skewed. The `gp_segment_configuration` table has the columns `role` (current role) and `preferred_role` (original role at the beginning). When a segment's `role` and `preferred_role` do not match the system may not be balanced. To rebalance the cluster and bring all the segments into their preferred roles, run the `gprecoverseg -r` command.

Simple Failover and Recovery Example

Consider a single primary-mirror segment instance pair where the primary segment has failed over to the mirror. The following table shows the segment instance preferred role, role, mode, and status from the `gp_segment_configuration` table before beginning recovery of the failed primary segment.

You can also run `gpstate -e` to display any issues with a primary or mirror segment instances.

Segment Type	`preferred_role`	`role`	`mode`	`status`
Primary	`p` (primary)	`m` (mirror)	`n` (Not In Sync)	`d` (down)
Mirror	`m` (mirror)	`p` (primary)	`n` (Not In Sync)	`u` (up)

The primary segment is down and segment instances are not in their preferred roles. The mirror segment is up and its role is now primary. However, it is not synchronized with its mirror (the former primary segment) because that segment is down. You must potentially fix either issues with the host the down segment is running on, issues with the segment instance itself, or both. You then use `gprecoverseg` to prepare failed segment instances for recovery and initiate synchronization between the primary and mirror instances.

After `gprecoverseg` has completed, the segments are in the states shown in the following table where the primary-mirror segment pair is up with the primary and mirror roles reversed from their preferred roles.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

> **Note** There might be a lag between when `gprecoverseg` completes and when the segment status is set to `u` (up).

Segment Type	`preferred_role`	`role`	`mode`	`status`
Primary	`p` (primary)	`m` (mirror)	`s` (Synchronized)	`u` (up)
Mirror	`m` (mirror)	`p` (primary)	`s` (Synchronized)	`u` (up)

The `gprecoverseg -r` command rebalances the system by returning the segment roles to their preferred roles.

Segment Type	`preferred_role`	`role`	`mode`	`status`
Primary	`p` (primary)	`p` (primary)	`s` (Synchronized)	`u` (up)
Mirror	`m` (mirror)	`m` (mirror)	`s` (Synchronized)	`u` (up)

The Three Types of Segment Recovery

WarehousePG can perform three types of segment recovery: full, differential, and incremental (the default).

Full recovery : Full recovery recovers all segments. Specifically, it erases all data files and directories on the current mirror segment and copies to the mirror segment the exact contents of the current primary segment. Full recovery uses the `pg_basebackup` utility to copy files.

With full recovery, you may recover:

- to the current host -- known as "in-place recovery"
- to a different host within the current cluster
- to a new host outside of the current cluster

Differential recovery Differential recovery performs a filesystem-level diff between the primary and mirror segments, and copies from the primary to the mirror only those files that have changed on the primary. With differential recovery, you may only do in-place recovery. Differential recovery uses the `rsync` command to copy files.

Incremental recovery (default) Incremental recovery brings the mirror segment contents into sync with the primary segment contents with the aid of write-ahead log files (WAL files). With incremental recovery, you may only do in-place recovery. Incremental recovery uses the `pg_rewind` utility to copy files.

```
By default, `gprecoverseg` performs an incremental recovery, placing the mirror into *Synchronizing* mode, which starts to replay the recorded changes from the primary onto the mirror. If the incremental recovery cannot be completed, the recovery fails and you should run `gprecoverseg` again with the `-F` option, to perform full recovery. This causes the primary to copy all of its data to the mirror.

>**Note**
>After a failed incremental recovery attempt you must perform a full recovery.

Whenever possible, you should perform an incremental recovery rather than a full recovery, as incremental recovery is substantially faster. If you **do** need to perform an in-place full recovery, you can speed up in-place full recovery with `gprecoverseg`'s `--differential` option, which causes `gprecoverseg` to skip recovery of any files and directories that are unchanged.
```

4.2.7.5 Recovering from Segment Failures

This topic walks you through what to do when one or more segments or hosts are down and you want to recover the down segments. The recovery path you follow depends primarily which of these 3 scenarios fits your circumstances:

- you want to recover in-place to the current host
- you want to recover to a different host, within the cluster
- you want to recover to a new host, outside of the cluster

The steps you follow within these scenarios can vary, depending on:

- whether you want to do an incremental or a full recovery
- whether you want to recover all segments or just a subset of segments

> **Note** Incremental recovery is only possible when recovering segments to the current host (in-place recovery).

This topic is divided into the following sections:

- Prerequisites
- Recovery Scenarios
- Post-Recovery Tasks

Parent topic: Enabling High Availability and Data Consistency Features

Prerequisites

- Mirroring is enabled for all segments.
- You've already identified which segments have failed. If necessary, see the topic Checking for Failed Segments.
- The coordinator host can connect to the segment host.
- All networking or hardware issues that caused the segment to fail have been resolved.

Recovery Scenarios

This section documents the steps for the 3 distinct segment recovery scenarios. Follow the link to instructions that walk you through each scenario.

- Recover In-Place to Current Host
  - Incremental Recovery
  - Full Recovery
  - Differential Recovery
- Recover to A Different Host within the Cluster
- Recover to A New Host, Outside of the Cluster

Recover In-Place to Current Host

When recovering in-place to the current host, you may choose between incremental recovery (the default), full recovery, and differential recovery.

Incremental Recovery

Follow these steps for incremental recovery:

1. To recover all segments, run `gprecoverseg` with no options:

   ```
   gprecoverseg
   ```

2. To recover a subset of segments:

   1. Manually create a `recover_config_file` file in a location of your choice, where each segment to recover has its own line with format `failedAddress|failedPort|failedDataDirectory` or `failedHostname|failedAddress|failedPort|failedDataDirectory`

      For multiple segments, create a new line for each segment you want to recover, specifying the hostname (optional), the address, port number and data directory for each down segment. For example:

      ```
      failedAddress1|failedPort1|failedDataDirectory1
      failedAddress2|failedPort2|failedDataDirectory2
      failedAddress3|failedPort3|failedDataDirectory3
      ```

      or

      ```
      failedHostname1|failedAddress1|failedPort1|failedDataDirectory1
      failedHostname2|failedAddress2|failedPort2|failedDataDirectory2
      failedHostname3|failedAddress3|failedPort3|failedDataDirectory3
      ```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

2. Alternatively, generate a sample recovery file using the following command; you may edit the resulting file if necessary:

    ```
    $ gprecoverseg -o /home/gpadmin/recover_config_file
    ```

3. Pass the `recover_config_file` to the `gprecoverseg -i` command:

    ```
    $ gprecoverseg -i /home/gpadmin/recover_config_file
    ```

3. Perform the post-recovery tasks summarized in the section Post-Recovery Tasks.

Full Recovery

1. To recover all segments, run `gprecoverseg -F`:

    ```
    gprecoverseg -F
    ```

2. To recover specific segments:

    1. Manually create a `recover_config_file` file in a location of your choice, where each segment to recover has its own line with following format:

        ```
        failedAddress1|failedPort1|failedDataDirectory1<SPACE>failedAddress2|failedPort2|failedDataDirectory2
        ```

        or

        ```
        failedHostname1|failedAddress1|failedPort1|failedDataDirectory1<SPACE>failedHostname2|failedAddress2|failedPort2|failedDataDirectory2
        ```

        Note the literal **SPACE** separating the lines.

    2. Alternatively, generate a sample recovery file using the following command and edit the resulting file to match your desired recovery configuration:

        ```
        $ gprecoverseg -o /home/gpadmin/recover_config_file
        ```

    3. Run the following command, passing in the config file generated in the previous step:

        ```
        $ gprecoverseg -i recover_config_file
        ```

3. Perform the post-recovery tasks summarized in the section Post-Recovery Tasks.

Differential Recovery

Follow these steps for differential recovery:

1. Run `gprecoverseg --differential`

Recover to A Different Host within the Cluster

> **Note** Only full recovery is possible when recovering to a different host in the cluster.

Follow these steps to recover all segments or just a subset of segments to a different host in the cluster:

1. Manually create a `recover_config_file` file in a location of your choice, where each segment to recover has its own line with following format:

    ```
    failedAddress|failedPort|failedDataDirectory<SPACE>newAddress|newPort|newDataDirectory
    ```

    or

    ```
    failedHostname|failedAddress|failedPort|failedDataDirectory<SPACE>newHostname|newAddress|newPort|newDataDirectory
    ```

    Note the literal **SPACE** separating the details of the down segment from the details of where the segment will be recovered to.

    Alternatively, generate a sample recovery file using the following command and edit the resulting file to match your desired recovery configuration:

    ```
    $ gprecoverseg -o -p /home/gpadmin/recover_config_file
    ```

2. Run the following command, passing in the config file generated in the previous step:

    ```
    $ gprecoverseg -i recover_config_file
    ```

3. Perform the post-recovery tasks summarized in the section Post-Recovery Tasks.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Recover to A New Host, Outside of the Cluster

Follow these steps if you are planning to do a hardware refresh on the host the segments are running on.

> **Note** Only full recovery is possible when recovering to a new host.

Requirements for New Host

The new host must:

- have the same WarehousePG software installed and configured as the failed host
- have the same hardware and OS configuration as the failed host (same hostname, OS version, OS configuration parameters applied, locales, gpadmin user account, data directory locations created, ssh keys exchanged, number of network interfaces, network interface naming convention, and so on)
- have sufficient disk space to accommodate the segments
- be able to connect password-less with all other existing segments and WarehousePG coordinator.

Steps to Recover to a New Host

1. Bring up the new host
2. Run the following command to recover all segments to the new host:

   ```
   gprecoverseg -p <new_host_name>
   ```

   You may also specify more than one host. However, be sure you do not trigger a double-fault scenario when recovering to two hosts at a time.

   ```
   gprecoverseg -p <new_host_name1>,<new_host_name2>
   ```

   > **Note** In the case of multiple failed segment hosts, you can specify the hosts to recover to with a comma-separated list. However, it is strongly recommended to recover to one host at a time. If you must recover to more than one host at a time, then it is critical to ensure that a double fault scenario does not occur, in which both the segment primary and corresponding mirror are offline.

3. Perform the post-recovery tasks summarized in the section Post-Recovery Tasks.

Post-Recovery Tasks

Follow these steps once `gprecoverseg` has completed:

1. Validate segement status and preferred roles:

   ```
   select * from gp_segment_configuration
   ```

2. Monitor mirror synchronization progress:

   ```
   gpstate -e
   ```

3. If necessary, run the following command to return segments to their preferred roles:

   ```
   gprecoverseg -r
   ```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.2.7.6 Recovering a Failed Coordinator

If the primary coordinator fails, the WarehousePG cluster is not accessible and WAL replication stops. Use gpactivatestandby to activate the standby coordinator. Upon activation of the standby coordinator, WarehousePG reconstructs the coordinator host state at the time of the last successfully committed transaction.

These steps assume a standby coordinator host is configured for the system. See Enabling Coordinator Mirroring.

To activate the standby coordinator

1. Run the `gpactivatestandby` utility from the standby coordinator host you are activating. For example:

   ```
   $ export PGPORT=5432
   $ gpactivatestandby -d /data/coordinator/gpseg-1
   ```

   Where `-d` specifies the data directory of the coordinator host you are activating.

   After you activate the standby, it becomes the *active* or *primary* coordinator for your WarehousePG cluster.

   > **NOTE** Before running `gpactivatestandby`, be sure to run `gpstate -f` to confirm that the standby coordinator is synchronized with the current coordinator node. If synchronized, the final line of the `gpstate -f` output will look similar to this: `20230607:06:50:06:004205 gpstate:test1-m:gpadmin-[INFO]:--Sync state: sync`

2. After the utility completes, run `gpstate` with the `-b` option to display a summary of the system status:

   ```
   $ gpstate -b
   ```

   The coordinator instance status should be `Active`. When a standby coordinator is not configured, the command displays `No coordinator standby configured` for the standby coordinator status. If you configured a new standby coordinator, its status is `Passive`.

3. Optional: If you have not already done so while activating the prior standby coordinator, you can run `gpinitstandby` on the active coordinator host to configure a new standby coordinator.

   > **Important** You must initialize a new standby coordinator to continue providing coordinator mirroring.

   For information about restoring the original coordinator and standby coordinator configuration, see Restoring Coordinator Mirroring After a Recovery.

- **Restoring Coordinator Mirroring After a Recovery**

Parent topic: Enabling High Availability and Data Consistency Features

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.2.7.7 Checking for Failed Segments

With mirroring enabled, you can have failed segment instances in the system without interruption of service or any indication that a failure has occurred. You can verify the status of your system using the `gpstate` utility, by examing the contents of the `gp_segment_configuration` catalog table, or by checking log files.

Check for failed segments using gpstate

The `gpstate` utility provides the status of each individual component of a WarehousePG cluster, including primary segments, mirror segments, coordinator, and standby coordinator.

On the coordinator host, run the gpstate utility with the `-e` option to show segment instances with error conditions:

```
$ gpstate -e
```

If the utility lists `Segments with Primary and Mirror Roles Switched`, the segment is not in its *preferred role* (the role to which it was assigned at system initialization). This means the system is in a potentially unbalanced state, as some segment hosts may have more active segments than is optimal for top system performance.

Segments that display the `Config status` as `Down` indicate the corresponding mirror segment is down.

See Recovering from Segment Failures for instructions to fix this situation.

Check for failed segments using the gp_segment_configuration table

To get detailed information about failed segments, you can check the gp_segment_configuration catalog table. For example:

```
$ psql postgres -c "SELECT * FROM gp_segment_configuration WHERE status='d';"
```

For failed segment instances, note the host, port, preferred role, and data directory. This information will help determine the host and segment instances to troubleshoot. To display information about mirror segment instances, run:

```
$ gpstate -m
```

Check for failed segments by examining log files

Log files can provide information to help determine an error's cause. The coordinator and segment instances each have their own log file in `log` of the data directory. The coordinator log file contains the most information and you should always check it first.

Use the gplogfilter utility to check the WarehousePG log files for additional information. To check the segment log files, run `gplogfilter` on the segment hosts using gpssh.

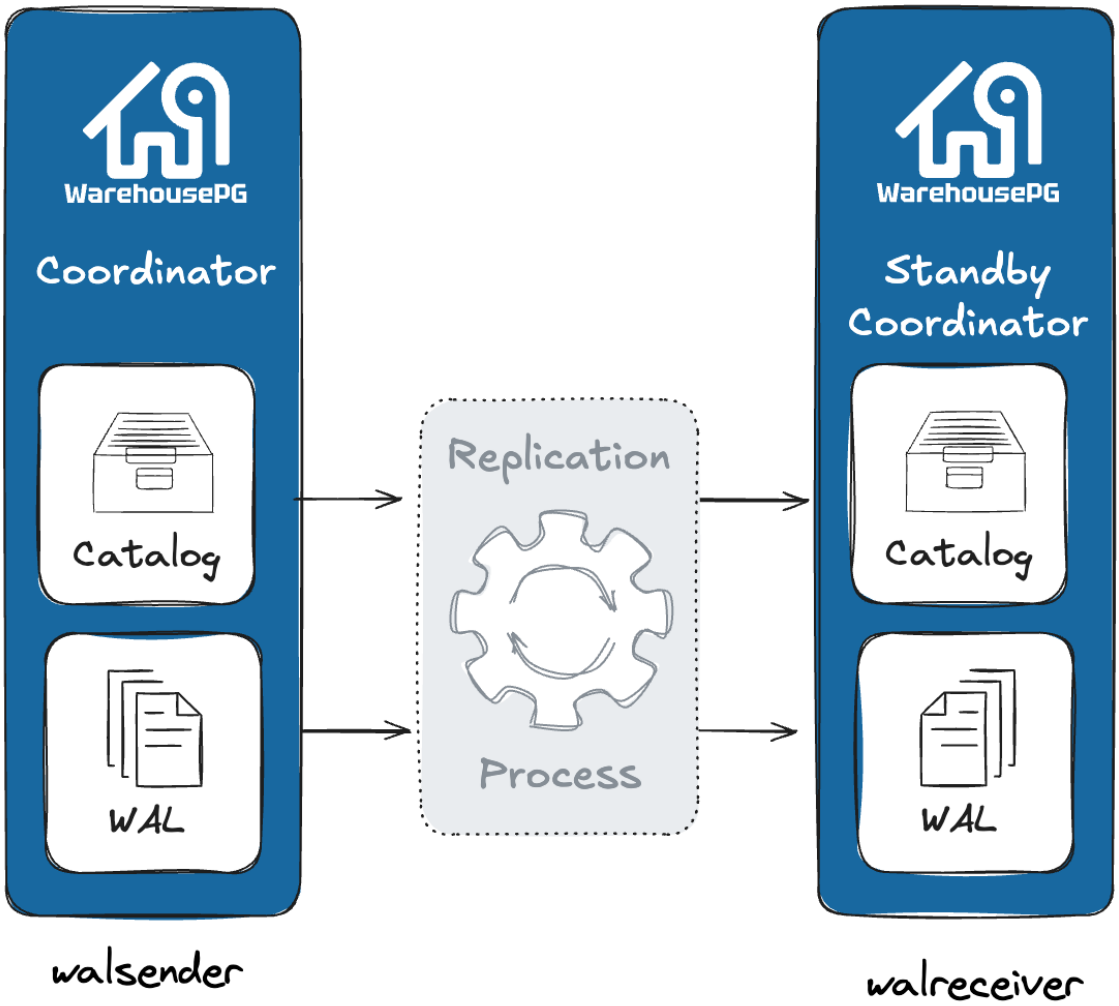
To check the log files

1. Use `gplogfilter` to check the coordinator log file for `WARNING`, `ERROR`, `FATAL` or `PANIC` log level messages:

   ```
   $ gplogfilter -t
   ```

2. Use `gpssh` to check for `WARNING`, `ERROR`, `FATAL`, or `PANIC` log level messages on each segment instance. For example:

   ```
   $ gpssh -f seg_hosts_file -e 'source
   /usr/edb/whpg7/greenplum_path.sh ; gplogfilter -t
   /data1/primary/*/log/gpdb*.log' > seglog.out
   ```



Parent topic: How WarehousePG Detects a Failed Segment

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.2.7.8 Overview of Coordinator Mirroring

You can deploy a backup or mirror of the coordinator instance on a separate host machine. The backup coordinator instance, called the *standby coordinator*, serves as a warm standby if the primary coordinator becomes nonoperational. You create a standby coordinator from the primary coordinator while the primary is online.

When you enable coordinator mirroring for an existing system, the primary coordinator continues to provide service to users while a snapshot of the primary coordinator instance is taken. While the snapshot is taken and deployed on the standby coordinator, changes to the primary coordinator are also recorded. After the snapshot has been deployed on the standby coordinator, the standby coordinator is synchronized and kept current using Write-Ahead Logging (WAL)-based streaming replication. WarehousePG WAL replication uses the `walsender` and `walreceiver` replication processes. The `walsender` process is a primary coordinator process. The `walreceiver` is a standby coordinator process.

Since the coordinator does not house user data, only system catalog tables are synchronized between the primary and standby coordinators. When these tables are updated, the replication logs that capture the changes are streamed to the standby coordinator to keep it current with the primary. During WAL replication, all database modifications are written to replication logs before being applied, to ensure data integrity for any in-process operations.

This is how WarehousePG handles a coordinator failure.

- If the primary coordinator fails, the WarehousePG cluster shuts down and the coordinator replication process stops. The administrator runs the `gpactivatestandby` utility to have the standby coordinator take over as the new primary coordinator. Upon activation of the standby coordinator, the replicated logs reconstruct the state of the primary coordinator at the time of the last successfully committed transaction. The activated standby coordinator then functions as the WarehousePG coordinator, accepting connections on the port specified when standby coordinator was initialized. See Recovering a Failed Coordinator.
- If the standby coordinator fails or becomes inaccessible while the primary coordinator is active, the primary coordinator tracks database changes in logs that are applied to the standby coordinator when it is recovered.

These WarehousePG cluster catalog tables contain mirroring and replication information.

- The catalog table gp_segment_configuration contains the current configuration and state of primary and mirror segment instances and the coordinator and standby coordinator instance.
- The catalog view gp_stat_replication contains replication statistics of the `walsender` processes that are used for WarehousePG coordinator and segment mirroring.

Parent topic: Overview of WarehousePG High Availability

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.2.7.9 Overview of Segment Mirroring

When WarehousePG High Availability is enabled, there are two types of segment instances: *primary* and *mirror*. Each primary segment has one corresponding mirror segment. A primary segment instance receives requests from the coordinator to make changes to the segment data and then replicates those changes to the corresponding mirror. If WarehousePG detects that a primary segment has failed or become unavailable, it changes the role of its mirror segment to primary segment and the role of the unavailable primary segment to mirror segment. Transactions in progress when the failure occurred roll back and must be restarted. The administrator must then recover the mirror segment, allow the mirror to synchronize with the current primary segment, and then exchange the primary and mirror segments so they are in their preferred roles.

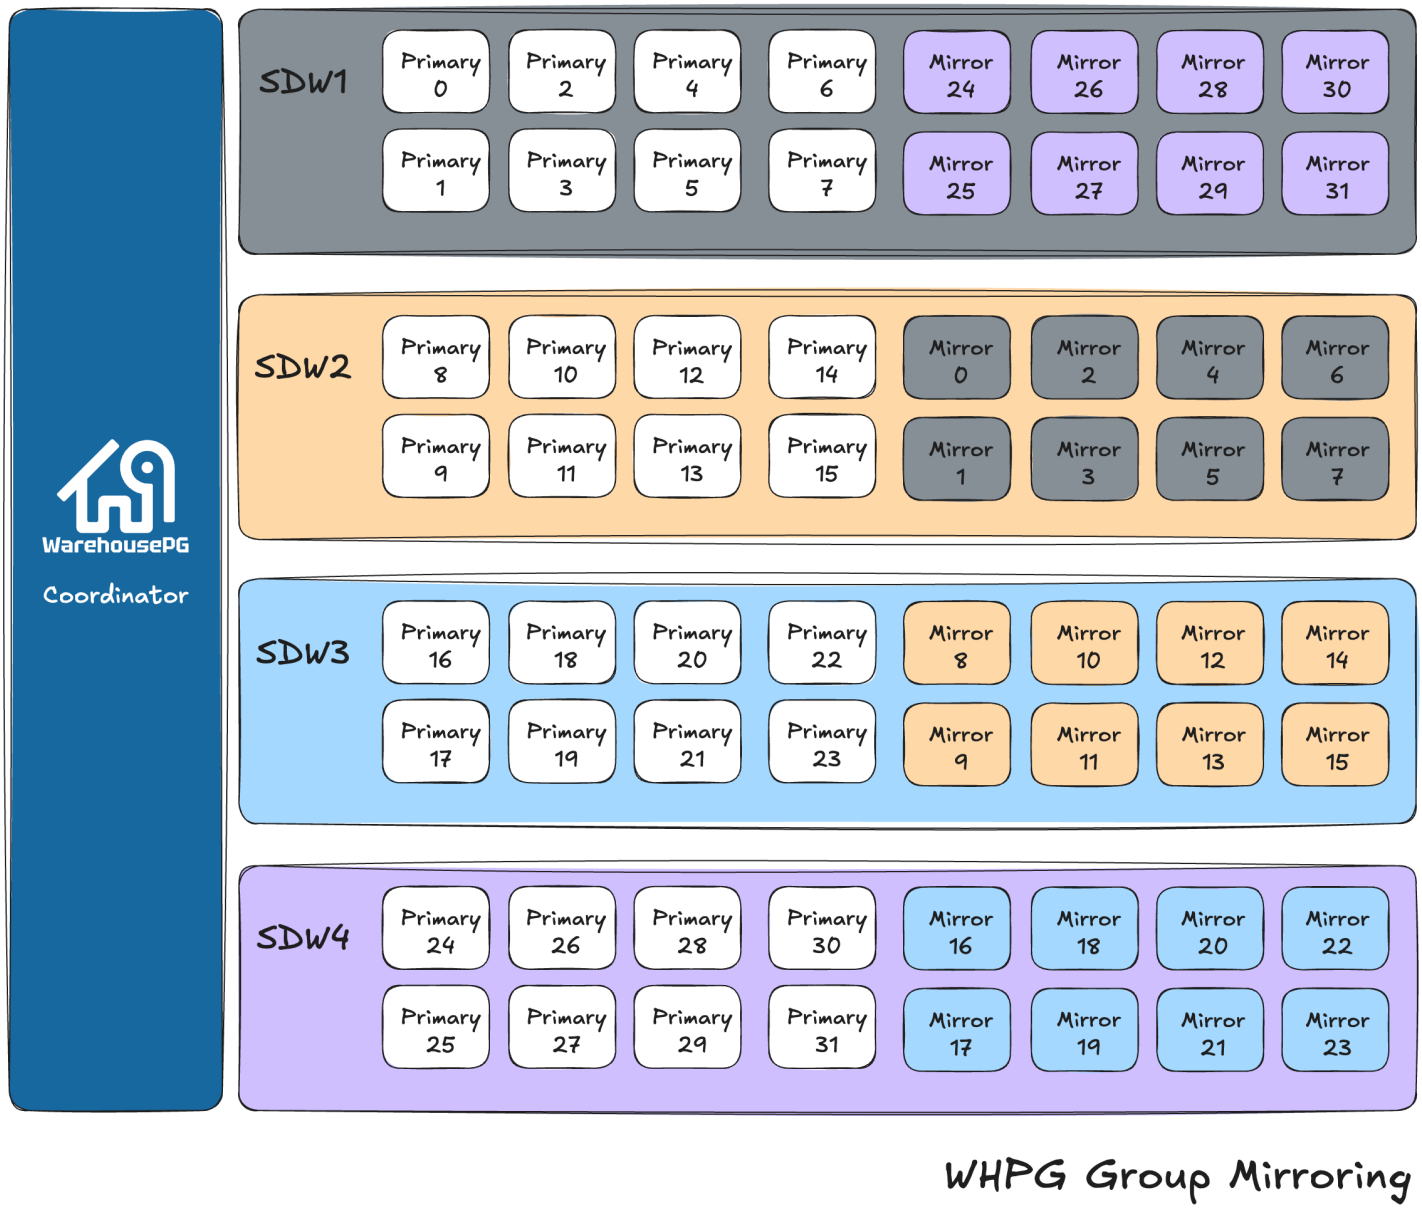
If segment mirroring is not enabled, the WarehousePG cluster shuts down if a segment instance fails. Administrators must manually recover all failed segments before WarehousePG operations can resume.

When segment mirroring is enabled for an existing system, the primary segment instances continue to provide service to users while a snapshot of the primary segments are taken. While the snapshots are taken and deployed on the mirror segment instances, changes to the primary segment are also recorded. After the snapshot has been deployed on the mirror segment, the mirror segment is synchronized and kept current using Write-Ahead Logging (WAL)-based streaming replication. WarehousePG WAL replication uses the `walsender` and `walreceiver` replication processes. The `walsender` process is a primary segment process. The `walreceiver` is a mirror segment process.

When database changes occur, the logs that capture the changes are streamed to the mirror segment to keep it current with the corresponding primary segments. During WAL replication, database changes are written to the logs before being applied, to ensure data integrity for any in-process operations.

When WarehousePG detects a primary segment failure, the WAL replication process stops and the mirror segment automatically starts as the active primary segment. If a mirror segment fails or becomes inaccessible while the primary is active, the primary segment tracks database changes in logs that are applied to the mirror when it is recovered. For information about segment fault detection and the recovery process, see How WarehousePG Detects a Failed Segment and Recovering from Segment Failures.

These WarehousePG cluster catalog tables contain mirroring and replication information.

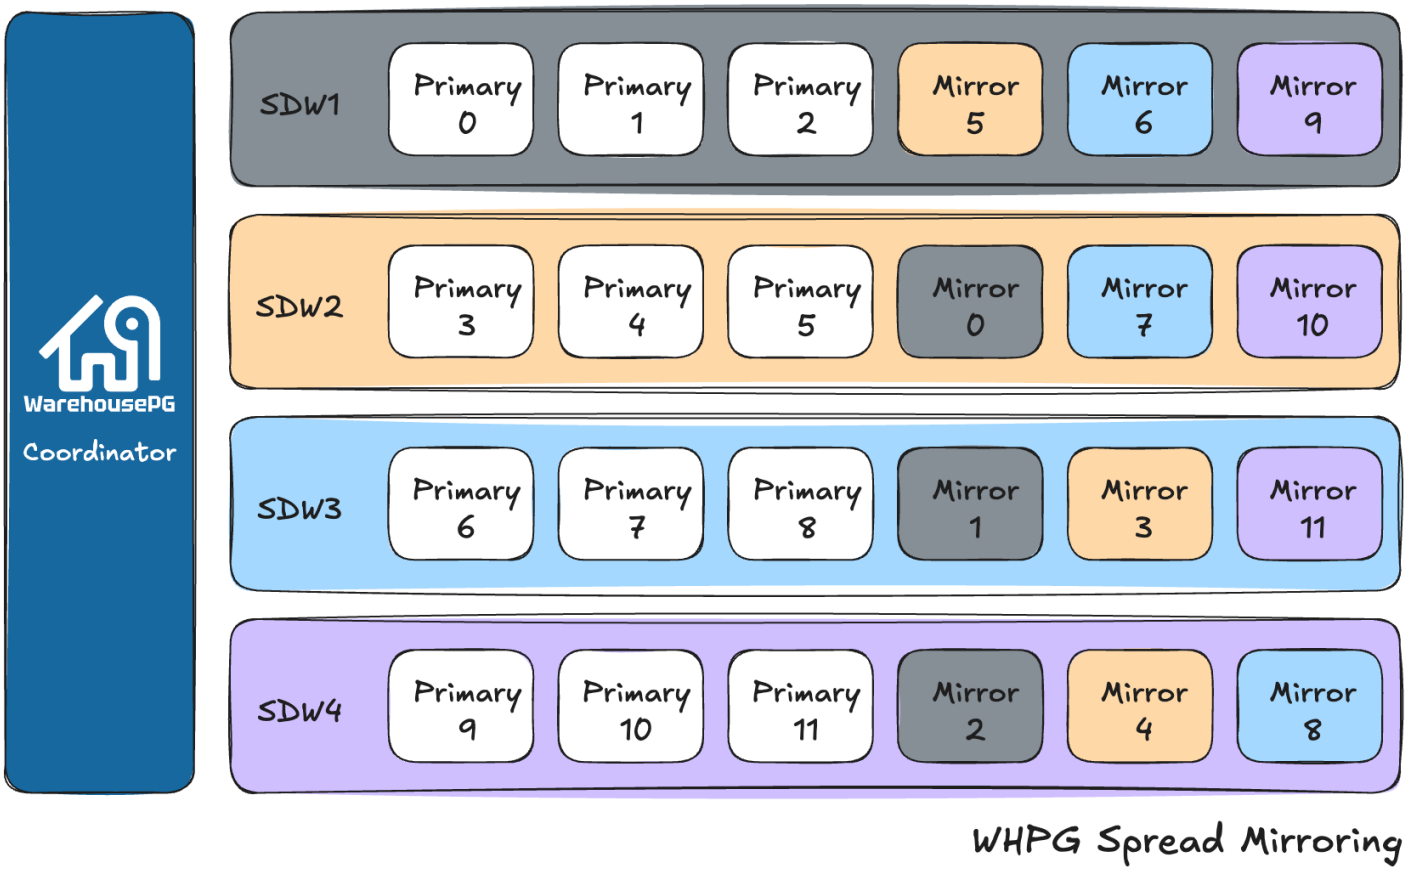


- The catalog table gp_segment_configuration contains the current configuration and state of primary and mirror segment instances and the coordinator and standby coordinator instance.
- The catalog view gp_stat_replication contains replication statistics of the `walsender` processes that are used for WarehousePG coordinator and segment mirroring.

About Segment Mirroring Configurations

Mirror segment instances can be placed on hosts in the cluster in different configurations. As a best practice, a primary segment and the corresponding mirror are placed on different hosts. Each host must have the same number of primary and mirror segments. When you create segment mirrors with the WarehousePG utilities gpinitsystem or gpaddmirrors you can specify the segment mirror configuration, group mirroring (the default) or spread mirroring. With `gpaddmirrors`, you can create custom mirroring configurations with a `gpaddmirrors` configuration file and specify the file on the command line.

Group mirroring is the default mirroring configuration when you enable mirroring during system initialization. The mirror segments for each host's primary segments are placed on one other host. If a single host fails, the number of active primary segments doubles on the host that backs the failed host. The following figure illustrates a group mirroring configuration.



Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

WHPG Group Mirroring

Spread mirroring can be specified during system initialization. This configuration spreads each host's mirrors over multiple hosts so that if any single host fails, no other host will have more than one mirror promoted to an active primary segment. Spread mirroring is possible only if there are more hosts than segments per host. The following figure illustrates the placement of mirrors in a spread segment mirroring configuration.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Note You must ensure you have the appropriate number of host systems for your mirroring configuration when you create a system or when you expand a system. For example, to create a system that is configured with spread mirroring requires more hosts than segment instances per host, and a system that is configured with group mirroring requires at least two new hosts when expanding the system. For information about segment mirroring configurations, see Segment Mirroring Configurations. For information about expanding systems with segment mirroring enabled, seePlanning Mirror Segments.

4.2.7.10 Restoring Coordinator Mirroring After a Recovery

After you activate a standby coordinator for recovery, the standby coordinator becomes the primary coordinator. You can continue running that instance as the primary coordinator if it has the same capabilities and dependability as the original coordinator host.

You must initialize a new standby coordinator to continue providing coordinator mirroring unless you have already done so while activating the prior standby coordinator. Run`gpinitstandby` on the active coordinator host to configure a new standby coordinator. See Enabling Coordinator Mirroring.

You can restore the primary and standby coordinator instances on the original hosts. This process swaps the roles of the primary and standby coordinator hosts, and it should be performed only if you strongly prefer to run the coordinator instances on the same hosts they occupied prior to the recovery scenario.

> **Important** Restoring the primary and standby coordinator instances to their original hosts is not an online operation. The coordinator host must be stopped to perform the operation.

For information about the WarehousePG utilities, see the *WarehousePG Utility Guide*.

Parent topic: Recovering a Failed Coordinator

To restore the coordinator mirroring after a recovery

1. Ensure the original coordinator host is in dependable running condition; ensure the cause of the original failure is fixed.
2. On the original coordinator host, move or remove the data directory, `gpseg-1`. This example moves the directory to `backup_gpseg-1`:

   ```
   $ mv /data/coordinator/gpseg-1 /data/coordinator/backup_gpseg-1
   ```

   You can remove the backup directory once the standby is successfully configured.
3. Initialize a standby coordinator on the original coordinator host. For example, run this command from the current coordinator host, scdw:

   ```
   $ gpinitstandby -s cdw
   ```
4. After the initialization completes, check the status of standby coordinator, cdw. Run`gpstate` with the `-f` option to check the standby coordinator status:

   ```
   $ gpstate -f
   ```

   The standby coordinator status should be `passive`, and the WAL sender state should be `streaming`.

To restore the coordinator and standby instances on original hosts (optional)

> **Note** Before performing the steps in this section, be sure you have followed the steps to restore coordinator mirroring after a recovery, as described in the`To restore the coordinator mirroring after a recovery`previous section.

1. Stop the WarehousePG coordinator instance on the standby coordinator. For example:

   ```
   $ gpstop -m
   ```
2. Run the `gpactivatestandby` utility from the original coordinator host, cdw, that is currently a standby coordinator. For example:

   ```
   $ gpactivatestandby -d $COORDINATOR_DATA_DIRECTORY
   ```

   Where the `-d` option specifies the data directory of the host you are activating.

   > **NOTE** Before running `gpactivatestandby`, be sure to run `gpstate -f` to confirm that the standby coordinator is synchronized with the current coordinator node. If synchronized, the final line of the `gpstate -f` output will look similar to this: `20230607:06:50:06:004205 gpstate:test1-m:gpadmin-[INFO]:--Sync state: sync`
3. After the utility completes, run `gpstate` with the `-b` option to display a summary of the system status:

   ```
   $ gpstate -b
   ```

   The coordinator instance status should be `Active`. When a standby coordinator is not configured, the command displays `No coordinator standby configured` for the standby coordinator state.
4. On the standby coordinator host, move or remove the data directory, `gpseg-1`. This example moves the directory:

   ```
   $ mv /data/coordinator/gpseg-1 /data//backup_gpseg-1
   ```

   You can remove the backup directory once the standby is successfully configured.
5. After the original coordinator host runs the primary WarehousePG coordinator, you can initialize a standby coordinator on the original standby coordinator host. For example:

   ```
   $ gpinitstandby -s scdw
   ```

   After the command completes, you can run the `gpstate -f` command on the primary coordinator host, to check the standby coordinator status.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

To check the status of the coordinator mirroring process (optional)

You can run the `gpstate` utility with the `-f` option to display details of the standby coordinator host.

```
$ gpstate -f
```

The standby coordinator status should be `passive`, and the WAL sender state should be `streaming`.

For information about the gpstate utility, see the *WarehousePG Utility Guide*.

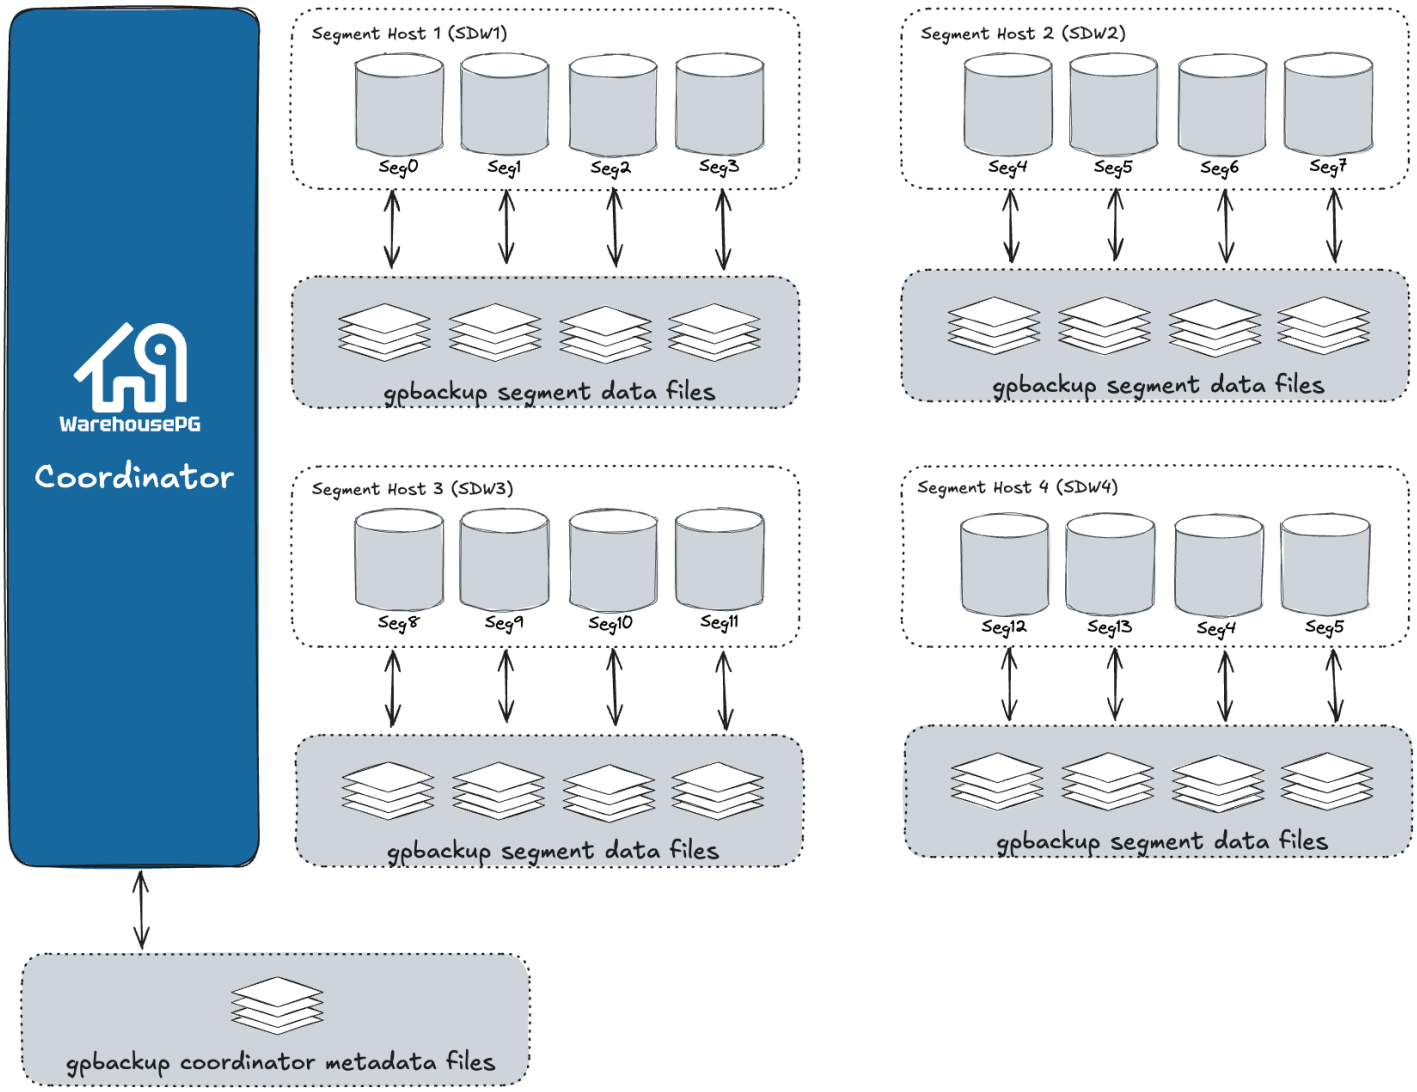
4.2.8 Backing Up and Restoring Databases



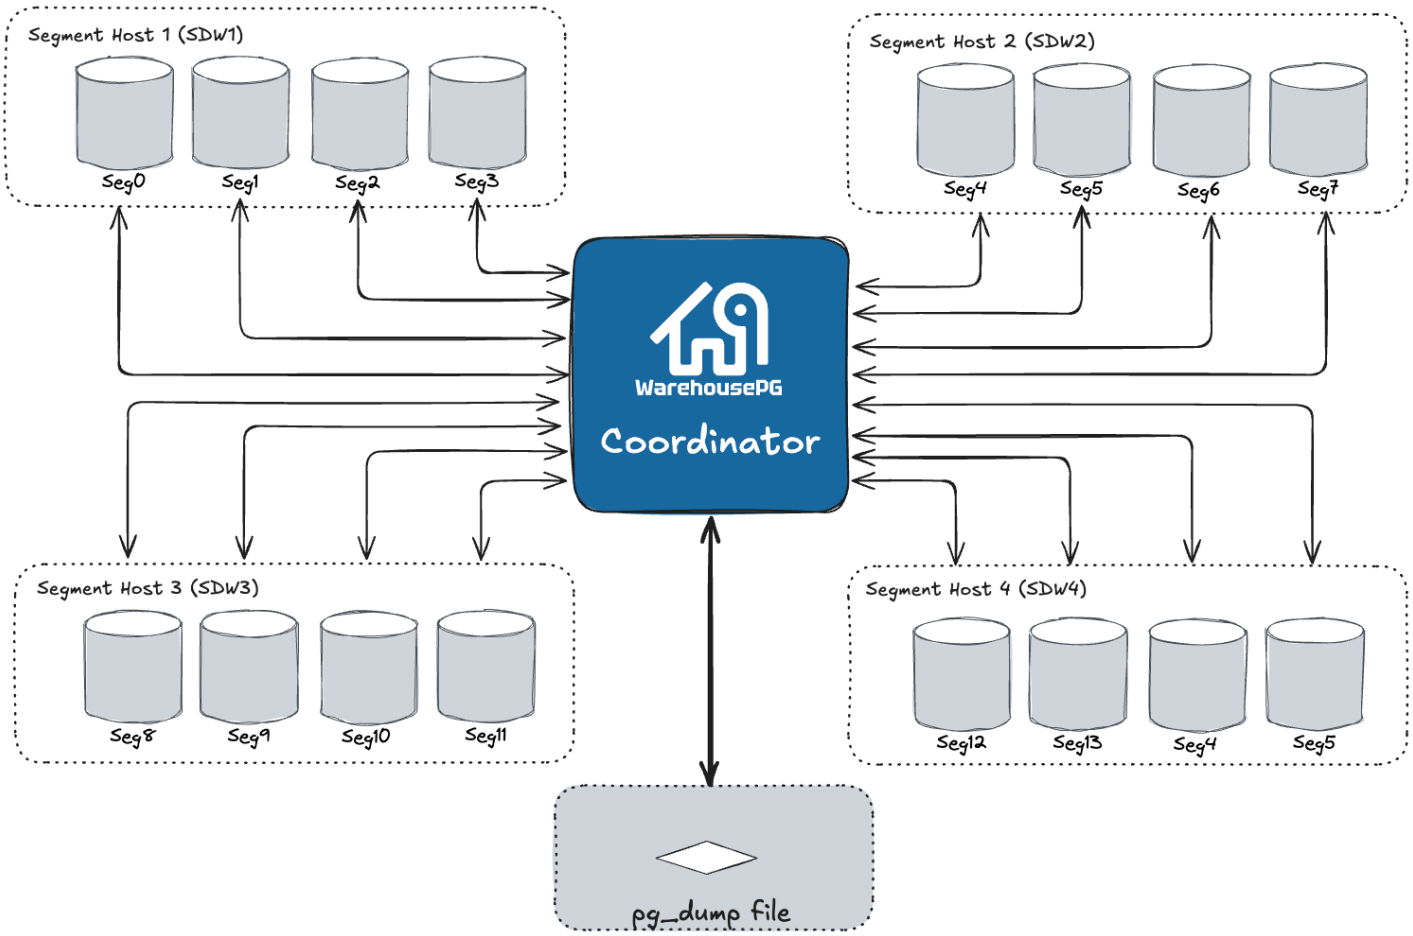
Performing backups regularly ensures that you can restore your data or rebuild your WarehousePG cluster if data corruption or a system failure occurs. You can also use backups to migrate data from one WarehousePG cluster to another.

WarehousePG supports parallel and non-parallel methods for backing up and restoring databases. Parallel operations scale regardless of the number of segments in your system, because segment hosts each write their data to local disk storage simultaneously. With non-parallel backup and restore operations, the data must be sent over the network from the segments to the coordinator, which writes all of the data to its storage. In addition to restricting I/O to one host, non-parallel backup requires that the coordinator have sufficient local disk storage to store the entire database.

Parallel Backup with gpbackup and gprestore

`gpbackup` and `gprestore` are the recommended WarehousePG backup and restore utilities. `gpbackup` utilizes `ACCESS SHARE` locks at the individual table level, instead of `EXCLUSIVE` locks on the `pg_class` catalog table. This enables you to run DML statements during the backup, such as `CREATE`, `ALTER`, `DROP`, and `TRUNCATE` operations, as long as those operations do not target the current backup set. Backup files created with `gpbackup` are designed to provide future capabilities for restoring individual database objects along with their dependencies, such as functions and required user-defined datatypes.

`gpbackup`, `gprestore`, and related utilities are provided as a separate download



Non-Parallel Backup with pg_dump

The PostgreSQL `pg_dump` and `pg_dumpall` non-parallel backup utilities can be used to create a single dump file on the coordinator host that contains all data from all active segments.

The PostgreSQL non-parallel utilities should be used only for special cases. They are much slower than using the WarehousePG backup utilities since all of the data must pass through the coordinator. Additionally, it is often the case that the coordinator host has insufficient disk space to save a backup of an entire distributed WarehousePG.

The `pg_restore` utility requires compressed dump files created by `pg_dump` or `pg_dumpall`. To perform a non-parallel restore using parallel backup files, you can copy the backup files from each segment host to the coordinator host, and then load them through the coordinator.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Another non-parallel method for backing up WarehousePG data is to use the `COPY TO` SQL command to copy all or a portion of a table out of the database to a delimited text file on the coordinator host.

4.2.9 Expanding a WarehousePG cluster

To scale up performance and storage capacity, expand your WarehousePG cluster by adding hosts to the system. In general, adding nodes to a WarehousePG cluster achieves a linear scaling of performance and storage capacity.

Data warehouses typically grow over time as additional data is gathered and the retention periods increase for existing data. At times, it is necessary to increase database capacity to consolidate different data warehouses into a single database. Additional computing capacity (CPU) may also be needed to accommodate newly added analytics projects. Although it is wise to provide capacity for growth when a system is initially specified, it is not generally possible to invest in resources long before they are required. Therefore, you should expect to run a database expansion project periodically.

Because of the WarehousePG MPP architecture, when you add resources to the system, the capacity and performance are the same as if the system had been originally implemented with the added resources. Unlike data warehouse systems that require substantial downtime in order to dump and restore the data, expanding a WarehousePG cluster is a phased process with minimal downtime. Regular and ad hoc workloads can continue while data is redistributed and transactional consistency is maintained. The administrator can schedule the distribution activity to fit into ongoing operations and can pause and resume as needed. Tables can be ranked so that datasets are redistributed in a prioritized sequence, either to ensure that critical workloads benefit from the expanded capacity sooner, or to free disk space needed to redistribute very large tables.

The expansion process uses standard WarehousePG operations so it is transparent and easy for administrators to troubleshoot. Segment mirroring and any replication mechanisms in place remain active, so fault-tolerance is uncompromised and disaster recovery measures remain effective.

- **System Expansion Overview**
  You can perform a WarehousePG expansion to add segment instances and segment hosts with minimal downtime. In general, adding nodes to a WarehousePG cluster achieves a linear scaling of performance and storage capacity.
- **Planning WarehousePG cluster Expansion**
  Careful planning will help to ensure a successful WarehousePG expansion project.
- **Preparing and Adding Hosts**
  Verify your new host systems are ready for integration into the existing WarehousePG cluster.
- **Initializing New Segments**
  Use the `gpexpand` utility to create and initialize the new segment instances and create the expansion schema.
- **Redistributing Tables**
  Redistribute tables to balance existing data over the newly expanded cluster.
- **Post Expansion Tasks**
  After the expansion is completed, you must perform different tasks depending on your environment.

Parent topic: Managing a WarehousePG cluster

4.2.9.1 System Expansion Overview

You can perform a WarehousePG expansion to add segment instances and segment hosts with minimal downtime. In general, adding nodes to a WarehousePG cluster achieves a linear scaling of performance and storage capacity.

Data warehouses typically grow over time, often at a continuous pace, as additional data is gathered and the retention period increases for existing data. At times, it is necessary to increase database capacity to consolidate disparate data warehouses into a single database. The data warehouse may also require additional computing capacity (CPU) to accommodate added analytics projects. It is good to provide capacity for growth when a system is initially specified, but even if you anticipate high rates of growth, it is generally unwise to invest in capacity long before it is required. Database expansion, therefore, is a project that you should expect to have to run periodically.

When you expand your database, you should expect the following qualities:

- Scalable capacity and performance. When you add resources to a WarehousePG, the capacity and performance are the same as if the system had been originally implemented with the added resources.
- Uninterrupted service during expansion, once past the initialization phase. Regular workloads, both scheduled and ad-hoc, are not interrupted.
- Transactional consistency.
- Fault tolerance. During the expansion, standard fault-tolerance mechanisms—such as segment mirroring—remain active, consistent, and effective.
- Replication and disaster recovery. Any existing replication mechanisms continue to function during expansion. Restore mechanisms needed in case of a failure or catastrophic event remain effective.
- Transparency of process. The expansion process employs standard WarehousePG mechanisms, so administrators can diagnose and troubleshoot any problems.
- Configurable process. Expansion can be a long running process, but it can be fit into a schedule of ongoing operations. The expansion schema's tables allow administrators to prioritize the order in which tables are redistributed, and the expansion activity can be paused and resumed.

The planning and physical aspects of an expansion project are a greater share of the work than expanding the database itself. It will take a multi-discipline team to plan and run the project. For on-premise installations, space must be acquired and prepared for the new servers. The servers must be specified, acquired, installed, cabled, configured, and tested. For cloud deployments, similar plans should also be made. Planning New Hardware Platforms describes general considerations for deploying new hardware.

After you provision the new hardware platforms and set up their networks, configure the operating systems and run performance tests using WarehousePG utilities. The WarehousePG software distribution includes utilities that are helpful to test and burn-in the new servers before beginning the software phase of the expansion. See Preparing and Adding Hosts for steps to prepare the new hosts for WarehousePG.

Once the new servers are installed and tested, the software phase of the WarehousePG expansion process begins. The software phase is designed to be minimally disruptive, transactionally consistent, reliable, and flexible.

- The first step of the software phase of expansion process is preparing the WarehousePG cluster: adding new segment hosts and initializing new segment instances. This phase can be scheduled to occur during a period of low activity to avoid disrupting ongoing business operations. During the initialization process, the following tasks are performed:
    - WarehousePG software is installed.
    - Databases and database objects are created in the new segment instances on the new segment hosts.
    - The *gpexpand* schema is created in the postgres database. You can use the tables and view in the schema to monitor and control the expansion process. After the system has been updated, the new segment instances on the new segment hosts are available.
    - New segments are immediately available and participate in new queries and data loads. The existing data, however, is skewed. It is concentrated on the original segments and must be redistributed across the new total number of primary segments.
    - Because some of the table data is skewed, some queries might be less efficient because more data motion operations might be needed.
- The last step of the software phase is redistributing table data. Using the expansion control tables in the*gpexpand* schema as a guide, tables are redistributed. For each table:
    - The gpexand utility redistributes the table data, across all of the servers, old and new, according to the distribution policy.
    - The table's status is updated in the expansion control tables.
    - After data redistribution, the query optimizer creates more efficient execution plans when data is not skewed. When all tables have been redistributed, the expansion is complete.

> **Important** The `gprestore` utility cannot restore backups you made before the expansion with the `gpbackup` utility, so back up your databases immediately after the system expansion is complete.

Redistributing table data is a long-running process that creates a large volume of network and disk activity. It can take days to redistribute some very large databases. To minimize the effects of the increased activity on business operations, system administrators can pause and resume expansion activity on an ad hoc basis, or according to a predetermined schedule. Datasets can be prioritized so that critical applications benefit first from the expansion.

In a typical operation, you run the `gpexpand` utility four times with different options during the complete expansion process.

1. To create an expansion input file:

    ```
    gpexpand -f <hosts_file>
    ```

2. To initialize segments and create the expansion schema:

    ```
    gpexpand -i <input_file>
    ```

    `gpexpand` creates a data directory, copies user tables from all existing databases on the new segments, and captures metadata for each table in an expansion schema for status tracking. After this process completes, the expansion operation is committed and irrevocable.

3. To redistribute table data:

    ```
    gpexpand -d <duration>
    ```

    During initialization, `gpexpand` adds and initializes new segment instances. To complete system expansion, you must run `gpexpand` to redistribute data tables across the newly added segment instances. Depending on the size and scale of your system, redistribution can be accomplished in a single session during low-use hours, or you can divide the process into batches over an extended period. Each table or partition is unavailable for read or write operations during redistribution. As each table is redistributed across the new segments, database performance should incrementally improve until it exceeds pre-expansion performance levels.

    You may need to run `gpexpand` several times to complete the expansion in large-scale systems that require multiple redistribution sessions. `gpexpand` can benefit from explicit table redistribution ranking; see Planning Table Redistribution.

    Users can access WarehousePG during initialization, but they may experience performance degradation on systems that rely heavily on hash distribution of tables. Normal operations such as ETL jobs, user queries, and reporting can continue, though users might experience slower response times.

4. To remove the expansion schema:

    ```
    gpexpand -c
    ```

4.2.9.2 Planning WarehousePG cluster Expansion

Careful planning will help to ensure a successful WarehousePG expansion project.

The topics in this section help to ensure that you are prepared to perform a system expansion.

- System Expansion Checklist is a checklist you can use to prepare for and perform the system expansion process.
- Planning New Hardware Platforms covers planning for acquiring and setting up the new hardware.
- Planning New Segment Initialization provides information about planning to initialize new segment hosts with `gpexpand`.
- Planning Table Redistribution provides information about planning the data redistribution after the new segment hosts have been initialized.

> **Important** When expanding a WarehousePG cluster, you must deactivate WarehousePG interconnect proxies before adding new hosts and segment instances to the system, and you must update the `gp_interconnect_proxy_addresses` parameter with the newly-added segment instances before you re-enable interconnect proxies. For example, these commands deactivate WarehousePG interconnect proxies by setting the interconnect to the default (`UDPIFC`) and reloading the `postgresql.conf` file to update the WarehousePG cluster configuration.

```
gpconfig -r gp_interconnect_type
gpstop -u
```

For information about WarehousePG interconnect proxies, see Configuring Proxies for the WarehousePG Interconnect.

Parent topic: Expanding a WarehousePG cluster

System Expansion Checklist

This checklist summarizes the tasks for a WarehousePG cluster expansion.

Online Pre-Expansion Tasks

System status: Up and available

- [ ] **Hardware Provisioning:** Plan for ordering, building, and networking new hardware platforms, or provisioning cloud resources.
- [ ] **Expansion Planning:** Devise a database expansion plan. Map the number of segments per host, schedule downtime for performance testing and schema creation, and set intervals for table redistribution.
- [ ] **Schema Backup:** Perform a complete schema dump.
- [ ] **Binary Installation:** Install WarehousePG binaries on new hosts.
- [ ] **SSH Configuration:** Copy SSH keys to the new hosts (`gpssh-exkeys`).
- [ ] **Hardware Validation:** Validate disk I/O and memory bandwidth of the new hardware or cloud resources (`gpcheckperf`).
- [ ] **Log Maintenance:** Validate that the coordinator data directory has no extremely large files in the `log` directory.

Offline Pre-Expansion Tasks

System status: Unavailable to all user activity during this process

- [ ] **Catalog Validation:** Validate that there are no catalog issues (`gpcheckcat`).
- [ ] **Full Cluster Validation:** Validate disk I/O and memory bandwidth of the combined existing and new hardware or cloud resources (`gpcheckperf`).

Online Segment Instance Initialization

System status: Up and available

- [ ] **Input File Preparation:** Prepare an expansion input file (`gpexpand`).
- [ ] **Initialization:** Initialize new segments into the system and create an expansion schema (`gpexpand -i input_file`).

Online Expansion and Table Redistribution

System status: Up and available

- [ ] **Resource Cleanup:** Before you start table redistribution, stop any automated snapshot processes or other processes that consume disk space.
- [ ] **Redistribution:** Redistribute tables through the expanded system (`gpexpand`).
- [ ] **Cleanup:** Remove expansion schema (`gpexpand -c`).
- [ ] **Statistics Update: Important:** Run `analyze` to update distribution statistics. During the expansion, use `gpexpand -a`, and post-expansion, use `analyze`.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Back Up Databases

System status: Up and available

- [ ] **Fresh Backup:** Back up databases using the `gpbackup` utility.

> **Note**
>
> Backups created before the system expansion cannot be restored to the newly expanded system because the `gprestore` utility can only restore backups to a WarehousePG cluster with the same number of segments.

Planning New Hardware Platforms

A deliberate, thorough approach to deploying compatible hardware greatly minimizes risk to the expansion process.

Hardware resources and configurations for new segment hosts should match those of the existing hosts.

The steps to plan and set up new hardware platforms vary for each deployment. Some considerations include how to:

- Prepare the physical space for the new hardware; consider cooling, power supply, and other physical factors.
- Determine the physical networking and cabling required to connect the new and existing hardware.
- Map the existing IP address spaces and developing a networking plan for the expanded system.
- Capture the system configuration (users, profiles, NICs, and so on) from existing hardware to use as a detailed list for ordering new hardware.
- Create a custom build plan for deploying hardware with the desired configuration in the particular site and environment.

After selecting and adding new hardware to your network environment, ensure you perform the tasks described inPreparing and Adding Hosts.

Planning New Segment Initialization

Expanding WarehousePG can be performed when the system is up and available. Run `gpexpand` to initialize new segment instances into the system and create an expansion schema.

The time required depends on the number of schema objects in the WarehousePG cluster and other factors related to hardware performance. In most environments, the initialization of new segments requires less than thirty minutes offline.

These utilities cannot be run while `gpexpand` is performing segment initialization.

- `gpbackup`
- `gpcheckcat`
- `gpconfig`
- `gprestore`

> **Important** After you begin initializing new segments, you can no longer restore the system using backup files created for the pre-expansion system. When initialization successfully completes, the expansion is committed and cannot be rolled back.

Planning Mirror Segments

If your existing system has mirror segments, the new segments must have mirroring configured. If there are no mirrors configured for existing segments, you cannot add mirrors to new hosts with the `gpexpand` utility. For more information about segment mirroring configurations that are available during system initialization, see About Segment Mirroring Configurations.

For WarehousePG clusters with mirror segments, ensure you add enough new host machines to accommodate new mirror segments. The number of new hosts required depends on your mirroring strategy:

- **Group Mirroring** — Add at least two new hosts so the mirrors for the first host can reside on the second host, and the mirrors for the second host can reside on the first. This is the default type of mirroring if you enable segment mirroring during system initialization.
- **Spread Mirroring** — Add at least one more host to the system than the number of segments per host. The number of separate hosts must be greater than the number of segment instances per host to ensure even spreading. You can specify this type of mirroring during system initialization or when you enable segment mirroring for an existing system.
- **Block Mirroring** — Adding one or more blocks of host systems. For example add a block of four or eight hosts. Block mirroring is a custom mirroring configuration. For more information about block mirroring, seeSegment Mirroring Configurations.

Increasing Segments Per Host

By default, new hosts are initialized with as many primary segments as existing hosts have. You can increase the segments per host or add new segments to existing hosts.

For example, if existing hosts currently have two segments per host, you can use `gpexpand` to initialize two additional segments on existing hosts for a total of four segments and initialize four new segments on new hosts.

The interactive process for creating an expansion input file prompts for this option; you can also specify new segment directories manually in the input configuration file. For more information, seeCreating an Input File for System Expansion.

About the Expansion Schema

At initialization, the `gpexpand` utility creates an expansion schema named *gpexpand* in the postgres database.

The expansion schema stores metadata for each table in the system so its status can be tracked throughout the expansion process. The expansion schema consists of two tables and a view for tracking expansion operation progress:

- *gpexpand.status*
- *gpexpand.status_detail*
- *gpexpand.expansion_progress*

Control expansion process aspects by modifying *gpexpand.status_detail*. For example, removing a record from this table prevents the system from expanding the table across new segments. Control the order in which tables are processed for redistribution by updating the `rank` value for a record. For more information, see Ranking Tables for Redistribution.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Planning Table Redistribution

Table redistribution is performed while the system is online. For many WarehousePG clusters, table redistribution completes in a single `gpexpand` session scheduled during a low-use period. Larger systems may require multiple sessions and setting the order of table redistribution to minimize performance impact. Complete the table redistribution in one session if possible.

> **Important** To perform table redistribution, your segment hosts must have enough disk space to temporarily hold a copy of your largest table. All tables are unavailable for read and write operations during redistribution.

The performance impact of table redistribution depends on the size, storage type, and partitioning design of a table. For any given table, redistributing it with `gpexpand` takes as much time as a `CREATE TABLE AS SELECT` operation would. When redistributing a terabyte-scale fact table, the expansion utility can use much of the available system resources, which could affect query performance or other database workloads.

Table Redistribution Method

WarehousePG uses a *rebuild* table distribution method to redistribute data during an expansion. WarehousePG:

1. Creates a new table.
2. Copies all of the data from the old table to the new table.
3. Replaces the old table.

The rebuild method is similar to creating a new table with a `CREATE TABLE AS SELECT` command. During data redistribution, WarehousePG acquires an `ACCESS EXCLUSIVE` lock on the table.

Managing Redistribution in Large-Scale WarehousePG clusters

When planning the redistribution phase, consider the impact of the `ACCESS EXCLUSIVE` lock taken on each table. User activity on a table can delay its redistribution, but also tables are unavailable for user activity during redistribution.

You can manage the order in which tables are redistributed by adjusting their ranking. SeeRanking Tables for Redistribution. Manipulating the redistribution order can help adjust for limited disk space and restore optimal query performance for high-priority queries sooner.

Systems with Abundant Free Disk Space

In systems with abundant free disk space (required to store a copy of the largest table), you can focus on restoring optimum query performance as soon as possible by first redistributing important tables that queries use heavily. Assign high ranking to these tables, and schedule redistribution operations for times of low system usage. Run one redistribution process at a time until large or critical tables have been redistributed.

Systems with Limited Free Disk Space

If your existing hosts have limited disk space, you may prefer to first redistribute smaller tables (such as dimension tables) to clear space to store a copy of the largest table. Available disk space on the original segments increases as each table is redistributed across the expanded system. When enough free space exists on all segments to store a copy of the largest table, you can redistribute large or critical tables. Redistribution of large tables requires exclusive locks; schedule this procedure for off-peak hours.

Also consider the following:

- Run multiple parallel redistribution processes during off-peak hours to maximize available system resources.
- When running multiple processes, operate within the connection limits for your WarehousePG cluster. For information about limiting concurrent connections, seeLimiting Concurrent Connections.

Redistributing Append-Optimized and Compressed Tables

`gpexpand` redistributes append-optimized and compressed append-optimized tables at different rates than heap tables. The CPU capacity required to compress and decompress data tends to increase the impact on system performance. For similar-sized tables with similar data, you may find overall performance differences like the following:

- Uncompressed append-optimized tables expand 10% faster than heap tables.
- Append-optimized tables that are defined to use data compression expand at a significantly slower rate than uncompressed append-optimized tables, potentially up to 80% slower.
- Systems with data compression such as ZFS/LZJB take longer to redistribute.

> **Important** If your system hosts use data compression, use identical compression settings on the new hosts to avoid disk space shortage.

Redistributing Partitioned Tables

Because the expansion utility can process each individual partition on a large table, an efficient partition design reduces the performance impact of table redistribution. Only the child tables of a partitioned table are set to a random distribution policy. The read/write lock for redistribution applies to only one child table at a time.

Redistributing Indexed Tables

Because the `gpexpand` utility must re-index each indexed table after redistribution, a high level of indexing has a large performance impact. Systems with intensive indexing have significantly slower rates of table redistribution.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.2.9.3 Preparing and Adding Hosts

Verify your new host systems are ready for integration into the existing WarehousePG cluster.

To prepare new host systems for expansion, install the WarehousePG software binaries, exchange the required SSH keys, and run performance tests.

Run performance tests first on the new hosts and then all hosts. Run the tests on all hosts with the system offline so user activity does not distort results.

Generally, you should run performance tests when an administrator modifies host networking or other special conditions in the system. For example, if you will run the expanded system on two network clusters, run tests on each cluster.

> **Note** Preparing host systems for use by a WarehousePG cluster assumes that the new hosts' operating system has been properly configured to match the existing hosts, described in Configure Operating System.

Parent topic: Expanding a WarehousePG cluster

Adding New Hosts to the Trusted Host Environment

New hosts must exchange SSH keys with the existing hosts to enable WarehousePG administrative utilities to connect to all segments without a password prompt. Perform the key exchange process twice with the gpssh-exkeys utility.

First perform the process as `root`, for administration convenience, and then as the user `gpadmin`, for management utilities. Perform the following tasks in order:

1. To exchange SSH keys as root
2. To create the gpadmin user
3. To exchange SSH keys as the gpadmin user

> **Note** The WarehousePG segment host naming convention is `sdwN` where `sdw` is a prefix and `N` is an integer (`sdw1`, `sdw2` and so on). For hosts with multiple interfaces, the convention is to append a dash (`-`) and number to the host name. For example, `sdw1-1` and `sdw1-2` are the two interface names for host `sdw1`.

To exchange SSH keys as root

1. Create a host file with the existing host names in your array and a separate host file with the new expansion host names. For existing hosts, you can use the same host file used to set up SSH keys in the system. In the files, list all hosts (coordinator, backup coordinator, and segment hosts) with one name per line and no extra lines or spaces. Exchange SSH keys using the configured host names for a given host if you use a multi-NIC configuration. In this example, `cdw` is configured with a single NIC, and `sdw1`, `sdw2`, and `sdw3` are configured with 4 NICs:

   ```
   cdw
   sdw1-1
   sdw1-2
   sdw1-3
   sdw1-4
   sdw2-1
   sdw2-2
   sdw2-3
   sdw2-4
   sdw3-1
   sdw3-2
   sdw3-3
   sdw3-4
   ```

2. Log in as `root` on the coordinator host, and source the `greenplum_path.sh` file from your WarehousePG installation.

   ```
   $ su -
   # source /usr/edb/whpg7/greenplum_path.sh
   ```

3. Run the `gpssh-exkeys` utility referencing the host list files. For example:

   ```
   # gpssh-exkeys -e /home/gpadmin/<existing_hosts_file> -x
   /home/gpadmin/<new_hosts_file>
   ```

4. `gpssh-exkeys` checks the remote hosts and performs the key exchange between all hosts. Enter the `root` user password when prompted. For example:

   ```
   ***Enter password for root@<hostname>: <root_password>
   ```

To create the gpadmin user

1. Use gpssh to create the `gpadmin` user on all the new segment hosts (if it does not exist already). Use the list of new hosts you created for the key exchange. For example:

   ```
   # gpssh -f <new_hosts_file> '/usr/sbin/useradd gpadmin -d
   /home/gpadmin -s /bin/bash'
   ```

2. Set a password for the new `gpadmin` user. On Linux, you can do this on all segment hosts simultaneously using `gpssh`. For example:

   ```
   # gpssh -f <new_hosts_file> 'echo <gpadmin_password> | passwd
   gpadmin --stdin'
   ```

3. Verify the `gpadmin` user has been created by looking for its home directory:

   ```
   # gpssh -f <new_hosts_file> ls -l /home
   ```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

To exchange SSH keys as the gpadmin user

1. Log in as `gpadmin` and run the `gpssh-exkeys` utility referencing the host list files. For example:

   ```
   # gpssh-exkeys -e /home/gpadmin/<existing_hosts_file> -x
   /home/gpadmin/<new_hosts_file>
   ```

2. `gpssh-exkeys` will check the remote hosts and perform the key exchange between all hosts. Enter the `gpadmin` user password when prompted. For example:

   ```
   ***Enter password for gpadmin@<hostname>: <gpadmin_password>
   ```

Validating Disk I/O and Memory Bandwidth

Use the gpcheckperf utility to test disk I/O and memory bandwidth.

To run gpcheckperf

1. Run the `gpcheckperf` utility using the host file for new hosts. Use the `-d` option to specify the file systems you want to test on each host. You must have write access to these directories. For example:

   ```
   $ gpcheckperf -f <new_hosts_file> -d /data1 -d /data2 -v
   ```

2. The utility may take a long time to perform the tests because it is copying very large files between the hosts. When it is finished, you will see the summary results for the Disk Write, Disk Read, and Stream tests.

For a network divided into subnets, repeat this procedure with a separate host file for each subnet.

Integrating New Hardware into the System

Before initializing the system with the new segments, shut down the system with `gpstop` to prevent user activity from skewing performance test results. Then, repeat the performance tests using host files that include *all* hosts, existing and new.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.2.9.4 Initializing New Segments

Use the `gpexpand` utility to create and initialize the new segment instances and create the expansion schema.

The first time you run gpexpand with a valid input file it creates and initializes segment instances and creates the expansion schema. After these steps are completed, running `gpexpand` detects if the expansion schema has been created and, if so, performs table redistribution.

> **Note** To prevent catalog inconsistency across existing and new segments, be sure that no DDL operations are running during the initialization phase.

- Creating an Input File for System Expansion
- Running gpexpand to Initialize New Segments
- Rolling Back a Failed Expansion Setup

Parent topic: Expanding a WarehousePG cluster

Creating an Input File for System Expansion

To begin expansion, `gpexpand` requires an input file containing information about the new segments and hosts. If you run `gpexpand` without specifying an input file, the utility displays an interactive interview that collects the required information and automatically creates an input file.

If you create the input file using the interactive interview, you may specify a file with a list of expansion hosts in the interview prompt. If your platform or command shell limits the length of the host list, specifying the hosts with `-f` may be mandatory.

Creating an input file in Interactive Mode

Before you run `gpexpand` to create an input file in interactive mode, ensure you know:

- The number of new hosts (or a hosts file)
- The new hostnames (or a hosts file)
- The mirroring strategy used in existing hosts, if any
- The number of segments to add per host, if any

The utility automatically generates an input file based on this information, `dbid`, `content` ID, and data directory values stored in *gp_segment_configuration*, and saves the file in the current directory.

To create an input file in interactive mode

1. Log in on the coordinator host as the user who will run your WarehousePG cluster; for example, `gpadmin`.
2. Run `gpexpand`. The utility displays messages about how to prepare for an expansion operation, and it prompts you to quit or continue.

   Optionally, specify a hosts file using `-f`. For example:

   ```
   $ gpexpand -f /home/gpadmin/<new_hosts_file>
   ```

3. At the prompt, select `Y` to continue.
4. Unless you specified a hosts file using `-f`, you are prompted to enter hostnames. Enter a comma separated list of the hostnames of the new expansion hosts. Do not include interface hostnames. For example:

   ```
   > sdw4, sdw5, sdw6, sdw7
   ```

   To add segments to existing hosts only, enter a blank line at this prompt. Do not specify `localhost` or any existing host name.
5. Enter the mirroring strategy used in your system, if any. Options are `spread|grouped|none`. The default setting is `grouped`.

   Ensure you have enough hosts for the selected grouping strategy. For more information about mirroring, see Planning Mirror Segments.
6. Enter the number of new primary segments to add, if any. By default, new hosts are initialized with the same number of primary segments as existing hosts. Increase segments per host by entering a number greater than zero. The number you enter will be the number of additional segments initialized on all hosts. For example, if existing hosts currently have two segments each, entering a value of `2` initializes two more segments on existing hosts, and four segments on new hosts.
7. If you are adding new primary segments, enter the new primary data directory root for the new segments. Do not specify the actual data directory name, which is created automatically by `gpexpand` based on the existing data directory names.

   For example, if your existing data directories are as follows:

   ```
   /gpdata/primary/gp0
   /gpdata/primary/gp1
   ```

   then enter the following (one at each prompt) to specify the data directories for two new primary segments:

   ```
   /gpdata/primary
   /gpdata/primary
   ```

   When the initialization runs, the utility creates the new directories `gp2` and `gp3` under `/gpdata/primary`.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

8. If you are adding new mirror segments, enter the new mirror data directory root for the new segments. Do not specify the data directory name; it is created automatically by `gpexpand` based on the existing data directory names.

   For example, if your existing data directories are as follows:

   ```
   /gpdata/mirror/gp0
   /gpdata/mirror/gp1
   ```

   enter the following (one at each prompt) to specify the data directories for two new mirror segments:

   ```
   /gpdata/mirror
   /gpdata/mirror
   ```

   When the initialization runs, the utility will create the new directories `gp2` and `gp3` under `/gpdata/mirror`.

   These primary and mirror root directories for new segments must exist on the hosts, and the user running `gpexpand` must have permissions to create directories in them.

   After you have entered all required information, the utility generates an input file and saves it in the current directory. For example:

   ```
   gpexpand_inputfile_yyyymmdd_145134
   ```

   If the WarehousePG cluster is configured with tablespaces, the utility automatically generates an additional tablespace mapping file. This file is required for later parsing by the utility so make sure it is present before proceeding with the next step. For example:

   ```
   gpexpand_inputfile_yyyymmdd_145134.ts
   ```

Expansion Input File Format

Use the interactive interview process to create your own input file unless your expansion scenario has atypical needs.

The format for expansion input files is:

```
hostname|address|port|datadir|dbid|content|preferred_role
```

For example:

```
sdw5|sdw5-1|50011|/gpdata/primary/gp9|11|9|p
sdw5|sdw5-2|50012|/gpdata/primary/gp10|12|10|p
sdw5|sdw5-2|60011|/gpdata/mirror/gp9|13|9|m
sdw5|sdw5-1|60012|/gpdata/mirror/gp10|14|10|m
```

For each new segment, this format of expansion input file requires the following:

Parameter	Valid Values	Description
hostname	Hostname	Hostname for the segment host.
port	An available port number	Database listener port for the segment, incremented on the existing segment *port* base number.
datadir	Directory name	The data directory location for a segment as per the gp_segment_configuration system catalog.
dbid	Integer. Must not conflict with existing *dbid* values.	Database ID for the segment. The values you enter should be incremented sequentially from existing *dbid* values shown in the system catalog `gp_segment_configuration`. For example, to add four segment instances to an existing ten-segment array with *dbid* values of 1-10, list new *dbid* values of 11, 12, 13 and 14.
content	Integer. Must not conflict with existing *content* values.	The content ID of the segment. A primary segment and its mirror should have the same content ID, incremented sequentially from existing values. For more information, see *content* in the reference for `gp_segment_configuration`.
preferred_role	`p` or `m`	Determines whether this segment is a primary or mirror. Specify `p` for primary and `m` for mirror.

Running gpexpand to Initialize New Segments

After you have created an input file, run `gpexpand` to initialize new segment instances.

To run gpexpand with an input file

1. Log in on the coordinator host as the user who will run your WarehousePG cluster; for example, `gpadmin`.
2. Run the `gpexpand` utility, specifying the input file with `-i`. For example:

   ```
   $ gpexpand -i input_file
   ```

   The utility detects if an expansion schema exists for the WarehousePG cluster. If a *gpexpand* schema exists, remove it with `gpexpand -c` before you start a new expansion operation. See Removing the Expansion Schema.

   When the new segments are initialized and the expansion schema is created, the utility prints a success message and exits.

When the initialization process completes, you can connect to WarehousePG and view the expansion schema. The *gpexpand* schema resides in the postgres database. For more information, see About the Expansion Schema.

After segment initialization is complete, redistribute the tables to balance existing data over the new segments.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Monitoring the Cluster Expansion State

At any time, you can check the state of cluster expansion by running the `gpstate` utility with the `-x` flag:

```
$ gpstate -x
```

If the expansion schema exists in the postgres database, `gpstate -x` reports on the progress of the expansion. During the first expansion phase, `gpstate` reports on the progress of new segment initialization. During the second phase, `gpstate` reports on the progress of table redistribution, and whether redistribution is paused or active.

You can also query the expansion schema to see expansion status. See Monitoring Table Redistribution for more information.

Rolling Back a Failed Expansion Setup

You can roll back an expansion setup operation (adding segment instances and segment hosts) only if the operation fails.

If the expansion fails during the initialization step, while the database is down, you must first restart the database in coordinator-only mode by running the `gpstart -m` command.

Roll back the failed expansion with the following command:

```
gpexpand --rollback
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.2.9.5 Redistributing Tables

Redistribute tables to balance existing data over the newly expanded cluster.

After creating an expansion schema, you can redistribute tables across the entire system with gpexpand. Plan to run this during low-use hours when the utility's CPU usage and table locks have minimal impact on operations. Rank tables to redistribute the largest or most critical tables first.

> **Note** When redistributing data, WarehousePG must be running in production mode. WarehousePG cannot be in restricted mode or in coordinator mode. The gpstart options `-R` or `-m` cannot be specified to start WarehousePG.

While table redistribution is underway, any new tables or partitions created are distributed across all segments exactly as they would be under normal operating conditions. Queries can access all segments, even before the relevant data is redistributed to tables on the new segments. The table or partition being redistributed is locked and unavailable for read or write operations. When its redistribution completes, normal operations resume.

- Ranking Tables for Redistribution
- Redistributing Tables Using gpexpand
- Monitoring Table Redistribution

Parent topic: Expanding a WarehousePG cluster

Ranking Tables for Redistribution

For large systems, you can control the table redistribution order. Adjust tables' `rank` values in the expansion schema to prioritize heavily-used tables and minimize performance impact. Available free disk space can affect table ranking; see Managing Redistribution in Large-Scale WarehousePG clusters.

To rank tables for redistribution by updating `rank` values in *gpexpand.status_detail*, connect to WarehousePG using `psql` or another supported client. Update *gpexpand.status_detail* with commands such as:

```
=> UPDATE gpexpand.status_detail SET rank=10;

=> UPDATE gpexpand.status_detail SET rank=1 WHERE fq_name = 'public.lineitem';
=> UPDATE gpexpand.status_detail SET rank=2 WHERE fq_name = 'public.orders';
```

These commands lower the priority of all tables to `10` and then assign a rank of `1` to `lineitem` and a rank of `2` to `orders`. When table redistribution begins, `lineitem` is redistributed first, followed by `orders` and all other tables in *gpexpand.status_detail*. To exclude a table from redistribution, remove the table from the *gpexpand.status_detail* table.

Redistributing Tables Using gpexpand

To redistribute tables with gpexpand

1. Log in on the coordinator host as the user who will run your WarehousePG cluster, for example, `gpadmin`.
2. Run the `gpexpand` utility. You can use the `-d` or `-e` option to define the expansion session time period. For example, to run the utility for up to 60 consecutive hours:

   ```
   $ gpexpand -d 60:00:00
   ```

   The utility redistributes tables until the last table in the schema completes or it reaches the specified duration or end time. `gpexpand` updates the status and time in *gpexpand.status* when a session starts and finishes.

> **Note** After completing table redistribution, run the `VACUUM ANALYZE` and `REINDEX` commands on the catalog tables to update table statistics, and rebuild indexes. See Routine Vacuum and Analyze in the *Administration Guide* and `VACUUM` in the *Reference Guide*.

Monitoring Table Redistribution

During the table redistribution process you can query the expansion schema to view:

- a current progress summary, the estimated rate of table redistribution, and the estimated time to completion. Use *gpexpand.expansion_progress*, as described in Viewing Expansion Status.
- per-table status information, using *gpexpand.status_detail*. See Viewing Table Status.

See also Monitoring the Cluster Expansion State for information about monitoring the overall expansion progress with the `gpstate` utility.

Viewing Expansion Status

After the first table completes redistribution, *gpexpand.expansion_progress* calculates its estimates and refreshes them based on all tables' redistribution rates. Calculations restart each time you start a table redistribution session with `gpexpand`. To monitor progress, connect to WarehousePG using `psql` or another supported client; query *gpexpand.expansion_progress* with a command like the following:

```
=# SELECT * FROM gpexpand.expansion_progress;
             name             |         value
------------------------------+-----------------------
 Bytes Left                   | 5534842880
 Bytes Done                   | 142475264
 Estimated Expansion Rate     | 680.75667095996092 MB/s
 Estimated Time to Completion | 00:01:01.008047
 Tables Expanded              | 4
 Tables Left                  | 4
(6 rows)
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Viewing Table Status

The table *gpexpand.status_detail* stores status, time of last update, and more facts about each table in the schema. To see a table's status, connect to WarehousePG using `psql` or another supported client and query *gpexpand.status_detail*:

```
=> SELECT status, expansion_started, source_bytes FROM
gpexpand.status_detail WHERE fq_name = 'public.sales';
  status   |     expansion_started      | source_bytes
-----------+----------------------------+--------------
 COMPLETED | 2017-02-20 10:54:10.043869 |   4929748992
(1 row)
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.2.9.6 Post Expansion Tasks

After the expansion is completed, you must perform different tasks depending on your environment.

- Removing the Expansion Schema
- Setting Up PXF on the New Host

Parent topic: Expanding a WarehousePG cluster

Removing the Expansion Schema

You must remove the existing expansion schema before you can perform another expansion operation on the WarehousePG cluster.

You can safely remove the expansion schema after the expansion operation is complete and verified. To run another expansion operation on a WarehousePG cluster, first remove the existing expansion schema.

1. Log in on the coordinator host as the user who will be running your WarehousePG cluster (for example, `gpadmin`).
2. Run the `gpexpand` utility with the `-c` option. For example:

```
$ gpexpand -c
```

> **Note** Some systems require you to press Enter twice.

Setting Up PXF on the New Host

If you are using PXF in your WarehousePG cluster, you must perform some configuration steps on the new hosts.

There are different steps to follow depending on your PXF version and the type of installation.

PXF 5

- You must install the same version of the PXF `rpm` or `deb` on the new hosts.
- Log into the WarehousePG Coordinator and run the following commands:

```
gpadmin@gpcoordinator$ pxf cluster reset
gpadmin@gpcoordinator$ pxf cluster init
```

PXF 6

- You must install the same version of the PXF `rpm` or `deb` on the new hosts.
- Log into the WarehousePG Coordinator and run the following commands:

```
gpadmin@gpcoordinator$ pxf cluster register
gpadmin@gpcoordinator$ pxf cluster sync
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.2.10 Monitoring a WarehousePG cluster

You can monitor a WarehousePG cluster using a variety of tools included with the system or available as add-ons.

Observing the WarehousePG cluster day-to-day performance helps administrators understand the system behavior, plan workflow, and troubleshoot problems. This chapter discusses tools for monitoring database performance and activity.

Also, be sure to review Recommended Monitoring and Maintenance Tasks for monitoring activities you can script to quickly detect problems in the system.

Parent topic: Managing a WarehousePG cluster

Monitoring System State

As a WarehousePG administrator, you must monitor the system for problem events such as a segment going down or running out of disk space on a segment host. The following topics describe how to monitor the health of a WarehousePG cluster and examine certain state information for a WarehousePG cluster.

- Checking System State
- Checking Disk Space Usage
- Checking for Data Distribution Skew
- Checking for and Terminating Overflowed Backends
- Viewing Metadata Information about Database Objects
- Viewing Session Memory Usage Information
- Viewing and Logging Per-Process Memory Usage Information
- Viewing Query Workfile Usage Information

Checking System State

A WarehousePG cluster is comprised of multiple PostgreSQL instances (the coordinator and segments) spanning multiple machines. To monitor a WarehousePG cluster, you need to know information about the system as a whole, as well as status information of the individual instances. The `gpstate` utility provides status information about a WarehousePG cluster.

Viewing Coordinator and Segment Status and Configuration

The default `gpstate` action is to check segment instances and show a brief status of the valid and failed segments. For example, to see a quick status of your WarehousePG cluster:

```
$ gpstate
```

To see more detailed information about your WarehousePG cluster configuration, use `gpstate` with the `-s` option:

```
$ gpstate -s
```

Viewing Your Mirroring Configuration and Status

If you are using mirroring for data redundancy, you may want to see the list of mirror segment instances in the system, their current synchronization status, and the mirror to primary mapping. For example, to see the mirror segments in the system and their status:

```
$ gpstate -m
```

To see the primary to mirror segment mappings:

```
$ gpstate -c
```

To see the status of the standby coordinator mirror:

```
$ gpstate -f
```

Checking Disk Space Usage

A database administrator's most important monitoring task is to make sure the file systems where the coordinator and segment data directories reside do not grow to more than 70 percent full. A filled data disk will not result in data corruption, but it may prevent normal database activity from continuing. If the disk grows too full, it can cause the database server to shut down.

You can use the `gp_disk_free` external table in the `gp_toolkit` administrative schema to check for remaining free space (in kilobytes) on the segment host file systems. For example:

```
=# SELECT * FROM gp_toolkit.gp_disk_free
   ORDER BY dfsegment;
```

Checking Sizing of Distributed Databases and Tables

The `gp_toolkit` administrative schema contains several views that you can use to determine the disk space usage for a distributed WarehousePG database, schema, table, or index.

For a list of the available sizing views for checking database object sizes and disk space, see the *WarehousePG Reference Guide*.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Viewing Disk Space Usage for a Database

To see the total size of a database (in bytes), use the *gp_size_of_database* view in the *gp_toolkit* administrative schema. For example:

```
=> SELECT * FROM gp_toolkit.gp_size_of_database
   ORDER BY sodddatname;
```

Viewing Disk Space Usage for a Table

The *gp_toolkit* administrative schema contains several views for checking the size of a table. The table sizing views list the table by object ID (not by name). To check the size of a table by name, you must look up the relation name (`relname`) in the *pg_class* table. For example:

```
=> SELECT relname AS name, sotdsize AS size, sotdtoastsize
   AS toast, sotdadditionalsize AS other
   FROM gp_toolkit.gp_size_of_table_disk as sotd, pg_class
   WHERE sotd.sotdoid=pg_class.oid ORDER BY relname;
```

For a list of the available table sizing views, see the *WarehousePG Reference Guide*.

Viewing Disk Space Usage for Indexes

The *gp_toolkit* administrative schema contains a number of views for checking index sizes. To see the total size of all index(es) on a table, use the *gp_size_of_all_table_indexes* view. To see the size of a particular index, use the *gp_size_of_index* view. The index sizing views list tables and indexes by object ID (not by name). To check the size of an index by name, you must look up the relation name (`relname`) in the *pg_class* table. For example:

```
=> SELECT soisize, relname as indexname
   FROM pg_class, gp_toolkit.gp_size_of_index
   WHERE pg_class.oid=gp_size_of_index.soioid
   AND pg_class.relkind='i';
```

Checking for Data Distribution Skew

All tables in WarehousePG are distributed, meaning their data is divided across all of the segments in the system. Unevenly distributed data may diminish query processing performance. A table's distribution policy, set at table creation time, determines how the table's rows are distributed. For information about choosing the table distribution policy, see the following topics:

- Viewing a Table's Distribution Key
- Viewing Data Distribution
- Checking for Query Processing Skew

The *gp_toolkit* administrative schema also contains a number of views for checking data distribution skew on a table. For information about how to check for uneven data distribution, see the *WarehousePG Reference Guide*.

Viewing a Table's Distribution Key

To see the columns used as the data distribution key for a table, you can use the `\d+` meta-command in `psql` to examine the definition of a table. For example:

```
=# `\d+ sales
`                Table "retail.sales"
 Column      |     Type     | Modifiers | Description
-------------+--------------+-----------+-------------
 sale_id     | integer      |           |
 amt         | float        |           |
 date        | date         |           |
Has OIDs: no
Distributed by: (sale_id)
```

When you create a *replicated* table, WarehousePG stores all rows in the table on every segment. Replicated tables have no distribution key. Where the `\d+` meta-command reports the distribution key for a normally distributed table, it shows `Distributed Replicated` for a replicated table.

Viewing Data Distribution

To see the data distribution of a table's rows (the number of rows on each segment), you can run a query such as:

```
=# SELECT gp_segment_id, count(*)
   FROM <table_name> GROUP BY gp_segment_id;
```

A table is considered to have a balanced distribution if all segments have roughly the same number of rows.

> **Note** If you run this query on a replicated table, it fails because WarehousePG does not permit user queries to reference the system column `gp_segment_id` (or the system columns `ctid`, `cmin`, `cmax`, `xmin`, and `xmax`) in replicated tables. Because every segment has all of the tables' rows, replicated tables are evenly distributed by definition.

Checking for Query Processing Skew

When a query is being processed, all segments should have equal workloads to ensure the best possible performance. If you identify a poorly-performing query, you may need to investigate further using the `EXPLAIN` command. For information about using the `EXPLAIN` command and query profiling, see Query Profiling.

Query processing workload can be skewed if the table's data distribution policy and the query predicates are not well matched. To check for processing skew, you can run a query such as:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
=# SELECT gp_segment_id, count(*) FROM <table_name>
   WHERE <column>='<value>' GROUP BY gp_segment_id;
```

This will show the number of rows returned by segment for the given `WHERE` predicate.

As noted in Viewing Data Distribution, this query will fail if you run it on a replicated table because you cannot reference the `gp_segment_id` system column in a query on a replicated table.

Avoiding an Extreme Skew Warning

You may receive the following warning message while running a query that performs a hash join operation:

`Extreme skew in the innerside of Hashjoin`

This occurs when the input to a hash join operator is skewed. It does not prevent the query from completing successfully. You can follow these steps to avoid skew in the plan:

1. Ensure that all fact tables are analyzed.
2. Verify that any populated temporary table used by the query is analyzed.
3. View the `EXPLAIN ANALYZE` plan for the query and look for the following:
    - If there are scans with multi-column filters that are producing more rows than estimated, then set the `gp_selectivity_damping_factor` server configuration parameter to 2 or higher and retest the query.
    - If the skew occurs while joining a single fact table that is relatively small (less than 5000 rows), set the `gp_segments_for_planner` server configuration parameter to 1 and retest the query.
4. Check whether the filters applied in the query match distribution keys of the base tables. If the filters and distribution keys are the same, consider redistributing some of the base tables with different distribution keys.
5. Check the cardinality of the join keys. If they have low cardinality, try to rewrite the query with different joining columns or additional filters on the tables to reduce the number of rows. These changes could change the query semantics.

Checking for and Terminating Overflowed Backends

Subtransaction overflow arises when a WarehousePG backend creates more than 64 subtransactions, resulting in a high lookup cost for visibility checks. This slows query performance, but even more so when it occurs in combination with long-running transactions, which result in still more lookups. Terminating suboverflowed backends and/or backends with long-running transactions can help prevent and alleviate performance problems.

WarehousePG includes a view -- `gp_suboverflowed_backend` -- that is run over a user-defined function to help users query for suboverflowed backends. Users can use segment id and process id information reported in the view to terminate the offending backends, thereby preventing degradation of performance.

Steps

Follow these steps below to identify and terminate overflowed backends.

1. Select all from the view:

    ```
    select * from gp_suboverflowed_backend`;
    ```

    This returns output similar to the following:

    ```
    segid |   pids
    -------+-----------
    -1 |
     0 | {1731513}
     1 | {1731514}
     2 | {1731515}
    (4 rows)
    ```

2. Connect to the database in utility mode and query `pg_stat_activity` to return the session id for the process id in the output for a segment. For example:

    ```
    select sess_id from pg_stat_activity where pid=1731513;
    ```

    ```
    sess_id
    ---------
      10
    (1 row)
    ```

3. Terminate the session, which will terminate all associated backends on all segments:

    ```
    select pg_terminate_backend(pid) from pg_stat_activity where sess_id=10;
    ```

4. Verify that there are no more suboverflowed backends:

    ```
    select * from gp_suboverflowed_backend`;
    ```

    ```
    segid |   pids
    -------+-----------
    -1 |
     0 |
     1 |
     2 |
    (4 rows)
    ```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Viewing Metadata Information about Database Objects

WarehousePG tracks various metadata information in its system catalogs about the objects stored in a database, such as tables, views, indexes and so on, as well as global objects such as roles and tablespaces.

Viewing the Last Operation Performed

You can use the system views *pg_stat_operations* and *pg_stat_partition_operations* to look up actions performed on an object, such as a table. For example, to see the actions performed on a table, such as when it was created and when it was last vacuumed and analyzed:

```
=> SELECT schemaname as schema, objname as table,
   usename as role, actionname as action,
   subtype as type, statime as time
   FROM pg_stat_operations
   WHERE objname='cust';
 schema | table | role | action  | type  | time
--------+-------+------+---------+-------+--------------------------
  sales | cust  | main | CREATE  | TABLE | 2016-02-09 18:10:07.867977-08
  sales | cust  | main | VACUUM  |       | 2016-02-10 13:32:39.068219-08
  sales | cust  | main | ANALYZE |       | 2016-02-25 16:07:01.157168-08
(3 rows)
```

Viewing the Definition of an Object

To see the definition of an object, such as a table or view, you can use the `\d+` meta-command when working in `psql`. For example, to see the definition of a table:

```
=> \d+ <mytable>
```

Viewing Session Memory Usage Information

You can create and use the *session_level_memory_consumption* view that provides information about the current memory utilization for sessions that are running queries on WarehousePG. The view contains session information and information such as the database that the session is connected to, the query that the session is currently running, and memory consumed by the session processes.

- Creating the session_level_memory_consumption View
- The session_level_memory_consumption View

Creating the session_level_memory_consumption View

To create the *session_state.session_level_memory_consumption* view in a WarehousePG, run the script `CREATE EXTENSION gp_internal_tools;` once for each database. For example, to install the view in the database `testdb`, use this command:

```
$ psql -d testdb -c "CREATE EXTENSION gp_internal_tools;"
```

The session_level_memory_consumption View

The *session_state.session_level_memory_consumption* view provides information about memory consumption and idle time for sessions that are running SQL queries.

When resource queue-based resource management is active, the column `is_runaway` indicates whether WarehousePG considers the session a runaway session based on the vmem memory consumption of the session's queries. Under the resource queue-based resource management scheme, WarehousePG considers the session a runaway when the queries consume an excessive amount of memory. The WarehousePG server configuration parameter `runaway_detector_activation_percent` governs the conditions under which WarehousePG considers a session a runaway session.

The `is_runaway`, `runaway_vmem_mb`, and `runaway_command_cnt` columns are not applicable when resource group-based resource management is active.

column	type	references	description
`datname`	name		Name of the database that the session is connected to.
`sess_id`	integer		Session ID.
`usename`	name		Name of the session user.
`query`	text		Current SQL query that the session is running.
`segid`	integer		Segment ID.
`vmem_mb`	integer		Total vmem memory usage for the session in MB.
`is_runaway`	boolean		Session is marked as runaway on the segment.
`qe_count`	integer		Number of query processes for the session.
`active_qe_count`	integer		Number of active query processes for the session.
`dirty_qe_count`	integer		Number of query processes that have not yet released their memory. The value is `-1` for sessions that are not running.
`runaway_vmem_mb`	integer		Amount of vmem memory that the session was consuming when it was marked as a runaway session.
`runaway_command_cnt`	integer		Command count for the session when it was marked as a runaway session.
`idle_start`	timestamptz		The last time a query process in this session became idle.

Viewing and Logging Per-Process Memory Usage Information

WarehousePG allocates all memory within memory contexts. Memory contexts provide a convenient way to manage allocations made in different places that need to live for differing amounts of time. Destroying a context releases all of the memory that was allocated in it.

Tracking the amount of memory used by a server process or a long-running query can help detect the source of a potential out-of-memory condition. WarehousePG provides a system view and administration functions that you can use for this purpose.

About the pg_backend_memory_contexts View

To display the memory usage of all active memory contexts in the server process attached to the current session, use thepg_backend_memory_contexts system view. This view is restricted to superusers, but access may be granted to other roles.

```
SELECT * FROM pg_backend_memory_contexts;
```

About the Memory Context Admin Functions

You can use the system administration function `pg_log_backend_memory_contexts()` to instruct WarehousePG to dump the memory usage of other sessions running on the coordinator host into the server log. Execution of this function is restricted to superusers only, and cannot be granted to other roles.

The signature of `pg_log_backend_memory_contexts()` function follows:

```
pg_log_backend_memory_contexts( pid integer )
```

where `pid` identifies the process whose memory contexts you want dumped.

`pg_log_backend_memory_contexts()` returns `true` when memory context logging is successfully activated for the process on the local host. When logging is activated, WarehousePG writes one message to the log for each memory context at the `LOG` message level. The log messages appear in the server log based on the log configuration set; refer to Error Reporting and Logging in the PostgreSQL documentation for more information. *The memory context log messages are not sent to the client.*

Memory context logging functions that dump memory usage across all WarehousePG segments, or dump usage for a specific segment are named `gp_log_backend_memory_contexts()`.

`gp_log_backend_memory_contexts()` has two signatures:

```
gp_log_backend_memory_contexts( sess_id integer )
gp_log_backend_memory_contexts( sess_id integer, contentId integer )
```

where `sess_id` is the WarehousePG identifier assigned to the session (typically obtained from the `pg_stat_activity` view), and `contentID` in the second signature identifies the segment instance of interest.

When you invoke `gp_log_backend_memory_contexts()` on the WarehousePG coordinator host, it invokes `pg_log_backend_memory_contexts()` on the individual segments, which in turn triggers a memory usage dump to each segment log. The functions return an integer identifying the number of segments on which memory context logging was successfully activated.

Sample Log Messages

The command:

```
SELECT pg_log_backend_memory_contexts( pg_backend_pid()
);
```

triggered the dumping of the following (subset of) memory context messages to the local server log file:

```
2023-03-23 16:45:57.228512 UTC,"gpadmin","testdb",p16389,th-557447104,"[local]",,2023-03-23 15:57:32 UTC,0,,cmd10,seg-1,,,,sx1,"LOG","00000","logging memory

Viewing Query Workfile Usage Information

The WarehousePG administrative schema *gp_toolkit* contains views that display information about WarehousePG workfiles. WarehousePG creates workfiles on disk if it does not have sufficient memory to run the query in memory. This information can be used for troubleshooting and tuning queries. The information in the views can also be used to specify the values for the WarehousePG configuration parameters `gp_workfile_limit_per_query` and `gp_workfile_limit_per_segment`.

These are the views in the schema *gp_toolkit*:

- The gp_workfile_entries view contains one row for each operator using disk space for workfiles on a segment at the current time.
- The gp_workfile_usage_per_query view contains one row for each query using disk space for workfiles on a segment at the current time.
- The gp_workfile_usage_per_segment view contains one row for each segment. Each row displays the total amount of disk space used for workfiles on the segment at the current time.

For information about using *gp_toolkit*, see Using gp_toolkit.

Viewing the Database Server Log Files

Every database instance in WarehousePG (coordinator and segments) runs a PostgreSQL database server with its own server log file. Log files are created in the `log` directory of the coordinator and each segment data directory.

Log File Format

The server log files are written in comma-separated values (CSV) format. Some log entries will not have values for all log fields. For example, only log entries associated with a query worker process will have the `slice_id` populated. You can identify related log entries of a particular query by the query's session identifier (`gp_session_id`) and command identifier (`gp_command_count`).

The following fields are written to the log:

Number	Field Name	Data Type	Description
1	event_time	timestamp with time zone	Time that the log entry was written to the log
2	user_name	varchar(100)	The database user name
3	database_name	varchar(100)	The database name
4	process_id	varchar(10)	The system process ID (prefixed with "p")
5	thread_id	varchar(50)	The thread count (prefixed with "th")
6	remote_host	varchar(100)	On the coordinator, the hostname/address of the client machine. On the segment, the hostname/address of the coordinator.
7	remote_port	varchar(10)	The segment or coordinator port number
8	session_start_time	timestamp with time zone	Time session connection was opened
9	transaction_id	int	Top-level transaction ID on the coordinator. This ID is the parent of any subtransactions.
10	gp_session_id	text	Session identifier number (prefixed with "con")
11	gp_command_count	text	The command number within a session (prefixed with "cmd")
12	gp_segment	text	The segment content identifier (prefixed with "seg" for primaries or "mir" for mirrors). The coordinator always has a content ID of -1.
13	slice_id	text	The slice ID (portion of the query plan being executed)
14	distr_tranx_id	text	Distributed transaction ID
15	local_tranx_id	text	Local transaction ID
16	sub_tranx_id	text	Subtransaction ID
17	event_severity	varchar(10)	Values include: LOG, ERROR, FATAL, PANIC, DEBUG1, DEBUG2
18	sql_state_code	varchar(10)	SQL state code associated with the log message
19	event_message	text	Log or error message text
20	event_detail	text	Detail message text associated with an error or warning message
21	event_hint	text	Hint message text associated with an error or warning message
22	internal_query	text	The internally-generated query text
23	internal_query_pos	int	The cursor index into the internally-generated query text
24	event_context	text	The context in which this message gets generated
25	debug_query_string	text	User-supplied query string with full detail for debugging. This string can be modified for internal use.
26	error_cursor_pos	int	The cursor index into the query string
27	func_name	text	The function in which this message is generated
28	file_name	text	The internal code file where the message originated
29	file_line	int	The line of the code file where the message originated
30	stack_trace	text	Stack trace text associated with this message

Searching the WarehousePG Server Log Files

WarehousePG provides a utility called `gplogfilter` can search through a WarehousePG log file for entries matching the specified criteria. By default, this utility searches through the WarehousePG coordinator log file in the default logging location. For example, to display the last three lines of each of the log files under the coordinator directory:

```
$ gplogfilter -n 3
```

To search through all segment log files simultaneously, run `gplogfilter` through the `gpssh` utility. For example, to display the last three lines of each segment log file:

```
$ gpssh -f seg_host_file
```

```
=> source /usr/edb/whpg7/greenplum_path.sh
=> gplogfilter -n 3 /gpdata/gp*/log/gpdb*.log
```

Using gp_toolkit

Use the WarehousePG administrative schema *gp_toolkit* to query the system catalogs, log files, and operating environment for system status information. The `gp_toolkit` schema contains several views you can access using SQL commands. The *gp_toolkit* schema is accessible to all database users. Some objects require superuser permissions. Use a command similar to the following to add the *gp_toolkit* schema to your schema search path:

```
=> ALTER ROLE myrole SET search_path TO myschema,gp_toolkit;
```

For a description of the available administrative schema views and their usages, see the *WarehousePG Reference Guide*.

SQL Standard Error Codes

The following table lists all the defined error codes. Some are not used, but are defined by the SQL standard. The error classes are also shown. For each error class there is a standard error code having the last three characters 000. This code is used only for error conditions that fall within the class but do not have any more-specific code assigned.

The PL/pgSQL condition name for each error code is the same as the phrase shown in the table, with underscores substituted for spaces. For example, code 22012, DIVISION BY ZERO, has condition name DIVISION_BY_ZERO. Condition names can be written in either upper or lower case.

> **Note** PL/pgSQL does not recognize warning, as opposed to error, condition names; those are classes 00, 01, and 02.

Error Code	Meaning	Constant
Class 00— Successful Completion		
00000	SUCCESSFUL COMPLETION	successful_completion
Class 01 — Warning		
01000	WARNING	warning
0100C	DYNAMIC RESULT SETS RETURNED	dynamic_result_sets_returned
01008	IMPLICIT ZERO BIT PADDING	implicit_zero_bit_padding
01003	NULL VALUE ELIMINATED IN SET FUNCTION	null_value_eliminated_in_set_function
01007	PRIVILEGE NOT GRANTED	privilege_not_granted
01006	PRIVILEGE NOT REVOKED	privilege_not_revoked
01004	STRING DATA RIGHT TRUNCATION	string_data_right_truncation
01P01	DEPRECATED FEATURE	deprecated_feature
Class 02 — No Data (this is also a warning class per the SQL standard)		
02000	NO DATA	no_data
02001	NO ADDITIONAL DYNAMIC RESULT SETS RETURNED	no_additional_dynamic_result_sets_returned
Class 03 — SQL Statement Not Yet Complete		
03000	SQL STATEMENT NOT YET COMPLETE	sql_statement_not_yet_complete
Class 08 — Connection Exception		
08000	CONNECTION EXCEPTION	connection_exception
08003	CONNECTION DOES NOT EXIST	connection_does_not_exist
08006	CONNECTION FAILURE	connection_failure
08001	SQLCLIENT UNABLE TO ESTABLISH SQLCONNECTION	sqlclient_unable_to_establish_sqlconnection
08004	SQLSERVER REJECTED ESTABLISHMENT OF SQLCONNECTION	sqlserver_rejected_establishment_of_sqlconnection
08007	TRANSACTION RESOLUTION UNKNOWN	transaction_resolution_unknown
08P01	PROTOCOL VIOLATION	protocol_violation
Class 09 — Triggered Action Exception		
09000	TRIGGERED ACTION EXCEPTION	triggered_action_exception
Class 0A — Feature Not Supported		
0A000	FEATURE NOT SUPPORTED	feature_not_supported

4.2.11 Monitoring Long-Running Operations

WarehousePG can report the progress of `ANALYZE`, `CLUSTER`, `COPY`, `CREATE INDEX`, `REINDEX`, and `VACUUM` commands during command execution. WarehousePG can also report the progress of a running base backup (initiated during gprecoverseg -F) command invocation, allowing you to monitor the progress of these possibly long-running operations.

WarehousePG reports the command progress via ephemeral system views, which return data only while the operations are running. Two sets of progress reporting views are provided:

- `gp_stat_progress_<command>` - displays the progress of running `<command>` invocations on the coordinator and all segments, with a row per segment instance
- `gp_stat_progress_<command>_summary` - aggregates `<command>` progress on the coordinator and all segments, and displays one row per running `<command>` invocation

WarehousePG reports progress in phases, where the phases are specific to the command. For example, `acquiring sample rows` is an analyze progress phase, while `building index` is an index creation progress phase. WarehousePG reports the progress for both heap and AO/CO tables. For most commands, heap and AO/CO table share the same phases. For vacuum and cluster operations, WarehousePG reports heap and AO/CO table progress in separate phases.

ANALYZE Progress Reporting

The gp_stat_progress_analyze system view reports the progress of running `ANALYZE` and `analyzedb` operations. The view displays a row per segment instance that is currently servicing an analyze operation.

For each active analyze operation, the `gp_stat_progress_analyze_summary` view aggregates across the WarehousePG cluster the metrics reported by `gp_stat_progress_analyze`.

The table below describes how to interpret the phase-specific information reported in the views:

Phase	Description
`initializing`	The command is preparing to begin scanning the heap. This phase is expected to be very brief.
`acquiring sample rows`	The command is currently scanning the table given by `relid` to obtain sample rows.
`acquiring inherited sample rows`	The command is currently scanning child tables to obtain sample rows. Columns `child_tables_total`, `child_tables_done`, and `current_child_table_relid` contain the progress information for this phase.
`computing statistics`	The command is computing statistics from the sample rows obtained during the table scan.
`computing extended statistics`	The command is computing extended statistics from the sample rows obtained during the table scan.
`finalizing analyze`	The command is updating `pg_class`. When this phase is completed, `ANALYZE` ends.

CLUSTER and VACUUM FULL Progress Reporting

The gp_stat_progress_cluster system view reports the progress of running `CLUSTER`, `clusterdb`, and `VACUUM FULL` (on a heap table) operations. (`VACUUM FULL` on a heap table is similar to `CLUSTER` in that WarehousePG performs a re-write of the table.) The view displays a row per segment instance that is currently servicing any of the mentioned commands.

For each active cluster or vacuum full operation, the `gp_stat_progress_cluster_summary` view aggregates across the WarehousePG cluster the metrics reported by `gp_stat_progress_cluster`.

Heap Table Cluster Phases

The table below describes how to interpret the *heap table* phase-specific information reported in the views:

Phase	Description
`initializing`	The command is preparing to begin scanning the heap. This phase is expected to be very brief.
`seq scanning heap`	The command is currently scanning the table using a sequential scan.
`index scanning heap`	`CLUSTER` is currently scanning the table using an index scan.
`sorting tuples`	`CLUSTER` is currently sorting tuples.
`writing new heap`	`CLUSTER` is currently writing the new heap.
`swapping relation files`	The command is currently swapping newly-built files into place.
`rebuilding index`	The command is currently rebuilding an index.
`performing final cleanup`	The command is performing final cleanup. When this phase is completed, `CLUSTER` or `VACUUM FULL` ends.

AO/CO Table Cluster Phases

The table below describes how to interpret the *AO/CO table* phase-specific information reported in the views:

Phase	Description
`initializing`	The command is preparing to begin scanning. This phase is expected to be very brief.
`seq scanning append-optimized`	The command is currently scanning the AO/CO table using a sequential scan.
`index scanning heap`	`CLUSTER` is currently scanning the table using an index scan.
`sorting tuples`	`CLUSTER` is currently sorting tuples.
`writing new append-optimized`	`CLUSTER` is currently writing the new AO/CO table.
`swapping relation files`	The command is currently swapping newly-built files into place.
`performing final cleanup`	The command is performing final cleanup. When this phase is completed, `CLUSTER` or `VACUUM FULL` ends.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

COPY Progress Reporting

The gp_stat_progress_copy system view reports the progress of running `COPY` operations. The view displays a row per segment instance that is currently servicing a copy operation.

For each active copy operation, the `gp_stat_progress_copy_summary` aggregates across the WarehousePG cluster the metrics reported by `gp_stat_progress_copy`.

You can also use these views to monitor the data movement progress of utilities that use `COPY` under the hood, such as `gpbackup/gprestore`.

WarehousePG calculates the `bytes_processed`, `bytes_total`, `tuples_processed`, and `tuples_excluded` column values differently for the `gp_stat_progress_copy_summary` view depending on the type of table and type of `COPY` operation. The table below identifies the table types, the types of `COPY` operations, and which of `sum()` or `average()` WarehousePG uses to calculate the final value:

Table type	COPY TO	COPY FROM	COPY TO/FROM ON SEGMENT
Distributed table	`sum()`	`sum()`	`sum()`
Replicated table	`sum()`	`average()`	`sum()`

WarehousePG uses `sum()` for `COPY ... ON SEGMENT` as the command explicitly operates on each segment irrespective of the table type.

WarehousePG uses `sum()` for `COPY TO` with replicated tables, as the actual copy originates from only a single segment.

CREATE INDEX Progress Reporting

The gp_stat_progress_create_index system view reports the progress of running `CREATE INDEX` and `REINDEX` operations. The view displays a row per segment instance that is currently servicing either command.

For each active index operation, the `gp_stat_progress_create_index_summary` view aggregates across the WarehousePG cluster the metrics reported by `gp_stat_progress_create_index`.

The table below describes how to interpret the phase-specific information reported in the views:

Phase	Description
`initializing`	`CREATE INDEX` or `REINDEX` is preparing to create the index. This phase is expected to be very brief.
`waiting for writers before build`	This phase is not applicable, WarehousePG does not support `CREATE INDEX CONCURRENTLY` or `REINDEX CONCURRENTLY`.
`building index`	The index is being built by the access method-specific code. In this phase, access methods that support progress reporting fill in their own progress data, and the subphase is indicated in this column. Typically, `blocks_total` and `blocks_done` will contain progress data, as well as potentially `tuples_total` and `tuples_done`.
`waiting for writers before validation`	This phase is not applicable, WarehousePG does not support `CREATE INDEX CONCURRENTLY` or `REINDEX CONCURRENTLY`.
`index validation: scanning index`	This phase is not applicable, WarehousePG does not support `CREATE INDEX CONCURRENTLY` or `REINDEX CONCURRENTLY`.
`index validation: sorting tuples`	This phase is not applicable, WarehousePG does not support `CREATE INDEX CONCURRENTLY` or `REINDEX CONCURRENTLY`.
`index validation: scanning table`	This phase is not applicable, WarehousePG does not support `CREATE INDEX CONCURRENTLY` or `REINDEX CONCURRENTLY`.
`waiting for old snapshots`	This phase is not applicable, WarehousePG does not support `CREATE INDEX CONCURRENTLY` or `REINDEX CONCURRENTLY`.
`waiting for readers before marking dead`	This phase is not applicable, WarehousePG does not support `REINDEX CONCURRENTLY`.
`waiting for readers before dropping`	This phase is not applicable, WarehousePG does not support `REINDEX CONCURRENTLY`.

WarehousePG skips several phases because it does not support concurrent index creation or concurrent reindexing.

VACUUM Progress Reporting

The gp_stat_progress_vacuum system view reports the progress of running `VACUUM` and `vacuumdb` operations on AO/CO and heap tables, and `VACUUM FULL` operations on AO/CO tables. The view displays a row per segment instance that is currently servicing a vacuum operation.

For each active vacuum operation, the `gp_stat_progress_vacuum_summary` view aggregates across the WarehousePG cluster the metrics reported by `gp_stat_progress_vacuum`.

Regular `VACUUM` modifies a heap table in place. `VACUUM FULL` on a heap table rewrites the table as does a `CLUSTER` operation. For information about progress reporting for `VACUUM FULL` on a heap table, see CLUSTER and VACUUM FULL Progress Reporting.

In WarehousePG, an AO/CO table vacuum behaves differently than a heap table vacuum. Because WarehousePG stores the logical EOF for each segment file, it does not need to scan physical blocks after the logical EOF, so WarehousePG can truncate them. WarehousePG always rewrites data into new segment files to get rid of dead tuples for AO/CO tables, and performs the same operations for both `VACUUM FULL` and `VACUUM`. Due to these difference, WarehousePG reports vacuum progress on heap and AO/CO tables using different phases.

Heap Table Vacuum Phases

The table below describes how to interpret the *heap table* phase-specific information reported in the views:

Heap Table Phase	Description
`initializing`	`VACUUM` is preparing to begin scanning the heap. This phase is expected to be very brief.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Heap Table Phase	Description
`scanning heap`	`VACUUM` is currently scanning the heap. It prunes and defragment seach page if required, and possibly performs freezing activity. Use the `heap_blks_scanned` column to monitor the progress of the scan.
`vacuuming indexes`	`VACUUM` is currently vacuuming the indexes. If a table has any indexes, this will happen at least once per vacuum, after the heap has been completely scanned. It may happen multiple times per vacuum if `maintenance_work_mem` (or, in the case of autovacuum, `autovacuum_work_mem` if set) is insufficient to store the number of dead tuples found.
`vacuuming heap`	`VACUUM` is currently vacuuming the heap. Vacuuming the heap is distinct from scanning the heap, and occurs after each instance of vacuuming indexes. If `heap_blks_scanned` is less than `heap_blks_total`, the system returns to scanning the heap after this phase is completed; otherwise, it begins cleaning up indexes after this phase is completed.
`cleaning up indexes`	`VACUUM` is currently cleaning up indexes. This occurs after the heap has been completely scanned and all vacuuming of the indexes and the heap has been completed.
`truncating heap`	`VACUUM` is currently truncating the heap so as to return empty pages at the end of the relation to the operating system. This occurs after cleaning up indexes.
`performing final cleanup`	`VACUUM` is performing final cleanup. During this phase, `VACUUM` will vacuum the free space map, update statistics in `pg_class`, and report statistics to the statistics collector. When this phase is completed, the `VACUUM` operation ends.

AO/CO Table Vacuum Phases

The table below describes how to interpret the *AO/CO table* phase-specific information reported in the views:

AO/CO Table Phase	Description
`initializing`	`VACUUM` is preparing to begin scanning AO/CO tables. This phase is expected to be very brief.
`vacuuming indexes`	For AO/CO tables, the `vacuuming indexes` phase is a sub-phase that may occur during both `append-optimized pre-cleanup` and `append-optimized post-cleanup` phases if the relation has an index and there are invisible awaiting-drop segment files.
`append-optimized pre-cleanup`	`VACUUM` is performing pre-cleanup of the AO/CO table; this includes recycling `AWAITING_DROP` segments that are no longer visible to anyone from previous `VACUUM` operations, and truncating all live segment files to their logcial EOFs. Use `heap_blks_vacuumed` and `index_vacuum_count` to monitor the progress.
`append-optimized compact`	`VACUUM` is vacuuming (or "compacting") the AO/CO table by scanning the segment files and rewriting only the surviving tuples into new segment files. Use `heap_blks_scanned` and `num_dead_tuples` to monitor the progress.
`append-optimized post-cleanup`	`VACUUM` is performing post-cleanup of the AO/CO table; this includes recycling old segments that are no longer visible after the "compact" phase, and truncating all live segment files to their logcial EOFs. Use `heap_blks_vacuumed` and `index_vacuum_count` to monitor the progress.

Base Backup Progress Reporting

The gp_stat_progress_basebackup system view reports the progress of running base backup operations, as is performed by `gprecoverseg -F` (full recovery). The view displays a row per segment instance that is currently servicing replication commands.

For each active base backup operation, the `gp_stat_progress_basebackup_summary` view aggregates across the WarehousePG cluster the metrics reported by `gp_stat_progress_basebackup`.

The table below describes how to interpret the phase-specific information reported in the views:

Phase	Description
`initializing`	The WAL sender process is preparing to begin the backup. This phase is expected to be very brief.
`waiting for checkpoint to finish`	The WAL sender process is currently performing `pg_backup_start` to prepare to take a base backup, and waiting for the start-of-backup checkpoint to finish.
`estimating backup size`	The WAL sender process is currently estimating the total amount of database files that will be streamed as a base backup.
`streaming database files`	The WAL sender process is currently streaming database files as a base backup.
`waiting for wal archiving to finish`	The WAL sender process is currently performing `pg_backup_stop` to finish the backup, and waiting for all the WAL files required for the base backup to be successfully archived. The backup ends when this phase is completed.
`transferring wal files`	The WAL sender process is currently transferring all WAL logs generated during the backup. This phase may occur after `waiting for wal archiving to finish` phase. The backup ends when this phase is completed.

Example: Viewing Real-Time Command Progress

The following example commands display the real-time progress of all running `VACUUM` commands every 0.5 seconds:

```
host$ cat > viewer.sql << EOF
SELECT * FROM gp_stat_progress_vacuum ORDER BY gp_segment_id;
SELECT * FROM gp_stat_progress_vacuum_summary;
EOF

host$ watch -n 0.5 "psql -af viewer.sql"
```

Additional Considerations

Take note of these additional considerations related to progress reporting in WarehousePG:

- Progress phases and their interpretation of attributes are slightly different for AO/AOCO tables and heap tables for the `CREATE INDEX/REINDEX`, `VACUUM`, and `CLUSTER` operations. Refer to the individual command topics for more information.
- The progress views for an `ANALYZE` operation on a partitioned table display the progress of each individual leaf partition. WarehousePG does not currently provide a measure of the combined progress of all partitions.
- WarehousePG does not support the `CLUSTER` operation on a partitioned table.

4.2.12 Routine System Maintenance Tasks

To keep a WarehousePG cluster running efficiently, the database must be regularly cleared of expired data and the table statistics must be updated so that the query optimizer has accurate information.

WarehousePG requires that certain tasks be performed regularly to achieve optimal performance. The tasks discussed here are required, but database administrators can automate them using standard UNIX tools such as `cron` scripts. An administrator sets up the appropriate scripts and checks that they ran successfully. See Recommended Monitoring and Maintenance Tasks for additional suggested maintenance activities you can implement to keep your WarehousePG cluster running optimally.

Parent topic: Managing a WarehousePG cluster

Routine Vacuum and Analyze

The design of the MVCC transaction concurrency model used in WarehousePG means that deleted or updated data rows still occupy physical space on disk even though they are not visible to new transactions. If your database has many updates and deletes, many expired rows exist and the space they use must be reclaimed with the `VACUUM` command. The `VACUUM` command also collects table-level statistics, such as numbers of rows and pages, so it is also necessary to vacuum append-optimized tables, even when there is no space to reclaim from updated or deleted rows.

Vacuuming an append-optimized table follows a different process than vacuuming heap tables. On each segment, a new segment file is created and visible rows are copied into it from the current segment. When the segment file has been copied, the original is scheduled to be dropped and the new segment file is made available. This requires sufficient available disk space for a copy of the visible rows until the original segment file is dropped.

If the ratio of hidden rows to total rows in a segment file is less than a threshold value (10, by default), the segment file is not compacted. The threshold value can be configured with the `gp_appendonly_compaction_threshold` server configuration parameter. `VACUUM FULL` ignores the value of `gp_appendonly_compaction_threshold` and rewrites the segment file regardless of the ratio.

You can use the `__gp_aovisimap_compaction_info()` function in the *gp_toolkit* schema to investigate the effectiveness of a VACUUM operation on append-optimized tables.

For information about the `__gp_aovisimap_compaction_info()` function, see Checking Append-Optimized Tables.

`VACUUM` can be deactivated for append-optimized tables using the `gp_appendonly_compaction` server configuration parameter.

For details about vacuuming a database, see Vacuuming the Database.

For information about the `gp_appendonly_compaction_threshold` server configuration parameter and the `VACUUM` command, see the *WarehousePG Reference Guide*.

Transaction ID Management

WarehousePG's MVCC transaction semantics depend on comparing transaction ID (XID) numbers to determine visibility to other transactions. Transaction ID numbers are compared using modulo 232 arithmetic, so a WarehousePG cluster that runs more than about two billion transactions can experience transaction ID wraparound, where past transactions appear to be in the future. This means past transactions' outputs become invisible. Therefore, it is necessary to `VACUUM` every table in every database at least once per two billion transactions.

WarehousePG assigns XID values only to transactions that involve DDL or DML operations, which are typically the only transactions that require an XID.

> **Important** WarehousePG monitors transaction IDs. If you do not vacuum the database regularly, WarehousePG will generate a warning and error.

WarehousePG issues the following warning when a significant portion of the transaction IDs are no longer available and before transaction ID wraparound occurs:

```
WARNING: database "database_name" must be vacuumed within *number\_of\_transactions* transactions
```

When the warning is issued, a `VACUUM` operation is required. If a `VACUUM` operation is not performed, WarehousePG stops creating transactions when it reaches a limit prior to when transaction ID wraparound occurs. WarehousePG issues this error when it stops creating transactions to avoid possible data loss:

```
FATAL: database is not accepting commands to avoid
wraparound data loss in database "database_name"
```

The WarehousePG configuration parameter `xid_warn_limit` controls when the warning is displayed. The parameter `xid_stop_limit` controls when WarehousePG stops creating transactions.

Recovering from a Transaction ID Limit Error

When WarehousePG reaches the `xid_stop_limit` transaction ID limit due to infrequent `VACUUM` maintenance, it becomes unresponsive. To recover from this situation, perform the following steps as database administrator:

1. Shut down WarehousePG.
2. Temporarily lower the `xid_stop_limit` by 10,000,000.
3. Start WarehousePG.
4. Run `VACUUM FREEZE` on all affected databases.
5. Reset the `xid_stop_limit` to its original value.
6. Restart WarehousePG.

For information about the configuration parameters, see the *WarehousePG Reference Guide*.

For information about transaction ID wraparound see the PostgreSQL documentation.

System Catalog Maintenance

Numerous database updates with `CREATE` and `DROP` commands increase the system catalog size and affect system performance. For example, running many `DROP TABLE` statements degrades the overall system performance due to excessive data scanning during metadata operations on catalog tables. The performance loss occurs between thousands to tens of thousands of `DROP TABLE` statements, depending on the system.

You should run a system catalog maintenance procedure regularly to reclaim the space occupied by deleted objects. If a regular procedure has not been run for a long time, you may need to run a more intensive procedure to clear the system catalog. This topic describes both procedures.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Regular System Catalog Maintenance

It is recommended that you periodically run `REINDEX` and `VACUUM` on the system catalog to clear the space that deleted objects occupy in the system indexes and tables. If regular database operations include numerous `DROP` statements, it is safe and appropriate to run a system catalog maintenance procedure with `VACUUM` daily at off-peak hours. You can do this while the system is available.

These are WarehousePG cluster catalog maintenance steps.

1. Perform a `REINDEX` on the system catalog tables to rebuild the system catalog indexes. This removes bloat in the indexes and improves `VACUUM` performance.

   > **Note** `REINDEX` causes locking of system catalog tables, which could affect currently running queries. To avoid disrupting ongoing business operations, schedule the `REINDEX` operation during a period of low activity.

2. Perform a `VACUUM` on the system catalog tables.

3. Perform an `ANALYZE` on the system catalog tables to update the catalog table statistics.

This example script performs a `REINDEX`, `VACUUM`, and `ANALYZE` of a WarehousePG cluster catalog. In the script, replace `<database-name>` with a database name.

```
#!/bin/bash
DBNAME="<database-name>"
SYSTABLES="' pg_catalog.' || relname || ';' FROM pg_class a, pg_namespace b
WHERE a.relnamespace=b.oid AND b.nspname='pg_catalog' AND a.relkind='r'"

reindexdb --system -d $DBNAME
psql -tc "SELECT 'VACUUM' || $SYSTABLES" $DBNAME | psql -a $DBNAME
analyzedb -as pg_catalog -d $DBNAME
```

> **Note** If you are performing catalog maintenance during a maintenance period and you need to stop a process due to time constraints, run the WarehousePG function `pg_cancel_backend(<PID>)` to safely stop the WarehousePG process.

Intensive System Catalog Maintenance

If system catalog maintenance has not been performed in a long time, the catalog can become bloated with dead space; this causes excessively long wait times for simple metadata operations. A wait of more than two seconds to list user tables, such as with the `\d` metacommand from within `psql`, is an indication of catalog bloat.

If you see indications of system catalog bloat, you must perform an intensive system catalog maintenance procedure with `VACUUM FULL` during a scheduled downtime period. During this period, stop all catalog activity on the system; the `VACUUM FULL` system catalog maintenance procedure takes exclusive locks against the system catalog.

Running regular system catalog maintenance procedures can prevent the need for this more costly procedure.

These are steps for intensive system catalog maintenance.

1. Stop all catalog activity on the WarehousePG cluster.
2. Perform a `REINDEX` on the system catalog tables to rebuild the system catalog indexes. This removes bloat in the indexes and improves `VACUUM` performance.
3. Perform a `VACUUM FULL` on the system catalog tables. See the following Note.
4. Perform an `ANALYZE` on the system catalog tables to update the catalog table statistics.

> **Note** The system catalog table `pg_attribute` is usually the largest catalog table. If the `pg_attribute` table is significantly bloated, a `VACUUM FULL` operation on the table might require a significant amount of time and might need to be performed separately. The presence of both of these conditions indicate a significantly bloated `pg_attribute` table that might require a long `VACUUM FULL` time:

- The `pg_attribute` table contains a large number of records.
- The diagnostic message for `pg_attribute` is `significant amount of bloat` in the `gp_toolkit.gp_bloat_diag` view.

Vacuum and Analyze for Query Optimization

WarehousePG uses a cost-based query optimizer that relies on database statistics. Accurate statistics allow the query optimizer to better estimate selectivity and the number of rows that a query operation retrieves. These estimates help it choose the most efficient query plan. The `ANALYZE` command collects column-level statistics for the query optimizer.

You can run both `VACUUM` and `ANALYZE` operations in the same command. For example:

```
=# VACUUM ANALYZE mytable;
```

Running the VACUUM ANALYZE command might produce incorrect statistics when the command is run on a table with a significant amount of bloat (a significant amount of table disk space is occupied by deleted or obsolete rows). For large tables, the `ANALYZE` command calculates statistics from a random sample of rows. It estimates the number rows in the table by multiplying the average number of rows per page in the sample by the number of actual pages in the table. If the sample contains many empty pages, the estimated row count can be inaccurate.

For a table, you can view information about the amount of unused disk space (space that is occupied by deleted or obsolete rows) in the *gp_toolkit* view *gp_bloat_diag*. If the `bdidiag` column for a table contains the value `significant amount of bloat suspected`, a significant amount of table disk space consists of unused space. Entries are added to the *gp_bloat_diag* view after a table has been vacuumed.

To remove unused disk space from the table, you can run the command VACUUM FULL on the table. Due to table lock requirements, VACUUM FULL might not be possible until a maintenance period.

As a temporary workaround, run ANALYZE to compute column statistics and then run VACUUM on the table to generate an accurate row count. This example runs ANALYZE and then VACUUM on the *cust_info* table.

```
ANALYZE cust_info;
VACUUM cust_info;
```

> **Important** If you intend to run queries on partitioned tables with GPORCA enabled (the default), you must collect statistics on the root partitioned table with the ANALYZE command. For information about GPORCA, see Overview of GPORCA.

> **Note** You can use the WarehousePG utility analyzedb to update table statistics. Tables can be analyzed concurrently. For append optimized tables, analyzedb updates statistics only if the statistics are not current. See the analyzedb utility.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Routine Reindexing

For B-tree indexes, a freshly-constructed index is slightly faster to access than one that has been updated many times because logically adjacent pages are usually also physically adjacent in a newly built index. Reindexing older indexes periodically can improve access speed. If all but a few index keys on a page have been deleted, there will be wasted space on the index page. A reindex will reclaim that wasted space. In WarehousePG it is often faster to drop an index (`DROP INDEX`) and then recreate it (`CREATE INDEX`) than it is to use the `REINDEX` command.

For table columns with indexes, some operations such as bulk updates or inserts to the table might perform more slowly because of the updates to the indexes. To enhance performance of bulk operations on tables with indexes, you can drop the indexes, perform the bulk operation, and then re-create the index.

Managing WarehousePG Log Files

- Database Server Log Files
- Management Utility Log Files

Database Server Log Files

WarehousePG log output tends to be voluminous, especially at higher debug levels, and you do not need to save it indefinitely. Administrators should purge older log files periodically.

WarehousePG by default has log file rotation enabled for the coordinator and segment database logs. Log files are created in the `log` subdirectory of the coordinator and each segment data directory using the following naming convention: `gpdb-*YYYY*-*MM*-*DD_hhmmss*.csv`. Administrators need to implement scripts or programs to periodically clean up old log files in the `log` directory of the coordinator and each segment instance.

Log rotation can be triggered by the size of the current log file or the age of the current log file. The `log_rotation_size` configuration parameter sets the size of an individual log file that triggers log rotation. When the log file size is equal to or greater than the specified size, the file is closed and a new log file is created. The `log_rotation_size` value is specified in kilobytes. The default is 1048576 kilobytes, or 1GB. If `log_rotation_size` is set to 0, size-based rotation is deactivated.

The `log_rotation_age` configuration parameter specifies the age of a log file that triggers rotation. When the specified amount of time has elapsed since the log file was created, the file is closed and a new log file is created. The default `log_rotation_age`, `1d`, creates a new log file 24 hours after the current log file was created. If `log_rotation_age` is set to 0, time-based rotation is deactivated.

For information about viewing the database server log files, see Viewing the Database Server Log Files.

Management Utility Log Files

Log files for the WarehousePG management utilities are written to `~/gpAdminLogs` by default. The naming convention for management log files is:

```
<script_name>_<date>.log
```

The log entry format is:

```
<timestamp>:<utility>:<host>:<user>:[INFO|WARN|FATAL]:<message>
```

The log file for a particular utility execution is appended to its daily log file each time that utility is run.

4.2.13 Recommended Monitoring and Maintenance Tasks

This section lists monitoring and maintenance activities recommended to ensure high availability and consistent performance of your WarehousePG cluster.

The tables in the following sections suggest activities that a WarehousePG cluster Administrator can perform periodically to ensure that all components of the system are operating optimally. Monitoring activities help you to detect and diagnose problems early. Maintenance activities help you to keep the system up-to-date and avoid deteriorating performance, for example, from bloated system tables or diminishing free disk space.

It is not necessary to implement all of these suggestions in every cluster; use the frequency and severity recommendations as a guide to implement measures according to your service requirements.

Parent topic: Managing a WarehousePG cluster

Database State Monitoring Activities

Table 1. Database State Monitoring Activities

Activity	Procedure	Corrective Actions
List segments that are currently down. If any rows are returned, this should generate a warning or alert. Recommended frequency: run every 5 to 10 minutes Severity: IMPORTANT	Run the following query in the `postgres` database: `SELECT * FROM gp_segment_configuration WHERE status = 'd';`	If the query returns any rows, follow these steps to correct the problem: 1. Verify that the hosts with down segments are responsive. 2. If hosts are OK, check the log files for the primaries and mirrors of the down segments to discover the root cause of the segments going down. 3. If no unexpected errors are found, run the `gprecoverseg` utility to bring the segments back online.
Check for segments that are up and not in sync. If rows are returned, this should generate a warning or alert. Recommended frequency: run every 5 to 10 minutes	Execute the following query in the `postgres` database: `SELECT * FROM gp_segment_configuration WHERE mode = 'n' and status = 'u' and content <> -1;`	If the query returns rows then the segment might be in the process of moving from `Not In Sync` to `Synchronized` mode. Use `gpstate -e` to track progress.
Check for segments that are not operating in their preferred role but are marked as up and `Synchronized`. If any segments are found, the cluster may not be balanced. If any rows are returned this should generate a warning or alert. Recommended frequency: run every 5 to 10 minutes Severity: IMPORTANT	Execute the following query in the `postgres` database: `SELECT * FROM gp_segment_configuration WHERE preferred_role <> role and status = 'u' and mode = 's';`	When the segments are not running in their preferred role, processing might be skewed. Run `gprecoverseg -r` to bring the segments back into their preferred roles.
Run a distributed query to test that it runs on all segments. One row should be returned for each primary segment. Recommended frequency: run every 5 to 10 minutes Severity: CRITICAL	Execute the following query in the `postgres` database: `SELECT gp_segment_id, count(*) FROM gp_dist_random('pg_class') GROUP BY 1;`	If this query fails, there is an issue dispatching to some segments in the cluster. This is a rare event. Check the hosts that are not able to be dispatched to ensure there is no hardware or networking issue.
Test the state of coordinator mirroring on WarehousePG. If the value is not "STREAMING", raise an alert or warning. Recommended frequency: run every 5 to 10 minutes Severity: IMPORTANT	Run the following `psql` command: `psql <dbname> -c 'SELECT pid, state FROM pg_stat_replication;'`	Check the log file from the coordinator and standby coordinator for errors. If there are no unexpected errors and the machines are up, run the `gpinitstandby` utility to bring the standby online.
Perform a basic check to see if the coordinator is up and functioning. Recommended frequency: run every 5 to 10 minutes Severity: CRITICAL	Run the following query in the `postgres` database: `SELECT count(*) FROM gp_segment_configuration;`	If this query fails, the active coordinator may be down. Try to start the database on the original coordinator if the server is up and running. If that fails, try to activate the standby coordinator as coordinator.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Hardware and Operating System Monitoring

Table 2. Hardware and Operating System Monitoring Activities

Activity	Procedure	Corrective Actions
Check disk space usage on volumes used for WarehousePG data storage and the OS. Recommended frequency: every 5 to 30 minutes Severity: CRITICAL	Set up a disk space check. • Set a threshold to raise an alert when a disk reaches a percentage of capacity. The recommended threshold is 75% full. • It is not recommended to run the system with capacities approaching 100%.	Use `VACUUM` / `VACUUM FULL` on user tables to reclaim space occupied by dead rows.
Check for errors or dropped packets on the network interfaces. Recommended frequency: hourly Severity: IMPORTANT	Set up a network interface checks.	Work with network and OS teams to resolve errors.
Check for RAID errors or degraded RAID performance. Recommended frequency: every 5 minutes Severity: CRITICAL	Set up a RAID check.	• Replace failed disks as soon as possible. • Work with system administration team to resolve other RAID or controller errors as soon as possible.
Check for adequate I/O bandwidth and I/O skew. Recommended frequency: when create a cluster or when hardware issues are suspected.	Run the WarehousePG `gpcheckperf` utility.	The cluster may be under-specified if data transfer rates are not similar to the following: • 2GB per second disk read • 1 GB per second disk write • 10 Gigabit per second network read and write If transfer rates are lower than expected, consult with your data architect regarding performance expectations. If the machines on the cluster display an uneven performance profile, work with the system administration team to fix faulty machines.

Catalog Monitoring

Table 3. Catalog Monitoring Activities

Activity	Procedure	Corrective Actions
Run catalog consistency checks in each database to ensure the catalog on each host in the cluster is consistent and in a good state. You may run this command while the database is up and running. Recommended frequency: weekly Severity: IMPORTANT	Run the WarehousePG `gpcheckcat` utility in each database: `gpcheckcat -O` Note: With the `-O` option, `gpcheckcat` runs just 10 of its usual 15 tests.	Run the repair scripts for any issues identified.
Check for `pg_class` entries that have no corresponding pg_`attribute` entry. Recommended frequency: monthly Severity: IMPORTANT	During a downtime, with no users on the system, run the WarehousePG `gpcheckcat` utility in each database: `gpcheckcat -R pgclass`	Run the repair scripts for any issues identified.
Check for leaked temporary schema and missing schema definition. Recommended frequency: monthly Severity: IMPORTANT	During a downtime, with no users on the system, run the WarehousePG `gpcheckcat` utility in each database: `gpcheckcat -R namespace`	Run the repair scripts for any issues identified.
Check constraints on randomly distributed tables. Recommended frequency: monthly Severity: IMPORTANT	During a downtime, with no users on the system, run the WarehousePG `gpcheckcat` utility in each database: `gpcheckcat -R distribution_policy`	Run the repair scripts for any issues identified.
Check for dependencies on non-existent objects. Recommended frequency: monthly Severity: IMPORTANT	During a downtime, with no users on the system, run the WarehousePG `gpcheckcat` utility in each database: `gpcheckcat -R dependency`	Run the repair scripts for any issues identified.

Data Maintenance

Table 4. Data Maintenance Activities

Activity	Procedure	Corrective Actions

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Activity	Procedure	Corrective Actions
Check for missing statistics on tables.	Check the `gp_stats_missing` view in each database: `SELECT * FROM gp_toolkit.gp_stats_missing;`	Run `ANALYZE` on tables that are missing statistics.
Check for tables that have bloat (dead space) in data files that cannot be recovered by a regular `VACUUM` command. Recommended frequency: weekly or monthly Severity: WARNING	Check the `gp_bloat_diag` view in each database: `SELECT * FROM gp_toolkit.gp_bloat_diag;`	`VACUUM FULL` acquires an `ACCESS EXCLUSIVE` lock on tables. Run `VACUUM FULL` during a time when users and applications do not require access to the tables, such as during a time of low activity, or during a maintenance window.

Database Maintenance

Table 5. Database Maintenance Activities

Activity	Procedure	Corrective Actions
Reclaim space occupied by deleted rows in the heap tables so that the space they occupy can be reused. Recommended frequency: daily Severity: CRITICAL	Vacuum user tables: `VACUUM <table>;`	Vacuum updated tables regularly to prevent bloating.
Update table statistics. Recommended frequency: after loading data and before executing queries Severity: CRITICAL	Analyze user tables. You can use the `analyzedb` management utility: `analyzedb -d <database> -a`	Analyze updated tables regularly so that the optimizer can produce efficient query execution plans.
Backup the database data. Recommended frequency: daily, or as required by your backup plan Severity: CRITICAL	Run the `gpbackup` utility to create a backup of the coordinator and segment databases in parallel.	Best practice is to have a current backup ready in case the database must be restored.

Vacuum, reindex, and analyze system catalogs to maintain an efficient catalog.
Recommended frequency: weekly, or more often if database objects are created and dropped frequently
	1. `VACUUM` the system tables in each database.
	2. Run `REINDEX SYSTEM` in each database, or use the `reindexdb` command-line utility with the `-s` option:
	`reindexdb -s <database>`
	3. `ANALYZE` each of the system tables:
	`analyzedb -s pg_catalog -d <database>`
		The optimizer retrieves information from the system tables to create query plans. If system tables and indexes are allowed to become bloated over time, scanning the system tables increases query execution time. It is important to run `ANALYZE` after reindexing, because `REINDEX` leaves indexes with no statistics.

Patching and Upgrading

Table 6. Patch and Upgrade Activities

Activity	Procedure	Corrective Actions
Ensure any bug fixes or enhancements are applied to the kernel. Recommended frequency: at least every 6 months Severity: IMPORTANT	Follow the vendor's instructions to update the Linux kernel.	Keep the kernel current to include bug fixes and security fixes, and to avoid difficult future upgrades.
Install WarehousePG minor releases, for example 5.0.*x*. Recommended frequency: quarterly Severity: IMPORTANT	Follow upgrade instructions in the WarehousePG *Release Notes*. Always upgrade to the latest in the series.	Keep the WarehousePG software current to incorporate bug fixes, performance enhancements, and feature enhancements into your WarehousePG cluster.

4.3 Managing WarehousePG Access

Securing WarehousePG includes protecting access to the database through network configuration, database user authentication, and encryption.

- Configuring Client Authentication
  This topic explains how to configure client connections and authentication for WarehousePG.
- Managing Roles and Privileges
  The WarehousePG authorization mechanism stores roles and permissions to access database objects in the database and is administered using SQL statements or command-line utilities.
- About Configuring Row-Level Security Policies
  This topic describes how to configure row-level security policies for WarehousePG tables.

Parent topic: WarehousePG Administrator Guide

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.3.1 Configuring Client Authentication

This topic explains how to configure client connections and authentication for WarehousePG.

When a WarehousePG cluster is first initialized, the system contains one predefined *superuser* role. This role will have the same name as the operating system user who initialized the WarehousePG cluster. This role is referred to as `gpadmin`. By default, the system is configured to only allow local connections to the database from the `gpadmin` role. If you want to allow any other roles to connect, or if you want to allow connections from remote hosts, you have to configure WarehousePG to allow such connections. This section explains how to configure client connections and authentication to WarehousePG.

- **Using LDAP Authentication with TLS/SSL**
  You can control access to WarehousePG with an LDAP server and, optionally, secure the connection with encryption by adding parameters to pg_hba.conf file entries.
- **Using Kerberos Authentication**
  You can control access to WarehousePG with a Kerberos authentication server.
- **Configuring Kerberos for Linux Clients**
  You can configure Linux client applications to connect to a WarehousePG cluster that is configured to authenticate with Kerberos.
- **Configuring Kerberos For Windows Clients**
  You can configure Microsoft Windows client applications to connect to a WarehousePG cluster that is configured to authenticate with Kerberos.

Parent topic: Managing WarehousePG Access

Allowing Connections to WarehousePG

Client access and authentication is controlled by the standard PostgreSQL host-based authentication file, pg_hba.conf. For detailed information about this file, see The pg_hba.conf File in the PostgreSQL documentation.

In WarehousePG, the pg_hba.conf file of the coordinator instance controls client access and authentication to your WarehousePG cluster. The WarehousePG segments also have pg_hba.conf files, but these are already correctly configured to allow only client connections from the coordinator host. The segments never accept outside client connections, so there is no need to alter the `pg_hba.conf` file on segments.

The general format of the pg_hba.conf file is a set of records, one per line. WarehousePG ignores blank lines and any text after the `#` comment character. A record consists of a number of fields that are separated by spaces or tabs. Fields can contain white space if the field value is quoted. Records cannot be continued across lines. Each remote client access record has the following format:

```
host   database   role   address   authentication-method
```

Each UNIX-domain socket access record is in this format:

```
local   database   role   authentication-method
```

The following table describes the meaning of each field in the `pg_hba.conf` file:

Field	Description
local	Matches connection attempts using UNIX-domain sockets. Without a record of this type, UNIX-domain socket connections are disallowed.
host	Matches connection attempts made using TCP/IP. Remote TCP/IP connections will not be possible unless the server is started with an appropriate value for the `listen_addresses` server configuration parameter.
hostssl	Matches connection attempts made using TCP/IP, but only when the connection is made with SSL encryption. SSL must be enabled at server start time by setting the `ssl` server configuration parameter.
hostnossl	Matches connection attempts made over TCP/IP that do not use SSL.
database	Specifies which database names this record matches. The value `all` specifies that it matches all databases. Multiple database names can be supplied by separating them with commas. A separate file containing database names can be specified by preceding the file name with a `@`.
role	Specifies which database role names this record matches. The value `all` specifies that it matches all roles. If the specified role is a group and you want all members of that group to be included, precede the role name with a `+`. Multiple role names can be supplied by separating them with commas. A separate file containing role names can be specified by preceding the file name with a `@`.
address	Specifies the client machine addresses that this record matches. This field can contain an IP address, an IP address range, or a host name. An IP address range is specified using standard numeric notation for the range's starting address, then a slash (`/`) and a CIDR mask length. The mask length indicates the number of high-order bits of the client IP address that must match. Bits to the right of this should be zero in the given IP address. There must not be any white space between the IP address, the `/`, and the CIDR mask length. Typical examples of an IPv4 address range specified this way are `172.20.143.89/32` for a single host, or `172.20.143.0/24` for a small network, or `10.6.0.0/16` for a larger one. An IPv6 address range might look like `::1/128` for a single host (in this case the IPv6 loopback address) or `fe80::7a31:c1ff:0000:0000/96` for a small network. `0.0.0.0/0` represents all IPv4 addresses, and `::0/0` represents all IPv6 addresses. To specify a single host, use a mask length of 32 for IPv4 or 128 for IPv6. In a network address, do not omit trailing zeroes. An entry given in IPv4 format will match only IPv4 connections, and an entry given in IPv6 format will match only IPv6 connections, even if the represented address is in the IPv4-in-IPv6 range. **Note:** Entries in IPv6 format will be rejected if the host system C library does not have support for IPv6 addresses. If a host name is specified (an address that is not an IP address or IP range is treated as a host name), that name is compared with the result of a reverse name resolution of the client IP address (for example, reverse DNS lookup, if DNS is used). Host name comparisons are case insensitive. If there is a match, then a forward name resolution (for example, forward DNS lookup) is performed on the host name to check whether any of the addresses it resolves to are equal to the client IP address. If both directions match, then the entry is considered to match. Some host name databases allow associating an IP address with multiple host names, but the operating system only returns one host name when asked to resolve an IP address. The host name that is used in `pg_hba.conf` must be the one that the address-to-name resolution of the client IP address returns, otherwise the line will not be considered a match. When host names are specified in `pg_hba.conf`, you should ensure that name resolution is reasonably fast. It can be of advantage to set up a local name resolution cache such as `nscd`. Also, you can enable the server configuration parameter `log_hostname` to see the client host name instead of the IP address in the log.
IP-address / IP-mask	These fields can be used as an alternative to the CIDR address notation. Instead of specifying the mask length, the actual mask is specified in a separate column. For example, `255.0.0.0` represents an IPv4 CIDR mask length of 8, and `255.255.255.255` represents a CIDR mask length of 32.
authentication-method	Specifies the authentication method to use when connecting. WarehousePG supports theauthentication methods supported by PostgreSQL 12.

Caution: For a more secure system, consider removing records for remote connections that use trust authentication from the `pg_hba.conf` file. Trust authentication grants any user who can connect to the server access to the database using any role they specify. You can safely replace trust authentication with ident authentication for local UNIX-socket connections. You can also use ident authentication for local and remote TCP clients, but the client host must be running an ident service and you must trust the integrity of that machine.

Editing the pg_hba.conf File

Initially, the `pg_hba.conf` file is set up with generous permissions for the gpadmin user and no database access for other WarehousePG roles. You will need to edit the `pg_hba.conf` file to enable users' access to databases and to secure the gpadmin user. Consider removing entries that have trust authentication, since they allow anyone with access to the server to connect with any role they choose. For local (UNIX socket) connections, use ident authentication, which requires the operating system user to match the role specified. For local and remote TCP connections, ident authentication requires the client's host to run an indent service. You can install an ident service on the coordinator host and then use ident authentication for local TCP connections, for example `127.0.0.1/28`. Using ident authentication for remote TCP connections is less secure because it requires you to trust the integrity of the ident service on the client's host.

This example shows how to edit the pg_hba.conf file of the coordinator to allow remote client access to all databases from all roles using encrypted password authentication.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Editing pg_hba.conf

1. Open the file $COORDINATOR_DATA_DIRECTORY/pg_hba.conf in a text editor.

2. Add a line to the file for each type of connection you want to allow. Records are read sequentially, so the order of the records is significant. Typically, earlier records will have tight connection match parameters and weaker authentication methods, while later records will have looser match parameters and stronger authentication methods. For example:

```
# allow the gpadmin user local access to all databases
# using ident authentication
local   all   gpadmin   ident         sameuser
host    all   gpadmin   127.0.0.1/32  ident
host    all   gpadmin   ::1/128       ident
# allow the 'dba' role access to any database from any
# host with IP address 192.168.x.x and use md5 encrypted
# passwords to authenticate the user
# Note that to use SHA-256 encryption, replace md5 with
# password in the line below
host    all   dba   192.168.0.0/32  md5
# allow all roles access to any database from any
# host and use ldap to authenticate the user. WarehousePG role
# names must match the LDAP common name.
host    all   all   192.168.0.0/32  ldap ldapserver=usldap1 ldapport=1389 ldapprefix="cn=" ldapsuffix=",ou=People,dc=company,dc=com"
```

3. Save and close the file.

4. Reload the pg_hba.conf configuration file for your changes to take effect:

```
$ gpstop -u
```

> **Note** Note that you can also control database access by setting object privileges as described in Managing Object Privileges. The pg_hba.conf file just controls who can initiate a database session and how those connections are authenticated.

Limiting Concurrent Connections

WarehousePG allocates some resources on a per-connection basis, so setting the maximum number of connections allowed is recommended.

To limit the number of active concurrent sessions to your WarehousePG cluster, you can configure the `max_connections` server configuration parameter. This is a *local* parameter, meaning that you must set it in the `postgresql.conf` file of the coordinator, the standby coordinator, and each segment instance (primary and mirror). The recommended value of `max_connections` on segments is 5-10 times the value on the coordinator.

When you set `max_connections`, you must also set the dependent parameter `max_prepared_transactions`. This value must be at least as large as the value of `max_connections` on the coordinator, and segment instances should be set to the same value as the coordinator.

For example:

- In `$COORDINATOR_DATA_DIRECTORY/postgresql.conf` (including standby coordinator):

```
max_connections=100
max_prepared_transactions=100
```

- In `SEGMENT_DATA_DIRECTORY/postgresql.conf` for all segment instances:

```
max_connections=500
max_prepared_transactions=100
```

The following steps set the parameter values with the WarehousePG utility `gpconfig`.

For information about `gpconfig`, see the *WarehousePG Utility Guide*.

To change the number of allowed connections

1. Log into the WarehousePG coordinator host as the WarehousePG administrator and source the file `$GPHOME/greenplum_path.sh`.

2. Set the value of the `max_connections` parameter. This `gpconfig` command sets the value on the segments to 1000 and the value on the coordinator to 200.

```
$ gpconfig -c max_connections -v 1000 -m 200
```

   The value on the segments must be greater than the value on the coordinator. The recommended value of `max_connections` on segments is 5-10 times the value on the coordinator.

3. Set the value of the `max_prepared_transactions` parameter. This `gpconfig` command sets the value to 200 on the coordinator and all segments.

```
$ gpconfig -c max_prepared_transactions -v 200
```

   The value of `max_prepared_transactions` must be greater than or equal to `max_connections` on the coordinator.

4. Stop and restart your WarehousePG cluster.

```
$ gpstop -r
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

5. You can check the value of parameters on the coordinator and segments with the `gpconfig -s` option. This `gpconfig` command displays the values of the `max_connections` parameter.

```
$ gpconfig -s max_connections
```

> **Note** Raising the values of these parameters may cause WarehousePG to request more shared memory. To mitigate this effect, consider decreasing other memory-related parameters such as `gp_cached_segworkers_threshold`.

Encrypting Client/Server Connections

Enable SSL for client connections to WarehousePG to encrypt the data passed over the network between the client and the database.

WarehousePG has native support for SSL connections between the client and the coordinator server. SSL connections prevent third parties from snooping on the packets, and also prevent man-in-the-middle attacks. SSL should be used whenever the client connection goes through an insecure link, and must be used whenever client certificate authentication is used.

Enabling WarehousePG in SSL mode requires the following items.

- OpenSSL installed on both the client and the coordinator server hosts (coordinator and standby coordinator).
- The SSL files server.key (server private key) and server.crt (server certificate) should be correctly generated for the coordinator host and standby coordinator host.
    - The private key should not be protected with a passphrase. The server does not prompt for a passphrase for the private key, and WarehousePG start up fails with an error if one is required.
    - On a production system, there should be a key and certificate pair for the coordinator host and a pair for the standby coordinator host with a subject CN (Common Name) for the coordinator host and standby coordinator host. A self-signed certificate can be used for testing, but a certificate signed by a certificate authority (CA) should be used in production, so the client can verify the identity of the server. Either a global or local CA can be used. If all the clients are local to the organization, a local CA is recommended.
- Ensure that WarehousePG can access server.key and server.crt, and any additional authentication files such as `root.crt` (for trusted certificate authorities). When starting in SSL mode, the WarehousePG coordinator looks for server.key and server.crt. As the default, WarehousePG does not start if the files are not in the coordinator data directory (`$COORDINATOR_DATA_DIRECTORY`). Also, if you use other SSL authentication files such as `root.crt` (trusted certificate authorities), the files must be on the coordinator host.

  If WarehousePG coordinator mirroring is enabled with SSL client authentication, SSL authentication files must be on both the coordinator host and standby coordinator host and *should not be placed* in the default directory `$COORDINATOR_DATA_DIRECTORY`. When coordinator mirroring is enabled, an `initstandby` operation copies the contents of the `$COORDINATOR_DATA_DIRECTORY` from the coordinator to the standby coordinator and the incorrect SSL key, and cert files (the coordinator files, and not the standby coordinator files) will prevent standby coordinator start up.

  You can specify a different directory for the location of the SSL server files with the `postgresql.conf` parameters `sslcert`, `sslkey`, `sslrootcert`, and `sslcrl`. For more information about the parameters, see SSL Client Authentication in the *Security Configuration Guide*.

WarehousePG can be started with SSL enabled by setting the server configuration parameter `ssl=on` in the `postgresql.conf` file on the coordinator and standby coordinator hosts. This `gpconfig` command sets the parameter:

```
gpconfig -c ssl -m on -v off
```

Setting the parameter requires a server restart. This command restarts the system: `gpstop -ra`.

Creating a Self-signed Certificate without a Passphrase for Testing Only

To create a quick self-signed certificate for the server for testing, use the following OpenSSL command:

```
# openssl req -new -text -out server.req
```

Enter the information requested by the prompts. Be sure to enter the local host name as *Common Name*. The challenge password can be left blank.

The program will generate a key that is passphrase protected, and does not accept a passphrase that is less than four characters long.

To use this certificate with WarehousePG, remove the passphrase with the following commands:

```
# openssl rsa -in privkey.pem -out server.key
# rm privkey.pem
```

Enter the old passphrase when prompted to unlock the existing key.

Then, enter the following command to turn the certificate into a self-signed certificate and to copy the key and certificate to a location where the server will look for them.

```
# openssl req -x509 -in server.req -text -key server.key -out server.crt
```

Finally, change the permissions on the key with the following command. The server will reject the file if the permissions are less restrictive than these.

```
# chmod og-rwx server.key
```

For more details on how to create your server private key and certificate, refer to theOpenSSL documentation.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.3.1.1 Using LDAP Authentication with TLS/SSL

You can control access to WarehousePG with an LDAP server and, optionally, secure the connection with encryption by adding parameters to pg_hba.conf file entries.

WarehousePG supports LDAP authentication with the TLS/SSL protocol to encrypt communication with an LDAP server:

- LDAP authentication with STARTTLS and TLS protocol – STARTTLS starts with a clear text connection (no encryption) and upgrades it to a secure connection (with encryption).
- LDAP authentication with a secure connection and TLS/SSL (LDAPS) – WarehousePG uses the TLS or SSL protocol based on the protocol that is used by the LDAP server.

If no protocol is specified, WarehousePG communicates with the LDAP server with a clear text connection.

To use LDAP authentication, the WarehousePG coordinator host must be configured as an LDAP client. See your LDAP documentation for information about configuring LDAP clients.

Enabling LDAP Authentication with STARTTLS and TLS

To enable STARTTLS with the TLS protocol, in the pg_hba.conf file, add an `ldap` line and specify the `ldaptls` parameter with the value `1`. The default port is 389. In this example, the authentication method parameters include the `ldaptls` parameter.

```
ldap ldapserver=myldap.com ldaptls=1 ldapprefix="uid=" ldapsuffix=",ou=People,dc=example,dc=com"
```

Specify a non-default port with the `ldapport` parameter. In this example, the authentication method includes the `ldaptls` parameter and the `ldapport` parameter to specify the port 500.

```
ldap ldapserver=myldap.com ldaptls=1 ldapport=500 ldapprefix="uid=" ldapsuffix=",ou=People,dc=example,dc=com"
```

Enabling LDAP Authentication with a Secure Connection and TLS/SSL

To enable a secure connection with TLS/SSL, add `ldaps://` as the prefix to the LDAP server name specified in the `ldapserver` parameter. The default port is 636.

This example `ldapserver` parameter specifies a secure connection and the TLS/SSL protocol for the LDAP server `myldap.com`.

```
ldapserver=ldaps://myldap.com
```

To specify a non-default port, add a colon (:) and the port number after the LDAP server name. This example `ldapserver` parameter includes the `ldaps://` prefix and the non-default port 550.

```
ldapserver=ldaps://myldap.com:550
```

Configuring Authentication with a System-wide OpenLDAP System

If you have a system-wide OpenLDAP system and logins are configured to use LDAP with TLS or SSL in the pg_hba.conf file, logins may fail with the following message:

```
could not start LDAP TLS session: error code '-11'
```

To use an existing OpenLDAP system for authentication, WarehousePG must be set up to use the LDAP server's CA certificate to validate user certificates. Follow these steps on both the coordinator and standby hosts to configure WarehousePG:

1. Copy the base64-encoded root CA chain file from the Active Directory or LDAP server to the WarehousePG coordinator and standby coordinator hosts. This example uses the directory `/etc/pki/tls/certs`.

2. Change to the directory where you copied the CA certificate file and, as the root user, generate the hash for OpenLDAP:

   ```
   # cd /etc/pki/tls/certs
   # openssl x509 -noout -hash -in <ca-certificate-file>
   # ln -s <ca-certificate-file> <ca-certificate-file>.0
   ```

3. Configure an OpenLDAP configuration file for WarehousePG with the CA certificate directory and certificate file specified.

   As the root user, edit the OpenLDAP configuration file `/etc/openldap/ldap.conf`:

   ```
   SASL_NOCANON on
    URI ldaps://ldapA.example.priv ldaps://ldapB.example.priv ldaps://ldapC.example.priv
    BASE dc=example,dc=priv
    TLS_CACERTDIR /etc/pki/tls/certs
    TLS_CACERT /etc/pki/tls/certs/<ca-certificate-file>
   ```

   > **Note** For certificate validation to succeed, the hostname in the certificate must match a hostname in the URI property. Otherwise, you must also add `TLS_REQCERT allow` to the file.

4. As the gpadmin user, edit `/usr/edb/whpg7/greenplum_path.sh` and add the following line.

   ```
   export LDAPCONF=/etc/openldap/ldap.conf
   ```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Notes

WarehousePG logs an error if the following are specified in an pg_hba.conf file entry:

- If both the `ldaps://` prefix and the `ldaptls=1` parameter are specified.
- If both the `ldaps://` prefix and the `ldapport` parameter are specified.

Enabling encrypted communication for LDAP authentication only encrypts the communication between WarehousePG and the LDAP server.

See Encrypting Client/Server Connections for information about encrypting client connections.

Examples

These are example entries from an pg_hba.conf file.

This example specifies LDAP authentication with no encryption between WarehousePG and the LDAP server.

```
host all plainuser 0.0.0.0/0 ldap ldapserver=myldap.com ldapprefix="uid=" ldapsuffix=",ou=People,dc=example,dc=com"
```

This example specifies LDAP authentication with the STARTTLS and TLS protocol between WarehousePG and the LDAP server.

```
host all tlsuser 0.0.0.0/0 ldap ldapserver=myldap.com ldaptls=1 ldapprefix="uid=" ldapsuffix=",ou=People,dc=example,dc=com"
```

This example specifies LDAP authentication with a secure connection and TLS/SSL protocol between WarehousePG and the LDAP server.

```
host all ldapsuser 0.0.0.0/0 ldap ldapserver=myldap.com ldapscheme=ldaps ldapprefix="uid=" ldapsuffix=",ou=People,dc=example,dc=com"
```

This example also specifies LDAP authentication with a secure connection and TLS/SSL protocol between WarehousePG and the LDAP server, using an alternative syntax.

```
host all ldapsuser 0.0.0.0/0 ldap ldapurl=ldaps://myldap.com ldapprefix="uid=" ldapsuffix=",ou=People,dc=example,dc=com"
```

Parent topic: Configuring Client Authentication

4.3.1.2 Using Kerberos Authentication

You can control access to WarehousePG with a Kerberos authentication server.

WarehousePG supports the Generic Security Service Application Program Interface (GSSAPI) with Kerberos authentication. GSSAPI provides automatic authentication (single sign-on) for systems that support it. You specify the WarehousePG users (roles) that require Kerberos authentication in the WarehousePG configuration file pg_hba.conf. The login fails if Kerberos authentication is not available when a role attempts to log in to WarehousePG.

Kerberos provides a secure, encrypted authentication service. It does not encrypt data exchanged between the client and database and provides no authorization services. To encrypt data exchanged over the network, you must use an SSL connection. To manage authorization for access to WarehousePGs and objects such as schemas and tables, you use settings in the pg_hba.conf file and privileges given to WarehousePG users and roles within the database. For information about managing authorization privileges, see Managing Roles and Privileges.

For more information about Kerberos, see http://web.mit.edu/kerberos/.

Prerequisites

Before configuring Kerberos authentication for WarehousePG, ensure that:

- You can identify the KDC server you use for Kerberos authentication and the Kerberos realm for your WarehousePG cluster. If you have not yet configured your MIT Kerberos KDC server, see Installing and Configuring a Kerberos KDC Server for example instructions.
- System time on the Kerberos Key Distribution Center (KDC) server and WarehousePG coordinator is synchronized. (For example, install the `ntp` package on both servers.)
- Network connectivity exists between the KDC server and the WarehousePG coordinator host.
- Java 1.7.0_17 or later is installed on all WarehousePG hosts. Java 1.7.0_17 is required to use Kerberos-authenticated JDBC on Red Hat Enterprise Linux 6.x or 7.x.

Procedure

Following are the tasks to complete to set up Kerberos authentication for WarehousePG.

- Creating WarehousePG Principals in the KDC Database
- Installing the Kerberos Client on the Coordinator Host

Parent topic: Configuring Client Authentication

Creating WarehousePG Principals in the KDC Database

Create a service principal for the WarehousePG service and a Kerberos admin principal that allows managing the KDC database as the gpadmin user.

1. Log in to the Kerberos KDC server as the root user.

   ```
   $ ssh root@<kdc-server>
   ```

2. Create a principal for the WarehousePG service.

   ```
   # kadmin.local -q "addprinc -randkey servicename/hostname@realm"
   ```

   The `-randkey` option prevents the command from prompting for a password.

   The `servicename` part of the principal is ordinarily `postgres`, but you may specify a different value via the `libpq`'s configuration parameter `krbsrvname`.

   The `hostname` part of the principal name must match the output of the `hostname` command on the WarehousePG coordinator host. If the `hostname` command shows the fully qualified domain name (FQDN), use it in the principal name, for example `postgres/cdw.example.com@GPDB.KRB`.

   The `realm` part of the principal name is the Kerberos realm name. For example, `GPDB.KRB`.

3. Create a principal for the gpadmin/admin role.

   ```
   # kadmin.local -q "addprinc gpadmin/admin@realm"
   ```

   This principal allows you to manage the KDC database when you are logged in as gpadmin. Make sure that the Kerberos `kadm.acl` configuration file contains an ACL to grant permissions to this principal. For example, this ACL grants all permissions to any admin user in the `GPDB.KRB` realm.

   ```
   */admin@GPDB.KRB *
   ```

4. Create a keytab file with `kadmin.local`. The following example creates a keytab file `gpdb-kerberos.keytab` in the current directory with authentication information for the WarehousePG service principal and the gpadmin/admin principal.

   ```
   # kadmin.local -q "ktadd -k gpdb-kerberos.keytab postgres/cdw@GPDB.KRB gpadmin/admin@GPDB.KRB"
   ```

5. Copy the keytab file to the coordinator host.

   ```
   # scp gpdb-kerberos.keytab gpadmin@cdw:~
   ```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Installing the Kerberos Client on the Coordinator Host

Install the Kerberos client utilities and libraries on the WarehousePG coordinator.

1. Install the Kerberos packages on the WarehousePG coordinator.

```
$ sudo yum install krb5-libs krb5-workstation
```

2. Copy the `/etc/krb5.conf` file from the KDC server to `/etc/krb5.conf` on the WarehousePG Coordinator host.

Configuring WarehousePG to use Kerberos Authentication

Configure WarehousePG to use Kerberos.

1. Log in to the WarehousePG coordinator host as the gpadmin user.

```
$ ssh gpadmin@<coordinator>
$ source /usr/edb/whpg7/greenplum_path.sh
```

2. Set the ownership and permissions of the keytab file you copied from the KDC server.

```
$ chown gpadmin:gpadmin /home/gpadmin/gpdb-kerberos.keytab
$ chmod 400 /home/gpadmin/gpdb-kerberos.keytab
```

3. Configure the location of the keytab file by setting the WarehousePG `krb_server_keyfile` server configuration parameter. This `gpconfig` command specifies the folder /home/gpadmin as the location of the keytab file gpdb-kerberos.keytab.

```
$ gpconfig -c krb_server_keyfile -v  '/home/gpadmin/gpdb-kerberos.keytab'
```

4. Modify the WarehousePG file `pg_hba.conf` to enable Kerberos support. For example, adding the following line to `pg_hba.conf` adds GSSAPI and Kerberos authentication support for connection requests from all users and hosts on the same network to all WarehousePG databases.

```
host all all 0.0.0.0/0 gss include_realm=0 krb_realm=GPDB.KRB
```

   Setting the `krb_realm` option to a realm name ensures that only users from that realm can successfully authenticate with Kerberos. Setting the `include_realm` option to `0` excludes the realm name from the authenticated user name. For information about the `pg_hba.conf` file, see The pg_hba.conf file in the PostgreSQL documentation.

5. Restart WarehousePG after updating the `krb_server_keyfile` parameter and the `pg_hba.conf` file.

```
$ gpstop -ar
```

6. Create the gpadmin/admin WarehousePG superuser role.

```
$ createuser gpadmin/admin --superuser
```

   The Kerberos keys for this database role are in the keyfile you copied from the KDC server.

7. Create a ticket using `kinit` and show the tickets in the Kerberos ticket cache with `klist`.

```
$ LD_LIBRARY_PATH= kinit -k -t /home/gpadmin/gpdb-kerberos.keytab gpadmin/admin@GPDB.KRB
$ LD_LIBRARY_PATH= klist
Ticket cache: FILE:/tmp/krb5cc_1000
Default principal: gpadmin/admin@GPDB.KRB

Valid starting       Expires              Service principal
06/13/2018 17:37:35  06/14/2018 17:37:35  krbtgt/GPDB.KRB@GPDB.KRB
```

> **Note** When you set up the WarehousePG environment by sourcing the `greenplum-db_path.sh` script, the `LD_LIBRARY_PATH` environment variable is set to include the WarehousePG `lib` directory, which includes Kerberos libraries. This may cause Kerberos utility commands such as `kinit` and `klist` to fail due to version conflicts. The solution is to run Kerberos utilities before you source the `greenplum-db_path.sh` file or temporarily unset the `LD_LIBRARY_PATH` variable when you run Kerberos utilities, as shown in the example.

8. As a test, log in to the postgres database with the `gpadmin/admin` role:

```
$ psql -U "gpadmin/admin" -h cdw postgres
psql (9.4.20)
Type "help" for help.

postgres=# select current_user;
 current_user
---------------
 gpadmin/admin
(1 row)
```

> **Note** When you start `psql` on the coordinator host, you must include the `-h <coordinator-hostname>` option to force a TCP connection because Kerberos authentication does not work with local connections.

If a Kerberos principal is not a WarehousePG user, a message similar to the following is displayed from the `psql` command line when the user attempts to log in to the database:

```
psql: krb5_sendauth: Bad response
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

The principal must be added as a WarehousePG user.

Mapping Kerberos Principals to WarehousePG Roles

To connect to a WarehousePG cluster with Kerberos authentication enabled, a user first requests a ticket-granting ticket from the KDC server using the `kinit` utility with a password or a keytab file provided by the Kerberos admin. When the user then connects to the Kerberos-enabled WarehousePG cluster, the user's Kerberos principle name will be the WarehousePG role name, subject to transformations specified in the options field of the `gss` entry in the WarehousePG `pg_hba.conf` file:

- If the `krb_realm=<realm>` option is present, WarehousePG only accepts Kerberos principals who are members pf the specified realm.
- If the `include_realm=0` option is specified, the WarehousePG role name is the Kerberos principal name without the Kerberos realm. If the `include_realm=1` option is instead specified, the Kerberos realm is not stripped from the WarehousePG rolename. The role must have been created with the WarehousePG `CREATE ROLE` command.
- If the `map=<map-name>` option is specified, the Kerberos principal name is compared to entries labeled with the specified `<map-name>` in the `$COORDINATOR_DATA_DIRECTORY/pg_ident.conf` file and replaced with the WarehousePG role name specified in the first matching entry.

A user name map is defined in the `$COORDINATOR_DATA_DIRECTORY/pg_ident.conf` configuration file. This example defines a map named `mymap` with two entries.

```
# MAPNAME    SYSTEM-USERNAME         GP-USERNAME
mymap        /^admin@GPDB.KRB$       gpadmin
mymap        /^(.*)_gp)@GPDB.KRB$    \1
```

The map name is specified in the `pg_hba.conf` Kerberos entry in the options field:

```
host all all 0.0.0.0/0 gss include_realm=0 krb_realm=GPDB.KRB map=mymap
```

The first map entry matches the Kerberos principal admin@GPDB.KRB and replaces it with the WarehousePG gpadmin role name. The second entry uses a wildcard to match any Kerberos principal in the GPDB-KRB realm with a name ending with the characters `_gp` and replaces it with the initial portion of the principal name. WarehousePG applies the first matching map entry in the `pg_ident.conf` file, so the order of entries is significant.

For more information about using username maps see Username maps in the PostgreSQL documentation.

Configuring JDBC Kerberos Authentication for WarehousePG

Enable Kerberos-authenticated JDBC access to WarehousePG.

You can configure WarehousePG to use Kerberos to run user-defined Java functions.

1. Ensure that Kerberos is installed and configured on the WarehousePG coordinator. See Installing the Kerberos Client on the Coordinator Host.

2. Create the file .java.login.config in the folder `/home/gpadmin` and add the following text to the file:

   ```
   pgjdbc {
     com.sun.security.auth.module.Krb5LoginModule required
     doNotPrompt=true
     useTicketCache=true
     debug=true
     client=true;
   };
   ```

3. Create a Java application that connects to WarehousePG using Kerberos authentication. The following example database connection URL uses a PostgreSQL JDBC driver and specifies parameters for Kerberos authentication:

   ```
   jdbc:postgresql://cdw:5432/mytest?kerberosServerName=postgres
   &jaasApplicationName=pgjdbc&user=gpadmin/gpdb-kdc
   ```

   The parameter names and values specified depend on how the Java application performs Kerberos authentication.

4. Test the Kerberos login by running a sample Java application from WarehousePG.

Installing and Configuring a Kerberos KDC Server

Steps to set up a Kerberos Key Distribution Center (KDC) server on a Red Hat Enterprise Linux host for use with WarehousePG.

If you do not already have a KDC, follow these steps to install and configure a KDC server on a Red Hat Enterprise Linux host with a `GPDB.KRB` realm. The host name of the KDC server in this example is gpdb-kdc.

1. Install the Kerberos server and client packages:

   ```
   $ sudo yum install krb5-libs krb5-server krb5-workstation
   ```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

2. Edit the /etc/krb5.conf configuration file. The following example shows a Kerberos server configured with a default `GPDB.KRB` realm.

```
[logging]
 default = FILE:/var/log/krb5libs.log
 kdc = FILE:/var/log/krb5kdc.log
 admin_server = FILE:/var/log/kadmind.log

[libdefaults]
 default_realm = GPDB.KRB
 dns_lookup_realm = false
 dns_lookup_kdc = false
 ticket_lifetime = 24h
 renew_lifetime = 7d
 forwardable = true
 default_tgs_enctypes = aes128-cts des3-hmac-sha1 des-cbc-crc des-cbc-md5
 default_tkt_enctypes = aes128-cts des3-hmac-sha1 des-cbc-crc des-cbc-md5
 permitted_enctypes = aes128-cts des3-hmac-sha1 des-cbc-crc des-cbc-md5

[realms]
 GPDB.KRB = {
  kdc = gpdb-kdc:88
  admin_server = gpdb-kdc:749
  default_domain = gpdb.krb
 }

[domain_realm]
 .gpdb.krb = GPDB.KRB
 gpdb.krb = GPDB.KRB

[appdefaults]
 pam = {
    debug = false
    ticket_lifetime = 36000
    renew_lifetime = 36000
    forwardable = true
    krb4_convert = false
 }
```

   The `kdc` and `admin_server` keys in the `[realms]` section specify the host (`gpdb-kdc`) and port where the Kerberos server is running. IP numbers can be used in place of host names.

   If your Kerberos server manages authentication for other realms, you would instead add the `GPDB.KRB` realm in the `[realms]` and `[domain_realm]` section of the `kdc.conf` file. See the Kerberos documentation for information about the `kdc.conf` file.

3. To create the Kerberos database, run the `kdb5_util`.

```
# kdb5_util create -s
```

   The `kdb5_util` create command creates the database to store keys for the Kerberos realms that are managed by this KDC server. The -s option creates a stash file. Without the stash file, every time the KDC server starts it requests a password.

4. Add an administrative user to the KDC database with the `kadmin.local` utility. Because it does not itself depend on Kerberos authentication, the `kadmin.local` utility allows you to add an initial administrative user to the local Kerberos server. To add the user `gpadmin` as an administrative user to the KDC database, run the following command:

```
# kadmin.local -q "addprinc gpadmin/admin"
```

   Most users do not need administrative access to the Kerberos server. They can use `kadmin` to manage their own principals (for example, to change their own password). For information about `kadmin`, see the Kerberos documentation.

5. If needed, edit the /var/kerberos/krb5kdc/kadm5.acl file to grant the appropriate permissions to `gpadmin`.

6. Start the Kerberos daemons:

```
# /sbin/service krb5kdc start#
/sbin/service kadmin start
```

7. To start Kerberos automatically upon restart:

```
# /sbin/chkconfig krb5kdc on
# /sbin/chkconfig kadmin on
```

4.3.1.3 Configuring Kerberos for Linux Clients

You can configure Linux client applications to connect to a WarehousePG cluster that is configured to authenticate with Kerberos.

If your JDBC application on Red Hat Enterprise Linux uses Kerberos authentication when it connects to your WarehousePG, your client system must be configured to use Kerberos authentication. If you are not using Kerberos authentication to connect to a WarehousePG, Kerberos is not needed on your client system.

- Requirements
- Setting Up Client System with Kerberos Authentication
- Running a Java Application

For information about enabling Kerberos authentication with WarehousePG, see the chapter "Setting Up Kerberos Authentication" in the *WarehousePG Administrator Guide*.

Parent topic: Configuring Client Authentication

Requirements

The following are requirements to connect to a WarehousePG that is enabled with Kerberos authentication from a client system with a JDBC application.

- Prerequisites
- Required Software on the Client Machine

Prerequisites

- Kerberos must be installed and configured on the WarehousePG coordinator host.

  > **Important** WarehousePG must be configured so that a remote user can connect to WarehousePG with Kerberos authentication. Authorization to access WarehousePG is controlled by the `pg_hba.conf` file. For details, see "Editing the pg_hba.conf File" in the *WarehousePG Administration Guide*, and also see the *WarehousePG Security Configuration Guide*.

- The client system requires the Kerberos configuration file `krb5.conf` from the WarehousePG coordinator.

- The client system requires a Kerberos keytab file that contains the authentication credentials for the WarehousePG user that is used to log into the database.

- The client machine must be able to connect to WarehousePG coordinator host.

  If necessary, add the WarehousePG coordinator host name and IP address to the system `hosts` file. On Linux systems, the `hosts` file is in `/etc`.

Required Software on the Client Machine

- The Kerberos `kinit` utility is required on the client machine. The `kinit` utility is available when you install the Kerberos packages:

  - krb5-libs
  - krb5-workstation

  > **Note** When you install the Kerberos packages, you can use other Kerberos utilities such as `klist` to display Kerberos ticket information.

Java applications require this additional software:

- Java JDK

  Java JDK 1.7.0_17 is supported on Red Hat Enterprise Linux 6.x.

- Ensure that JAVA_HOME is set to the installation directory of the supported Java JDK.

Setting Up Client System with Kerberos Authentication

To connect to WarehousePG with Kerberos authentication requires a Kerberos ticket. On client systems, tickets are generated from Kerberos keytab files with the `kinit` utility and are stored in a cache file.

1. Install a copy of the Kerberos configuration file `krb5.conf` from the WarehousePG coordinator. The file is used by the WarehousePG client software and the Kerberos utilities.

   Install `krb5.conf` in the directory `/etc`.

   If needed, add the parameter `default_ccache_name` to the `[libdefaults]` section of the `krb5.ini` file and specify location of the Kerberos ticket cache file on the client system.

2. Obtain a Kerberos keytab file that contains the authentication credentials for the WarehousePG user.

3. Run `kinit` specifying the keytab file to create a ticket on the client machine. For this example, the keytab file `gpdb-kerberos.keytab` is in the current directory. The ticket cache file is in the `gpadmin` user home directory.

   ```
   > kinit -k -t gpdb-kerberos.keytab -c /home/gpadmin/cache.txt
     gpadmin/kerberos-gpdb@KRB.EXAMPLE.COM
   ```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Running psql

From a remote system, you can access a WarehousePG that has Kerberos authentication enabled.

To connect to WarehousePG with psql

1. As the gpadmin user, open a command window.
2. Start `psql` from the command window and specify a connection to the WarehousePG specifying the user that is configured with Kerberos authentication.

   The following example logs into the WarehousePG on the machine `kerberos-gpdb` as the `gpadmin` user with the Kerberos credentials `gpadmin/kerberos-gpdb`:

   ```
   $ psql -U "gpadmin/kerberos-gpdb" -h kerberos-gpdb postgres
   ```

Running a Java Application

Accessing WarehousePG from a Java application with Kerberos authentication uses the Java Authentication and Authorization Service (JAAS)

1. Create the file `.java.login.config` in the user home folder.

   For example, on a Linux system, the home folder is similar to `/home/gpadmin`.

   Add the following text to the file:

   ```
   pgjdbc {
     com.sun.security.auth.module.Krb5LoginModule required
     doNotPrompt=true
     useTicketCache=true
     ticketCache = "/home/gpadmin/cache.txt"
     debug=true
     client=true;
   };
   ```

2. Create a Java application that connects to WarehousePG using Kerberos authentication and run the application as the user.

This example database connection URL uses a PostgreSQL JDBC driver and specifies parameters for Kerberos authentication.

```
jdbc:postgresql://kerberos-gpdb:5432/mytest?
  kerberosServerName=postgres&jaasApplicationName=pgjdbc&
  user=gpadmin/kerberos-gpdb
```

The parameter names and values specified depend on how the Java application performs Kerberos authentication.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.3.1.4 Configuring Kerberos For Windows Clients

You can configure Microsoft Windows client applications to connect to a WarehousePG cluster that is configured to authenticate with Kerberos.

When a WarehousePG cluster is configured to authenticate with Kerberos, you can configure Kerberos authentication for the WarehousePG client utilities `gpload` and `psql` on a Microsoft Windows system. The WarehousePG clients authenticate with Kerberos directly.

This section contains the following information.

- Installing and Configuring Kerberos on a Windows System
- Running the psql Utility
- Example gpload YAML File
- Creating a Kerberos Keytab File
- Issues and Possible Solutions

These topics assume that the WarehousePG cluster is configured to authenticate with Kerberos. For information about configuring WarehousePG with Kerberos authentication, refer to Using Kerberos Authentication.

Parent topic: Configuring Client Authentication

Installing and Configuring Kerberos on a Windows System

The `kinit`, `kdestroy`, and `klist` MIT Kerberos Windows client programs and supporting libraries are installed on your system when you install the WarehousePG Client and Load Tools package:

- `kinit` - generate a Kerberos ticket
- `kdestroy` - destroy active Kerberos tickets
- `klist` - list Kerberos tickets

You must configure Kerberos on the Windows client to authenticate with WarehousePG:

1. Copy the Kerberos configuration file `/etc/krb5.conf` from the WarehousePG coordinator to the Windows system, rename it to `krb5.ini`, and place it in the default Kerberos location on the Windows system, `C:\ProgramData\MIT\Kerberos5\krb5.ini`. This directory may be hidden. This step requires administrative privileges on the Windows client system. You may also choose to place the `/etc/krb5.ini` file in a custom location. If you choose to do this, you must configure and set a system environment variable named `KRB5_CONFIG` to the custom location.

2. Locate the `[libdefaults]` section of the `krb5.ini` file, and remove the entry identifying the location of the Kerberos credentials cache file, `default_ccache_name`. This step requires administrative privileges on the Windows client system.

   This is an example configuration file with `default_ccache_name` removed. The `[logging]` section is also removed.

   ```
   [libdefaults]
    debug = true
    default_etypes = aes256-cts-hmac-sha1-96
    default_realm = EXAMPLE.LOCAL
    dns_lookup_realm = false
    dns_lookup_kdc = false
    ticket_lifetime = 24h
    renew_lifetime = 7d
    forwardable = true

   [realms]
    EXAMPLE.LOCAL = {
     kdc =bocdc.example.local
     admin_server = bocdc.example.local
    }

   [domain_realm]
    .example.local = EXAMPLE.LOCAL
    example.local = EXAMPLE.LOCAL
   ```

3. Set up the Kerberos credential cache file. On the Windows system, set the environment variable `KRB5CCNAME` to specify the file system location of the cache file. The file must be named `krb5cache`. This location identifies a file, not a directory, and should be unique to each login on the server. When you set `KRB5CCNAME`, you can specify the value in either a local user environment or within a session. For example, the following command sets `KRB5CCNAME` in the session:

   ```
   set KRB5CCNAME=%USERPROFILE%\krb5cache
   ```

4. Obtain your Kerberos principal and password or keytab file from your system administrator.

5. Generate a Kerberos ticket using a password or a keytab. For example, to generate a ticket using a password:

   ```
   kinit [<principal>]
   ```

   To generate a ticket using a keytab (as described in Creating a Kerberos Keytab File):

   ```
   kinit -k -t <keytab_filepath> [<principal>]
   ```

6. Set up the WarehousePG clients environment:

   ```
   set PGGSSLIB=gssapi
   "c:\Program Files\WarehousePG\greenplum-clients\greenplum_clients_path.bat"
   ```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Running the psql Utility

After you configure Kerberos and generate the Kerberos ticket on a Windows system, you can run the WarehousePG command line client `psql`.

If you get warnings indicating that the Console code page differs from Windows code page, you can run the Windows utility `chcp` to change the code page. This is an example of the warning and fix:

```
psql -h prod1.example.local warehouse
psql (9.4.20)
WARNING: Console code page (850) differs from Windows code page (1252)
 8-bit characters might not work correctly. See psql reference
 page "Notes for Windows users" for details.
Type "help" for help.

warehouse=# \q

chcp 1252
Active code page: 1252

psql -h prod1.example.local warehouse
psql (9.4.20)
Type "help" for help.
```

Creating a Kerberos Keytab File

You can create and use a Kerberos `keytab` file to avoid entering a password at the command line or listing a password in a script file when you connect to a WarehousePG cluster, perhaps when automating a scheduled WarehousePG task such as `gpload`. You can create a keytab file with the Java JRE keytab utility `ktab`. If you use AES256-CTS-HMAC-SHA1-96 encryption, you need to download and install the Java extension *Java Cryptography Extension (JCE) Unlimited Strength Jurisdiction Policy Files for JDK/JRE* from Oracle.

> **Note** You must enter the password to create a keytab file. The password is visible onscreen as you enter it.

This example runs the Java `ktab.exe` program to create a keytab file (`-a` option) and list the keytab name and entries (`-l` `-e` `-t` options).

```
C:\Users\dev1>"\Program Files\Java\jre1.8.0_77\bin"\ktab -a dev1
Password for dev1@EXAMPLE.LOCAL:<your_password>
Done!
Service key for dev1 is saved in C:\Users\dev1\krb5.keytab

C:\Users\dev1>"\Program Files\Java\jre1.8.0_77\bin"\ktab -l -e -t
Keytab name: C:\Users\dev1\krb5.keytab
KVNO Timestamp Principal
---- -------------- ------------------------------------------------------
 4 13/04/16 19:14 dev1@EXAMPLE.LOCAL (18:AES256 CTS mode with HMAC SHA1-96)
 4 13/04/16 19:14 dev1@EXAMPLE.LOCAL (17:AES128 CTS mode with HMAC SHA1-96)
 4 13/04/16 19:14 dev1@EXAMPLE.LOCAL (16:DES3 CBC mode with SHA1-KD)
 4 13/04/16 19:14 dev1@EXAMPLE.LOCAL (23:RC4 with HMAC)
```

You can then generate a Kerberos ticket using a keytab with the following command:

```
kinit -kt dev1.keytab dev1
```

or

```
kinit -kt %USERPROFILE%\krb5.keytab dev1
```

Example gpload YAML File

When you initiate a `gpload` job to a WarehousePG cluster using Kerberos authentication, you omit the `USER:` property and value from the YAML control file.

This example `gpload` YAML control file named `test.yaml` does not include a `USER:` entry:

```
---
VERSION: 1.0.0.1
DATABASE: warehouse
HOST: prod1.example.local
PORT: 5432

GPLOAD:
   INPUT:
    - SOURCE:
         PORT_RANGE: [18080,18080]
         FILE:
           - /Users/dev1/Downloads/test.csv
    - FORMAT: text
    - DELIMITER: ','
    - QUOTE: '"'
    - ERROR_LIMIT: 25
    - LOG_ERRORS: true
   OUTPUT:
    - TABLE: public.test
    - MODE: INSERT
   PRELOAD:
    - REUSE_TABLES: true
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

These commands run `kinit` using a keytab file, run `gpload.bat` with the `test.yaml` file, and then display successful `gpload` output.

```
kinit -kt %USERPROFILE%\krb5.keytab dev1

gpload.bat -f test.yaml
2016-04-10 16:54:12|INFO|gpload session started 2016-04-10 16:54:12
2016-04-10 16:54:12|INFO|started gpfdist -p 18080 -P 18080 -f "/Users/dev1/Downloads/test.csv" -t 30
2016-04-10 16:54:13|INFO|running time: 0.23 seconds
2016-04-10 16:54:13|INFO|rows Inserted = 3
2016-04-10 16:54:13|INFO|rows Updated = 0
2016-04-10 16:54:13|INFO|data formatting errors = 0
2016-04-10 16:54:13|INFO|gpload succeeded
```

Issues and Possible Solutions

- This message indicates that Kerberos cannot find your Kerberos credentials cache file:

  ```
  Credentials cache I/O operation failed XXX
  (Kerberos error 193)
  krb5_cc_default() failed
  ```

  To ensure that Kerberos can find the file, set the environment variable `KRB5CCNAME` and run `kinit`.

  ```
  set KRB5CCNAME=%USERPROFILE%\krb5cache
  kinit
  ```

- This `kinit` message indicates that the `kinit -k -t` command could not find the keytab.

  ```
  kinit: Generic preauthentication failure while getting initial credentials
  ```

  Confirm that the full path and filename for the Kerberos keytab file is correct.

4.3.2 Managing Roles and Privileges

The WarehousePG authorization mechanism stores roles and permissions to access database objects in the database and is administered using SQL statements or command-line utilities.

WarehousePG manages database access permissions using *roles*. The concept of roles subsumes the concepts of *users* and *groups*. A role can be a database user, a group, or both. Roles can own database objects (for example, tables) and can assign privileges on those objects to other roles to control access to the objects. Roles can be members of other roles, thus a member role can inherit the object privileges of its parent role.

Every WarehousePG cluster contains a set of database roles (users and groups). Those roles are separate from the users and groups managed by the operating system on which the server runs. However, for convenience you may want to maintain a relationship between operating system user names and WarehousePG role names, since many of the client applications use the current operating system user name as the default.

In WarehousePG, users log in and connect through the coordinator instance, which then verifies their role and access privileges. The coordinator then issues commands to the segment instances behind the scenes as the currently logged in role.

Roles are defined at the system level, meaning they are valid for all databases in the system.

In order to bootstrap the WarehousePG cluster, a freshly initialized system always contains one predefined *superuser* role (also referred to as the system user). This role will have the same name as the operating system user that initialized the WarehousePG cluster. Customarily, this role is named `gpadmin`. In order to create more roles you first have to connect as this initial role.

Parent topic: Managing WarehousePG Access

Security Best Practices for Roles and Privileges

- **Secure the gpadmin system user.** WarehousePG requires a UNIX user id to install and initialize the WarehousePG cluster. This system user is referred to as `gpadmin` in the WarehousePG documentation. This `gpadmin` user is the default database superuser in WarehousePG, as well as the file system owner of the WarehousePG installation and its underlying data files. This default administrator account is fundamental to the design of WarehousePG. The system cannot run without it, and there is no way to limit the access of this gpadmin user id. Use roles to manage who has access to the database for specific purposes. You should only use the `gpadmin` account for system maintenance tasks such as expansion and upgrade. Anyone who logs on to a WarehousePG host as this user id can read, alter or delete any data; including system catalog data and database access rights. Therefore, it is very important to secure the gpadmin user id and only provide access to essential system administrators. Administrators should only log in to WarehousePG as `gpadmin` when performing certain system maintenance tasks (such as upgrade or expansion). Database users should never log on as `gpadmin`, and ETL or production workloads should never run as `gpadmin`.
- **Assign a distinct role to each user that logs in.** For logging and auditing purposes, each user that is allowed to log in to WarehousePG should be given their own database role. For applications or web services, consider creating a distinct role for each application or service. See Creating New Roles (Users).
- **Use groups to manage access privileges.** See Role Membership.
- **Limit users who have the SUPERUSER role attribute.** Roles that are superusers bypass all access privilege checks in WarehousePG, as well as resource queuing. Only system administrators should be given superuser rights. See Altering Role Attributes.

Creating New Roles (Users)

A user-level role is considered to be a database role that can log in to the database and initiate a database session. Therefore, when you create a new user-level role using the `CREATE ROLE` command, you must specify the `LOGIN` privilege. For example:

```
=# CREATE ROLE jsmith WITH LOGIN;
```

A database role may have a number of attributes that define what sort of tasks that role can perform in the database. You can set these attributes when you create the role, or later using the `ALTER ROLE` command.

Altering Role Attributes

A database role may have a number of attributes that define what sort of tasks that role can perform in the database.

Attributes	Description
`SUPERUSER` or `NOSUPERUSER`	Determines if the role is a superuser. You must yourself be a superuser to create a new superuser. `NOSUPERUSER` is the default.
`CREATEDB` or `NOCREATEDB`	Determines if the role is allowed to create databases. `NOCREATEDB` is the default.
`CREATEROLE` or `NOCREATEROLE`	Determines if the role is allowed to create and manage other roles. `NOCREATEROLE` is the default.
`INHERIT` or `NOINHERIT`	Determines whether a role inherits the privileges of roles it is a member of. A role with the `INHERIT` attribute can automatically use whatever database privileges have been granted to all roles it is directly or indirectly a member of. `INHERIT` is the default.
`LOGIN` or `NOLOGIN`	Determines whether a role is allowed to log in. A role having the `LOGIN` attribute can be thought of as a user. Roles without this attribute are useful for managing database privileges (groups). `NOLOGIN` is the default.
`CONNECTION LIMIT *connlimit*`	If role can log in, this specifies how many concurrent connections the role can make. -1 (the default) means no limit.
`CREATEEXTTABLE` or `NOCREATEEXTTABLE`	Determines whether a role is allowed to create external tables. `NOCREATEEXTTABLE` is the default. For a role with the `CREATEEXTTABLE` attribute, the default external table `type` is `readable` and the default `protocol` is `gpfdist`. Note that external tables that use the `file` or `execute` protocols can only be created by superusers.
`PASSWORD '*password*'`	Sets the role's password. If you do not plan to use password authentication you can omit this option. If no password is specified, the password will be set to null and password authentication will always fail for that user. A null password can optionally be written explicitly as `PASSWORD NULL`.
`ENCRYPTED`	The password is always stored encrypted in the system catalogs. The `ENCRYPTED` keyword has no effect, but is accepted for backwards compatibility. The method of encryption is determined by the configuration parameter `password_encryption`. If the presented password string is already in MD5-encrypted or SCRAM-encrypted format, then it is stored as-is regardless of `password_encryption`, since the system cannot decrypt the specified encrypted password string, to encrypt it in a different format). This allows reloading of encrypted passwords during dump/restore. See Protecting Passwords in WarehousePG for additional information about protecting login passwords.
`VALID UNTIL 'timestamp'`	Sets a date and time after which the role's password is no longer valid. If omitted the password will be valid for all time.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Attributes	Description
`RESOURCE QUEUE queue_name`	Assigns the role to the named resource queue for workload management. Any statement that role issues is then subject to the resource queue's limits. Note that the `RESOURCE QUEUE` attribute is not inherited; it must be set on each user-level (`LOGIN`) role.
`DENY deny_interval` or `DENY deny_point`	Restricts access during an interval, specified by day or day and time. For more information see Time-based Authentication.

You can set these attributes when you create the role, or later using the `ALTER ROLE` command. For example:

```
=# ALTER ROLE jsmith WITH PASSWORD 'passwd123';
=# ALTER ROLE admin VALID UNTIL 'infinity';
=# ALTER ROLE jsmith LOGIN;
=# ALTER ROLE jsmith RESOURCE QUEUE adhoc;
=# ALTER ROLE jsmith DENY DAY 'Sunday';
```

A role can also have role-specific defaults for many of the server configuration settings. For example, to set the default schema search path for a role:

```
=# ALTER ROLE admin SET search_path TO myschema, public;
```

Role Membership

It is frequently convenient to group users together to ease management of object privileges: that way, privileges can be granted to, or revoked from, a group as a whole. In WarehousePG this is done by creating a role that represents the group, and then granting membership in the group role to individual user roles.

Use the `CREATE ROLE` SQL command to create a new group role. For example:

```
=# CREATE ROLE admin CREATEROLE CREATEDB;
```

Once the group role exists, you can add and remove members (user roles) using the `GRANT` and `REVOKE` commands. For example:

```
=# GRANT admin TO john, sally;
=# REVOKE admin FROM bob;
```

For managing object privileges, you would then grant the appropriate permissions to the group-level role only (see Managing Object Privileges). The member user roles then inherit the object privileges of the group role. For example:

```
=# GRANT ALL ON TABLE mytable TO admin;
=# GRANT ALL ON SCHEMA myschema TO admin;
=# GRANT ALL ON DATABASE mydb TO admin;
```

The role attributes `LOGIN` , `SUPERUSER` , `CREATEDB` , `CREATEROLE` , `CREATEEXTTABLE` , and `RESOURCE QUEUE` are never inherited as ordinary privileges on database objects are. User members must actually `SET ROLE` to a specific role having one of these attributes in order to make use of the attribute. In the above example, we gave `CREATEDB` and `CREATEROLE` to the `admin` role. If `sally` is a member of `admin` , then `sally` could issue the following command to assume the role attributes of the parent role:

```
=> SET ROLE admin;
```

Managing Object Privileges

When an object (table, view, sequence, database, function, language, schema, or tablespace) is created, it is assigned an owner. The owner is normally the role that ran the creation statement. For most kinds of objects, the initial state is that only the owner (or a superuser) can do anything with the object. To allow other roles to use it, privileges must be granted. WarehousePG supports the following privileges for each object type:

Table 2. Object Privileges

Object Type	Privileges

Tables, External Tables, Views	`SELECT`
	`INSERT`
	`UPDATE`
	`DELETE`
	`REFERENCES`
	`TRIGGER`
	`TRUNCATE`
	`ALL`

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Object Type	Privileges
Columns	`SELECT` `INSERT` `UPDATE` `REFERENCES` `ALL`
Sequences	`USAGE` `SELECT` `UPDATE` `ALL`
Databases	`CREATE` `CONNECT` `TEMPORARY` `TEMP` `ALL`
Domains	`USAGE` `ALL`
Foreign Data Wrappers	`USAGE` `ALL`
Foreign Servers	`USAGE` `ALL`
Functions	`EXECUTE` `ALL`
Procedural Languages	`USAGE` `ALL`
Schemas	`CREATE` `USAGE` `ALL`
Tablespaces	`CREATE` `ALL`
Types	`USAGE` `ALL`

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Object Type	Privileges

Protocols	`SELECT`
	`INSERT`
	`ALL`

> **Note** You must grant privileges for each object individually. For example, granting `ALL` on a database does not grant full access to the objects within that database. It only grants all of the database-level privileges (`CONNECT` , `CREATE` , `TEMPORARY`) to the database itself.

Use the `GRANT` SQL command to give a specified role privileges on an object. For example, to grant the role named `jsmith` insert privileges on the table named `mytable` :

```
=# GRANT INSERT ON mytable TO jsmith;
```

Similarly, to grant `jsmith` select privileges only to the column named `col1` in the table named `table2` :

```
=# GRANT SELECT (col1) on TABLE table2 TO jsmith;
```

To revoke privileges, use the `REVOKE` command. For example:

```
=# REVOKE ALL PRIVILEGES ON mytable FROM jsmith;
```

You can also use the `DROP OWNED` and `REASSIGN OWNED` commands for managing objects owned by deprecated roles (Note: only an object's owner or a superuser can drop an object or reassign ownership). For example:

```
=# REASSIGN OWNED BY sally TO bob;
=# DROP OWNED BY visitor;
```

Encrypting Data

WarehousePG is installed with an optional module of encryption/decryption functions called `pgcrypto` . The `pgcrypto` functions allow database administrators to store certain columns of data in encrypted form. This adds an extra layer of protection for sensitive data, as data stored in WarehousePG in encrypted form cannot be read by anyone who does not have the encryption key, nor can it be read directly from the disks.

> **Note** The `pgcrypto` functions run inside the database server, which means that all the data and passwords move between `pgcrypto` and the client application in clear-text. For optimal security, consider also using SSL connections between the client and the WarehousePG coordinator server.

To use `pgcrypto` functions, register the `pgcrypto` extension in each database in which you want to use the functions. For example:

```
psql -d testdb -c "CREATE EXTENSION pgcrypto"
```

See pgcrypto in the PostgreSQL documentation for more information about individual functions.

Protecting Passwords in WarehousePG

In its default configuration, WarehousePG saves MD5 or SCRAM-SHA-256 hashes of login users' passwords in the `pg_authid` system catalog rather than saving clear text passwords. Anyone who is able to view the `pg_authid` table can see hash strings, but no passwords. This also ensures that passwords are obscured when the database is dumped to backup files.

The hash function runs when the password is set by using any of the following commands:

- `CREATE USER name WITH PASSWORD 'password'`
- `CREATE ROLE name WITH LOGIN PASSWORD 'password'`
- `ALTER USER name WITH PASSWORD 'password'`
- `ALTER ROLE name WITH PASSWORD 'password'`

> **Note** The SQL command syntax and `password_encryption` configuration variable include the term *encrypt*, but the passwords are not technically encrypted. They are *hashed* and therefore cannot be decrypted.

The hash is calculated on the concatenated clear text password and role name. The MD5 hash produces a 32-byte hexadecimal string prefixed with the characters `md5` while the SCRAM-SHA-256 hash produces a 64-byte hexadecimal string prefixed with the characters `SCRAM-SHA-256` . The hashed password is saved in the `rolpassword` column of the `pg_authid` system table.

To set `password_encryption` globally, run these commands in a shell as the `gpadmin` user:

```
$ gpconfig -c password_encryption -v 'scram-sha-256'
$ gpstop -u
```

To set `password_encryption` in a session, use the SQL `SET` command:

```
SET password_encryption = 'md5';
```

Time-based Authentication

WarehousePG enables the administrator to restrict access to certain times by role. Use the `CREATE ROLE` or `ALTER ROLE` commands to specify time-based constraints.

For details, refer to the *WarehousePG Security Configuration Guide*.

4.3.3 About Configuring Row-Level Security Policies

In addition to the SQL-standard privilege system available through GRANT, tables can have row security policies that restrict, on a per-user basis, which rows can be returned by normal queries or inserted, updated, or deleted by data modification commands. This feature is also known as *Row-Level Security*. By default, tables do not have any policies, so that if a user has access privileges to a table according to the SQL privilege system, all rows within it are equally available for querying or updating.

When row security is enabled on a table (with `ALTER TABLE ... ENABLE ROW LEVEL SECURITY`), all normal access to the table for selecting rows or modifying rows must be allowed by a row security policy. (However, the table's owner is typically not subject to row security policies.) If no policy exists for the table, a default-deny policy is used, meaning that no rows are visible or can be modified. Operations that apply to the whole table, such as `TRUNCATE` and `REFERENCES`, are not subject to row security.

Row security policies can be specific to commands, or to roles, or to both. A policy can be specified to apply to `ALL` commands, or to `SELECT`, `INSERT`, `UPDATE`, or `DELETE`. Multiple roles can be assigned to a given policy, and normal role membership and inheritance rules apply.

To specify which rows are visible or modifiable according to a policy, an expression is required that returns a Boolean result. This expression will be evaluated for each row prior to any conditions or functions coming from the user's query. (The only exceptions to this rule are leakproof functions, which are guaranteed to not leak information; the optimizer may choose to apply such functions ahead of the row-security check.) Rows for which the expression does not return true will not be processed. Separate expressions may be specified to provide independent control over the rows which are visible and the rows which are allowed to be modified. Policy expressions are run as part of the query and with the privileges of the user running the query, although security-definer functions can be used to access data not available to the calling user.

Superusers and roles with the `BYPASSRLS` attribute always bypass the row security system when accessing a table. Table owners normally bypass row security as well, though a table owner can choose to be subject to row security with `ALTER TABLE ... FORCE ROW LEVEL SECURITY`.

Enabling and disabling row security, as well as adding policies to a table, is always the privilege of the table owner only.

You create policies using the CREATE POLICY command, alter policies using the ALTER POLICY command, and drop policies using the DROP POLICY command. To enable and disable row security for a given table, use the ALTER TABLE command.

Each policy has a name, and you can define multiple policies for a table. As policies are table-specific, each policy for a table must have a unique name. Different tables may have policies with the same name.

When multiple policies apply to a given query, they are combined using either `OR` (for permissive policies, which are the default) or using `AND` (for restrictive policies). This is similar to the rule that a given role has the privileges of all roles of which they are a member. Permissive vs. restrictive policies are discussed further below.

Here is a simple example that creates a policy on the `account` relation to allow only members of the `managers` role to access rows, and only rows of their accounts:

```
CREATE TABLE accounts (manager text, company text, contact_email text);

ALTER TABLE accounts ENABLE ROW LEVEL SECURITY;

CREATE POLICY account_managers ON accounts TO managers
    USING (manager = current_user);
```

The policy above implicitly provides a `WITH CHECK` clause identical to its `USING` clause, so that the constraint applies both to rows selected by a command (so a manager cannot `SELECT`, `UPDATE`, or `DELETE` existing rows belonging to a different manager) and to rows modified by a command (so rows belonging to a different manager cannot be created via `INSERT` or `UPDATE`).

If no role is specified, or the special user name `PUBLIC` is used, then the policy applies to all users on the system. To allow all users to access only their own row in a `users` table, you can create a simple policy as follows:

```
CREATE POLICY user_policy ON users
    USING (user_name = current_user);
```

This works similarly to the previous example.

To use a different policy for rows that are being added to the table compared to those rows that are visible, you can combine multiple policies. This pair of policies would allow all users to view all rows in the `users` table, but modify only their own:

```
CREATE POLICY user_sel_policy ON users
    FOR SELECT
    USING (true);
CREATE POLICY user_mod_policy ON users
    USING (user_name = current_user);
```

In a `SELECT` command, these two policies are combined using `OR`, with the net effect being that all rows can be selected. In other command types, only the second policy applies, so that the effects are the same as before.

Row security can also be disabled with the `ALTER TABLE` command. Disabling row security does not remove any policies that are defined on the table; they are simply ignored. Then all rows in the table are visible and modifiable, subject to the standard SQL privileges system.

The example below is more comprehensive. The table `passwd` emulates a Unix password file:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
-- Simple passwd-file based example
CREATE TABLE passwd (
  user_name             text UNIQUE NOT NULL,
  pwhash                text,
  uid                   int  PRIMARY KEY,
  gid                   int  NOT NULL,
  real_name             text NOT NULL,
  home_phone            text,
  extra_info            text,
  home_dir              text NOT NULL,
  shell                 text NOT NULL
);

CREATE ROLE admin;  -- Administrator
CREATE ROLE bob;    -- Normal user
CREATE ROLE alice;  -- Normal user

-- Populate the table
INSERT INTO passwd VALUES
  ('admin','xxx',0,0,'Admin','111-222-3333',null,'/root','/bin/dash');
INSERT INTO passwd VALUES
  ('bob','xxx',1,1,'Bob','123-456-7890',null,'/home/bob','/bin/zsh');
INSERT INTO passwd VALUES
  ('alice','xxx',2,1,'Alice','098-765-4321',null,'/home/alice','/bin/zsh');

-- Be sure to enable row level security on the table
ALTER TABLE passwd ENABLE ROW LEVEL SECURITY;

-- Create policies
-- Administrator can see all rows and add any rows
CREATE POLICY admin_all ON passwd TO admin USING (true) WITH CHECK (true);
-- Normal users can view all rows
CREATE POLICY all_view ON passwd FOR SELECT USING (true);
-- Normal users can update their own records, but
-- limit which shells a normal user is allowed to set
CREATE POLICY user_mod ON passwd FOR UPDATE
  USING (current_user = user_name)
  WITH CHECK (
    current_user = user_name AND
    shell IN ('/bin/bash','/bin/sh','/bin/dash','/bin/zsh','/bin/tcsh')
  );

-- Allow admin all normal rights
GRANT SELECT, INSERT, UPDATE, DELETE ON passwd TO admin;
-- Users only get select access on public columns
GRANT SELECT
  (user_name, uid, gid, real_name, home_phone, extra_info, home_dir, shell)
  ON passwd TO public;
-- Allow users to update certain columns
GRANT UPDATE
  (pwhash, real_name, home_phone, extra_info, shell)
  ON passwd TO public;
```

As with any security settings, it's important to test and ensure that the system is behaving as expected. Using the example above, this demonstrates that the permission system is working properly.

```
-- admin can view all rows and fields
postgres=> set role admin;
SET
postgres=> table passwd;
 user_name | pwhash | uid | gid | real_name |  home_phone  | extra_info | home_dir    |   shell
-----------+--------+-----+-----+-----------+--------------+------------+-------------+-----------
 admin     | xxx    |   0 |   0 | Admin     | 111-222-3333 |            | /root       | /bin/dash
 bob       | xxx    |   1 |   1 | Bob       | 123-456-7890 |            | /home/bob   | /bin/zsh
 alice     | xxx    |   2 |   1 | Alice     | 098-765-4321 |            | /home/alice | /bin/zsh
(3 rows)

-- Test what Alice is able to do
postgres=> set role alice;
SET
postgres=> table passwd;
ERROR:  permission denied for relation passwd
postgres=> select user_name,real_name,home_phone,extra_info,home_dir,shell from passwd;
 user_name | real_name |  home_phone  | extra_info | home_dir    |   shell
-----------+-----------+--------------+------------+-------------+-----------
 admin     | Admin     | 111-222-3333 |            | /root       | /bin/dash
 bob       | Bob       | 123-456-7890 |            | /home/bob   | /bin/zsh
 alice     | Alice     | 098-765-4321 |            | /home/alice | /bin/zsh
(3 rows)

postgres=> update passwd set user_name = 'joe';
ERROR:  permission denied for relation passwd
-- Alice is allowed to change her own real_name, but no others
postgres=> update passwd set real_name = 'Alice Doe';
UPDATE 1
postgres=> update passwd set real_name = 'John Doe' where user_name = 'admin';
UPDATE 0
postgres=> update passwd set shell = '/bin/xx';
ERROR:  new row violates WITH CHECK OPTION for "passwd"
postgres=> delete from passwd;
ERROR:  permission denied for relation passwd
postgres=> insert into passwd (user_name) values ('xxx');
ERROR:  permission denied for relation passwd
-- Alice can change her own password; RLS silently prevents updating other rows
postgres=> update passwd set pwhash = 'abc';
UPDATE 1
```

All of the policies constructed thus far have been permissive policies; this means that when multiple policies are applied they are combined using the `OR` Boolean operator. While permissive policies can be constructed to only allow access to rows in the intended cases, it can be simpler to combine permissive policies with restrictive policies (which the records must pass and which are combined using the `AND` Boolean operator). Building on the example above, we add a restrictive policy to require the administrator to be connected over a local Unix socket to access the records of the `passwd` table:

```
CREATE POLICY admin_local_only ON passwd AS RESTRICTIVE TO admin
    USING (pg_catalog.inet_client_addr() IS NULL);
```

We can then see that an administrator connecting over a network will not see any records, due to the restrictive policy:

```
=> SELECT current_user;
 current_user
--------------
 admin
(1 row)

=> select inet_client_addr();
 inet_client_addr
------------------
 127.0.0.1
(1 row)

=> SELECT current_user;
 current_user
--------------
 admin
(1 row)

=> TABLE passwd;
 user_name | pwhash | uid | gid | real_name | home_phone | extra_info | home_dir | shell
-----------+--------+-----+-----+-----------+------------+------------+----------+-------
(0 rows)

=> UPDATE passwd set pwhash = NULL;
UPDATE 0
```

Referential integrity checks, such as unique or primary key constraints and foreign key references, always bypass row security to ensure that data integrity is maintained. Take care when developing schemas and row-level policies to avoid "covert channel" leaks of information through such referential integrity checks.

In some contexts, it is important to be sure that row security is not being applied. For example, when taking a backup, it could be disastrous if row security silently caused some rows to be omitted from the backup. In such a situation, you can set the row_security configuration parameter to `off`. This does not in itself bypass row security; what it does is throw an error if any query's results would get filtered by a policy. You can then investigate the reason for the error and fix it.

In the examples above, the policy expressions consider only the current values in the row to be accessed or updated. This is the simplest and best-performing case; when possible, it is best to design row security applications to work this way. If it is necessary to consult other rows or other tables to make a policy decision, that can be accomplished using sub-`SELECT`s, or functions that contain `SELECT`s, in the policy expressions. Be aware, however, that such accesses can create race conditions that could allow information leakage if care is not taken. As an example, consider the following table design:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
-- definition of privilege groups
CREATE TABLE groups (group_id int PRIMARY KEY,
                     group_name text NOT NULL);

INSERT INTO groups VALUES
  (1, 'low'),
  (2, 'medium'),
  (5, 'high');

GRANT ALL ON groups TO alice;  -- alice is the administrator
GRANT SELECT ON groups TO public;

-- definition of users' privilege levels
CREATE TABLE users (user_name text PRIMARY KEY,
                    group_id int NOT NULL REFERENCES groups);

INSERT INTO users VALUES
  ('alice', 5),
  ('bob', 2),
  ('mallory', 2);

GRANT ALL ON users TO alice;
GRANT SELECT ON users TO public;

-- table holding the information to be protected
CREATE TABLE information (info text,
                          group_id int NOT NULL REFERENCES groups);

INSERT INTO information VALUES
  ('barely secret', 1),
  ('slightly secret', 2),
  ('very secret', 5);

ALTER TABLE information ENABLE ROW LEVEL SECURITY;

-- a row should be visible to/updatable by users whose security group_id is
-- greater than or equal to the row's group_id
CREATE POLICY fp_s ON information FOR SELECT
  USING (group_id <= (SELECT group_id FROM users WHERE user_name = current_user));
CREATE POLICY fp_u ON information FOR UPDATE
  USING (group_id <= (SELECT group_id FROM users WHERE user_name = current_user));

-- we rely only on RLS to protect the information table
GRANT ALL ON information TO public;
```

Now suppose that `alice` wishes to change the "slightly secret" information, but decides that `mallory` should not be trusted with the new content of that row, so she runs the following commands:

```
BEGIN;
UPDATE users SET group_id = 1 WHERE user_name = 'mallory';
UPDATE information SET info = 'secret from mallory' WHERE group_id = 2;
COMMIT;
```

That looks safe; there is no window wherein `mallory` should be able to see the `"secret from mallory"` string. However, there is a race condition here. If `mallory` is concurrently doing, say,

```
SELECT * FROM information WHERE group_id = 2 FOR UPDATE;
```

and her transaction is in `READ COMMITTED` mode, it is possible for her to see `"secret from mallory"`. That happens if her transaction reaches the information row just after `alice`'s does. It blocks waiting for `alice`'s transaction to commit, then fetches the updated row contents thanks to the `FOR UPDATE` clause. However, it does not fetch an updated row for the implicit `SELECT` from `users`, because that sub- `SELECT` did not have `FOR UPDATE`; instead the `users` row is read with the snapshot taken at the start of the query. Therefore, the policy expression tests the old value of `mallory`'s privilege level and allows her to see the updated row.

There are several ways around this problem. One simple answer is to use `SELECT ... FOR SHARE` in sub- `SELECT`s in row security policies. However, that requires granting `UPDATE` privilege on the referenced table (here `users`) to the affected users, which might be undesirable. (But another row security policy could be applied to prevent them from actually exercising that privilege; or the sub `SELECT` could be embedded into a security definer function.) Also, heavy concurrent use of row share locks on the referenced table could pose a performance problem, especially if updates of it are frequent. Another solution, practical if updates of the referenced table are infrequent, is to take an `ACCESS EXCLUSIVE` lock on the referenced table when updating it, so that no concurrent transactions could be examining old row values. Or one could just wait for all concurrent transactions to end after committing an update of the referenced table and before making changes that rely on the new security situation.

For additional details see CREATE POLICY and ALTER TABLE.

About Row-Level Security for Views

You can simulate row-level access by using views to restrict the rows that are selected. You can simulate row-level labels by adding an extra column to the table to store sensitivity information, and then using views to control row-level access based on this column. You can then grant roles access to the views rather than to the base table.

While views can hide the contents of certain columns, they cannot be used to reliably conceal the data in unseen rows. When it is necessary for a view to provide row-level security, you must apply the `security_barrier` attribute to the view. This prevents maliciously-chosen functions and operators from being passed values from rows until after the view has done its work. For example, this view is secure:

```
CREATE VIEW phone_number WITH (security_barrier) AS
    SELECT person, phone FROM phone_data WHERE phone NOT LIKE '412%';
```

Views created with the `security_barrier` attribute may perform far worse than views created without this option. In general, there is no way to avoid this: the fastest possible plan must be rejected if it may compromise security. For this reason, the `security_barrier` option is not enabled by default.

Be sure to review Rules and Privileges in the PostgreSQL documentation for detailed information about securing views.

4.4 DDL: Defining Database Objects

This section covers data definition language (DDL) in WarehousePG and how to create and manage database objects.

Creating objects in a WarehousePG includes making up-front choices about data distribution, storage options, data loading, and other WarehousePG features that will affect the ongoing performance of your database system. Understanding the options that are available and how the database will be used will help you make the right decisions.

Most of the advanced WarehousePG features are enabled with extensions to the SQL `CREATE` DDL statements.

Parent topic: WarehousePG Administrator Guide

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.4.1 Creating and Managing Databases

A WarehousePG cluster is a single instance of WarehousePG. There can be several separate WarehousePG clusters installed, but usually just one is selected by environment variable settings. See your WarehousePG administrator for details.

There can be multiple databases in a WarehousePG cluster. This is different from some database management systems (such as Oracle) where the database instance*is* the database. Although you can create many databases in a WarehousePG cluster, client programs can connect to and access only one database at a time — you cannot cross-query between databases.

Parent topic: DDL: Defining Database Objects

About Template and Default Databases

WarehousePG provides some template databases and a default database, *template1*, *template0*, and *postgres*.

By default, each new database you create is based on a *template* database. WarehousePG uses *template1* to create databases unless you specify another template. Creating objects in *template1* is not recommended. The objects will be in every database you create using the default template database.

WarehousePG uses another database template, *template0*, internally. Do not drop or modify *template0*. You can use *template0* to create a completely clean database containing only the standard objects predefined by WarehousePG at initialization.

You can use the *postgres* database to connect to WarehousePG for the first time. WarehousePG uses *postgres* as the default database for administrative connections. For example, *postgres* is used by startup processes, the Global Deadlock Detector process, and the FTS (Fault Tolerance Server) process for catalog access.

Creating a Database

The `CREATE DATABASE` command creates a new database. For example:

```
=> CREATE DATABASE <new_dbname>;
```

To create a database, you must have privileges to create a database or be a WarehousePG superuser. If you do not have the correct privileges, you cannot create a database. Contact your WarehousePG administrator to either give you the necessary privilege or to create a database for you.

You can also use the client program `createdb` to create a database. For example, running the following command in a command line terminal connects to WarehousePG using the provided host name and port and creates a database named *mydatabase*:

```
$ createdb -h coordinator_host -p 5432 mydatabase
```

The host name and port must match the host name and port of the installed WarehousePG cluster.

Some objects, such as roles, are shared by all the databases in a WarehousePG cluster. Other objects, such as tables that you create, are known only in the database in which you create them.

> **Caution** The `CREATE DATABASE` command is not transactional.

Cloning a Database

By default, a new database is created by cloning the standard system database template, *template1*. Any database can be used as a template when creating a new database, thereby providing the capability to 'clone' or copy an existing database and all objects and data within that database. For example:

```
=> CREATE DATABASE <new_dbname> TEMPLATE <old_dbname>;
```

Creating a Database with a Different Owner

Another database owner can be assigned when a database is created:

```
=> CREATE DATABASE <new_dbname> WITH <owner=new_user>;
```

Viewing the List of Databases

If you are working in the `psql` client program, you can use the `\l` meta-command to show the list of databases and templates in your WarehousePG cluster. If using another client program and you are a superuser, you can query the list of databases from the `pg_database` system catalog table. For example:

```
=> SELECT datname from pg_database;
```

Altering a Database

The ALTER DATABASE command changes database attributes such as owner, name, or default configuration attributes. For example, the following command alters a database by setting its default schema search path (the `search_path` configuration parameter):

```
=> ALTER DATABASE mydatabase SET search_path TO myschema, public, pg_catalog;
```

To alter a database, you must be the owner of the database or a superuser.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Dropping a Database

The `DROP DATABASE` command drops (or deletes) a database. It removes the system catalog entries for the database and deletes the database directory on disk that contains the data. You must be the database owner or a superuser to drop a database, and you cannot drop a database while you or anyone else is connected to it. Connect to `postgres` (or another database) before dropping a database. For example:

```
=> \c postgres
=> DROP DATABASE mydatabase;
```

You can also use the client program `dropdb` to drop a database. For example, the following command connects to WarehousePG using the provided host name and port and drops the database *mydatabase*:

```
$ dropdb -h coordinator_host -p 5432 mydatabase
```

> **Caution** Dropping a database cannot be undone.

The `DROP DATABASE` command is not transactional.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.4.2 Creating and Managing Tablespaces

Tablespaces allow database administrators to have multiple file systems per machine and decide how to best use physical storage to store database objects. Tablespaces allow you to assign different storage for frequently and infrequently used database objects or to control the I/O performance on certain database objects. For example, place frequently-used tables on file systems that use high performance solid-state drives (SSD), and place other tables on standard hard drives.

A tablespace requires a host file system location to store its database files. In WarehousePG, the file system location must exist on all hosts including the hosts running the coordinator, standby coordinator, each primary segment, and each mirror segment.

A tablespace is WarehousePG cluster object (a global object), you can use a tablespace from any database if you have appropriate privileges.

> **Note** WarehousePG does not support different tablespace locations for a primary-mirror pair with the same content ID. It is only possible to configure different locations for different content IDs. Do not modify symbolic links under the `pg_tblspc` directory so that primary-mirror pairs point to different file locations; this will lead to erroneous behavior.

Parent topic: DDL: Defining Database Objects

Creating a Tablespace

The `CREATE TABLESPACE` command defines a tablespace. For example:

```
CREATE TABLESPACE fastspace LOCATION '/fastdisk/gpdb';
```

Database superusers define tablespaces and grant access to database users with the `GRANT``CREATE` command. For example:

```
GRANT CREATE ON TABLESPACE fastspace TO admin;
```

Using a Tablespace to Store Database Objects

Users with the `CREATE` privilege on a tablespace can create database objects in that tablespace, such as tables, indexes, and databases. The command is:

```
CREATE TABLE tablename(options) TABLESPACE spacename
```

For example, the following command creates a table in the tablespace*space1*:

```
CREATE TABLE foo(i int) TABLESPACE space1;
```

You can also use the `default_tablespace` parameter to specify the default tablespace for `CREATE TABLE` and `CREATE INDEX` commands that do not specify a tablespace:

```
SET default_tablespace = space1;
CREATE TABLE foo(i int);
```

There is also the `temp_tablespaces` configuration parameter, which determines the placement of temporary tables and indexes, as well as temporary files that are used for purposes such as sorting large data sets. This can be a comma-separate list of tablespace names, rather than only one, so that the load associated with temporary objects can be spread over multiple tablespaces. A random member of the list is picked each time a temporary object is to be created.

The tablespace associated with a database stores that database's system catalogs, temporary files created by server processes using that database, and is the default tablespace selected for tables and indexes created within the database, if no `TABLESPACE` is specified when the objects are created. If you do not specify a tablespace when you create a database, the database uses the same tablespace used by its template database.

You can use a tablespace from any database in the WarehousePG cluster if you have appropriate privileges.

Viewing Existing Tablespaces

Every WarehousePG cluster has the following default tablespaces.

- `pg_global` for shared system catalogs.
- `pg_default` , the default tablespace. Used by the *template1* and *template0* databases.

These tablespaces use the default system location, the data directory locations created at system initialization.

To see tablespace information, use the `pg_tablespace` catalog table to get the object ID (OID) of the tablespace and then use `gp_tablespace_location()` function to display the tablespace directories. This is an example that lists one user-defined tablespace, `myspace` :

```
SELECT oid, * FROM pg_tablespace ;

  oid  |  spcname   | spcowner | spcacl | spcoptions
-------+------------+----------+--------+------------
  1663 | pg_default |       10 |        |
  1664 | pg_global  |       10 |        |
 16391 | myspace    |       10 |        |
(3 rows)
```

The OID for the tablespace `myspace` is `16391` . Run `gp_tablespace_location()` to display the tablespace locations for a system that consists of two segment instances and the coordinator.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
# SELECT * FROM gp_tablespace_location(16391);
 gp_segment_id |    tblspc_loc
---------------+------------------
             0 | /data/mytblspace
             1 | /data/mytblspace
            -1 | /data/mytblspace
(3 rows)
```

This query uses `gp_tablespace_location()` the `gp_segment_configuration` catalog table to display segment instance information with the file system location for the `myspace` tablespace.

```
WITH spc AS (SELECT * FROM  gp_tablespace_location(16391))
  SELECT seg.role, spc.gp_segment_id as seg_id, seg.hostname, seg.datadir, tblspc_loc
    FROM spc, gp_segment_configuration AS seg
    WHERE spc.gp_segment_id = seg.content ORDER BY seg_id;
```

This is information for a test system that consists of two segment instances and the coordinator on a single host.

```
 role | seg_id | hostname |       datadir        |    tblspc_loc
------+--------+----------+----------------------+------------------
 p    |     -1 | testhost | /data/coordinator/gpseg-1 | /data/mytblspace
 p    |      0 | testhost | /data/data1/gpseg0   | /data/mytblspace
 p    |      1 | testhost | /data/data2/gpseg1   | /data/mytblspace
(3 rows)
```

Dropping Tablespaces

To drop a tablespace, you must be the tablespace owner or a superuser. You cannot drop a tablespace until all objects in all databases using the tablespace are removed.

The `DROP TABLESPACE` command removes an empty tablespace.

> **Note** You cannot drop a tablespace if it is not empty or if it stores temporary or transaction files.

Moving the Location of Temporary or Transaction Files

You can move temporary or transaction files to a specific tablespace to improve database performance when running queries, creating backups, and to store data more sequentially.

The WarehousePG server configuration parameter `temp_tablespaces` controls the location for both temporary tables and temporary spill files for hash aggregate and hash join queries. Temporary files for purposes such as sorting large data sets are also created in these tablespaces.

`temp_tablespaces` specifies tablespaces in which to create temporary objects (temp tables and indexes on temp tables) when a `CREATE` command does not explicitly specify a tablespace.

Also note the following information about temporary or transaction files:

- You can dedicate only one tablespace for temporary or transaction files, although you can use the same tablespace to store other types of files.
- You cannot drop a tablespace if it used by temporary files.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.4.3 Creating and Managing Schemas

Schemas logically organize objects and data in a database. Schemas allow you to have more than one object (such as tables) with the same name in the database without conflict if the objects are in different schemas.

Parent topic: DDL: Defining Database Objects

The Default "Public" Schema

Every database has a default schema named *public*. If you do not create any schemas, objects are created in the *public* schema. All database roles (users) have `CREATE` and `USAGE` privileges in the *public* schema. When you create a schema, you grant privileges to your users to allow access to the schema.

Creating a Schema

Use the `CREATE SCHEMA` command to create a new schema. For example:

```
=> CREATE SCHEMA myschema;
```

To create or access objects in a schema, write a qualified name consisting of the schema name and table name separated by a period. For example:

```
myschema.table
```

See Schema Search Paths for information about accessing a schema.

You can create a schema owned by someone else, for example, to restrict the activities of your users to well-defined namespaces. The syntax is:

```
=> CREATE SCHEMA `schemaname` AUTHORIZATION `username`;
```

Schema Search Paths

To specify an object's location in a database, use the schema-qualified name. For example:

```
=> SELECT * FROM myschema.mytable;
```

You can set the `search_path` configuration parameter to specify the order in which to search the available schemas for objects. The schema listed first in the search path becomes the *default* schema. If a schema is not specified, objects are created in the default schema.

Setting the Schema Search Path

The `search_path` configuration parameter sets the schema search order. The `ALTER DATABASE` command sets the search path. For example:

```
=> ALTER DATABASE mydatabase SET search_path TO myschema,
public, pg_catalog;
```

You can also set `search_path` for a particular role (user) using the `ALTER ROLE` command. For example:

```
=> ALTER ROLE sally SET search_path TO myschema, public,
pg_catalog;
```

Viewing the Current Schema

Use the `current_schema()` function to view the current schema. For example:

```
=> SELECT current_schema();
```

Use the `SHOW` command to view the current search path. For example:

```
=> SHOW search_path;
```

Dropping a Schema

Use the `DROP SCHEMA` command to drop (delete) a schema. For example:

```
=> DROP SCHEMA myschema;
```

By default, the schema must be empty before you can drop it. To drop a schema and all of its objects (tables, data, functions, and so on) use:

```
=> DROP SCHEMA myschema CASCADE;
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

System Schemas

The following system-level schemas exist in every database:

- `pg_catalog` contains the system catalog tables, built-in data types, functions, and operators. It is always part of the schema search path, even if it is not explicitly named in the search path.
- `information_schema` consists of a standardized set of views that contain information about the objects in the database. These views get system information from the system catalog tables in a standardized way.
- `pg_toast` stores large objects such as records that exceed the page size. This schema is used internally by the WarehousePG cluster.
- `pg_bitmapindex` stores bitmap index objects such as lists of values. This schema is used internally by the WarehousePG cluster.
- `pg_aoseg` stores append-optimized table objects. This schema is used internally by the WarehousePG cluster.
- `gp_toolkit` is an administrative schema that contains external tables, views, and functions that you can access with SQL commands. All database users can access `gp_toolkit` to view and query the system log files and other system metrics.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.4.4 About Table Definition Basics

A table in a relational database is much like a table on paper: It consists of rows and columns. The number and order of the columns is fixed, and each column has a name. The number of rows is variable — it reflects how much data is stored at a given moment. SQL does not make any guarantees about the order of the rows in a table. When a table is read, the rows will appear in an unspecified order, unless sorting is explicitly requested. Furthermore, SQL does not assign unique identifiers to rows, so it is possible to have several completely identical rows in a table.

Each column has a data type. The data type constrains the set of possible values that can be assigned to a column and assigns semantics to the data stored in the column so that it can be used for computations. For instance, a column declared to be of a numerical type will not accept arbitrary text strings, and the data stored in such a column can be used for mathematical computations. By contrast, a column declared to be of a character string type will accept almost any kind of data but it does not lend itself to mathematical calculations, although other operations such as string concatenation are available.

WarehousePG includes a sizable set of built-in data types that fit many applications. Users can also define their own data types. Most built-in data types have obvious names and semantics. Some of the frequently used data types are `integer` for whole numbers, `numeric` for possibly fractional numbers, `text` for character strings, `date` for dates, `time` for time-of-day values, and `timestamp` for values containing both date and time.

To create a table, you use the aptly named CREATE TABLE command. In this command, you specify at least a name for the new table, the names of the columns and the data type of each column. For example:

```
CREATE TABLE my_first_table
(
    first_column text,
    second_column integer
);
```

This command creates a table named `my_first_table` with two columns. The first column is named `first_column` and has a data type of `text`; the second column has the name `second_column` and the type `integer`. The table and column names follow the identifier syntax explained in Identifiers and Key Words in the PostgreSQL documentation. The type names are usually also identifiers, but there are some exceptions. The column list is comma-separated and surrounded by parentheses.

Normally, you would specify names for your tables and columns that convey the kind of data that they store, for example:

```
CREATE TABLE products
(
    product_no integer,
    name text,
    price numeric
);
```

(The `numeric` type can store fractional components, as would be typical of monetary amounts.)

Tip: When you create many interrelated tables, it is wise to choose a consistent naming pattern for the tables and columns. For instance, you may choose using singular or plural nouns for table names.

WarehousePG limits the number of columns that a table can contain. Depending on the column types, the maximum is between 250 and 1600. Defining a table with anywhere near the maximum number of columns is highly unusual and often a questionable design.

If you no longer need a table, you can remove it using the DROP TABLE command. For example:

```
DROP TABLE my_first_table;
DROP TABLE products;
```

Attempting to drop a table that does not exist is an error. It is common in SQL script files to unconditionally try to drop each table before creating it, ignoring any error messages, so that the script works whether or not the table exists. You can use the `DROP TABLE IF EXISTS` variant to avoid the error messages, but this is not standard SQL.

Default Column Values

You can assign a column a default value. When a new row is created and no values are specified for some of the columns, WarehousePG assigns those columns their respective default values. A data manipulation command can also request explicitly that a column be set to its default value, without having to know what that value is.

If you do not explicitly declare a default for a column, the default value is the null value, which can be considered to represent unknown data.

In a table definition, specify the default value after the column data type. For example:

```
CREATE TABLE products
(
    product_no integer,
    name text,
    price numeric DEFAULT 9.99
);
```

The default value can be an expression, which WarehousePG evaluates whenever the default value is inserted (not when the table is created). A common example is for a timestamp column to have a default of `CURRENT_TIMESTAMP`, so that it gets set to the time of row insertion. Another common example is generating a "serial number" for each row. In WarehousePG, you can do this as follows:

```
CREATE TABLE products
(
    product_no integer DEFAULT
nextval('products_product_no_seq'),
    ...
);
```

where the `nextval()` function supplies successive values from a sequence object. This situation is sufficiently common that there's a special shorthand for it:

```
CREATE TABLE products (
    product_no SERIAL,
    ...
);
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Generated Columns

A generated column is a special column that is always computed from other columns; it is for columns what a view is for tables. There are two kinds of generated columns: stored and virtual. A stored generated column is computed when it is written (inserted or updated) and occupies storage as if it were a normal column. A virtual generated column occupies no storage and is computed when it is read.

A virtual generated column is similar to a view and a stored generated column is similar to a materialized view (except that it is always updated automatically). *WarehousePG currently implements only stored generated columns.*

To create a generated column, use the `GENERATED ALWAYS AS` clause in `CREATE TABLE`, for example:

```
CREATE TABLE people
(
    ...,
    height_cm numeric,
    height_in numeric GENERATED ALWAYS AS (height_cm / 2.54)
STORED
);
```

The keyword `STORED` must be specified to choose the stored kind of generated column. See CREATE TABLE for more details.

You cannot write directly to a generated column. While you may not specify a value for a generated column in an `INSERT` or `UPDATE` command, you can specify the keyword `DEFAULT`.

Note the following differences between a column with a default and a generated column:

- The column default is evaluated once when the row is first inserted if no other value was provided; a generated column is updated whenever the row changes and cannot be overridden.
- A column default may not refer to other columns of the table; a generation expression would normally do so.
- A column default can use volatile functions, for example `random()` or functions referring to the current time; WarehousePG does not permit this for generated columns.

Several restrictions apply to the definition of generated columns and tables involving generated columns:

- The generation expression can use only immutable functions and cannot use subqueries or reference anything other than the current row in any way.
- A generation expression cannot reference another generated column.
- A generation expression cannot reference a system column, except `tableoid`.
- A generated column cannot have a column default or an identity definition.
- A generated column cannot be used as a distribution key.
- A generated column cannot be part of a partition key.
- You may specify a generated column in a root partitioned table but not in a child table.
- For inheritance:
    - If a parent column is a generated column, a child column must also be a generated column using the same expression. Omit the `GENERATED` clause in the definition of the child column, it will be copied from the parent.
    - In the case of multiple inheritance, if one parent column is a generated column, then all parent columns must be generated columns and with the same expression.
    - If a parent column is not a generated column, a child column may be defined to be either a generated column or not.

Additional considerations apply to the use of generated columns:

- Foreign tables can have generated columns. See CREATE FOREIGN TABLE for details.
- Generated columns maintain access privileges separately from their underlying base columns. So, it is possible to grant privileges such that a particular role can read from a generated column but not from the underlying base columns.
- Generated columns are, conceptually, updated after `BEFORE` triggers have run. Changes made to base columns in a `BEFORE` trigger will be reflected in generated columns. But conversely, WarehousePG does not permit access to generated columns in `BEFORE` triggers.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.4.5 Creating and Managing Tables

WarehousePG tables are similar to tables in any relational database, except that table rows are distributed across the different segments in the system. When you create a table, you specify the table's distribution policy.

Creating a Table

The `CREATE TABLE` command creates a table and defines its structure. When you create a table, you define:

- The columns of the table and their associated data types. See Choosing Column Data Types.
- Any table or column constraints to limit the data that a column or table can contain. See Setting Table and Column Constraints.
- The distribution policy of the table, which determines how WarehousePG divides data across the segments. See Choosing the Table Distribution Policy.
- The way the table is stored on disk. See Choosing the Table Storage Model.
- The table partitioning strategy for large tables. See Creating and Managing Databases.

Choosing Column Data Types

The data type of a column determines the types of data values the column can contain. Choose the data type that uses the least possible space but can still accommodate your data and that best constrains the data. For example, use character data types for strings, date or timestamp data types for dates, and numeric data types for numbers.

For table columns that contain textual data, specify the data type `VARCHAR` or `TEXT` . Specifying the data type `CHAR` is not recommended. In WarehousePG, the data types `VARCHAR` or `TEXT` handle padding added to the data (space characters added after the last non-space character) as significant characters, the data type `CHAR` does not. For information on the character data types, see the `CREATE TABLE` command in the *WarehousePG Reference Guide*.

Use the smallest numeric data type that will accommodate your numeric data and allow for future expansion. For example, using `BIGINT` for data that fits in `INT` or `SMALLINT` wastes storage space. If you expect that your data values will expand over time, consider that changing from a smaller datatype to a larger datatype after loading large amounts of data is costly. For example, if your current data values fit in a `SMALLINT` but it is likely that the values will expand, `INT` is the better long-term choice.

Use the same data types for columns that you plan to use in cross-table joins. Cross-table joins usually use the primary key in one table and a foreign key in the other table. When the data types are different, the database must convert one of them so that the data values can be compared correctly, which adds unnecessary overhead.

WarehousePG has a rich set of native data types available to users. See the *WarehousePG Reference Guide* for information about the built-in data types.

Setting Table and Column Constraints

You can define constraints on columns and tables to restrict the data in your tables. WarehousePG support for constraints is the same as PostgreSQL with some limitations, including:

- `CHECK` constraints can refer only to the table on which they are defined.
- `UNIQUE` and `PRIMARY KEY` constraints must be compatible with their table's distribution key and partitioning key, if any.

  > **Note** `UNIQUE` and `PRIMARY KEY` constraints are not allowed on append-optimized tables because the `UNIQUE` indexes that are created by the constraints are not allowed on append-optimized tables.

- `FOREIGN KEY` constraints are allowed, but not enforced.
- Constraints that you define on partitioned tables apply to the partitioned table as a whole. You cannot define constraints on the individual parts of the table.

Check Constraints

Check constraints allow you to specify that the value in a certain column must satisfy a Boolean (truth-value) expression. For example, to require positive product prices:

```
=> CREATE TABLE products
            ( product_no integer,
              name text,
              price numeric CHECK (price > 0) );
```

Not-Null Constraints

Not-null constraints specify that a column must not assume the null value. A not-null constraint is always written as a column constraint. For example:

```
=> CREATE TABLE products
       ( product_no integer NOT NULL,
         name text NOT NULL,
         price numeric );
```

Unique Constraints

Unique constraints ensure that the data contained in a column or a group of columns is unique with respect to all the rows in the table. The table must be hash-distributed or replicated (not `DISTRIBUTED RANDOMLY`). If the table is hash-distributed, the constraint columns must be the same as (or a superset of) the table's distribution key columns. For example:

```
=> CREATE TABLE products
       ( `product_no` integer `UNIQUE`,
         name text,
         price numeric)
`      DISTRIBUTED BY (``product_no``)`;
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Primary Keys

A primary key constraint is a combination of a `UNIQUE` constraint and a `NOT NULL` constraint. The table must be hash-distributed (not `DISTRIBUTED RANDOMLY`), and the primary key columns must be the same as (or a superset of) the table's distribution key columns. If a table has a primary key, this column (or group of columns) is chosen as the distribution key for the table by default. For example:

```
=> CREATE TABLE products
       ( `product_no` integer `PRIMARY KEY`,
         name text,
         price numeric)
`      DISTRIBUTED BY (``product_no``)`;
```

Foreign Keys

Foreign keys are not supported. You can declare them, but referential integrity is not enforced.

Foreign key constraints specify that the values in a column or a group of columns must match the values appearing in some row of another table to maintain referential integrity between two related tables. Referential integrity checks cannot be enforced between the distributed table segments of a WarehousePG.

Exclusion Constraints

Exclusion constraints ensure that if any two rows are compared on the specified columns or expressions using the specified operators, at least one of these operator comparisons will return false or null. The syntax is:

```
CREATE TABLE circles
(
    c
circle,
    EXCLUDE USING gist (c WITH
&&)
) DISTRIBUTED
REPLICATED;
```

Similar to unique constraints, an exclusion constraint is permitted only for replicated tables or when the distribution key columns are part of the constraint, with the same `=` operator as in the distribution key's hash operator class.

Exclusion constraints are not supported for partitioned tables.

See also CREATE TABLE ... CONSTRAINT ... EXCLUDE for details.

Adding an exclusion constraint automatically creates an index of the type specified in the constraint declaration.

Choosing the Table Distribution Policy

All WarehousePG tables are distributed. When you create or alter a table, you optionally specify `DISTRIBUTED BY` (hash distribution), `DISTRIBUTED RANDOMLY` (random distribution), `DISTRIBUTED REPLICATED` (fully distributed), or `DISTRIBUTED COORDINATOR ONLY` (local to coordinator) to determine the table row distribution.

> **Note** The WarehousePG server configuration parameter `gp_create_table_random_default_distribution` controls the table distribution policy if the DISTRIBUTED BY clause is not specified when you create a table.

For information about the parameter, see "Server Configuration Parameters" of the *WarehousePG Reference Guide*.

Consider the following points when deciding on a table distribution policy.

- **Even Data Distribution** — For the best possible performance, all segments should contain equal portions of data. If the data is unbalanced or skewed, the segments with more data must work harder to perform their portion of the query processing. Choose a distribution key that is unique for each record, such as the primary key.
- **Local and Distributed Operations** — Local operations are faster than distributed operations. Query processing is fastest if the work associated with join, sort, or aggregation operations is done locally, at the segment level. Work done at the system level requires distributing tuples across the segments, which is less efficient. When tables share a common distribution key, the work of joining or sorting on their shared distribution key columns is done locally. With a random distribution policy, local join operations are not an option.
- **Even Query Processing** — For best performance, all segments should handle an equal share of the query workload. Query workload can be skewed if a table's data distribution policy and the query predicates are not well matched. For example, suppose that a sales transactions table is distributed on the customer ID column (the distribution key). If a predicate in a query references a single customer ID, the query processing work is concentrated on just one segment.

The primary use cases for replicated tables are to:

- remove restrictions on operations that user-defined functions can perform on segments, and
- improve query performance by making it unnecessary to broadcast frequently used tables to all segments.

The replicated table distribution policy (`DISTRIBUTED REPLICATED`) should be used only for small tables. Replicating data to every segment is costly in both storage and maintenance, and prohibitive for large fact tables.

The coordinator-only table distribution policy (`DISTRIBUTED COORDINATOR ONLY`) stores data exclusively on the coordinator node. This is a specialized policy intended for small lookup tables or metadata that must be consulted during the planning phase of query processing, before distributed execution begins.

> **Note** The hidden system columns (`ctid`, `cmin`, `cmax`, `xmin`, `xmax`, and `gp_segment_id`) cannot be referenced in user queries on replicated tables because they have no single, unambiguous value. WarehousePG returns a `column does not exist` error for the query.

Declaring Distribution Keys

`CREATE TABLE`'s optional clauses `DISTRIBUTED BY`, `DISTRIBUTED RANDOMLY`, `DISTRIBUTED REPLICATED`, and `DISTRIBUTED COORDINATOR ONLY` specify the distribution policy for a table. The default is a hash distribution policy that uses either the `PRIMARY KEY` (if the table has one) or the first column of the table as the distribution key. Columns with geometric or user-defined data types are not eligible as WarehousePG distribution key columns. If a table does not have an eligible column, WarehousePG distributes the rows randomly.

Replicated tables have no distribution key because every row is distributed to every WarehousePG segment instance.

Coordinator-only tables have no distribution key because every row is on the coordinator only.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

To ensure even distribution of hash-distributed data, choose a distribution key that is unique for each record. If that is not possible, choose `DISTRIBUTED RANDOMLY`. For example:

```
=> CREATE TABLE products
`                        (name varchar(40),
                         prod_id integer,
                         supplier_id integer)
             DISTRIBUTED BY (prod_id);
`
```

```
=> CREATE TABLE random_stuff
`                        (things text,
                         doodads text,
                         etc text)
             DISTRIBUTED RANDOMLY;
`
```

> **Important** If a primary key exists, it is the default distribution key for the table. If no primary key exists, but a unique key exists, this is the default distribution key for the table.

Custom Distribution Key Hash Functions

The hash function used for hash distribution policy is defined by the hash operator class for the column's data type. As the default WarehousePG uses the data type's default hash operator class, the same operator class used for hash joins and hash aggregates, which is suitable for most use cases. However, you can declare a non-default hash operator class in the `DISTRIBUTED BY` clause.

Using a custom hash operator class can be useful to support co-located joins on a different operator than the default equality operator (`=`).

Example Custom Hash Operator Class

This example creates a custom hash operator class for the integer data type that is used to improve query performance. The operator class compares the absolute values of integers.

Create a function and an equality operator that returns true if the absolute values of two integers are equal.

```
CREATE FUNCTION abseq(int, int) RETURNS BOOL AS
$$
  begin return abs($1) = abs($2); end;
$$ LANGUAGE plpgsql STRICT IMMUTABLE;

CREATE OPERATOR |=| (
  PROCEDURE = abseq,
  LEFTARG = int,
  RIGHTARG = int,
  COMMUTATOR = |=|,
  hashes, merges);
```

Now, create a hash function and operator class that uses the operator.

```
CREATE FUNCTION abshashfunc(int) RETURNS int AS
$$
  begin return hashint4(abs($1)); end;
$$ LANGUAGE plpgsql STRICT IMMUTABLE;

CREATE OPERATOR CLASS abs_int_hash_ops FOR TYPE int4
  USING hash AS
  OPERATOR 1 |=|,
  FUNCTION 1 abshashfunc(int);
```

Also, create less than and greater than operators, and a btree operator class for them. We don't need them for our queries, but the Postgres-based planner will not consider co-location of joins without them.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
CREATE FUNCTION abslt(int, int) RETURNS BOOL AS
$$
  begin return abs($1) < abs($2); end;
$$ LANGUAGE plpgsql STRICT IMMUTABLE;

CREATE OPERATOR |<| (
  PROCEDURE = abslt,
  LEFTARG = int,
  RIGHTARG = int);

CREATE FUNCTION absgt(int, int) RETURNS BOOL AS
$$
  begin return abs($1) > abs($2); end;
$$ LANGUAGE plpgsql STRICT IMMUTABLE;

CREATE OPERATOR |>| (
  PROCEDURE = absgt,
  LEFTARG = int,
  RIGHTARG = int);

CREATE FUNCTION abscmp(int, int) RETURNS int AS
$$
  begin return btint4cmp(abs($1),abs($2)); end;
$$ LANGUAGE plpgsql STRICT IMMUTABLE;

CREATE OPERATOR CLASS abs_int_btree_ops FOR TYPE int4
  USING btree AS
  OPERATOR 1 |<|,
  OPERATOR 3 |=|,
  OPERATOR 5 |>|,
  FUNCTION 1 abscmp(int, int);
```

Now, you can use the custom hash operator class in tables.

```
CREATE TABLE atab (a int) DISTRIBUTED BY (a abs_int_hash_ops);
CREATE TABLE btab (b int) DISTRIBUTED BY (b abs_int_hash_ops);

INSERT INTO atab VALUES (-1), (0), (1);
INSERT INTO btab VALUES (-1), (0), (1), (2);
```

Queries that perform a join that use the custom equality operator `|=|` can take advantage of the co-location.

With the default integer opclass, this query requires Redistribute Motion nodes.

```
EXPLAIN (COSTS OFF) SELECT a, b FROM atab, btab WHERE a = b;
                           QUERY PLAN
-----------------------------------------------------------------
 Gather Motion 4:1  (slice3; segments: 4)
   ->  Hash Join
         Hash Cond: (atab.a = btab.b)
         ->  Redistribute Motion 4:4  (slice1; segments: 4)
               Hash Key: atab.a
               ->  Seq Scan on atab
         ->  Hash
               ->  Redistribute Motion 4:4  (slice2; segments: 4)
                     Hash Key: btab.b
                     ->  Seq Scan on btab
 Optimizer: Postgres-based planner
(11 rows)
```

With the custom opclass, a more efficient plan is possible.

```
EXPLAIN (COSTS OFF) SELECT a, b FROM atab, btab WHERE a |=| b;
                           QUERY PLAN
-----------------------------------------------------------------
  Gather Motion 4:1  (slice1; segments: 4)
   ->  Hash Join
         Hash Cond: (atab.a |=| btab.b)
         ->  Seq Scan on atab
         ->  Hash
               ->  Seq Scan on btab
 Optimizer: Postgres-based planner
(7 rows)
```

4.4.6 Choosing the Table Storage Model

WarehousePG supports several storage models and a mix of storage models. When you create a table, you choose how to store its data. This topic explains the options for table storage and how to choose the best storage model for your workload.

- Heap Storage
- Append-Optimized Storage
- Choosing Row or Column-Oriented Storage
- Using Compression (Append-Optimized Tables Only)
- Checking the Compression and Distribution of an Append-Optimized Table
- Altering a Table
- Dropping a Table

> **Note** To simplify the creation of database tables, you can specify the default values for some table storage options with the WarehousePG server configuration parameter `gp_default_storage_options`.

For information about the parameter, see "Server Configuration Parameters" in the *WarehousePG Reference Guide*.

Parent topic: DDL: Defining Database Objects

Heap Storage

By default, WarehousePG uses the same heap storage model as PostgreSQL. Heap table storage works best with OLTP-type workloads where the data is often modified after it is initially loaded. `UPDATE` and `DELETE` operations require storing row-level versioning information to ensure reliable database transaction processing. Heap tables are best suited for smaller tables, such as dimension tables, that are often updated after they are initially loaded.

Append-Optimized Storage

Append-optimized table storage works best with denormalized fact tables in a data warehouse environment. Denormalized fact tables are typically the largest tables in the system. Fact tables are usually loaded in batches and accessed by read-only queries. Moving large fact tables to an append-optimized storage model eliminates the storage overhead of the per-row update visibility information, saving about 20 bytes per row. This allows for a leaner and easier-to-optimize page structure. The storage model of append-optimized tables is optimized for bulk data loading. Single row `INSERT` statements are not recommended.

To create a heap table

Row-oriented heap tables are the default storage type.

```
=> CREATE TABLE foo (a int, b text) DISTRIBUTED BY (a);
```

Use the `WITH` clause of the `CREATE TABLE` command to declare the table storage options. The default is to create the table as a regular row-oriented heap-storage table. For example, to create an append-optimized table with no compression:

```
=> CREATE TABLE bar (a int, b text)
    WITH (appendoptimized=true)
    DISTRIBUTED BY (a);
```

> **Note** You use the `appendoptimized=value` syntax to specify the append-optimized table storage type. `appendoptimized` is a thin alias for the `appendonly` legacy storage option. WarehousePG stores `appendonly` in the catalog, and displays the same when listing storage options for append-optimized tables.

`UPDATE` and `DELETE` are not allowed on append-optimized tables in a repeatable read or serizalizable transaction and will cause the transaction to end prematurely `DECLARE...FOR UPDATE` and triggers are not supported with append-optimized tables. `CLUSTER` on append-optimized tables is only supported over B-tree indexes.

Choosing Row or Column-Oriented Storage

WarehousePG provides a choice of storage orientation models: row, column, or a combination of both. This topic provides general guidelines for choosing the optimum storage orientation for a table. Evaluate performance using your own data and query workloads.

- Row-oriented storage: good for OLTP types of workloads with many iterative transactions and many columns of a single row needed all at once, so retrieving is efficient.
- Column-oriented storage: good for data warehouse workloads with aggregations of data computed over a small number of columns, or for single columns that require regular updates without modifying other column data.

For most general purpose or mixed workloads, row-oriented storage offers the best combination of flexibility and performance. However, there are use cases where a column-oriented storage model provides more efficient I/O and storage. Consider the following requirements when deciding on the storage orientation model for a table:

- **Updates of table data.** If you load and update the table data frequently, choose a row-orientedheap table. Column-oriented table storage is only available on append-optimized tables.

  See Heap Storage for more information.

- **Frequent INSERTs.** If rows are frequently inserted into the table, consider a row-oriented model. Column-oriented tables are not optimized for write operations, as column values for a row must be written to different places on disk.

- **Number of columns requested in queries.** If you typically request all or the majority of columns in the `SELECT` list or `WHERE` clause of your queries, consider a row-oriented model. Column-oriented tables are best suited to queries that aggregate many values of a single column where the `WHERE` or `HAVING` predicate is also on the aggregate column. For example:

  ```
  SELECT SUM(salary)...
  ```

  ```
  SELECT AVG(salary)... WHERE salary > 10000
  ```

  Or where the `WHERE` predicate is on a single column and returns a relatively small number of rows. For example:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
SELECT salary, dept ... WHERE state='CA'
```

- **Number of columns in the table.** Row-oriented storage is more efficient when many columns are required at the same time, or when the row-size of a table is relatively small. Column-oriented tables can offer better query performance on tables with many columns where you access a small subset of columns in your queries.
- **Compression.** Column data has the same data type, so storage size optimizations are available in column-oriented data that are not available in row-oriented data. For example, many compression schemes use the similarity of adjacent data to compress. However, the greater adjacent compression achieved, the more difficult random access can become, as data must be uncompressed to be read.

To create a column-oriented table

The `WITH` clause of the `CREATE TABLE` command specifies the table's storage options. The default is a row-orientedheap table. Tables that use column-oriented storage must be append-optimized tables. For example, to create a column-oriented table:

```
=> CREATE TABLE bar (a int, b text)
    WITH (appendoptimized=true, orientation=column)
    DISTRIBUTED BY (a);
```

Using Compression (Append-Optimized Tables Only)

There are two types of in-database compression available in the WarehousePG for append-optimized tables:

- Table-level compression is applied to an entire table.
- Column-level compression is applied to a specific column. You can apply different column-level compression algorithms to different columns.

The following table summarizes the available compression algorithms.

Table Orientation	Available Compression Types	Supported Algorithms
Row	Table	`ZLIB` and `ZSTD`
Column	Column and Table	`RLE_TYPE`, `ZLIB`, and `ZSTD`

When choosing a compression type and level for append-optimized tables, consider these factors:

- CPU usage. Your segment systems must have the available CPU power to compress and uncompress the data.
- Compression ratio/disk size. Minimizing disk size is one factor, but also consider the time and CPU capacity required to compress and scan data. Find the optimal settings for efficiently compressing data without causing excessively long compression times or slow scan rates.
- Speed of compression. Higher compression levels can yield different compression ratios (always at the cost of speed). This varies by compression type: `ZLIB` versus `ZTSD`.
- Speed of decompression/scan rate. Performance with compressed append-optimized tables depends on hardware, query tuning settings, and other factors. Perform comparison testing to determine the actual performance in your environment.

> **Note** Do not create compressed append-optimized tables on file systems that use compression. If the file system on which your segment data directory resides is a compressed file system, your append-optimized table must not use compression.

Performance with compressed append-optimized tables depends on hardware, query tuning settings, and other factors. You should perform comparison testing to determine the actual performance in your environment.

> **Note** `ZTSD` compression level can be set to values between 1 and 19. Compression level with `ZLIB` can be set to values from 1 - 9. Compression level with `RLE` can be set to values from 1 - 4.

An `ENCODING` clause specifies compression type and level for individual columns. When an `ENCODING` clause conflicts with a `WITH` clause, the `ENCODING` clause has higher precedence than the `WITH` clause.

To create a compressed table

The `WITH` clause of the `CREATE TABLE` command declares the table storage options. Tables that use compression must be append-optimized tables. For example, to create an append-optimized table with zlib compression at a compression level of 5:

```
=> CREATE TABLE foo (a int, b text)
   WITH (appendoptimized=true, compresstype=zlib, compresslevel=5);
```

Checking the Compression and Distribution of an Append-Optimized Table

WarehousePG provides built-in functions to check the compression ratio and the distribution of an append-optimized table. The functions take either the object ID or a table name. You can qualify the table name with a schema name.

Table 2. Functions for compressed append-optimized table metadata

Function	Return Type	Description
get_ao_distribution(name) get_ao_distribution(oid)	Set of (dbid, tuplecount) rows	Shows the distribution of an append-optimized table's rows across the array. Returns a set of rows, each of which includes a segment *dbid* and the number of tuples stored on the segment.
get_ao_compression_ratio(name) get_ao_compression_ratio(oid)	float8	Calculates the compression ratio for a compressed append-optimized table. If information is not available, this function returns a value of -1.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

The compression ratio is returned as a common ratio. For example, a returned value of `3.19`, or `3.19:1`, means that the uncompressed table is slightly larger than three times the size of the compressed table.

The distribution of the table is returned as a set of rows that indicate how many tuples are stored on each segment. For example, in a system with four primary segments with*dbid* values ranging from 0 - 3, the function returns four rows similar to the following:

```
=# SELECT get_ao_distribution('lineitem_comp');
 get_ao_distribution
---------------------
(0,7500721)
(1,7501365)
(2,7499978)
(3,7497731)
(4 rows)
```

Support for Run-length Encoding

WarehousePG supports Run-length Encoding (RLE) for column-level compression. RLE data compression stores repeated data as a single data value and a count. For example, in a table with two columns, a date and a description, that contains 200,000 entries containing the value `date1` and 400,000 entries containing the value `date2`, RLE compression for the date field is similar to `date1 200000 date2 400000`. RLE is not useful with files that do not have large sets of repeated data as it can greatly increase the file size.

There are four levels of RLE compression available. The levels progressively increase the compression ratio, but decrease the compression speed.

WarehousePG versions 4.2.1 and later support column-oriented RLE compression. To back up a table with RLE compression that you intend to restore to an earlier version of WarehousePG, alter the table to have no compression or a compression type supported in the earlier version before you start the backup operation.

WarehousePG combines delta compression with RLE compression for data in columns of type `BIGINT`, `INTEGER`, `DATE`, `TIME`, or `TIMESTAMP`. The delta compression algorithm is based on the change between consecutive column values and is designed to improve compression when data is loaded in sorted order or when the compression is applied to data in sorted order.

Adding Column-level Compression

You can add the following storage parameters to a column for append-optimized tables with column orientation:

- Compression type
- Compression level
- Block size for a column

Add storage parameters using the `CREATE TABLE`, `ALTER TABLE`, and `CREATE TYPE` commands.

The following table details the types of storage parameters and possible values for each.

Table 3. Storage Parameters for Column-level Compression

Name	Definition	Values	Comment
`compresstype`	Type of compression.	`zstd:` Zstandard algorithm `zlib:` deflate algorithm `RLE_TYPE`: run-length encoding `none`: no compression	Values are not case-sensitive.
		`zlib` compression: `1` - `9`	`1` is the fastest method with the least compression. `1` is the default. `9` is the slowest method with the most compression.
		`zstd` compression: `1` - `19`	`1` is the fastest method with the least compression. `1` is the default. `19` is the slowest method with the most compression.
`compresslevel`	Compression level.		

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Name	Definition	Values	Comment		
		`RLE_TYPE` compression: `1` - `6` `1` - apply RLE only `2` - apply RLE then apply zlib compression level 1 `3` - apply RLE then apply zlib compression level 5 `4` - apply RLE then apply zlib compression level 9 `5` - apply RLE then apply zstd compression level 1 `6` - apply RLE then apply zstd compression level 3	`1` is the fastest method with the least compression. `1` is the default method. Within each compression sub-type (RLE with zlib or RLE with zstd), higher compression levels yield higher compression ratios at the cost of speed. Since zstd outperforms zlib in terms of compression ratios and speed, we highly recommend using levels 5 or above.		
		`blocksize`	The size in bytes for each block in the table	`8192 - 2097152`	The value must be a multiple of 8192.

The following is the format for adding storage parameters.

```
[ ENCODING ( <storage_parameter [,…] ) ]
```

where the word ENCODING is required and the storage parameter has three parts:

- The name of the parameter
- An equals sign
- The specification

Separate multiple storage parameters with a comma. Apply a storage parameter to a single column or designate it as the default for all columns, as shown in the following `CREATE TABLE` clauses.

General Usage:

```
<column_name> <data_type> ENCODING ( <storage_directive> [, … ] ), …
```

```
COLUMN <column_name> ENCODING ( <storage_directive> [, … ] ), …
```

```
DEFAULT COLUMN ENCODING ( <storage_directive> [, … ] )
```

Example:

```
C1 char ENCODING (compresstype=zstd, blocksize=65536)
```

```
COLUMN C1 ENCODING (compresstype=zlib, compresslevel=6, blocksize=65536)
```

```
DEFAULT COLUMN ENCODING (compresstype=zlib)
```

Default Compression Values

If the compression type, compression level and block size are not defined, the default is no compression, and the block size is set to the Server Configuration Parameter `block_size`.

Precedence of Compression Settings

Column compression settings are inherited from the type level to the table level to the partition level to the sub-partition level. The lowest-level settings have priority.

- Column compression settings defined at the table level override any compression settings for the type.
- Column compression settings specified at the table level override any compression settings for the entire table.
- Column compression settings specified for partitions override any compression settings at the column or table levels.
- Column compression settings specified for sub-partitions override any compression settings at the partition, column or table levels.
- When an `ENCODING` clause conflicts with a `WITH` clause, the `ENCODING` clause has higher precedence than the `WITH` clause.

> **Note** The `INHERITS` clause is not allowed in a table that contains a storage parameter or a column reference storage parameter.

Tables created using the `LIKE` clause ignore storage parameter and column reference storage parameters.

Optimal Location for Column Compression Settings

The best practice is to set the column compression settings at the level where the data resides. See Example 5, which shows a table with a partition depth of 2. `RLE_TYPE` compression is added to a column at the sub-partition level.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Storage Parameters Examples

The following examples show the use of storage parameters in `CREATE TABLE` statements.

Example 1

In this example, column `c1` is compressed using `zstd` and uses the block size defined by the system. Column `c2` is compressed with `zlib`, and uses a block size of `65536`. Column `c3` is not compressed and uses the block size defined by the system.

```
CREATE TABLE T1 (c1 int ENCODING (compresstype=zstd),
                 c2 char ENCODING (compresstype=zlib, blocksize=65536),
                 c3 char)    WITH (appendoptimized=true, orientation=column);
```

Example 2

In this example, column `c1` is compressed using `zlib` and uses the block size defined by the system. Column `c2` is compressed with `zstd`, and uses a block size of `65536`. Column `c3` is compressed using `RLE_TYPE` and uses the block size defined by the system.

```
CREATE TABLE T2 (c1 int ENCODING (compresstype=zlib),
                 c2 char ENCODING (compresstype=zstd, blocksize=65536),
                 c3 char,
                 COLUMN c3 ENCODING (compresstype=RLE_TYPE)
                 )
    WITH (appendoptimized=true, orientation=column);
```

Example 3

In this example, column `c1` is compressed using `zlib` and uses the block size defined by the system. Column `c2` is compressed with `zstd`, and uses a block size of `65536`. Column `c3` is compressed using `zlib` and uses the block size defined by the system. Note that column `c3` uses `zlib` (not `RLE_TYPE`) in the partitions, because the column storage in the partition clause has precedence over the storage parameter in the column definition for the table.

```
CREATE TABLE T3 (c1 int ENCODING (compresstype=zlib),
                 c2 char ENCODING (compresstype=zstd, blocksize=65536),
                 c3 text, COLUMN c3 ENCODING (compresstype=RLE_TYPE) )
    WITH (appendoptimized=true, orientation=column)
    PARTITION BY RANGE (c3) (START ('1900-01-01'::DATE)
                             END ('2100-12-31'::DATE),
                             COLUMN c3 ENCODING (compresstype=zlib));
```

Example 4

In this example, `CREATE TABLE` assigns the `zlib` `compresstype` storage parameter to `c1`. Column `c2` has no storage parameter and inherits the compression type (`zstd`) and block size (`65536`) from the `DEFAULT COLUMN ENCODING` clause.

Column `c3`'s `ENCODING` clause defines its compression type, `RLE_TYPE`. The `ENCODING` clause defined for a specific column overrides the `DEFAULT ENCODING` clause, so column `c3` uses the default block size, `32768`.

Column `c4` has a compress type of `none` and uses the default block size.

```
CREATE TABLE T4 (c1 int ENCODING (compresstype=zlib),
                 c2 char,
                 c3 text,
                 c4 smallint ENCODING (compresstype=none),
                 DEFAULT COLUMN ENCODING (compresstype=zstd,
                                          blocksize=65536),
                 COLUMN c3 ENCODING (compresstype=RLE_TYPE)
                 )
   WITH (appendoptimized=true, orientation=column);
```

Example 5

This example creates an append-optimized, column-oriented table, T5. T5 has two partitions, `p1` and `p2`, each of which has sub-partitions. Each sub-partition has `ENCODING` clauses:

- The `ENCODING` clause for partition `p1`'s sub-partition `sp1` defines column `i`'s compression type as `zlib` and block size as 65536.
- The `ENCODING` clauses for partition `p2`'s sub-partition `sp1` defines column `i`'s compression type as `rle_type` and block size is the default value. Column `k` uses the default compression and its block size is 8192.

```
CREATE TABLE T5(i int, j int, k int, l int)
    WITH (appendoptimized=true, orientation=column)
    PARTITION BY range(i) SUBPARTITION BY range(j)
    (
       partition p1 start(1) end(2)
       ( subpartition sp1 start(1) end(2)
         column i encoding(compresstype=zlib, blocksize=65536)
       ),
       partition p2 start(2) end(3)
       ( subpartition sp1 start(1) end(2)
           column i encoding(compresstype=rle_type)
           column k encoding(blocksize=8192)
       )
    );
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

For an example showing how to add a compressed column to an existing table with the `ALTER TABLE` command, see Adding a Compressed Column to Table.

Adding Compression in a TYPE Command

When you create a new type, you can define default compression attributes for the type. For example, the following `CREATE TYPE` command defines a type named `int33` that specifies `zlib` compression.

First, you must define the input and output functions for the new type, `int33_in` and `int33_out`:

```
CREATE FUNCTION int33_in(cstring) RETURNS int33
  STRICT IMMUTABLE LANGUAGE internal AS 'int4in';
CREATE FUNCTION int33_out(int33) RETURNS cstring
  STRICT IMMUTABLE LANGUAGE internal AS 'int4out';
```

Next, you define the type named `int33`:

```
CREATE TYPE int33 (
   internallength = 4,
   input = int33_in,
   output = int33_out,
   alignment = int4,
   default = 123,
   passedbyvalue,
   compresstype="zlib",
   blocksize=65536,
   compresslevel=1
   );
```

When you specify `int33` as a column type in a `CREATE TABLE` command, the column is created with the storage parameters you specified for the type:

```
CREATE TABLE t2 (c1 int33)
    WITH (appendoptimized=true, orientation=column);
```

Table- or column- level storage attributes that you specify in a table definition override type-level storage attributes. For information about creating and adding compression attributes to a type, seeCREATE TYPE. For information about changing compression specifications in a type, see ALTER TYPE.

Choosing Block Size

The blocksize is the size, in bytes, for each block in a table. Block sizes must be between 8192 and 2097152 bytes, and be a multiple of 8192. The default is 32768.

Specifying large block sizes can consume large amounts of memory. Block size determines buffering in the storage layer. WarehousePG maintains a buffer per partition, and per column in column-oriented tables. Tables with many partitions or columns consume large amounts of memory.

Altering a Table

The `ALTER TABLE` command changes the definition of a table. Use `ALTER TABLE` to change table attributes such as column definitions, distribution policy, access method, storage parameters, and partition structure (see also Partitioning Large Tables). For example, to add a not-null constraint to a table column:

```
=> ALTER TABLE address ALTER COLUMN street SET NOT NULL;
```

Altering Table Distribution

`ALTER TABLE` provides options to change a table's distribution policy. When the table distribution options change, the table data may be redistributed on disk, which can be resource intensive. You can also redistribute table data using the existing distribution policy.

Changing the Distribution Policy

For partitioned tables, changes to the distribution policy apply recursively to the child partitions. This operation preserves the ownership and all other attributes of the table. For example, the following command redistributes the table sales across all segments using the customer_id column as the distribution key:

```
ALTER TABLE sales SET DISTRIBUTED BY (customer_id);
```

When you change the hash distribution of a table, table data is automatically redistributed. Changing the distribution policy to a random distribution does not cause the data to be redistributed. For example, the following `ALTER TABLE` command has no immediate effect:

```
ALTER TABLE sales SET DISTRIBUTED RANDOMLY;
```

Changing the distribution policy of a table to `DISTRIBUTED REPLICATED` or from `DISTRIBUTED REPLICATED` automatically redistributes the table data.

Redistributing Table Data

To redistribute table data for tables with a random distribution policy (or when the hash distribution policy has not changed) use `REORGANIZE=TRUE`. Reorganizing data may be necessary to correct a data skew problem, or when segment resources are added to the system. For example, the following command redistributes table data across all segments using the current distribution policy, including random distribution.

```
ALTER TABLE sales SET WITH (REORGANIZE=TRUE);
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Changing the distribution policy of a table to `DISTRIBUTED REPLICATED` or from `DISTRIBUTED REPLICATED` always redistributes the table data, even when you use `REORGANIZE=FALSE`.

Altering the Table Access Method

You may alter the method for accessing a table using the `SET ACCESS METHOD` clause. Set to `heap` to alter the table to be a heap-storage table, `ao_row` to alter the table to be append-optimized with row-oriented storage (AO), or `ao_column` to alter the table to be append-optimized with column-oriented storage (AOCO).

> **Note: Note:** Although you can specify the table's access method using `SET <storage_parameter>` or `SET WITH<storage_parameter>`, WarehousePG recommends that you use `SET ACCESS METHOD <access_method>` instead.

Altering the Table Storage Model

You may dynamically update a table's storage model -- including whether the table is heap, AO or AOCO; the table's compression and blocksize settings; and the table's fillfactor; -- by setting a variety of storage parameters when you invoke `ALTER TABLE` with the `SET <storage_parameter>` clause. This is true for both regular tables and partitioned tables.

Inheritance Rules for Altering a Partitioned Table's Storage Model

The following inheritance rules apply to the storage model of a partitioned table:

- Altering the storage model at the partition root changes the storage model for all existing children and all future children.
- Altering the storage model at the partition root with the `ONLY` keyword changes the storage model only for all future children.
- Altering the storage model at a leaf changes the storage model only for that leaf.

Adding a Compressed Column to Table

Use `ALTER TABLE` command to add a compressed column to a table. All of the options and constraints for compressed columns described in Adding Column-level Compression apply to columns added with the `ALTER TABLE` command.

The following example shows how to add a column with `zlib` compression to a table, `T1`.

```
ALTER TABLE T1
      ADD COLUMN c4 int DEFAULT 0
      ENCODING (compresstype=zlib);
```

Inheritance of Compression Settings

A partition added to a table that has sub-partitions defined with compression settings inherits the compression settings from the sub-partition. The following example shows how to create a table with sub-partition encodings, then alter it to add a partition.

```
CREATE TABLE ccddl (i int, j int, k int, l int)
  WITH
    (appendoptimized = TRUE, orientation=COLUMN)
  PARTITION BY range(j)
  SUBPARTITION BY list (k)
  SUBPARTITION template(
    SUBPARTITION sp1 values(1, 2, 3, 4, 5),
    COLUMN i ENCODING(compresstype=ZLIB),
    COLUMN j ENCODING(compresstype=ZLIB),
    COLUMN k ENCODING(compresstype=ZLIB),
    COLUMN l ENCODING(compresstype=ZLIB))
  (PARTITION p1 START(1) END(10),
   PARTITION p2 START(10) END(20))
;

ALTER TABLE ccddl
  ADD PARTITION p3 START(20) END(30)
;
```

Running the `ALTER TABLE` command creates partitions of table `ccddl` named `ccddl_1_prt_p3` and `ccddl_1_prt_p3_2_prt_sp1`. Partition `ccddl_1_prt_p3` inherits the different compression encodings of sub-partition `sp1`.

Dropping a Table

The `DROP TABLE` command removes tables from the database. For example:

```
DROP TABLE mytable;
```

To empty a table of rows without removing the table definition, use `DELETE` or `TRUNCATE`. For example:

```
DELETE FROM mytable;

TRUNCATE mytable;
```

`DROP TABLE` always removes any indexes, rules, triggers, and constraints that exist for the target table. Specify `CASCADE` to drop a table that is referenced by a view. `CASCADE` removes dependent views.

4.4.7 Partitioning Large Tables

Table partitioning in WarehousePG enables you to logically divide large tables, such as fact tables, into smaller, more manageable pieces. Partitioning tables can improve query performance when it allows the WarehousePG query optimizer to scan only the data needed to satisfy a given query instead of scanning the complete contents of a large table.

Partitioning does not change the physical distribution of table data across the segments. Table distribution is physical: WarehousePG physically divides partitioned tables and non-partitioned tables across segments to enable parallel query processing. Table *partitioning* is logical: WarehousePG logically divides big tables to improve query performance and facilitate data warehouse maintenance tasks, such as rolling old data out of the data warehouse.

Parent topic: DDL: Defining Database Objects

Why Table Partitioning?

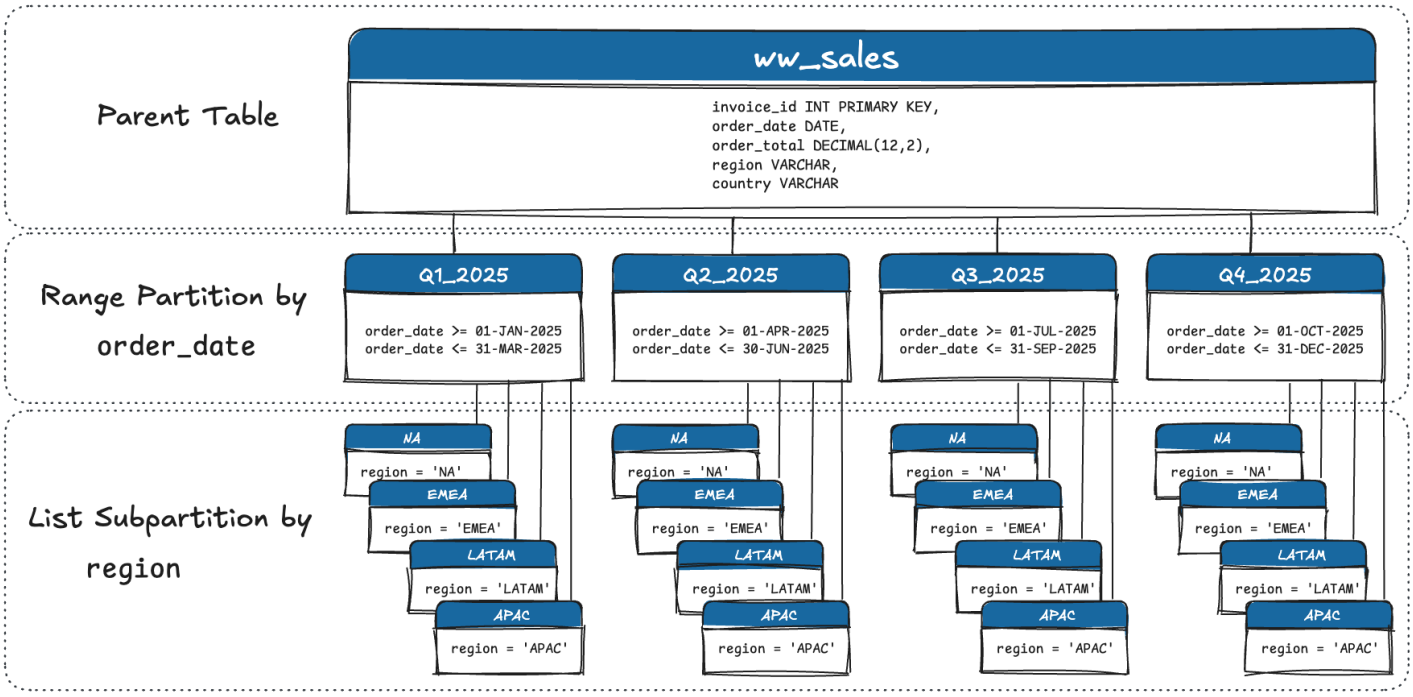
Partitioning can provide several benefits:

- Dramatically improves query performance in certain situations, particularly when most of the heavily accessed rows of the table are in a single partition or a small number of partitions. Partitioning effectively substitutes for the upper tree levels of indexes, making it more likely that the heavily-used parts of the indexes fit in memory.
- When queries or updates access a large percentage of a single partition, you can improve performance by using a sequential scan of that partition instead of using an index, which would require random-access reads scattered across the whole table.
- When the partitioning design accounts for the usage pattern, you can perform bulk loads and deletes by adding or removing partitions. Dropping an individual partition using `DROP TABLE`, or doing `ALTER TABLE DETACH PARTITION`, is far faster than a bulk operation. These commands also entirely prevent the `VACUUM` overhead caused by a bulk `DELETE`.
- You can migrate seldom-used data to cheaper and slower storage media.

These benefits will normally be worthwhile only when a table would otherwise be very large. The exact point at which a table will benefit from partitioning depends on the application, although a rule of thumb is that the size of the table should exceed the physical memory of the database server.

About the Table Partitioning Methods

WarehousePG supports the following forms of table partitioning:



Range Partitioning The table is partitioned into "ranges" defined by a key column or set of columns, with no overlap between the ranges of values assigned to different partitions. For example, one might partition by date ranges, or by ranges of identifiers for particular business objects. Each range's bounds are understood as being inclusive at the lower end and exclusive at the upper end. For example, if one partition's range is from `1` to `10`, and the next one's range is from `10` to `20`, the value `10` belongs to the second partition not the first.

List Partitioning The table is partitioned by explicitly listing which key value(s) appear in each partition, for example sales territory or product line.

Hash Partitioning The table is partitioned by specifying a modulus and a remainder for each partition. Each partition holds the rows for which the hash value of the partition key divided by the specified modulus produces the specified remainder.

The following figure illustrates a multi-level partition design utilizing both date-range and list partitioning.

Multi-Level Partitioning

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

About Table Partitioning in WarehousePG

WarehousePG allows you to declare that a table is divided into partitions. The table that is divided is a *partitioned table*. The declaration includes the *partitioning method* as described above, plus a list of columns or expressions to be used as the *partition key*.

The partitioned table itself is a "virtual" table having no storage of its own. Instead, the storage belongs to partitions, which are otherwise ordinary tables associated with the partitioned table. Each partition stores a subset of the data as defined by its *partition bounds*. WarehousePG routes all rows inserted into a partitioned table to the appropriate partitions based on the values of the partition key column(s). WarehousePG will move a row to a different partition if you update the partition key and the key no longer satisfies the partition bounds of its original partition.

You initially partition tables during creation by specifying the `PARTITION BY` or `PARTITION OF` clause to the CREATE TABLE command. When you created a partitioned table, you create a top-level *root partitioned table* with one or more levels of *child* tables. The table at the level immediately above a child table is the *parent*. A table at the highest level in a partition hierarchy is a *leaf partition*. A leaf partition has no child tables, and leaf partitions in the same partition hierarchy may reside at different depths.

WarehousePG uses the partition criteria (boundaries) defined during table creation to create each partition with a distinct partition constraint, which limits the data that table can contain. The query optimizers use partition constraints to determine which table partitions to scan to satisfy a given query predicate.

A partition itself may be defined as a partitioned table, resulting in sub-partitioning. Although all partitions must have the same columns as their partitioned parent, partitions may have their own indexes, constraints, and default values, distinct from those of other partitions. Refer to the CREATE TABLE command reference for more details on creating partitioned tables and partitions.

Each partition's definition must specify bounds that correspond to the partitioning method and partition key of the parent. WarehousePG returns an error if the bounds of a new partition's values overlap with those in one or more existing partitions. Partitions are in every way normal WarehousePG tables (or, possibly, external or foreign tables). You can specify a tablespace and storage parameters for each partition separately.

Because partitions themselves are independent tables, if a table that is part of a partition hierarchy itself is writable, you can write to it through its parent also, as long as granted the correct permission.

You cannot turn a regular table into a partitioned table or vice-versa. However, it is possible to add an existing regular or partitioned table as a partition of a partitioned table, or to remove a partition from a partitioned table turning it into a standalone table; these operations can simplify and speed up many maintenance processes. Refer to the ALTER TABLE command reference to learn more about the syntax for these operations.

While a partition can also be an external table or foreign table, take extra care because it becomes your responsibility to ensure that the contents of the table satisfy the partitioning rule. There are other restrictions for foreign tables as well; refer to the CREATE FOREIGN TABLE command reference for more information.

Deciding on a Table Partitioning Strategy

Not all hash-distributed or randomly distributed tables are good candidates for partitioning. If the answer is **yes** to all or most of the following questions, table partitioning is a viable database design strategy for improving query performance. If the answer is **no** to most of the following questions, table partitioning is not the right solution for that table. Always test your design strategy to ensure that query performance improves as expected.

- **Is the table large enough?** Large fact tables are good candidates for table partitioning. If you have millions or billions of records in a table, you may see performance benefits from logically breaking that data up into smaller chunks. For smaller tables with only a few thousand rows or less, the administrative overhead of maintaining the partitions may outweigh any performance benefits that you might see.
- **Are you experiencing unsatisfactory performance?** As with any performance tuning initiative, a table should be partitioned only if queries against that table are producing slower response times than desired.
- **Do your query predicates have identifiable access patterns?** Examine the `WHERE` clauses of your query workload and look for table columns that are consistently used to access data. For example, if most of your queries tend to look up records by date, then a monthly or weekly date-partitioning design might be beneficial. Or if you tend to access records by region, consider a list-partitioning design to divide the table by region.
- **Does your data warehouse maintain a window of historical data?** Another consideration for partition design is your organization's business requirements for maintaining historical data. For example, your data warehouse may require that you keep data for the past twelve months. If the data is partitioned by month, you can easily drop the oldest monthly partition from the warehouse and load current data into the most recent monthly partition.
- **Can the data be divided into somewhat equal parts based on some defining criteria?** Choose partitioning criteria that will divide your data as evenly as possible. If the partitions contain a relatively equal number of records, query performance improves based on the number of partitions created. For example, by dividing a large table into 10 partitions, a query will run 10 times faster than it would against the unpartitioned table, provided that the partitions are designed to support the query's criteria.

Do not create more partitions than are needed. Creating too many partitions can slow down management and maintenance jobs, such as vacuuming, recovering segments, expanding the cluster, checking disk usage, and others.

Partitioning does not improve query performance unless the query optimizer can eliminate partitions based on the query predicates. Queries that scan every partition run slower than if the table were not partitioned, so avoid partitioning if few of your queries achieve partition elimination. Check the explain plan for queries to make sure that partitions are eliminated. See Query Profiling for more about partition elimination.

> **Caution** Be very careful with multi-level partitioning, as the number of partition files can grow very quickly. For example, if a table is partitioned by both day and city, and there are 1,000 days of data and 1,000 cities, the total number of partitions is one million. Column-oriented tables store each column in a physical table, so if this table has 100 columns, the system would be required to manage 100 million files for the table, for each segment.

Before settling on a multi-level partitioning strategy, consider a single level partition with bitmap indexes. Indexes slow down data loads, so performance testing with your data and schema is recommended to decide on the best strategy.

Choosing the Partitioning Syntax

WarehousePG 7 retains most aspects of the partitioning syntax of prior versions of WarehousePG, referred to as the *classic* syntax. Version 7 also introduces support for a *modern* syntax, derived from the PostgreSQL declarative partitioning syntax.

The classic syntax is provided for backwards compatibility with previous WarehousePG versions. It is appropriate for a homogenous partitioned table, where all partitions are at the same leaf level and have the same partition rule.

> **Note** The modern syntax is less specialized and easier to use, and is recommended for new users and new partitioned table definitions.

The classic and modern partitioning syntaxes are alternatives, you choose the one that meets your needs.

If you are familiar with the WarehousePG 6 partitioning syntax or already have partitioned tables that were defined using this syntax, you may choose to continue using the classic syntax. (Refer to About Changes to Table Partitioning in WarehousePG 7 for more information about partitioning syntax and behavior changes introduced in version 7.)

The following table provides a feature comparison to help you choose the syntax most appropriate for your data model:

Feature	Classic Syntax	Modern Syntax
Heterogeneous partition hierarchy	Not supported. All leaf partitions are at the same level.	Supported. Leaf partitions are permitted at different levels. You can specify different partitioning rules for individual child tables, including different partition columns and different partitioning strategies.
Expressions in partition key	Not supported.	Supported.
Multi-column range partitioning	Not supported.	Supported.
Multi-column list partitioning	Supported (via composite type).	Not supported.
Hash partitioning	Not supported.	Supported.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Feature	Classic Syntax	Modern Syntax
Adding a Partition	Adding a partition acquires an `ACCESS EXCLUSIVE` lock on the parent table.	Attaching a partition acquires a less restrictive `SHARE UPDATE EXCLUSIVE` lock on the parent table.
Removing a Partition	Dropping a partition deletes the table contents. Must create a dummy table and swap.	Supported. Can directly detach a partition, retaining the table contents.
Sub-partition templating	Supported. The definitions of the parent and child tables are consistent by default.	Not supported. You ensure that the table definitions are consistent.
Partition maintenance	You operate on a child table via the parent, requiring knowledge of the partition hierarchy.	You operate directly on the child table, no knowledge of the partition hierarchy is required.

> **Important** After creation, operate on the partition hierarchy using the `CREATE TABLE` and `ALTER TABLE` clauses identified for the syntax that you chose. WarehousePG does not recommend mixing and matching the classic and modern partitioning syntaxes for partition maintenance operations.

Creating a Partitioned Table

You partition a table when you create it with the CREATE TABLE command. Before you create the table, you should:

1. Choose the partition method: date range, numeric range, list of values, hash.
2. Choose the column(s) on which to partition the table.
3. Determine the appropriate number of partitions and partition levels. For example, you may choose to create a table that is date-range partitioned by month, and then sub-partition the monthly partitions by sales region.
4. Create the partitioned table.
5. Create the partitions.

You are not required to manually create table constraints describing the partition boundary conditions for partitions, WarehousePG creates such constraints automatically.

After you create a partition, WarehousePG directs to the partition any data inserted into the root partitioned table that matches this partition's partition constraints. The partition key specified may overlap with the parent's partition key, although take care when specifying the bounds of a sub-partition such that the set of data it accepts constitutes a subset of what the partition's own bounds allow; WarehousePG does not check whether that's really the case.

You can use the same partition key column to create sub-partitions if necessary, for example, to partition by month and then sub-partition by day. Consider partitioning by the most granular level. For example, for a table partitioned by date, you can partition by day and have 365 daily partitions, rather than partition by year then sub-partition by month then sub-partition by day. A multi-level design can reduce query planning time, but a flat partition design typically runs faster.

> **Important** The examples in the next section use the modern partitioning syntax. Refer to Examples Using the Classic Partitioning Syntax for information about the classic partitioning syntax and parallel examples.

Creating Partitioned Tables with the Modern Syntax

The following subsections provide modern syntax examples for creating tables with various partition designs.

Defining a Date-Range Partitioned Table

A date-range partitioned table uses a `date` or `timestamp` column as the partition key column.

> **Note** The modern partitioning syntax supports specifying multiple partition key columns for range partitioned tables.

Example Requirements: In this example, you construct a database for a large ice cream company. The company measures peak temperatures every day as well as ice cream sales in each region. The main use of the table is to prepare online reports for management, so most queries will access just the last week's, month's, or quarter's data. To reduce the amount of old data that needs to be stored, retain only the most recent 2 years worth of data. At the beginning of each month, remove the oldest month's data.

Create a range-partitioned table named `measurement` that is partitioned on a `logdate` column:

```
CREATE TABLE measurement (
    city_id         int not null,
    logdate         date not null,
    peaktemp        int,
    unitsales       int )
DISTRIBUTED BY (city_id)
PARTITION BY RANGE (logdate);
```

Create partitions. Each partition should hold one month's worth of data, to match the requirement of deleting one month's data at a time.

```
CREATE TABLE measurement_y2021m01 PARTITION OF measurement
  FOR VALUES FROM ('2021-01-01') TO ('2021-02-01');

CREATE TABLE measurement_y2021m02 PARTITION OF measurement
  FOR VALUES FROM ('2021-02-01') TO ('2021-03-01');

CREATE TABLE measurement_y2021m03 PARTITION OF measurement
  FOR VALUES FROM ('2021-03-01') TO ('2021-04-01');

...

CREATE TABLE measurement_y2021m11 PARTITION OF measurement
  FOR VALUES FROM ('2021-11-01') TO ('2021-12-01');

CREATE TABLE measurement_y2022m12 PARTITION OF measurement
  FOR VALUES FROM ('2022-12-01') TO ('2022-01-01')
  TABLESPACE fasttablespace;

CREATE TABLE measurement_y2023m01 PARTITION OF measurement
  FOR VALUES FROM ('2023-01-01') TO ('2023-02-01')
  WITH (parallel_workers = 4)
  TABLESPACE fasttablespace;
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Recall that adjacent partitions can share a bound value, since WarehousePG treats range upper bounds as exclusive bounds.

Any data inserted into `measurement` is redirected to the appropriate partition based on the `logdate` column. WarehousePG returns an error when data is inserted into the parent table that does not map to one of the existing partitions.

In this example scenario, a new partition will be created each month. You might write a script that generates the required DDL automatically.

Defining a Numeric-Range Partitioned Table

A numeric-range partitioned table uses a numeric-type column as the partition key column. The modern syntax supports specifying multiple partition key columns for range partitioned tables.

For example, create a numeric-range partitioned table named `numpart` that is partitioned on a `year` column:

```
CREATE TABLE numpart (id int, rank int, year int, color char(1), count int)
  DISTRIBUTED BY (id)
  PARTITION BY RANGE (year);
```

Create the partitions for four years of data:

```
CREATE TABLE numpart_y2019 PARTITION OF numpart FOR VALUES FROM (2019) TO (2020);
CREATE TABLE numpart_y2020 PARTITION OF numpart FOR VALUES FROM (2020) TO (2021);
CREATE TABLE numpart_y2021 PARTITION OF numpart FOR VALUES FROM (2021) TO (2022);
CREATE TABLE numpart_y2022 PARTITION OF numpart FOR VALUES FROM (2022) TO (2023);
```

Defining a List Partitioned Table

A list partitioned table can use any data type column that allows equality comparisons as its partition key column.

> **Note** The modern syntax allows only a single column as the partition key for a list partition.

You must declare a partition specification for every list value that you create.

The following example creates a partitioned table named `listpart` that is list-partitioned on a `color` column:

```
CREATE TABLE listpart (id int, rank int, year int, color char(1), count int)
  DISTRIBUTED BY (id)
  PARTITION BY LIST (color);
```

Create the partitions:

```
CREATE TABLE listpart_red PARTITION OF listpart FOR VALUES IN ('r');
CREATE TABLE listpart_green PARTITION OF listpart FOR VALUES IN ('g');
CREATE TABLE listpart_blue PARTITION OF listpart FOR VALUES IN ('b');
CREATE TABLE listpart_other PARTITION OF listpart DEFAULT;
```

Note that the `listpart_other` table is created with the `DEFAULT` keyword. This identifies the table as the default partition; WarehousePG routes any data that falls outside of the boundaries of all partitions to this table. See Adding a Default Partition for more information.

Defining a Hash Partitioned Table

> **Note** You can create a hash partitioned table only with the modern partitioning syntax.

A hash partitioned table uses a single hashable column as its partition key column. For hash partitions, you must declare a partition specification for every partition (modulus/remainder combination) that you want to create.

For example, create a table named `hpt` that is partitioned by the hash of the `text` column `c`:

```
CREATE TABLE hpt (a int, b int, c text) PARTITION BY HASH(c);
```

Create the partitions:

```
CREATE TABLE hpt_p1 PARTITION OF hpt FOR VALUES WITH (MODULUS 3, REMAINDER 0);
CREATE TABLE hpt_p2 PARTITION OF hpt FOR VALUES WITH (MODULUS 3, REMAINDER 1);
CREATE TABLE hpt_p3 PARTITION OF hpt FOR VALUES WITH (MODULUS 3, REMAINDER 2);
```

Insert some data into the partitioned table, and then display the number of rows in each partition:

```
INSERT INTO hpt SELECT i, i, to_char(i/50, 'FM0000') FROM generate_series(0, 599, 2) i;
SELECT 'hpt_p1' AS partition, count(*) AS row_count FROM hpt_p1
  UNION ALL SELECT 'hpt_p2', count(*) FROM hpt_p2
  UNION ALL SELECT 'hpt_p3', count(*) FROM hpt_p3;
```

Defining a Multi-level Partitioned Table

You can create a multi-level partition hierarchy by sub-partitioning partitions.

The following modern syntax commands create a two-level partition design similar to that shown in the figure at the beginning of this topic.

Create a table named `msales` that is partitioned by year:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
CREATE TABLE msales (trans_id int, year int, amount decimal(9,2), region text)
  DISTRIBUTED BY (trans_id)
  PARTITION BY RANGE (year);
```

Create the yearly partitions, which are themselves partitioned by region:

```
CREATE TABLE msales_2021 PARTITION OF msales FOR VALUES FROM (2021) TO (2022)
  PARTITION BY LIST (region);
CREATE TABLE msales_2022 PARTITION OF msales FOR VALUES FROM (2022) TO (2023)
  PARTITION BY LIST (region);
CREATE TABLE msales_2023 PARTITION OF msales FOR VALUES FROM (2023) TO (2024)
  PARTITION BY LIST (region);
```

Create the region partitions:

```
CREATE TABLE msales_2021_usa PARTITION OF msales_2021 FOR VALUES IN ('usa');
CREATE TABLE msales_2021_asia PARTITION OF msales_2021 FOR VALUES IN ('asia');
CREATE TABLE msales_2021_europe PARTITION OF msales_2021 FOR VALUES IN ('europe');
CREATE TABLE msales_2022_usa PARTITION OF msales_2022 FOR VALUES IN ('usa');
CREATE TABLE msales_2022_asia PARTITION OF msales_2022 FOR VALUES IN ('asia');
CREATE TABLE msales_2022_europe PARTITION OF msales_2022 FOR VALUES IN ('europe');
CREATE TABLE msales_2023_usa PARTITION OF msales_2023 FOR VALUES IN ('usa');
CREATE TABLE msales_2023_asia PARTITION OF msales_2023 FOR VALUES IN ('asia');
CREATE TABLE msales_2023_europe PARTITION OF msales_2023 FOR VALUES IN ('europe');
```

Partitioning an Existing Table

Tables can be partitioned only at creation. If you have an existing table that you want to partition, you must create a partitioned table, load the data from the original table to the new table, drop the original table, and rename the new table to the original table name. You must also re-grant any table permissions.

For example:

```
CREATE TABLE msales2 (LIKE msales) PARTITION BY RANGE (year);
-- create the partitions
INSERT INTO msales2 SELECT * FROM msales;
DROP TABLE msales;
ALTER TABLE msales2 RENAME TO msales;
GRANT ALL PRIVILEGES ON msales TO admin;
GRANT SELECT ON msales TO guest;
```

> **Note** The `LIKE` clause does not copy over partition structures when you use it to create a new table.

Loading Data into a Partitioned Table

After you create the partitioned table structure, the top-level root partitioned table is empty. When you insert data into the root, WarehousePG routes the data to the bottom-level leaf partitions. In a multi-level partition design, only the leaf partitions at the bottom-most levels of the hierarchy will contain data.

WarehousePG rejects rows that cannot be mapped to a leaf partition, and the load fails. To avoid rejection of unmapped rows at load time, define your partition hierarchy with a `DEFAULT` partition. Any rows that do not match the partition constraint of all partitions load into the `DEFAULT` partition. Refer to Adding a Default Partition for more information.

At runtime, the query optimizer scans the entire partition hierarchy and uses the partition constraints to determine which of the child partitions to scan to satisfy the query's conditions. Because WarehousePG always scans the `DEFAULT` partition (if your hierarchy has one), `DEFAULT` partitions that contain data can slow down the overall scan time.

When you use `COPY` or `INSERT` to load data into a parent table, WarehousePG automatically routes the data to the correct leaf partition, just as it does with a regular table.

A best practice for loading data into partitioned tables is to create an intermediate staging table, load it, and then attach it into your partition hierarchy. See Adding a Partition.

Verifying the Partition Strategy

When a table is partitioned based on the query predicate, you can use EXPLAIN to verify that the query optimizer scans only the relevant data to examine the query plan.

For example, suppose a table named `msales` is year-range partitioned and sub-partitioned by `region`. For the following query:

```
EXPLAIN SELECT * FROM msales WHERE year='2021' AND region='usa';
```

The query plan for this query should show a table scan of only the following tables:

- the default partition returning 0-1 rows (if your partition design has one)
- the 2021 partition (`msales_2021`) returning 0-1 rows
- the USA region sub-partition (`msales_2021_usa`) returning *some number* of rows.

The following example shows the relevant portion of the query plan.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
                                QUERY PLAN
------------------------------------------------------------------------------
 Gather Motion 3:1  (slice1; segments: 3)  (cost=0.00..228.52 rows=1 width=54)
   ->  Seq Scan on msales_2021_usa  (cost=0.00..228.50 rows=1 width=54)
         Filter: ((year = 2021) AND (region = 'usa'::text))
 Optimizer: Postgres-based planner
(4 rows)
```

Ensure that the query optimizer does not scan unnecessary partitions or sub-partitions (for example, scans of months or regions not specified in the query predicate), and that scans of the top-level tables return 0-1 rows.

Troubleshooting Selective Partition Scanning

The following limitations can result in a query plan that shows a non-selective scan of your partition hierarchy.

- The query optimizer can selectively scan partitioned tables only when the query contains a direct and simple restriction of the table using immutable operators such as: `=`, `<`, `<=`, `>`, `>=`, and `<>`.
- Selective scanning recognizes `STABLE` and `IMMUTABLE` functions, but does not recognize `VOLATILE` functions within a query. For example, `WHERE` clauses such as `date > CURRENT_DATE` cause the query optimizer to selectively scan partitioned tables, but `time > TIMEOFDAY` does not.

About Viewing Your Partition Design

Partitioning information is stored in the pg_partitioned_table system catalog, and in additional fields in thepg_class (`relispartition` and `relpartbound`) catalog.

You can also use the following functions to obtain information about the partitioned tables in the database:

Name	Return Type	Description
pg_partition_tree(regclass)	setof record	Lists information about tables or indexes in a partition hierarchy for a given partitioned table or partitioned index, with one row for each partition. Information provided includes the name of the partition, the name of its immediate parent, a `boolean` value indicating if the partition is a leaf, and an `integer` identifying its level in the hierarchy. The value of level begins at `0` for the input table or index in its role as the root of the partition hierarchy, `1` for its partitions, `2` for their partitions, and so on.
pg_partition_ancestors(regclass)	setof regclass	Lists the ancestor relations of the given partition, including the partition itself.
pg_partition_root(regclass)	regclass	Returns the topmost parent of the partition hierarchy to which the given relation belongs.

For example, the following command displays the partition inheritance structure of the `msales` table:

```
SELECT * FROM pg_partition_tree( 'msales' );
```

Viewing a Classic Syntax Sub-Partition Template

For a partitioned table that you create using the classic syntax, thegp_partition_template system catalog table describes the relationship between the partitioned table and the sub-partition template defined at each level in the partition hierarchy.

Use the `pg_get_expr()` helper function with `gp_partition_template` to get a more user-friendly view of the template, as follows:

```
SELECT pg_get_expr(template, relid) FROM gp_partition_template
  WHERE relid = '<table_name>'::regclass;
```

Constructing a pg_partitions-Equivalent Query

Refer to Migrating Partition Maintenance Scripts to the New WarehousePG 7 Partitioning Catalogs for information about mapping WarehousePG 6 partitioning catalogs to the new definitions in WarehousePG 7.

About Partition Pruning

Partition pruning is a query optimization technique that improves performance for declaratively partitioned tables.

You can enable or disable partition pruning for the Postgres-based planner by setting the enable_partition_pruning server configuration parameter.

As an example:

```
SET enable_partition_pruning = on;                -- the default
SELECT count(*) FROM measurement WHERE logdate >= DATE '2021-01-01';
```

Without partition pruning, the above query would scan each of the partitions of the `measurement` table. With partition pruning enabled, the planner or query optimizer examines the definition of each partition to prove that the partition need not be scanned because it could not contain any rows meeting the query's `WHERE` clause. When the planner or query optimizer can prove this, it excludes (prunes) the partition from the query plan.

Using the `EXPLAIN` command and the `enable_partition_pruning` configuration parameter, it's possible to show the difference between a plan for which partitions have been pruned and one for which they have not. A typical unoptimized plan from the Postgres-based planner for this type of table setup is:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
SET enable_partition_pruning = off;
EXPLAIN SELECT count(*) FROM measurement WHERE logdate >= DATE '2021-01-01';

                                  QUERY PLAN
-------------------------------------------------------------------------------
 Aggregate  (cost=188.76..188.77 rows=1 width=8)
   ->  Append  (cost=0.00..181.05 rows=3085 width=0)
         ->  Seq Scan on measurement_y2021m01  (cost=0.00..33.12 rows=617 width=0)
               Filter: (logdate >= '2021-01-01'::date)
         ->  Seq Scan on measurement_y2021m02  (cost=0.00..33.12 rows=617 width=0)
               Filter: (logdate >= '2021-01-01'::date)
...
         ->  Seq Scan on measurement_y2023m01  (cost=0.00..33.12 rows=617 width=0)
               Filter: (logdate >= '2021-01-01'::date)
```

Some or all of the partitions might use index scans instead of full-table sequential scans, but the point is that there is no need to scan the older partitions to answer this query. With partition pruning enabled, a significantly cheaper plan is generated that delivers the same answer:

```
SET enable_partition_pruning = on;
EXPLAIN SELECT count(*) FROM measurement WHERE logdate >= DATE '2008-01-01';

                                  QUERY PLAN
-------------------------------------------------------------------------------
 Aggregate  (cost=37.75..37.76 rows=1 width=8)
   ->  Seq Scan on measurement_y2021m01  (cost=0.00..33.12 rows=617 width=0)
         Filter: (logdate >= '2021-01-01'::date)
```

Note that partition pruning is driven only by the constraints defined implicitly by the partition keys, not by the presence of indexes. Therefore it isn't necessary to define indexes on the key columns. Whether you should create an index for a given partition depends on whether you expect that queries that scan the partition will generally scan a large part of the partition or just a small part. An index will be helpful in the latter case but not the former.

Partition pruning can be performed not only during the planning of a given query, but also during its execution. This is useful because it can allow more partitions to be pruned when clauses contain expressions whose values are not known at query planning time, for example, parameters defined in a `PREPARE` statement, using a value obtained from a subquery, or using a parameterized value on the inner side of a nested loop join. Partition pruning during execution can be performed at any of the following times:

- During initialization of the query plan. Partition pruning can be performed here for parameter values which are known during the initialization phase of execution. Partitions which are pruned during this stage will not show up in the query's `EXPLAIN` or `EXPLAIN ANALYZE`. It is possible to determine the number of partitions which were removed during this phase by observing the "Subplans Removed" property in the `EXPLAIN` output.
- During actual execution of the query plan. Partition pruning may also be performed here to remove partitions using values which are only known when running the actual query. This includes values from subqueries and values from run-time parameters such as those from parameterized nested loop joins. Since the value of these parameters may change many times during the execution of the query, WarehousePG performs partition pruning whenever one of the run-time parameters being used by partition pruning changes. Determining whether partitions were pruned during this phase requires careful inspection of the loops property in the `EXPLAIN ANALYZE` output. Subplans corresponding to different partitions may have different values for it depending on how many times each of them was pruned during execution. Some may be shown as `(never executed)` if they were pruned every time.

Partition Maintenance

Normally, the set of partitions established when initially defining the table is not intended to remain static. Common scenarios include removing partitions holding old data and periodically adding new partitions for new data. One of the biggest advantages of partitioning is precisely that it allows you to perform these tasks nearly instantaneously by manipulating the partition structure, rather than physically moving around large amounts of data.

> **Important** The examples in the next section use the modern partitioning syntax. Refer to Partition Maintenance with the Classic Syntax for information about the maintenance activities and commands for partitioned tables that you created using the classic partitioning syntax.

Partition Maintenance with the Modern Syntax

To maintain a partitioned table that you created with the modern syntax, you use the `ALTER TABLE` command against the top-level root partitioned table or the partition itself.

Adding a Partition

You add a new partition to handle new data. You can add a partition to a partition hierarchy both at the time of, or after, table creation.

To add to the partition hierarchy during table creation, use the `CREATE TABLE ... PARTITION OF` command. For example:

```
CREATE TABLE msales_mfeb20 PARTITION OF msales
    FOR VALUES FROM ('2020-02-01') TO ('2020-03-01');
```

Alternatively, it is sometimes more convenient to create the new table outside of the partition structure, and make it a proper partition later. This allows data to be loaded, checked, and transformed prior to it appearing in a partitioned table. The `CREATE TABLE ... LIKE` command form avoids having to repeat the parent table's definition:

```
-- create like the parent table
CREATE TABLE msales_mfeb20 (LIKE msales INCLUDING DEFAULTS INCLUDING CONSTRAINTS);

-- add constraints
ALTER TABLE msales_mfeb20 ADD CONSTRAINT y2020m02
   CHECK ( logdate >= DATE '2020-02-01' AND logdate < DATE '2020-03-01' );

-- add data or other prep work
```

To add this existing table to a partition hierarchy, use `ALTER TABLE ... ATTACH PARTITION`: For example:

```
-- attach to the partition hierarchy, specifying the boundaries/constraints
ALTER TABLE msales ATTACH PARTITION msales_mfeb20
  FOR VALUES FROM ('2020-02-01') TO ('2020-03-01');
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

The `ATTACH PARTITION` command requires taking a `SHARE UPDATE EXCLUSIVE` lock on the partitioned table.

Before running the `ATTACH PARTITION` command, consider creating a `CHECK` constraint on the table to be attached that matches the expected partition constraint, as illustrated above. If you do this, the system skips the scan which is otherwise required to validate the implicit partition constraint. Without the `CHECK` constraint, WarehousePG scans the table to validate the partition constraint while holding an `ACCESS EXCLUSIVE` lock on that partition. Be sure to drop the now-redundant `CHECK` constraint after the `ATTACH PARTITION` completes. If the table being attached is itself a partitioned table, then WarehousePG recursively locks and scans each of its sub-partitions until it encounters either a suitable `CHECK` constraint or reaches the leaf partitions.

Similarly, if the partitioned table has a `DEFAULT` partition, consider creating a `CHECK` constraint that excludes the to-be-attached partition's constraint. If you do not do this, WarehousePG scans the `DEFAULT` partition to verify that it contains no records which should be located in the partition being attached. WarehousePG performs this operation whiling holding an `ACCESS EXCLUSIVE` lock on the `DEFAULT` partition. If the `DEFAULT` partition is itself a partitioned table, then WarehousePG recursively checks each of its partitions in the same way as the table being attached, as mentioned above.

Indexing Partitioned Tables

Creating an index on the key column(s) of a partitioned table automatically creates a matching index on each partition, and any partitions that you create or attach later will also have such an index. An index or unique constraint declared on a partitioned table is "virtual" in the same way that the partitioned table is: the actual data is in child indexes on the individual partition tables.

Creating indexes on partitioned tables so that they are applied automatically to the entire hierarchy is very convenient; not only will the existing partitions be indexed, but any partitions that are created in the future will be indexed as well. To avoid long lock times, you can `CREATE INDEX ON ONLY` the partitioned table. Such an index is marked invalid, and WarehousePG does not apply the index automatically to the partitions. You can create the indexes on partitions individually, and then attach to the index on the parent using `ALTER INDEX .. ATTACH PARTITION`. After indexes for all partitions are attached to the parent index, the parent index is marked valid automatically. For example:

```
CREATE INDEX measurement_usls_idx ON ONLY measurement (unitsales);

CREATE INDEX measurement_usls_202102_idx
    ON measurement_y2021m02 (unitsales);
ALTER INDEX measurement_usls_idx
    ATTACH PARTITION measurement_usls_202102_idx;
...
```

You can use this technique with `UNIQUE` and `PRIMARY KEY` constraints too; the indexes are created implicitly when the constraint is created. Example:

```
ALTER TABLE ONLY measurement ADD UNIQUE (city_id, logdate);

ALTER TABLE measurement_y2021m02 ADD UNIQUE (city_id, logdate);
ALTER INDEX measurement_city_id_logdate_key
    ATTACH PARTITION measurement_y2021m02_city_id_logdate_key;
...
```

Renaming a Partition

You rename a partition in a partition hierarchy in the same way you rename a table, using the `ALTER TABLE ... RENAME TO` command.

```
ALTER TABLE msales_mfeb17 RENAME TO msales_month_feb17;
```

Adding a Default Partition

The `DEFAULT` keyword identifies a partition as the default partition. When it encounters data that falls outside of the boundaries of all partitions, Greeplum Database routes the data to the default partition. WarehousePG will reject incoming data if it does not match the constraint of any partition and there is no default partition defined, and returns an error. Identifying a default partition ensures that incoming data that does not match a partition is inserted into the partitioned table.

A partitioned table can only have one default partition. You can add a default partition to a partition hierarchy during or after table creation.

To identify a partition as a default partition when you create the table:

```
CREATE TABLE msales_other PARTITION OF msales DEFAULT;
```

To identify a table as a default partition after table creation:

```
-- previously created table that has the same schema as the root
CREATE TABLE msales_other (LIKE msales);
```

```
-- attach to the partition hierarchy
ALTER TABLE msales ATTACH PARTITION msales_other DEFAULT;
```

Dropping a Partition

The simplest option for removing old data is to drop the partition that is no longer necessary:

```
DROP TABLE measurement_y2020m02;
```

This operation can very quickly delete millions of records because it doesn't have to individually delete every record. Note, however, that the above command requires taking an `ACCESS EXCLUSIVE` lock on the parent table.

Another option is to remove the partition from the partitioned table but retain access to it as a table in its own right. See Detaching a Partition below.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Detaching a Partition

You can detach a partition from your partition hierarchy using the `ALTER TABLE ... DETACH PARTITION` command. Detaching a partition removes it from the partition hierarchy, but *does not drop the table*. Detaching a partition that has sub-partitions automatically detaches those partitions as well.

For range partitions, it is common to detach the older partitions to roll old data out of the data warehouse. For example:

```
ALTER TABLE msales DETACH PARTITION msales_2021;
```

Detaching allows further operations to be performed on the data before it is dropped. For example, this may be an opportune time to back up the data using `COPY` or similar tools. You might also choose to aggregate data into smaller formats, perform other data manipulations, or run reports.

Truncating a Partition

Truncating a partition is the same as truncating any table. When you truncate a partition that is partitioned itself, WarehousePG automatically truncates the sub-partitions as well.

Truncate a partition:

```
TRUNCATE ONLY msales_other;
```

Truncate the whole partitioned table:

```
TRUNCATE msales;
```

Exchanging a Partition

Exchanging a partition swaps one table in place of an existing partition. To exchanging a partition, `DETACH` the original partition and then `ATTACH` the new partition. You can exchange partitions only at the lowest level of your partition hierarchy (only partitions that contain data can be exchanged).

You cannot exchange a partition with a replicated table. Exchanging a partition with a partitioned table or a non-leaf child partition of a partitioned table is also not supported.

> **Note** WarehousePG always validates the data against the partition constraint. You must ensure that the data in the table that you are attaching is valid against the constraints on the partition.

```
ALTER TABLE msales DETACH PARTITION msales_2021;
ALTER TABLE msales ATTACH PARTITION msales_2021_new FOR VALUES FROM (2021) TO (2022);
```

Best Practices

Choose the table partitioning strategy carefully, as the performance of query planning and execution can be negatively affected by poor design.

One of the most critical design decisions you must make is choosing the column or columns by which you partition your data. The best choice is often to partition by the column or set of columns which most commonly appear in `WHERE` clauses of queries being run on the partitioned table. WarehousePG can use `WHERE` clauses that are compatible with the partition bound constraints to prune unneeded partitions. However, you may be forced into making other decisions by requirements for the `PRIMARY KEY` or a `UNIQUE` constraint. Removal of unwanted data is also a factor to consider when you plann your partitioning strategy. An entire partition can be detached fairly quickly, so it may be beneficial to design the partition strategy in such a way that all data that you wnat to remove at once is located in a single partition.

Choosing the target number of partitions that the table should be divided into is also a critical decision. Not having enough partitions may mean that indexes remain too large and that data locality remains poor, which could result in low cache hit ratios. However, dividing the table into too many partitions can also cause issues. Too many partitions can result in longer query planning times and higher memory consumption during both query planning and execution, as further described below. When choosing how to partition your table, it's also important to consider what changes may occur in the future. For example, if you choose to have one partition per customer and you currently have a small number of large customers, consider the implications if in several years you instead find yourself with a large number of small customers. In this case, it may be better to choose to partition by `HASH` and choose a reasonable number of partitions rather than trying to partition by `LIST` and hoping that the number of customers does not increase beyond what it is practical to partition the data by.

Sub-partitioning can be useful to further divide partitions that are expected to become larger than other partitions. Another option is to use range partitioning with multiple columns in the partition key. Either of these can easily lead to excessive numbers of partitions, so restraint is advisable.

It is important to consider the overhead of partitioning during query planning and execution. The query planner and optimizer are generally able to handle partition hierarchies with up to a few thousand partitions fairly well, provided that typical queries allow the query planner to prune all but a small number of partitions. Planning times become longer and memory consumption becomes higher when more partitions remain after the planner performs partition pruning. This is particularly true for the `UPDATE` and `DELETE` commands. Another reason for concern about a large number of partitions is that the server's memory consumption may grow significantly over time, especially if many sessions touch large numbers of partitions. That's because each partition requires its metadata to be loaded into the local memory of each session that touches it.

If your workloads are performing data warehousing tasks, it can make sense to use a larger number of partitions than with an OLTP type workload. Generally, in data warehouses, query planning time is less of a concern as the majority of processing time is spent during query execution. With either of these two types of workload, it is important to make the right decisions early, as re-partitioning large quantities of data can be painfully slow. Simulations of the intended workload are often beneficial for optimizing the partitioning strategy. Never just assume that more partitions are better than fewer partitions, nor vice-versa.

Limitations

Take note of the following WarehousePG partitioned table limitations:

- A partitioned table can have a maximum of 32,767 partitions at each level.
- WarehousePG does not support partitioning replicated tables (tables created with the `DISTRIBUTED REPLICATED` distribution policy).
- The WarehousePG query optimizer (GPORCA) does not support uniform multi-level partitioned tables. If GPORCA is enabled (the default) and the partitioned table is multi-level, WarehousePG runs queries against the table with the Postgres-based planner.
- The WarehousePG `gpbackup` utility does not back up data from a leaf partition of a partitioned table when the leaf partition is an external or foreign table.
- To create a unique or primary key constraint on a partitioned table, the partition keys must not include any expressions or function calls and the constraint's columns must include all of the partition key columns. This limitation exists because the individual indexes making up the constraint can only directly enforce uniqueness within their own partitions; the partition structure itself must guarantee that there are not duplicates in different partitions.
- There is no way to create an exclusion constraint spanning the whole partitioned table. You can put such a constraint only on each leaf partition individually. This limitation stems from not being able to enforce cross-partition restrictions.
- Mixing temporary and permanent relations in the same partition hierarchy is not allowed. If the partitioned table is permanent, so must be its partitions and likewise if the partitioned table is temporary. When using temporary relations, all members of the partition hierarchy must be from the same session.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Individual partitions are linked to their partitioned table using inheritance behind the scenes. However, it is not possible to use all of the generic features of inheritance with declaratively partitioned tables or their partitions, as discussed below. Notably, a partition cannot have any parents other than the partitioned table it is a partition of, nor can a table inherit from both a partitioned table and a regular table. Partitioned tables and their partitions never share an inheritance hierarchy with regular tables.

Since a partition hierarchy consisting of the partitioned table and its partitions is still an inheritance hierarchy, `tableoid` and all of the normal rules of inheritance apply as described in Inheritance in the PostgreSQL documentation, with a few exceptions:

- Partitions cannot have columns that are not present in the parent. It is not possible to specify columns when creating partitions with `CREATE TABLE`, nor is it possible to add columns to partitions after-the-fact using `ALTER TABLE`. Tables may be added as a partition with `ALTER TABLE ... ATTACH PARTITION` only if their columns exactly match the parent.
- Both `CHECK` and `NOT NULL` constraints of a partitioned table are always inherited by all of its partitions. WarehousePG does not permit `CHECK` constraints that are marked `NO INHERIT` to be created on partitioned tables. You cannot drop a `NOT NULL` constraint on a partition's column if the same constraint is present in the parent table.
- Using `ONLY` to add or drop a constraint on only the partitioned table is supported as long as there are no partitions. Once partitions exist, using `ONLY` will result in an error. Instead, constraints on the partitions themselves can be added and (if they are not present in the parent table) dropped.
- As a partitioned table does not have any data itself, attempts to use `TRUNCATE ONLY` on a partitioned table always return an error.

When a leaf partition is an external or foreign table, the following limitations hold:

- If the external or foreign table partition is not writable or the user does not have permission to write to the table, commands that attempt to modify data in the external or foreign partition (`INSERT`, `DELETE`, `UPDATE`, or `TRUNCATE`) return an error.
- A `COPY` command cannot copy data to a partitioned table that updates an external or foreign table partition.
- A `COPY` command that attempts to copy from an external or foreign table partition returns an error unless you specify the `IGNORE EXTERNAL PARTITIONS` clause. When you specify the clause, WarehousePG does not copy data from external or foreign table partitions.

  To use the `COPY` command against a partitioned table with a leaf partition that is an external or foreign table, use an SQL expression rather than the partitioned table name to copy the data. For example, if the table `my_sales` contains a leaf partition that is an external table, this command sends the data to `stdout`:

  ```
  COPY (SELECT * from my_sales ) TO stdout
  ```

- `VACUUM` commands skip external and foreign table partitions.
- If the external or foreign table partition is not writable or the user does not have permission to write to the table, WarehousePG returns an error on the following operations:
  - Adding or dropping a column.
  - Changing the data type of a column.

These (*classic syntax*) `ALTER TABLE ... ALTER PARTITION` operations are not supported when the partitioned table contains an external or foreign table partition:

- Setting a sub-partition template.
- Altering the partition properties.
- Creating a default partition.
- Setting a distribution policy.
- Setting or dropping a `NOT NULL` constraint of column.
- Adding or dropping constraints.
- Splitting an external partition.

4.4.7.1 About Changes to Table Partitioning in WarehousePG 7

WarehousePG 7 retains most aspects of the partitioning syntax of prior versions of WarehousePG, now referred to as the *classic* partitioning syntax. Version 7 also introduces support for a *modern* syntax, derived from the PostgreSQL declarative partitioning syntax.

This topic describes the WarehousePG 7 partitioning syntax and behavior changes, and is geared toward existing users of WarehousePG 6.

(Refer to Partitioning Large Tables for information about using both syntaxes to create and manage partitioned tables.)

Parent topic: DDL: Defining Database Objects

What's New?

The following partitioning-related features are *new* in WarehousePG 7:

- Support for PostgreSQL declarative partitioning syntax, which introduces these new features *for the modern syntax only*:
    - Partitions are first-class tables.
    - The table name of a partition is just that, not an alias.
    - Support for the hash partitioning strategy.
    - Support for multi-column range partitioning.
    - Support for specifying an expression in the partition key.
    - A partitioned table may have zero partitions.
    - Support for a heterogeneous partition hierarchy that allows child partitions of different levels and allows for different partitioning strategies amongst the child partitions.
- Less restrictive locking in `ATTACH PARTITION`. You can now attach a partition to a partition hierarchy without disrupting many normal query executions on the partition.
- `GRANT ... ONLY` and `REVOKE ... ONLY` syntaxes that direct WarehousePG to apply the operation to the named table only (does not recurse the operation to child tables).
- `ALTER TABLE ONLY` syntax that directs WarehousePG to apply the operation to the named table only (does not recurse the operation to child tables).

What Hasn't Changed With Classic Syntax?

The following classic partitioning syntax and behaviors *have not* changed in WarehousePG 7:

- WarehousePG 7 supports the classic partitioning syntax of WarehousePG 6 except where called out in the What Has Changed? section.
- Support for range and list partition strategies.
- Support for sub-partition templates.
- A partitioned table must be defined with at least one partition.
- Only leaf partitions contain data.
- The name that you assign a partition table is an alias.
- By default, a `GRANT` or `REVOKE` operation on a parent partitioned table recurses to its child tables.
- By default, an `ALTER TABLE` operation on a parent partitioned table recurses to its child tables.

What Has Changed?

The following items describe the WarehousePG 7 *changes* to classic partitioning syntax and behaviors compared to WarehousePG 6:

- New internal data structures and catalogs are used to represent partitioned tables.

    > **Important** WarehousePG 7 represents and operates on partitioned tables using the new internal data structures and catalog, regardless of the partitioning syntax used to create the table. Operations that you invoke using the classic partitioning syntax are internally mapped to the new data structures, and any output generated by WarehousePG, such as DDL, is displayed in that format.

- These partitioning-related catalog tables, views, and functions are removed:
    - `pg_partition`
    - `pg_partition_rule`
    - `pg_partition_columns`
    - `pg_partition_encoding`
    - `pg_partition_rule`
    - `pg_partition_templates`
    - `pg_partitions`
    - `pg_stat_partition_operations`
    - `pg_partition_def()`

    The new pg_partitioned_table catalog table and `pg_partition_tree()`, `pg_partition_ancestors()`, and `pg_partition_root()` functions provide similar information. Refer to About Viewing Your Partition Design for more information on these new functions.

- The `FOR (RANK(<value>))` clause is no longer supported. When creating or altering a partitioned table, you must locate a partition by `VALUE`.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

- Partition boundaries are no longer represented as `CHECK` constraints, but rather internally-constructed partition constraints.
- The level of a partition in the partition hierarchy differs in WarehousePG 6 and WarehousePG 7. In WarehousePG 6, the level of the immediate child of a partitioned table is 0. In WarehousePG 7, the level of the partitioned table itself is 0, and the level of its immediate child is 1.
- The interpretation of `START` / `END` and `EXCLUSIVE` / `INCLUSIVE` clauses for range partition boundaries has changed:
  - When a clause is not specified, the start boundary is always inclusive and the end boundary exclusive (same behaviour as WarehousePG 6).
  - When `START EXCLUSIVE <n>` is specified, WarehousePG now implicitly converts this to a `START INCLUSIVE <n>+1`.
  - When an `END INCLUSIVE <n>` is specified, WarehousePG now implicitly converts this to an `END EXCLUSIVE <n>+1`.
  - Because of the implicit conversion mentioned in the previous points, `START EXCLUSIVE` and `END INCLUSIVE` boundaries are now permitted only for data types that have a suitable `+` operator like `integer` and `timestamp` (but not `float` or `text`).
- Partition-specific information displayed in `psql` `\d+` output has changed:
  - Partition boundaries are now tagged `Partition constraint`.
  - Instead of `Inherits`, the parent table is now identified with the tag `Partition of`
  - Range partition boundaries defined with `START` / `END` are displayed using the (modern syntax) `FOR VALUES [ FROM/TO | IN | WITH ]` keywords.
  - Example:

```
\d+ jan_sales
                                Table "public.jan_sales"
 Column |     Type      | Collation | Nullable | Default | Storage | Stats target | Description
|--------+---------------+-----------+----------+---------+---------+--------------+-------------
 id     | integer       |           |          |         | plain   |              |
 date   | date          |           |          |         | plain   |              |
 amt    | numeric(10,2) |           |          |         | main    |              |
Partition of: sales FOR VALUES FROM ('2023-01-01') TO ('2023-02-01')
Partition constraint: ((date IS NOT NULL) AND (date >= '2023-01-01'::date) AND (date < '2023-02-01'::date))
Distributed by: (id)
```

- The `EXCHANGE PARTITION` command has changed:
  - This command is now internally implemented with the `DETACH PARTITION` and `ATTACH PARTITION` commands introduced with the modern syntax.
  - The partition-to-exchange is no longer required to have the same owner as the parent table.
  - The partition-to-exchange is no longer required to have the same index as the parent table. The command will create one if it is missing.
  - The partition-to-exchange must have the same constraint as the parent table.
  - Previous versions renamed the tables and also renamed the index and constraints, in WarehousePG 7, this command only renames the table.
- Property inheritance changes:
  - A created/added partition inherits the properties of its parent.
  - The partitions created from a `SPLIT PARTITION` inherit the properties of the split child.
  - An attached partition maintains its original properties.

> **Note** The WarehousePG query optimizer (GPORCA) does not support multi-level partitioned tables.

Additional Considerations

Additional factors to consider:

- You must change any scripts that you wrote that depend on DDL or `psql \d` output.
- WarehousePG 7 dumps and restores the DDL of partitioned tables defined with classic syntax using the new catalog structures.

4.4.7.2 Examples Using the Classic Partitioning Syntax

The classic partitioning syntax reflects the partitioning syntax of prior versions of WarehousePG. It is most appropriate for a homogenous partitioned table, where all partitions are at the same leaf level and have the same partition rule.

If you are already familiar with the *classic* partitioning syntax, refer to About Changes to Table Partitioning in WarehousePG 7 for information about syntax and behavior changes introduced in version 7.

Creating Partitioned Tables with the Classic Syntax

This section includes several examples that use the classic syntax for creating a partitioned table.

Creating a Date-Range Partitioned Table

A date-range partitioned table uses a single date type column as the partition key column.

With the classic syntax, you can instruct WarehousePG to automatically generate partitions by providing a `START` value, an `END` value, and an `EVERY` clause that defines the partition increment value. By default, `START` values are always inclusive and `END` values are always exclusive. For example, to create a daily-partitioned table named `sales:

```
CREATE TABLE sales (id int, date date, amt decimal(10,2))
DISTRIBUTED BY (id)
PARTITION BY RANGE (date)
( START (date '2022-01-01') INCLUSIVE
   END (date '2023-01-01') EXCLUSIVE
   EVERY (INTERVAL '1 day') );
```

You can also declare and name each partition individually. For example:

```
CREATE TABLE sales (id int, date date, amt decimal(10,2))
DISTRIBUTED BY (id)
PARTITION BY RANGE (date)
( PARTITION Jan22 START (date '2022-01-01') INCLUSIVE ,
  PARTITION Feb22 START (date '2022-02-01') INCLUSIVE ,
  PARTITION Mar22 START (date '2022-03-01') INCLUSIVE ,
  PARTITION Apr22 START (date '2022-04-01') INCLUSIVE ,
  PARTITION May22 START (date '2022-05-01') INCLUSIVE ,
  PARTITION Jun22 START (date '2022-06-01') INCLUSIVE ,
  PARTITION Jul22 START (date '2022-07-01') INCLUSIVE ,
  PARTITION Aug22 START (date '2022-08-01') INCLUSIVE ,
  PARTITION Sep22 START (date '2022-09-01') INCLUSIVE ,
  PARTITION Oct22 START (date '2022-10-01') INCLUSIVE ,
  PARTITION Nov22 START (date '2022-11-01') INCLUSIVE ,
  PARTITION Dec22 START (date '2022-12-01') INCLUSIVE
                  END (date '2023-01-01') EXCLUSIVE );
```

You need not declare an `END` value for each partition, only the last one. In this example, `Jan22` ends where `Feb22` starts.

Creating a Numeric-Range Partitioned Table

A numeric-range partitioned table uses a single numeric type column as the partition key column.

For example, create a table named `nrank` that is numeric-range partitioned on the `int` column `year`:

```
CREATE TABLE nrank (id int, rank int, year int, color char(1), count int)
DISTRIBUTED BY (id)
PARTITION BY RANGE (year)
( START (2012) END (2022) EVERY (1),
  DEFAULT PARTITION extra );
```

Creating a List Partitioned Table

A list partitioned table can use any data type column that allows equality comparisons as its partition key column. With the classic syntax, a list partition can have a multi-column (composite) partition key. For list partitions, you must declare a partition for every list value. For example:

```
CREATE TABLE rank (id int, rank int, year int, color char(1), count int )
DISTRIBUTED BY (id)
PARTITION BY LIST (color)
( PARTITION red VALUES ('r'),
  PARTITION blue VALUES ('b'),
  PARTITION green VALUES ('g'),
  DEFAULT PARTITION other );
```

> **Note** While the Postgres-based planner allows list partitions with multi-column (composite) partition keys, the WarehousePG query optimizer (GPORCA) does not support this.

Defining Multi-level Partitions

You can create a multi-level partition design with sub-partitions of partitions. Using a *sub-partition template* ensures that every partition has the same sub-partition design, including partitions that you add later. For example, the following SQL creates the two-level partition design shown in Example Multi-Level Partition Design:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
CREATE TABLE sales (trans_id int, date date, amount decimal(9,2), region text)
DISTRIBUTED BY (trans_id)
PARTITION BY RANGE (date)
SUBPARTITION BY LIST (region)
SUBPARTITION TEMPLATE
( SUBPARTITION usa VALUES ('usa'),
  SUBPARTITION asia VALUES ('asia'),
  SUBPARTITION europe VALUES ('europe'),
  DEFAULT SUBPARTITION other_regions)
  (START (date '2011-01-01') INCLUSIVE
   END (date '2012-01-01') EXCLUSIVE
   EVERY (INTERVAL '1 month'),
   DEFAULT PARTITION outlying_dates );
```

The following example shows a three-level partition design where the `sales` table is partitioned by `year`, then `month`, then `region`. The `SUBPARTITION TEMPLATE` clauses ensure that each yearly partition has the same sub-partition structure. The example declares a `DEFAULT` partition at each level of the hierarchy.

```
CREATE TABLE p3_sales (id int, year int, month int, day int,
region text)
DISTRIBUTED BY (id)
PARTITION BY RANGE (year)
    SUBPARTITION BY RANGE (month)
       SUBPARTITION TEMPLATE (
        START (1) END (13) EVERY (1),
        DEFAULT SUBPARTITION other_months )
           SUBPARTITION BY LIST (region)
             SUBPARTITION TEMPLATE (
               SUBPARTITION usa VALUES ('usa'),
               SUBPARTITION europe VALUES ('europe'),
               SUBPARTITION asia VALUES ('asia'),
               DEFAULT SUBPARTITION other_regions )
( START (2002) END (2012) EVERY (1),
  DEFAULT PARTITION outlying_years );
```

CAUTION: When you create multi-level partitions on ranges, it is easy to create a large number of sub-partitions, some containing little or no data. This can add many entries to the system tables, which increases the time and memory required to optimize and run queries. Increase the range interval or choose a different partitioning strategy to reduce the number of sub-partitions created.

Partitioning an Existing Table

With classic syntax, tables can be partitioned only at creation. If you have a table that you want to partition, you must create a partitioned table, load the data from the original table into the new table, drop the original table, and rename the partitioned table with the original table's name. You must also re-grant any table permissions. For example:

```
CREATE TABLE sales2 (LIKE sales)
PARTITION BY RANGE (date)
( START (date 2016-01-01') INCLUSIVE
   END (date '2017-01-01') EXCLUSIVE
   EVERY (INTERVAL '1 month') );
INSERT INTO sales2 SELECT * FROM sales;
DROP TABLE sales;
ALTER TABLE sales2 RENAME TO sales;
GRANT ALL PRIVILEGES ON sales TO admin;
GRANT SELECT ON sales TO guest;
```

> **Note** The `LIKE` clause does not copy over partition structures when creating a new table.

Partition Maintenance with the Classic Syntax

To maintain a partitioned table that you created with the classic syntax, use the `ALTER TABLE` command against the top-level root partitioned table. The most common scenario is to drop old partitions and add new ones to maintain a rolling window of data in a range partition design. You can convert (*exchange*) older partitions to the append-optimized compressed storage format to save space. If you have a default partition in your partition design, you add a partition by *splitting* the default partition.

- Adding a Partition
- Renaming a Partition
- Adding a Default Partition
- Dropping a Partition
- Truncating a Partition
- Exchanging a Partition
- Splitting a Partition
- Modifying a Sub-Partition Template
- Exchanging a Leaf Partition with an External Table

> **Important** When defining and altering partition designs, use the given partition name, not the table object name. The given partition name is the `relid` column returned by the `pg_partition_tree()` function. Although you can query and load any table (including partitioned tables) directly using SQL commands, you can only modify the structure of a partitioned table that you create with classic partitioning syntax using the `ALTER TABLE ... PARTITION` clauses.

Partitions are not required to have names. If a partition does not have a name, use the following expression to identify a partition: `PARTITION FOR (value)`.

For a multi-level partitioned table, you identify a specific partition to change with `ALTER PARTITION` clauses. For each partition level in the table hierarchy that is above the target partition, specify the partition that is related to the target partition in an `ALTER PARTITION` clause. For example, if you have a partitioned table that consists of three levels, year, quarter, and region, this `ALTER TABLE` command exchanges a leaf partition `region` with the table `region_new`.

```
ALTER TABLE sales ALTER PARTITION year_1 ALTER PARTITION quarter_4 EXCHANGE PARTITION region WITH TABLE region_new ;
```

The two `ALTER PARTITION` clauses identify which `region` partition to exchange. Both clauses are required to identify the specific leaf partition to exchange.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Adding a Partition

You can add a partition to a partition design with the `ALTER TABLE` command. If the original partition design included sub-partitions defined by a *sub-partition template*, the newly added partition is sub-partitioned according to that template. For example:

```
ALTER TABLE sales ADD PARTITION
            START (date '2017-02-01') INCLUSIVE
            END (date '2017-03-01') EXCLUSIVE;
```

If you did not use a sub-partition template when you created the table, you define sub-partitions when adding a partition:

```
ALTER TABLE sales ADD PARTITION
            START (date '2017-02-01') INCLUSIVE
            END (date '2017-03-01') EXCLUSIVE
      ( SUBPARTITION usa VALUES ('usa'),
        SUBPARTITION asia VALUES ('asia'),
        SUBPARTITION europe VALUES ('europe') );
```

When you add a sub-partition to an existing partition, you can specify the partition to alter. For example:

```
ALTER TABLE sales ALTER PARTITION FOR ('2017-02-07'::date)
      ADD PARTITION africa VALUES ('africa');
```

> **Note** You cannot add a partition to a partition design that has a default partition. You must split the default partition to add a partition. See Splitting a Partition.

Renaming a Partition

Sub-partition tables created with the classic syntax use the following naming convention. Partitioned subtable names are subject to uniqueness requirements and length limitations.

```
<parentname>_<level>_prt_<partition_name>
```

For example:

```
sales_1_prt_jan16
```

For auto-generated range partitions, where a number is assigned when no name is given:

```
sales_1_prt_1
```

To rename a partitioned child table, rename the top-level parent table. The `<parentname>` changes in the table names of all associated child tables. For example, the following command:

```
ALTER TABLE sales RENAME TO globalsales;
```

Changes the associated table names:

```
globalsales_1_prt_1
```

You can change the name of a partition to make it easier to identify. For example:

```
ALTER TABLE sales RENAME PARTITION FOR ('2016-01-01') TO jan16;
```

Changes the associated table name as follows:

```
sales_1_prt_jan16
```

When altering partitioned tables with the `ALTER TABLE` command, always refer to the tables by their partition name (`jan16`) and not their full table name (`sales_1_prt_jan16`).

> **Note** The table name cannot be a partition name in an `ALTER TABLE` statement. For example, `ALTER TABLE sales...` is correct, `ALTER TABLE sales_1_part_jan16...` is not allowed.

Adding a Default Partition

You can add a default partition to a partition design with the `ALTER TABLE` command.

```
ALTER TABLE sales ADD DEFAULT PARTITION other;
```

If your partition design is multi-level, each level in the hierarchy must have a default partition. For example:

```
ALTER TABLE sales ALTER PARTITION FOR ('2017-03-01'::date) ADD DEFAULT PARTITION other;

ALTER TABLE sales ALTER PARTITION FOR ('2017-05-01'::date) ADD DEFAULT PARTITION other;

ALTER TABLE sales ALTER PARTITION FOR (2017-07-01::date) ADD DEFAULT PARTITION other;
```

If incoming data does not match a partition's constraint and there is no default partition, the data is rejected. Default partitions ensure that incoming data that does not match a partition is inserted into the default partition.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Dropping a Partition

You can drop a partition from your partition design using the `ALTER TABLE` command. When you drop a partition that has sub-partitions, the sub-partitions (and all data in them) are automatically dropped as well. For range partitions, it is common to drop the older partitions from the range as old data is rolled out of the data warehouse. For example:

```
ALTER TABLE sales DROP PARTITION FOR ('2017-03-01'::date);
```

Truncating a Partition

You can truncate a partition using the `ALTER TABLE` command. When you truncate a partition that has sub-partitions, the sub-partitions are automatically truncated as well.

```
ALTER TABLE sales TRUNCATE PARTITION FOR ('2017-02-01'::date);
```

Exchanging a Partition

You can exchange a partition using the `ALTER TABLE` command. Exchanging a partition swaps one table in place of an existing partition. You can exchange partitions only at the lowest level of your partition hierarchy (only partitions that contain data can be exchanged).

Internally, WarehousePG converts an `ALTER TABLE ... EXCHANGE PARTITION` command into modern syntax `DETACH PARTITION` and `ATTACH PARTITION` commands (with some name swapping).

You cannot exchange a partition with a replicated table. Exchanging a partition with a partitioned table or a child partition of a partitioned table is not supported.

> **Note** WarehousePG always validates the data against the partition constraint. You must ensure that the data in the table that you are attaching is valid against the constraints on the partition.

Splitting a Partition

Splitting a partition divides a partition into two partitions. You can split a partition using the `ALTER TABLE` command. You can split partitions only at the lowest level of your partition hierarchy (partitions that contain data). For a multi-level partition, only range partitions can be split, not list partitions. The split value you specify goes into the *latter* partition.

For example, to split a monthly partition into two with the first partition containing dates January 1-15 and the second partition containing dates January 16-31:

```
ALTER TABLE sales SPLIT PARTITION FOR ('2017-01-01')
AT ('2017-01-16')
INTO (PARTITION jan171to15, PARTITION jan1716to31);
```

If your partition design has a default partition, you must split the default partition to add a partition.

When using the `INTO` clause, specify the current default partition as the second partition name. For example, to split a default range partition to add a new monthly partition for January 2017:

```
ALTER TABLE sales SPLIT DEFAULT PARTITION
START ('2017-01-01') INCLUSIVE
END ('2017-02-01') EXCLUSIVE
INTO (PARTITION jan17, default partition);
```

Modifying a Sub-Partition Template

Use `ALTER TABLE ... SET SUBPARTITION TEMPLATE` to modify the sub-partition template of a partitioned table. Partitions added after you set a new sub-partition template have the new partition design. Existing partitions are not modified.

The following example alters the sub-partition template of this partitioned table:

```
CREATE TABLE sales (trans_id int, date date, amount decimal(9,2), region text)
  DISTRIBUTED BY (trans_id)
  PARTITION BY RANGE (date)
  SUBPARTITION BY LIST (region)
  SUBPARTITION TEMPLATE
    ( SUBPARTITION usa VALUES ('usa'),
      SUBPARTITION asia VALUES ('asia'),
      SUBPARTITION europe VALUES ('europe'),
      DEFAULT SUBPARTITION other_regions )
  ( START (date '2014-01-01') INCLUSIVE
    END (date '2014-04-01') EXCLUSIVE
    EVERY (INTERVAL '1 month') );
```

This `ALTER TABLE` command, modifies the sub-partition template.

```
ALTER TABLE sales SET SUBPARTITION TEMPLATE
( SUBPARTITION usa VALUES ('usa'),
  SUBPARTITION asia VALUES ('asia'),
  SUBPARTITION europe VALUES ('europe'),
  SUBPARTITION africa VALUES ('africa'),
  DEFAULT SUBPARTITION regions );
```

When you add a date-range partition of the table sales, it includes the new regional list sub-partition for Africa. For example, the following command creates the sub-partitions `usa`, `asia`, `europe`, `africa`, and a default partition named `other`:

```
ALTER TABLE sales ADD PARTITION "4"
  START ('2014-04-01') INCLUSIVE
  END ('2014-05-01') EXCLUSIVE;
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

To view the tables created for the partitioned table `sales`, you can use the command `\dt sales*` from the psql command line.

To remove a sub-partition template, use `SET SUBPARTITION TEMPLATE` with empty parentheses. For example, to clear the sales table sub-partition template:

```
ALTER TABLE sales SET SUBPARTITION TEMPLATE ();
```

Exchanging a Leaf Partition with an External Table

You can exchange a leaf partition of a partitioned table with a readable external table. The external table data can reside on a host file system, an NFS mount, or a Hadoop file system (HDFS).

For example, if you have a partitioned table that is created with monthly partitions and most of the queries against the table only access the newer data, you can copy the older, less accessed data to external tables and exchange older partitions with the external tables. For queries that only access the newer data, you could create queries that use partition elimination to prevent scanning the older, unneeded partitions.

Exchanging a leaf partition with an external table is not supported if the partitioned table contains a column with a check constraint or a `NOT NULL` constraint.

For information about exchanging and altering a leaf partition, see the ALTER TABLE command reference.

For information about limitations of partitioned tables that contain a external table partition, see Limitations of Partitioned Tables.

Example Exchanging a Partition with an External Table

This is a simple example that exchanges a leaf partition of this partitioned table for an external table. The partitioned table contains data for the years 2010 through 2013.

```
CREATE TABLE sales (id int, year int, qtr int, day int, region text)
  DISTRIBUTED BY (id)
  PARTITION BY RANGE (year)
  ( PARTITION yr START (2010) END (2014) EVERY (1) ) ;
```

There are four leaf partitions for the partitioned table. Each leaf partition contains the data for a single year. The leaf partition `sales_1_prt_yr_1` contains the data for the year 2010. These steps exchange the table `sales_1_prt_yr_1` with an external table the uses the `gpfdist` protocol:

1. Ensure that the external table protocol is enabled for the WarehousePG cluster.

   This example uses the `gpfdist` protocol. This command starts the `gpfdist` protocol.

   ```
   $ gpfdist
   ```

2. Create a writable external table.

   This `CREATE WRITABLE EXTERNAL TABLE` command creates a writable external table with the same columns as the partitioned table.

   ```
   CREATE WRITABLE EXTERNAL TABLE my_sales_ext ( LIKE sales_1_prt_yr_1 )
     LOCATION ( 'gpfdist://gpdb_test/sales_2010' )
     FORMAT 'csv'
     DISTRIBUTED BY (id) ;
   ```

3. Create a readable external table that reads the data from that destination of the writable external table created in the previous step.

   This `CREATE EXTERNAL TABLE` create a readable external that uses the same external data as the writable external data.

   ```
   CREATE EXTERNAL TABLE sales_2010_ext (LIKE sales_1_prt_yr_1)
     LOCATION ( 'gpfdist://gpdb_test/sales_2010' )
     FORMAT 'csv' ;
   ```

4. Copy the data from the leaf partition into the writable external table.

   This `INSERT` command copies the data from the leaf partition into the external table.

   ```
   INSERT INTO my_sales_ext SELECT * FROM sales_1_prt_yr_1;
   ```

5. Exchange the existing leaf partition with the external table.

   This `ALTER TABLE` command specifies the `EXCHANGE PARTITION` clause to switch the readable external table and the leaf partition.

   ```
   ALTER TABLE sales ALTER PARTITION yr_1
      EXCHANGE PARTITION yr_1
      WITH TABLE sales_2010_ext WITHOUT VALIDATION;
   ```

   The external table becomes the leaf partition with the table name `sales_1_prt_yr_1` and the old leaf partition becomes the table `sales_2010_ext`.

   > **Caution** In order to ensure queries against the partitioned table return the correct results, the external table data must be valid against the constraints on the leaf partition.

6. Drop the table that was rolled out of the partitioned table.

   ```
   DROP TABLE sales_2010_ext ;
   ```

You can rename the name of the leaf partition to indicate that `sales_1_prt_yr_1` is an external table.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

This example command changes the `partitionname` to `yr_1_ext` and the name of the leaf partition to `sales_1_prt_yr_1_ext`.

```
ALTER TABLE sales RENAME PARTITION yr_1 TO  yr_1_ext ;
```

4.4.8 Creating and Using Sequences

A WarehousePG sequence object is a special single row table that functions as a number generator. You can use a sequence to generate unique integer identifiers for a row that you add to a table. Declaring a column of type `SERIAL` implicitly creates a sequence counter for use in that table column.

WarehousePG provides commands to create, alter, and drop a sequence. WarehousePG also provides built-in functions to return the next value in the sequence (`nextval()`) or to set the sequence to a specific start value (`setval()`).

> **Note** The PostgreSQL `currval()` and `lastval()` sequence functions are not supported in WarehousePG.

Attributes of a sequence object include the name of the sequence, its increment value, and the last, minimum, and maximum values of the sequence counter. Sequences also have a special boolean attribute named `is_called` that governs the auto-increment behavior of a `nextval()` operation on the sequence counter. When a sequence's `is_called` attribute is `true` , `nextval()` increments the sequence counter before returning the value. When the `is_called` attribute value of a sequence is `false` , `nextval()` does not increment the counter before returning the value.

Parent topic: DDL: Defining Database Objects

Creating a Sequence

The CREATE SEQUENCE command creates and initializes a sequence with the given sequence name and optional start value. The sequence name must be distinct from the name of any other sequence, table, index, or view in the same schema. For example:

```
CREATE SEQUENCE myserial START 101;
```

When you create a new sequence, WarehousePG sets the sequence `is_called` attribute to `false` . Invoking `nextval()` on a newly-created sequence does not increment the sequence counter, but returns the sequence start value and sets `is_called` to `true` .

Using a Sequence

After you create a sequence with the `CREATE SEQUENCE` command, you can examine the sequence and use the sequence built-in functions.

Examining Sequence Attributes

To examine the current attributes of a sequence, query the sequence directly. For example, to examine a sequence named `myserial` :

```
SELECT * FROM myserial;
```

Returning the Next Sequence Counter Value

You can invoke the `nextval()` built-in function to return and use the next value in a sequence. The following command inserts the next value of the sequence named `myserial` into the first column of a table named `vendors` :

```
INSERT INTO vendors VALUES (nextval('myserial'), 'acme');
```

`nextval()` uses the sequence's `is_called` attribute value to determine whether or not to increment the sequence counter before returning the value. `nextval()` advances the counter when `is_called` is `true` . `nextval()` sets the sequence `is_called` attribute to `true` before returning.

A `nextval()` operation is never rolled back. A fetched value is considered used, even if the transaction that performed the `nextval()` fails. This means that failed transactions can leave unused holes in the sequence of assigned values.

> **Note** You cannot use the `nextval()` function in `UPDATE` or `DELETE` statements if mirroring is enabled in WarehousePG.

Setting the Sequence Counter Value

You can use the WarehousePG `setval()` built-in function to set the counter value for a sequence. For example, the following command sets the counter value of the sequence named `myserial` to `201` :

```
SELECT setval('myserial', 201);
```

`setval()` has two function signatures: `setval(sequence, start_val)` and `setval(sequence, start_val, is_called)` . The default behaviour of `setval(sequence, start_val)` sets the sequence `is_called` attribute value to `true` .

If you do not want the sequence counter advanced on the next `nextval()` call, use the `setval(sequence, start_val, is_called)` function signature, passing a `false` argument:

```
SELECT setval('myserial', 201, false);
```

`setval()` operations are never rolled back.

nextval() and setval() Caution

To avoid blocking concurrent transactions that obtain numbers from the same sequence, the value obtained by `nextval()` is not reclaimed for re-use if the calling transaction later aborts. As such, transaction aborts or database crashes can result in gaps in the sequence of assigned values. This situation can occur without a transaction abort, also. For example, an `INSERT` with an `ON CONFLICT` clause will compute the to-be-inserted tuple, including invoking any required `nextval()` calls, before detecting any conflict that would cause it to follow the `ON CONFLICT` rule instead. Consequently, you cannot use WarehousePG sequence objects to obtain "gapless" sequences.

Similarly, sequence state changes made by `setval()` are immediately visible to other transactions, and are not undone if the calling transaction rolls back.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

If the database cluster crashes before committing a transaction containing a `nextval()` or `setval()` call, the sequence state change may not have been propogated to persistent storage, so that it is uncertain whether the sequence has its original or updated state after the cluster restarts. This is harmless for usage of the sequence within the database, since other effects of uncommitted transactions are visible either. However, if you wish to use a sequence value for persistent outside-the-database purposes, ensure that the `nextval()` call has been committed before doing so.

Altering a Sequence

The ALTER SEQUENCE command changes the attributes of an existing sequence. You can alter the sequence start, minimum, maximum, and increment values. You can also restart the sequence at the start value or at a specified value.

Any parameters not set in the `ALTER SEQUENCE` command retain their prior settings.

`ALTER SEQUENCE sequence START WITH start_value` sets the sequence's `start_value` attribute to the new starting value. It has no effect on the `last_value` attribute or the value returned by the `nextval(sequence)` function.

`ALTER SEQUENCE sequence RESTART` resets the sequence's `last_value` attribute to the current value of the `start_value` attribute and the `is_called` attribute to `false`. The next call to the `nextval(sequence)` function returns `start_value`.

`ALTER SEQUENCE sequence RESTART WITH restart_value` sets the sequence's `last_value` attribute to the new value and the `is_called` attribute to `false`. The next call to the `nextval(sequence)` returns `restart_value`. This is the equivalent of calling `setval(sequence, restart_value, false)`.

The following command restarts the sequence named `myserial` at value `105`:

```
ALTER SEQUENCE myserial RESTART WITH 105;
```

Dropping a Sequence

The DROP SEQUENCE command removes a sequence. For example, the following command removes the sequence named `myserial`:

```
DROP SEQUENCE myserial;
```

Specifying a Sequence as the Default Value for a Column

You can reference a sequence directly in the CREATE TABLE command in addition to using the `SERIAL` or `BIGSERIAL` types. For example:

```
CREATE TABLE tablename ( id INT4 DEFAULT nextval('myserial'), name text );
```

You can also alter a table column to set its default value to a sequence counter:

```
ALTER TABLE tablename ALTER COLUMN id SET DEFAULT nextval('myserial');
```

Sequence Wraparound

By default, a sequence does not wrap around. That is, when a sequence reaches the max value (`+32767` for `SMALLSERIAL`, `+2147483647` for `SERIAL`, `+9223372036854775807` for `BIGSERIAL`), every subsequent `nextval()` call produces an error. You can alter a sequence to make it cycle around and start at `1` again:

```
ALTER SEQUENCE myserial CYCLE;
```

You can also specify the wraparound behaviour when you create the sequence:

```
CREATE SEQUENCE myserial CYCLE;
```

4.4.9 Using Indexes in WarehousePG

In most traditional databases, indexes can greatly improve data access times. However, in a distributed database such as WarehousePG, indexes should be used more sparingly. WarehousePG performs very fast sequential scans; indexes use a random seek pattern to locate records on disk. WarehousePG data is distributed across the segments, so each segment scans a smaller portion of the overall data to get the result. With table partitioning, the total data to scan may be even smaller. Because business intelligence (BI) query workloads generally return very large data sets, using indexes is not efficient.

First try your query workload without adding indexes. Indexes are more likely to improve performance for OLTP workloads, where the query is returning a single record or a small subset of data. Indexes can also improve performance on compressed append-optimized tables for queries that return a targeted set of rows, as the optimizer can use an index access method rather than a full table scan when appropriate. For compressed data, an index access method means only the necessary rows are uncompressed.

WarehousePG automatically creates `PRIMARY KEY` constraints for tables with primary keys. To create an index on a partitioned table, create an index on the partitioned table that you created. The index is propagated to all the child tables created by WarehousePG. Creating an index on a table that is created by WarehousePG for use by a partitioned table is not supported.

Note that a `UNIQUE CONSTRAINT` (such as a `PRIMARY KEY CONSTRAINT`) implicitly creates a `UNIQUE INDEX` that must include all the columns of the distribution key and any partitioning key. The `UNIQUE CONSTRAINT` is enforced across the entire table, including all table partitions (if any).

Indexes add some database overhead — they use storage space and must be maintained when the table is updated. Ensure that the query workload uses the indexes that you create, and check that the indexes you add improve query performance (as compared to a sequential scan of the table). To determine whether indexes are being used, examine the query `EXPLAIN` plans. See Query Profiling.

Consider the following points when you create indexes.

- **Your Query Workload.** Indexes improve performance for workloads where queries return a single record or a very small data set, such as OLTP workloads.
- Compressed Tables. Indexes can improve performance on compressed append-optimized tables for queries that return a targeted set of rows. For compressed data, an index access method means only the necessary rows are uncompressed.
- **Avoid indexes on frequently updated columns.** Creating an index on a column that is frequently updated increases the number of writes required when the column is updated.
- **Create selective B-tree indexes.** Index selectivity is a ratio of the number of distinct values a column has divided by the number of rows in a table. For example, if a table has 1000 rows and a column has 800 distinct values, the selectivity of the index is 0.8, which is considered good. Unique indexes always have a selectivity ratio of 1.0, which is the best possible. WarehousePG allows unique indexes only on distribution key columns.
- **Use Bitmap indexes for low selectivity columns.** The WarehousePG Bitmap index type is not available in regular PostgreSQL. See About Bitmap Indexes.
- **Index columns used in joins.** An index on a column used for frequent joins (such as a foreign key column) can improve join performance by enabling more join methods for the query optimizer to use.
- **Index columns frequently used in predicates.** Columns that are frequently referenced in `WHERE` clauses are good candidates for indexes.
- **Avoid overlapping indexes.** Indexes that have the same leading column are redundant.
- **Drop indexes for bulk loads.** For mass loads of data into a table, consider dropping the indexes and re-creating them after the load completes. This is often faster than updating the indexes.
- **Consider a clustered index.** Clustering an index means that the records are physically ordered on disk according to the index. If the records you need are distributed randomly on disk, the database has to seek across the disk to fetch the records requested. If the records are stored close together, the fetching operation is more efficient. For example, a clustered index on a date column where the data is ordered sequentially by date. A query against a specific date range results in an ordered fetch from the disk, which leverages fast sequential access.

Parent topic: DDL: Defining Database Objects

To cluster an index in WarehousePG

Using the `CLUSTER` command to physically reorder a table based on an index can take a long time with very large tables. To achieve the same results much faster, you can manually reorder the data on disk by creating an intermediate table and loading the data in the desired order. For example:

```
CREATE TABLE new_table (LIKE old_table)
       AS SELECT * FROM old_table ORDER BY myixcolumn;
DROP old_table;
ALTER TABLE new_table RENAME TO old_table;
CREATE INDEX myixcolumn_ix ON old_table;
VACUUM ANALYZE old_table;
```

Index Types

WarehousePG supports the Postgres index types B-tree, hash, GiST, SP-GiST, GIN, and BRIN. Each index type uses a different algorithm that is best suited to different types of queries. B-tree indexes fit the most common situations and are the default index type. See Index Types in the PostgreSQL documentation for a description of these types.

> **Note** WarehousePG allows unique indexes only if the columns of the index key are the same as (or a superset of) the WarehousePG distribution key. On a partitioned table, a unique index cannot be enforced across all child tables; a unique index is supported only within a child partition.

About Bitmap Indexes

WarehousePG provides the Bitmap index type. Bitmap indexes are best suited to data warehousing applications and decision support systems with large amounts of data, many ad hoc queries, and few data modification (DML) transactions.

An index provides pointers to the rows in a table that contain a given key value. A regular index stores a list of tuple IDs for each key corresponding to the rows with that key value. Bitmap indexes store a bitmap for each key value. Regular indexes can be several times larger than the data in the table, but bitmap indexes provide the same functionality as a regular index and use a fraction of the size of the indexed data.

Each bit in the bitmap corresponds to a possible tuple ID. If the bit is set, the row with the corresponding tuple ID contains the key value. A mapping function converts the bit position to a tuple ID. Bitmaps are compressed for storage. If the number of distinct key values is small, bitmap indexes are much smaller, compress better, and save considerable space compared with a regular index. The size of a bitmap index is proportional to the number of rows in the table times the number of distinct values in the indexed column.

Bitmap indexes are most effective for queries that contain multiple conditions in the `WHERE` clause. Rows that satisfy some, but not all, conditions are filtered out before the table is accessed. This improves response time, often dramatically.

When to Use Bitmap Indexes

Bitmap indexes are best suited to data warehousing applications where users query the data rather than update it. Bitmap indexes perform best for columns that have between 100 and 100,000 distinct values and when the indexed column is often queried in conjunction with other indexed columns. Columns with fewer than 100 distinct values, such as a gender column with two distinct values (male and female), usually do not benefit much from any type of index. On a column with more than 100,000 distinct values, the performance and space efficiency of a bitmap index decline.

Bitmap indexes can improve query performance for ad hoc queries. `AND` and `OR` conditions in the `WHERE` clause of a query can be resolved quickly by performing the corresponding Boolean operations directly on the bitmaps before converting the resulting bitmap to tuple ids. If the resulting number of rows is small, the query can be answered quickly without resorting to a full table scan.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

When Not to Use Bitmap Indexes

Do not use bitmap indexes for unique columns or columns with high cardinality data, such as customer names or phone numbers. The performance gains and disk space advantages of bitmap indexes start to diminish on columns with 100,000 or more unique values, regardless of the number of rows in the table.

Bitmap indexes are not suitable for OLTP applications with large numbers of concurrent transactions modifying the data.

Use bitmap indexes sparingly. Test and compare query performance with and without an index. Add an index only if query performance improves with indexed columns.

Creating an Index

The `CREATE INDEX` command defines an index on a table. A B-tree index is the default index type. For example, to create a B-tree index on the column *gender* in the table *employee*:

```
CREATE INDEX gender_idx ON employee (gender);
```

To create a bitmap index on the column *title* in the table *films*:

```
CREATE INDEX title_bmp_idx ON films USING bitmap (title);
```

Indexes on Expressions

An index column need not be just a column of the underlying table, but can be a function or scalar expression computed from one or more columns of the table. This feature is useful to obtain fast access to tables based on the results of computations.

Index expressions are relatively expensive to maintain, because the derived expressions must be computed for each row upon insertion and whenever it is updated. However, the index expressions are not recomputed during an indexed search, since they are already stored in the index. In both of the following examples, the system sees the query as just `WHERE indexedcolumn = 'constant'` and so the speed of the search is equivalent to any other simple index query. Thus, indexes on expressions are useful when retrieval speed is more important than insertion and update speed.

The first example is a common way to do case-insensitive comparisons with the `lower` function:

```
SELECT * FROM test1 WHERE lower(col1) = 'value';
```

This query can use an index if one has been defined on the result of the `lower(col1)` function:

```
CREATE INDEX test1_lower_col1_idx ON test1 (lower(col1));
```

This example assumes the following type of query is performed often.

```
SELECT * FROM people WHERE (first_name || ' ' || last_name) = 'John Smith';
```

The query might benefit from the following index.

```
CREATE INDEX people_names ON people ((first_name || ' ' || last_name));
```

The syntax of the `CREATE INDEX` command normally requires writing parentheses around index expressions, as shown in the second example. The parentheses can be omitted when the expression is just a function call, as in the first example.

Examining Index Usage

WarehousePG indexes do not require maintenance and tuning. You can check which indexes are used by the real-life query workload. Use the `EXPLAIN` command to examine index usage for a query.

The query plan shows the steps or *plan nodes* that the database will take to answer a query and time estimates for each plan node. To examine the use of indexes, look for the following query plan node types in your `EXPLAIN` output:

- **Index Scan** - A scan of an index.
- **Bitmap Heap Scan** - Retrieves all
- from the bitmap generated by BitmapAnd, BitmapOr, or BitmapIndexScan and accesses the heap to retrieve the relevant rows.
- **Bitmap Index Scan** - Compute a bitmap by OR-ing all bitmaps that satisfy the query predicates from the underlying index.
- **BitmapAnd** or **BitmapOr** - Takes the bitmaps generated from multiple BitmapIndexScan nodes, ANDs or ORs them together, and generates a new bitmap as its output.

You have to experiment to determine the indexes to create. Consider the following points.

- Run `ANALYZE` after you create or update an index. `ANALYZE` collects table statistics. The query optimizer uses table statistics to estimate the number of rows returned by a query and to assign realistic costs to each possible query plan.
- Use real data for experimentation. Using test data for setting up indexes tells you what indexes you need for the test data, but that is all.
- Do not use very small test data sets as the results can be unrealistic or skewed.
- Be careful when developing test data. Values that are similar, completely random, or inserted in sorted order will skew the statistics away from the distribution that real data would have.
- You can force the use of indexes for testing purposes by using run-time parameters to turn off specific plan types. For example, turn off sequential scans (`enable_seqscan`) and nested-loop joins (`enable_nestloop`), the most basic plans, to force the system to use a different plan. Time your query with and without indexes and use the `EXPLAIN ANALYZE` command to compare the results.

Managing Indexes

Use the `REINDEX` command to rebuild a poorly-performing index. `REINDEX` rebuilds an index using the data stored in the index's table, replacing the old copy of the index.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

To rebuild all indexes on a table

```
REINDEX my_table;
```

```
REINDEX my_index;
```

Dropping an Index

The `DROP INDEX` command removes an index. For example:

```
DROP INDEX title_idx;
```

When loading data, it can be faster to drop all indexes, load, then recreate the indexes.

About Indexes on Expressions

An index column need not be just a column of the underlying table, but can be a function or scalar expression computed from one or more columns of the table. This is useful to obtain fast access to a table based on the results of computations.

For example, a common way to do case-insensitive comparisons is to use the `lower()` function:

```
SELECT * FROM test1 WHERE lower(col1) = 'value';
```

This query can use an index if one has been defined on the result of the `lower(col1)` function:

```
CREATE INDEX test1_lower_col1_idx ON test1 (lower(col1));
```

If you declare this index `UNIQUE`, it prevents creation of rows whose `col1` values differ only in case, as well as rows whose `col1` values are actually identical. So, you can use indexes on expressions to enforce constraints that are not definable as simple unique constraints.

As another example, if you often invoke queries like:

```
SELECT * FROM people WHERE (first_name || ' ' || last_name) = 'John Smith';
```

then it might be worth creating an index like this:

```
CREATE INDEX people_names ON people ((first_name || ' ' || last_name));
```

The syntax of the `CREATE INDEX` command normally requires writing parentheses around index expressions, as shown in the second example. You can omit the parentheses when the expression is just a function call, as in the first example.

Index expressions are relatively expensive to maintain, because WarehousePG must compute the derived expression(s) for each row insertion and non-HOT update. However, WarehousePG does not recompute the index expressions during an indexed search, since they are already stored in the index. In both examples above, WarehousePG views the query as just `WHERE indexedcolumn = 'constant'` and so the speed of the search is equivalent to any other simple index query. Indexes on expressions are useful when retrieval speed is more important than insertion and update speed.

About Partial Indexes

A *partial index* is an index built over a subset of a table; the subset is defined by a conditional expression (called the predicate of the partial index). The index contains entries only for those table rows that satisfy the predicate. There are several situations in which a partial index is particularly useful.

One common reason for using a partial index is to avoid indexing common values. Since a query searching for a common value (one that accounts for more than a few percent of all the table rows) will not use the index anyway, there is no point in keeping those rows in the index at all. This reduces the size of the index, which will speed up those queries that do use the index. It will also speed up many table update operations because the index does not need to be updated in all cases.

Example: Setting up a Partial Index to Exclude Common Values

Suppose you are storing web server access logs in a database. Most accesses originate from the IP address range of your organization but some are from elsewhere (say, employees on dial-up connections). If your searches by IP are primarily for outside accesses, you probably do not need to index the IP range that corresponds to your organization's subnet.

Assume a table defined as such:

```
CREATE TABLE access_log (
    url varchar,
    client_ip inet,
    ...
);
```

To create a partial index that suits the example scenario, use the following command:

```
CREATE INDEX access_log_client_ip_ix ON access_log (client_ip)
WHERE NOT (client_ip > inet '192.168.100.0' AND
           client_ip < inet '192.168.100.255');
```

A typical query that can use this index follows:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
SELECT *
FROM access_log
WHERE url = '/index.html' AND client_ip = inet '212.78.10.32';
```

Here the query's IP address is covered by the partial index. The following query cannot use the partial index, as it uses an IP address that is excluded from the index:

```
SELECT *
FROM access_log
WHERE url = '/index.html' AND client_ip = inet '192.168.100.23';
```

Observe that this kind of partial index requires that the common values be predetermined, so such partial indexes are best used for data distributions that do not change. Such indexes can be recreated occasionally to adjust for new data distributions, adding to the maintenance effort.

Example: Setting up a Partial Index to Exclude Uninteresting Values

Another use for a partial index is to exclude values from the index that the typical query workload is not interested in. This results in the same advantages as listed above, but it prevents the "uninteresting" values from being accessed via that index, even if an index scan might be profitable in that case. Setting up partial indexes for this kind of scenario requires a lot of care and experimentation.

If you have a table that contains both billed and unbilled orders, where the unbilled orders take up a small fraction of the total table and yet those are the most-accessed rows, you can improve performance by creating an index on just the unbilled rows. The following command creates the index:

```
CREATE INDEX orders_unbilled_index ON orders (order_nr)
    WHERE billed is not true;
```

A query to use this index follows:

```
SELECT * FROM orders WHERE billed is not true AND order_nr < 10000;
```

However, you can also use the index in a query that does not involve `order_nr` at all, for example:

```
SELECT * FROM orders WHERE billed is not true AND amount > 5000.00;
```

This is not as efficient as a partial index on the `amount` column, since WarehousePG must scan the entire index. Yet, if there are relatively few unbilled orders, using this partial index just to find the unbilled orders could be a win.

Note that the following query cannot use this index:

```
SELECT * FROM orders WHERE order_nr = 3501;
```

The order `3501` might be among the billed or unbilled orders.

This example also illustrates that the indexed column and the column used in the predicate do not need to match. WarehousePG supports partial indexes with arbitrary predicates, so long as only columns of the table being indexed are involved. Keep in mind that the predicate must match the conditions used in the queries that are supposed to benefit from the index. To be precise, you can use a partial index in a query only if WarehousePG can recognize that the `WHERE` condition of the query mathematically implies the predicate of the index. WarehousePG cannot recognize mathematically equivalent expressions that are written in different forms. WarehousePG can recognize simple inequality implications, for example "x < 1" implies "x < 2"; otherwise the predicate condition must exactly match part of the query's `WHERE` condition or the index will not be recognized as usable. Matching takes place at query planning time, not at run time. As a result, parameterized query clauses do not work with a partial index. For example a prepared query with a parameter might specify "x < ?" which will never imply "x < 2" for all possible values of the parameter.

Example: Setting up a Partial Unique Index

A third possible use for partial indexes does not require the index to be used in queries at all. The idea here is to create a unique index over a subset of a table. This enforces uniqueness among the rows that satisfy the index predicate, without constraining those that do not.

Suppose that you have a table describing test outcomes. You want to ensure that there is only one "successful" entry for a given subject and target combination, but there might be any number of "unsuccessful" entries. Here is one way to satisfy those conditions:

```
CREATE TABLE tests (
    subject text,
    target text,
    success boolean,
    ...
);

CREATE UNIQUE INDEX tests_success_constraint ON tests (subject, target)
    WHERE success;
```

This is a particularly efficient approach when there are few successful tests and many unsuccessful ones. It is also possible to allow only one null in a column by creating a unique partial index with an `IS NULL` restriction.

Finally, a partial index can also be used to override WarehousePG's query plan choices. Also, data sets with peculiar distributions might cause the system to use an index when it really should not. In that case the index can be set up so that it is not available for the offending query. Normally, WarehousePG makes reasonable choices about index usage (it avoids them when retrieving common values, so the earlier example really only saves index size, it is not required to avoid index usage), and grossly incorrect plan choices are cause for a bug report.

Example: Do Not Use Partial Indexes as a Substitute for Partitioning

Keep in mind that setting up a partial index indicates that you know at least as much as the query planner knows, in particular you know when an index might be profitable. Forming this knowledge requires experience and understanding of how indexes in WarehousePG work. In most cases, the advantage of a partial index over a regular index will be minimal. There are cases where they are quite counterproductive.

Suppose you create a large set of non-overlapping partial indexes, for example:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
CREATE INDEX mytable_cat_1 ON mytable (data) WHERE category = 1;
CREATE INDEX mytable_cat_2 ON mytable (data) WHERE category = 2;
CREATE INDEX mytable_cat_3 ON mytable (data) WHERE category = 3;
...
CREATE INDEX mytable_cat_N ON mytable (data) WHERE category = N;
```

This is a bad idea! Almost certainly, you are better off with a single non-partial index, declared like:

```
CREATE INDEX mytable_cat_data ON mytable (category, data);
```

While a search in this larger index might have to descend through a couple more tree levels than a search in a smaller index, that's almost certainly going to be cheaper than the planner effort needed to select the appropriate one of the partial indexes. The core of the problem is that WarehousePG does not understand the relationship among the partial indexes, and tests each one to see if it is applicable to the current query.

If your table is large enough that a single index really is a bad idea, you should look into using partitioning instead. With that mechanism, WarehousePG does understand that the tables and indexes are non-overlapping, so far better performance is possible.

Understanding Index-Only Scans and Covering Indexes

> **Note** WarehousePG selects index-only and covering index scan options for a query plan only for new tables that you create in WarehousePG 7. WarehousePG does not select these plan types for tables that you have upgraded from WarehousePG 6.

All indexes in WarehousePG are secondary indexes, meaning that each index is stored separately from the table's main data area (which is called the table's heap). In an ordinary index scan, each row retrieval requires fetching data from both the index and the heap. While the index entries that match a given indexable `WHERE` condition are often close together in the index, the table rows they reference might reside anywhere in the heap. The heap-access portion of an index scan can involve a lot of random access into the heap, which can be slow, particularly on traditional rotating media. Bitmap scans try to alleviate this cost by doing the heap accesses in sorted order, but that only goes so far.

WarehousePG supports index-only scans to address the performance issue. Index-only scans can answer queries from an index alone without any heap access. WarehousePG returns values directly out of each index entry instead of consulting the associated heap entry. There are two fundamental restrictions on when WarehousePG can use this method:

1. The index type must support index-only scans. B-tree indexes always do. GiST and SP-GiST indexes support index-only scans for some operator classes but not others. Other index types have no support. The underlying requirement is that the index must physically store, or else be able to reconstruct, the original data value for each index entry. As a counterexample, GIN indexes cannot support index-only scans because each index entry typically holds only part of the original data value.

2. The query must reference only columns stored in the index. For example, given an index on columns `x` and `y` of a table that also has a column `z`, these queries could use index-only scans:

   ```
   SELECT x, y FROM tab WHERE x = 'key';
   SELECT x FROM tab WHERE x = 'key' AND y < 42;
   ```

   but these queries could not:

   ```
   SELECT x, z FROM tab WHERE x = 'key';
   SELECT x FROM tab WHERE x = 'key' AND z < 42;
   ```

   (Expression indexes and partial indexes complicate this rule, as discussed below.)

If these two fundamental requirements are met, then all the data values required by the query are available from the index, so an index-only scan is physically possible. But there is an additional requirement for any table scan in WarehousePG: it must verify that each retrieved row be "visible" to the query's MVCC snapshot. Because visibility information is not stored in index entries, only in heap entries, it might seem that every row retrieval would require a heap access anyway. And this is indeed the case, if the table row has been modified recently. However, for seldom-changing data there is a way around this problem. WarehousePG tracks, for each page in a table's heap, whether all rows stored in that page are old enough to be visible to all current and future transactions. This information is stored in a bit in the table's visibility map. An index-only scan, after finding a candidate index entry, checks the visibility map bit for the corresponding heap page. If it is set, the row is known visible and so WarehousePG can return the data with no further work. If it is not set, WarehousePG must visit the heap entry to find out whether it is visible, so no performance advantage is gained over a standard index scan. Even in the successful case, this approach trades visibility map accesses for heap accesses; but since the visibility map is four orders of magnitude smaller than the heap it describes, far less physical I/O is required to access it. In most situations the visibility map remains cached in memory all the time.

To summarize, while an index-only scan is possible given the two fundamental requirements, it will be a win only if a significant fraction of the table's heap pages have their all-visible map bits set. Because tables in which a large fraction of the rows are unchanging are common enough, this type of scan is very useful in practice.

To make effective use of the index-only scan feature, you may choose to create a covering index, which is an index specifically designed to include the columns required by a particular type of query that you run frequently. Since queries typically need to retrieve more columns than just the ones they search on, WarehousePG allows you to create an index in which some columns are just "payload" and are not part of the search key. You signal this by adding an `INCLUDE` clause that lists the extra columns. For example, if you commonly run queries like:

```
SELECT y FROM tab WHERE x = 'key';
```

the traditional approach to speeding up such queries would be to create an index on `x` only. However, an index defined as:

```
CREATE INDEX tab_x_y ON tab(x) INCLUDE (y);
```

could handle these queries as index-only scans, because `y` can be obtained from the index without visiting the heap.

Because column `y` is not part of the index's search key, it does not have to be of a data type that the index can handle; it is merely stored in the index and is not interpreted by the index machinery. Also, if the index is a unique index, that is:

```
CREATE UNIQUE INDEX tab_x_y ON tab(x) INCLUDE (y);
```

the uniqueness condition applies to just column `x`, not to the combination of `x` and `y`. (An `INCLUDE` clause can also be written in `UNIQUE` and `PRIMARY KEY` constraints, providing alternative syntax for setting up an index like this.)

Be conservative about adding non-key payload columns to an index, especially wide columns. If an index tuple exceeds the maximum size allowed for the index type, data insertion fails. Because non-key columns duplicate data from the index's table and bloat the size of the index, they can potentially slow searches. And remember that there is little point in including payload columns in an index unless the table changes slowly enough that an index-only scan is likely to not need to access the heap. If the heap tuple must be visited anyway, it costs nothing more to get the column's value from there. Other restrictions are that expressions are not currently supported as included columns, and that only B-tree and GiST indexes currently support included columns.

Before WarehousePG supported the INCLUDE feature, covering indexes were created by including the payload columns as ordinary index columns, for example:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
CREATE INDEX tab_x_y ON tab(x, y);
```

even though they had no intention of ever using `y` as part of a `WHERE` clause. This works fine as long as the extra columns are trailing columns. However, this method doesn't support the case where you want the index to enforce uniqueness on the key column(s).

Suffix truncation always removes non-key columns from upper B-Tree levels. As payload columns, they are never used to guide index scans. The truncation process also removes one or more trailing key column(s) when the remaining prefix of key column(s) happens to be sufficient to describe tuples on the lowest B-Tree level. In practice, covering indexes without an `INCLUDE` clause often avoid storing columns that are effectively payload in the upper levels. However, explicitly defining payload columns as non-key columns reliably keeps the tuples in upper levels small.

In principle, index-only scans can be used with expression indexes. For example, given an index on `f(x)` where `x` is a table column, it should be possible to execute

```
SELECT f(x) FROM tab WHERE f(x) < 1;
```

as an index-only scan; and this is very attractive if `f()` is an expensive-to-compute function. However, WarehousePG's planner is currently not very smart about such cases. It considers a query to be potentially executable by index-only scan only when all columns required by the query are available from the index. In this example, `x` is not needed except in the context `f(x)`, but the planner does not notice that and concludes that an index-only scan is not possible. If an index-only scan seems sufficiently worthwhile, you can work around this by adding `x` as an included column, for example:

```
CREATE INDEX tab_f_x ON tab (f(x)) INCLUDE (x);
```

An additional caveat, if the goal is to avoid recalculating `f(x)`, is that the planner won't necessarily match uses of `f(x)` that aren't in indexable `WHERE` clauses to the index column. It will usually get this right in simple queries such as shown above, but not in queries that involve joins.

Partial indexes also have interesting interactions with index-only scans. Consider the following partial index:

```
CREATE UNIQUE INDEX tests_success_constraint ON tests (subject, target)
    WHERE success;
```

In principle, WarehousePG could perform an index-only scan on this index to satisfy a query like:

```
SELECT target FROM tests WHERE subject = 'some-subject' AND success;
```

But there is a problem: the `WHERE` clause refers to success which is not available as a result column of the index. Nonetheless, an index-only scan is possible because the plan does not need to recheck that part of the `WHERE` clause at run time: all entries found in the index necessarily have `success = true` so this need not be explicitly checked in the plan. WarehousePG version 7 recognizes such cases and generates index-only scans, but older versions do not.

4.4.9.1 BRIN Indexes

Use Block Range Index (BRIN) for handling very large tables in which certain columns have some natural correlation with their physical location within the table. BRIN works in terms of block ranges (or page ranges), which are groups of pages that are physically adjacent in the table. BRIN stores summary information for each block range. For example, a table storing a store's sale orders might have a date column on which each order was placed, and most of the time the entries for earlier orders will appear earlier in the table as well; a table storing a ZIP code column might have all codes for a city grouped together naturally.

BRIN indexes can satisfy queries via regular bitmap index scans, and return all tuples in all pages within each range if the summary info stored by the index is consistent with the query conditions. The query executor is in charge of rechecking these tuples and discarding those that do not match the query conditions — in other words, these indexes are lossy. Because a BRIN index is very small, scanning the index adds little overhead compared to a sequential scan, but may avoid scanning large parts of the table that are known not to contain matching tuples.

The specific data that a BRIN index stores, as well as the specific queries that the index will be able to satisfy, depend on the operator class selected for each column of the index. Data types that have a linear sort order can have operator classes that store the minimum and maximum value within each block range, for instance; geometrical types store the bounding box for all the objects in the block range.

The size of the block range is determined at index creation time by the `pages_per_range` storage parameter. The number of index entries is equal to the size of the relation in pages divided by the selected value for `pages_per_range`. Therefore, the smaller the number, the larger the index becomes (because of the need to store more index entries), but at the same time the summary data stored can be more precise and more data blocks can be skipped during an index scan. The default value for `pages_per_range` is 32 for heap tables, and 1 for append-optimized tables.

Index Maintenance

At the time of creation, WarehousePG scans all existing heap pages and creates a summary index tuple for each range, including the possibly-incomplete range at the end. As new pages are filled with data, page ranges that are already summarized will cause the summary information to be updated with data from the new tuples. When a new page is created that does not fall within the last summarized range, the range that the new page belongs into does not automatically acquire a summary tuple; those tuples remain unsummarized until a summarization run is invoked later, creating the initial summary for that range.

There are several ways to trigger the initial summarization of a page range. If the table is vacuumed, all existing unsummarized page ranges are summarized.

You may use the following functions:

`brin_summarize_new_values(regclass)` summarizes all unsummarized ranges; `brin_summarize_range(regclass, bigint)` summarizes only the range containing the given page, if it is unsummarized.

Conversely, you may de-summarize a range using the `brin_desummarize_range(regclass, bigint)` function, which is useful when the index tuple is no longer a very good representation because the existing values have changed.

The following table lists the functions available for index maintenance tasks. You cannot execute these functions cannot during recovery. Use of these functions is restricted to superusers and the owner of the given index.

Name	Return Type	Description
brin_summarize_new_values(index regclass)	integer	summarize page ranges not already summarized
brin_summarize_range(index regclass, blockNumber bigint)	integer	summarize the page range covering the given block, if not already summarized
brin_desummarize_range(index regclass, blockNumber bigint)	integer	de-summarize the page range covering the given block, if summarized

`brin_summarize_new_values` accepts the OID or name of a BRIN index and inspects the index to find page ranges in the base table that are not currently summarized by the index; for any such range it creates a new summary index tuple by scanning the table pages. It returns the number of new page range summaries that were inserted into the index. `brin_summarize_range` does the same, except it only summarizes the range that covers the given block number.

> **Note** `brin_summarize_range` and `brin_desummarize_range` only operate on ranges that exist. If you provide a block number that does not exist in the table, the functions return 0. Additionally, a specific range may only exist on some segments, due to data skew. In this case, the functions return the number of segments for which they were able to summarize or desummarize the range.

Built-in Operator Classes

WarehousePG includes the BRIN operator classes shown in the table below.

The `minmax` operator classes store the minimum and the maximum values appearing in the indexed column within the range. The `inclusion` operator classes store a value which includes the values in the indexed column within the range.

Name	Indexed Data Type	Indexable Operators
int8_minmax_ops	bigint	`< <= = >= >`
bit_minmax_ops	bit	`< <= = >= >`
varbit_minmax_ops	bit varying	`< <= = >= >`
box_inclusion_ops	box	`<< &< && <> >> ~= @> <@ &< << >> &>`
bytea_minmax_ops	bytea	`< <= = >= >`
bpchar_minmax_ops	character	`< <= = >= >`
char_minmax_ops	"char"	`< <= = >= >`
date_minmax_ops	date	`< <= = >= >`
float8_minmax_ops	double precision	`< <= = >= >`
inet_minmax_ops	inet	`< <= = >= >`
network_inclusion_ops	inet	`&& >>= <<= = >> <<`
int4_minmax_ops	integer	`< <= = >= >`
interval_minmax_ops	interval	`< <= = >= >`
macaddr_minmax_ops	macaddr	`< <= = >= >`
macaddr8_minmax_op	macaddr8	`< <= = >= >`
name_minmax_ops	name	`< <= = >= >`
numeric_minmax_ops	numeric	`< <= = >= >`

4.4.10 Creating and Managing Views

Views enable you to save frequently used or complex queries, then access them in a `SELECT` statement as if they were a table. A view is not physically materialized on disk: the query runs as a subquery when you access the view.

These topics describe various aspects of creating and managing views:

- Best Practices when Creating Views outlines best practices when creating views.
- Working with View Dependencies contains examples of listing view information and determining what views depend on a certain object.
- About View Storage in WarehousePG describes the mechanics behind view dependencies.

Creating Views

The `CREATE VIEW` command defines a view of a query. For example:

```
CREATE VIEW comedies AS SELECT * FROM films WHERE kind = 'comedy';
```

Views ignore `ORDER BY` and `SORT` operations stored in the view.

Dropping Views

The `DROP VIEW` command removes a view. For example:

```
DROP VIEW topten;
```

The `DROP VIEW...CASCADE` command also removes all dependent objects. As an example, if another view depends on the view which is about to be dropped, the other view will be dropped as well. Without the `CASCADE` option, the `DROP VIEW` command will fail.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.4.10.1 Best Practices when Creating Views

When defining and using a view, remember that a view is just an SQL statement and is replaced by its definition when the query is run.

These are some common uses of views.

- They allow you to have a recurring SQL query or expression in one place for easy reuse.
- They can be used as an interface to abstract from the actual table definitions, so that you can reorganize the tables without having to modify the interface.

If a subquery is associated with a single query, consider using the `WITH` clause of the `SELECT` command instead of creating a seldom-used view.

In general, these uses do not require nesting views, that is, defining views based on other views.

These are two patterns of creating views that tend to be problematic because the view's SQL is used during query execution.

- Defining many layers of views so that your final queries look deceptively simple.

  Problems arise when you try to enhance or troubleshoot queries that use the views, for example by examining the execution plan. The query's execution plan tends to be complicated and it is difficult to understand and how to improve it.

- Defining a denormalized "world" view. A view that joins a large number of database tables that is used for a wide variety of queries.

  Performance issues can occur for some queries that use the view for some `WHERE` conditions while other `WHERE` conditions work well.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.4.10.2 Working with View Dependencies

If there are view dependencies on a table you must use the `CASCADE` keyword to drop it. Also, you cannot alter the table if there are view dependencies on it. This example shows a view dependency on a table.

```
CREATE TABLE t (id integer PRIMARY KEY);
CREATE VIEW v AS SELECT * FROM t;

DROP TABLE t;
ERROR:  cannot drop table t because other objects depend on it
DETAIL:  view v depends on table t
HINT:  Use DROP ... CASCADE to drop the dependent objects too.

ALTER TABLE t DROP id;
ERROR:  cannot drop column id of table t because other objects depend on it
DETAIL:  view v depends on column id of table t
HINT:  Use DROP ... CASCADE to drop the dependent objects too.
```

As the previous example shows, altering a table can be quite a challenge if there is a deep hierarchy of views, because you have to create the views in the correct order. You cannot create a view unless all the objects it requires are present.

You can use view dependency information when you want to alter a table that is referenced by a view. For example, you might want to change a table's column data type from `integer` to `bigint` because you realize you need to store larger numbers. However, you cannot do that if there are views that use the column. You first have to drop those views, then change the column and then run all the `CREATE VIEW` statements to create the views again.

Finding View Dependencies

The following example queries list view information on dependencies on tables and columns.

- Finding Direct View Dependencies on a Table
- Finding Direct Dependencies on a Table Column
- Listing View Schemas
- Listing View Definitions
- Listing Nested Views

The example output is based on the Example Data at the end of this topic.

Also, you can use the first example query Finding Direct View Dependencies on a Table to find dependencies on user-defined functions (or procedures). The query uses the catalog table `pg_class` that contains information about tables and views. For functions, you can use the catalog table `pg_proc` to get information about functions.

For detailed information about the system catalog tables that store view information, see About View Storage in WarehousePG.

Finding Direct View Dependencies on a Table

To find out which views directly depend on table `t1`, create a query that performs a join among the catalog tables that contain the dependency information, and qualify the query to return only view dependencies.

```
SELECT v.oid::regclass AS view,
  d.refobjid::regclass AS ref_object    -- name of table
  -- d.refobjid::regproc AS ref_object  -- name of function
FROM pg_depend AS d      -- objects that depend on a table
  JOIN pg_rewrite AS r  -- rules depending on a table
     ON r.oid = d.objid
  JOIN pg_class AS v    -- views for the rules
     ON v.oid = r.ev_class
WHERE v.relkind = 'v'         -- filter views only
  -- dependency must be a rule depending on a relation
  AND d.classid = 'pg_rewrite'::regclass
  AND d.deptype = 'n'         -- normal dependency
  -- qualify object
  AND d.refclassid = 'pg_class'::regclass   -- dependent table
  AND d.refobjid = 't1'::regclass
  -- AND d.refclassid = 'pg_proc'::regclass -- dependent function
  -- AND d.refobjid = 'f'::regproc
;
    view    | ref_object
------------+------------
 v1         | t1
 v2         | t1
 v2         | t1
 v3         | t1
 mytest.vt1 | t1
 mytest.v2a | t1
 mytest.v2a | t1
(7 rows)
```

The query performs casts to the `regclass` object identifier type. For information about object identifier types, see the PostgeSQL documentation on Object Identifier Types.

In some cases, the views are listed multiple times because the view references multiple table columns. You can remove those duplicates using `DISTINCT`.

You can alter the query to find views with direct dependencies on the function `f`.

- In the `SELECT` clause replace the name of the table `d.refobjid::regclass as ref_object` with the name of the function `d.refobjid::regproc as ref_object`
- In the `WHERE` clause replace the catalog of the referenced object from `d.refclassid = 'pg_class'::regclass` for tables, to `d.refclassid = 'pg_proc'::regclass` for procedures (functions). Also change the object name from `d.refobjid = 't1'::regclass` to `d.refobjid = 'f'::regproc`
- In the `WHERE` clause, replace the name of the table `refobjid = 't1'::regclass` with the name of the function `refobjid = 'f'::regproc`.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

In the example query, the changes have been commented out (prefixed with `--`). You can comment out the lines for the table and enable the lines for the function.

Finding Direct Dependencies on a Table Column

You can modify the previous query to find those views that depend on a certain table column, which can be useful if you are planning to drop a column (adding a column to the base table is never a problem). The query uses the table column information in the `pg_attribute` catalog table.

This query finds the views that depend on the column `id` of table `t1`:

```
SELECT v.oid::regclass AS view,
  d.refobjid::regclass AS ref_object, -- name of table
  a.attname AS col_name               -- column name
FROM pg_attribute AS a   -- columns for a table
  JOIN pg_depend AS d    -- objects that depend on a column
    ON d.refobjsubid = a.attnum AND d.refobjid = a.attrelid
  JOIN pg_rewrite AS r   -- rules depending on the column
    ON r.oid = d.objid
  JOIN pg_class AS v     -- views for the rules
    ON v.oid = r.ev_class
WHERE v.relkind = 'v'    -- filter views only
  -- dependency must be a rule depending on a relation
  AND d.classid = 'pg_rewrite'::regclass
  AND d.refclassid = 'pg_class'::regclass
  AND d.deptype = 'n'    -- normal dependency
  AND a.attrelid = 't1'::regclass
  AND a.attname = 'id'
;
    view    | ref_object | col_name
------------+------------+----------
 v1         | t1         | id
 v2         | t1         | id
 mytest.vt1 | t1         | id
 mytest.v2a | t1         | id
(4 rows)
```

Listing View Schemas

If you have created views in multiple schemas, you can also list views, each view's schema, and the table referenced by the view. The query retrieves the schema from the catalog table `pg_namespace` and excludes the system schemas `pg_catalog`, `information_schema`, and `gp_toolkit`. Also, the query does not list a view if the view refers to itself.

```
SELECT v.oid::regclass AS view,
  ns.nspname AS schema,       -- view schema,
  d.refobjid::regclass AS ref_object -- name of table
FROM pg_depend AS d            -- objects that depend on a table
  JOIN pg_rewrite AS r         -- rules depending on a table
    ON r.oid = d.objid
  JOIN pg_class AS v           -- views for the rules
    ON v.oid = r.ev_class
  JOIN pg_namespace AS ns      -- schema information
    ON ns.oid = v.relnamespace
WHERE v.relkind = 'v'          -- filter views only
  -- dependency must be a rule depending on a relation
  AND d.classid = 'pg_rewrite'::regclass
  AND d.refclassid = 'pg_class'::regclass  -- referenced objects in pg_class -- tables and views
  AND d.deptype = 'n'          -- normal dependency
  -- qualify object
  AND ns.nspname NOT IN ('pg_catalog', 'information_schema', 'gp_toolkit') -- system schemas
  AND NOT (v.oid = d.refobjid) -- not self-referencing dependency
;
    view    | schema | ref_object
------------+--------+------------
 v1         | public | t1
 v2         | public | t1
 v2         | public | t1
 v2         | public | v1
 v3         | public | t1
 vm1        | public | mytest.tm1
 mytest.vm1 | mytest | t1
 vm2        | public | mytest.tm1
 mytest.v2a | mytest | t1
 mytest.v2a | mytest | t1
 mytest.v2a | mytest | v1
(11 rows)
```

Listing View Definitions

This query lists the views that depend on `t1`, the column referenced, and the view definition. The `CREATE VIEW` command is created by adding the appropriate text to the view definition.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
SELECT v.relname AS view,
  d.refobjid::regclass as ref_object,
  d.refobjsubid as ref_col,
  'CREATE VIEW ' || v.relname || ' AS ' || pg_get_viewdef(v.oid) AS view_def
FROM pg_depend AS d
  JOIN pg_rewrite AS r
    ON r.oid = d.objid
  JOIN pg_class AS v
    ON v.oid = r.ev_class
WHERE NOT (v.oid = d.refobjid)
  AND d.refobjid = 't1'::regclass
  ORDER BY d.refobjsubid
;
 view | ref_object | ref_col |                  view_def
------+------------+---------+---------------------------------------------
 v1   | t1         |       1 | CREATE VIEW v1 AS  SELECT max(t1.id) AS id+
      |            |         |    FROM t1;
 v2a  | t1         |       1 | CREATE VIEW v2a AS  SELECT t1.val         +
      |            |         |    FROM (t1                               +
      |            |         |      JOIN v1 USING (id));
 vt1  | t1         |       1 | CREATE VIEW vt1 AS  SELECT t1.id          +
      |            |         |    FROM t1                                +
      |            |         |   WHERE (t1.id < 3);
 v2   | t1         |       1 | CREATE VIEW v2 AS  SELECT t1.val          +
      |            |         |    FROM (t1                               +
      |            |         |      JOIN v1 USING (id));
 v2a  | t1         |       2 | CREATE VIEW v2a AS  SELECT t1.val         +
      |            |         |    FROM (t1                               +
      |            |         |      JOIN v1 USING (id));
 v3   | t1         |       2 | CREATE VIEW v3 AS  SELECT (t1.val || f()) +
      |            |         |    FROM t1;
 v2   | t1         |       2 | CREATE VIEW v2 AS  SELECT t1.val          +
      |            |         |    FROM (t1                               +
      |            |         |      JOIN v1 USING (id));
(7 rows)
```

Listing Nested Views

This CTE query lists information about views that reference another view.

The `WITH` clause in this CTE query selects all the views in the user schemas. The main `SELECT` statement finds all views that reference another view.

```
WITH views AS ( SELECT v.relname AS view,
  d.refobjid AS ref_object,
  v.oid AS view_oid,
  ns.nspname AS namespace
FROM pg_depend AS d
  JOIN pg_rewrite AS r
    ON r.oid = d.objid
  JOIN pg_class AS v
    ON v.oid = r.ev_class
  JOIN pg_namespace AS ns
    ON ns.oid = v.relnamespace
WHERE v.relkind = 'v'
  AND ns.nspname NOT IN ('pg_catalog', 'information_schema', 'gp_toolkit') -- exclude system schemas
  AND d.deptype = 'n'    -- normal dependency
  AND NOT (v.oid = d.refobjid) -- not a self-referencing dependency
 )
SELECT views.view, views.namespace AS schema,
  views.ref_object::regclass AS ref_view,
  ref_nspace.nspname AS ref_schema
FROM views
  JOIN pg_depend as dep
    ON dep.refobjid = views.view_oid
  JOIN pg_class AS class
    ON views.ref_object = class.oid
  JOIN  pg_namespace AS ref_nspace
     ON class.relnamespace = ref_nspace.oid
  WHERE class.relkind = 'v'
    AND dep.deptype = 'n'
;
 view | schema | ref_view | ref_schema
------+--------+----------+------------
 v2   | public | v1       | public
 v2a  | mytest | v1       | public
```

Example Data

The output for the example queries is based on these database objects and data.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
CREATE TABLE t1 (
   id integer PRIMARY KEY,
   val text NOT NULL
);

INSERT INTO t1 VALUES
   (1, 'one'), (2, 'two'), (3, 'three');

CREATE FUNCTION f() RETURNS text
   LANGUAGE sql AS 'SELECT ''suffix''::text';

CREATE VIEW v1 AS
  SELECT max(id) AS id
  FROM t1;

CREATE VIEW v2 AS
  SELECT t1.val
  FROM t1 JOIN v1 USING (id);

CREATE VIEW v3 AS
  SELECT val || f()
  FROM t1;

CREATE VIEW v5 AS
  SELECT f() ;

CREATE SCHEMA mytest ;

CREATE TABLE mytest.tm1 (
   id integer PRIMARY KEY,
   val text NOT NULL
);

INSERT INTO mytest.tm1 VALUES
   (1, 'one'), (2, 'two'), (3, 'three');

CREATE VIEW vm1 AS
  SELECT id FROM mytest.tm1 WHERE id < 3 ;

CREATE VIEW mytest.vm1 AS
  SELECT id FROM public.t1 WHERE id < 3 ;

CREATE VIEW vm2 AS
  SELECT max(id) AS id
  FROM mytest.tm1;

CREATE VIEW mytest.v2a AS
  SELECT t1.val
  FROM public.t1 JOIN public.v1 USING (id);
```

4.4.10.3 About View Storage in WarehousePG

A view is similar to a table, both are relations - that is "something with columns". All such objects are stored in the catalog table `pg_class`. These are the general differences:

- A view has no data files (because it holds no data).
- The value of `pg_class.relkind` for a view is `v` rather than `r`.
- A view has an `ON SELECT` query rewrite rule called `_RETURN`.

  The rewrite rule contains the definition of the view and is stored in the `ev_action` column of the `pg_rewrite` catalog table.

For more technical information about views, see the PostgreSQL documentation aboutViews and the Rule System.

Also, a view definition is *not* stored as a string, but in the form of a query parse tree. Views are parsed when they are created, which has several consequences:

- Object names are resolved during `CREATE VIEW`, so the current setting of `search_path` affects the view definition.
- Objects are referred to by their internal immutable object ID rather than by their name. Consequently, renaming an object or column referenced in a view definition can be performed without dropping the view.
- WarehousePG can determine exactly which objects are used in the view definition, so it can add dependencies on them.

Note that the way WarehousePG handles views is quite different from the way WarehousePG handles functions: function bodies are stored as strings and are not parsed when they are created. Consequently, WarehousePG does not know on which objects a given function depends.

Where View Dependency Information is Stored

These system catalog tables contain the information used to determine the tables on which a view depends.

- `pg_class` - object information including tables and views. The `relkind` column describes the type of object.
- `pg_depend` - object dependency information for database-specific (non-shared) objects.
- `pg_rewrite` - rewrite rules for tables and views.
- `pg_attribute` - information about table columns.
- `pg_namespace` - information about schemas (namespaces).

It is important to note that there is no direct dependency of a view on the objects it uses: the dependent object is actually the view's rewrite rule. That adds another layer of indirection to view dependency information.

4.4.11 Creating and Managing Materialized Views

Materialized views are similar to views. A materialized view enables you to save a frequently used or complex query, then access the query results in a `SELECT` statement as if they were a table. Materialized views persist the query results in a table-like form. While access to the data stored in a materialized view can be much faster than accessing the underlying tables directly or through a view, the data is not always current.

The materialized view data cannot be directly updated. To refresh the materialized view data, use the `REFRESH MATERIALIZED VIEW` command. The query used to create the materialized view is stored in exactly the same way that a view's query is stored. For example, you can create a materialized view that quickly displays a summary of historical sales data for situations where having incomplete data for the current date would be acceptable.

```
CREATE MATERIALIZED VIEW sales_summary AS
  SELECT seller_no, invoice_date, sum(invoice_amt)::numeric(13,2) as sales_amt
    FROM invoice
    WHERE invoice_date < CURRENT_DATE
    GROUP BY seller_no, invoice_date
    ORDER BY seller_no, invoice_date;

CREATE UNIQUE INDEX sales_summary_seller
  ON sales_summary (seller_no, invoice_date);
```

The materialized view might be useful for displaying a graph in the dashboard created for sales people. You could schedule a job to update the summary information each night using this command.

```
REFRESH MATERIALIZED VIEW sales_summary;
```

The information about a materialized view in the WarehousePG cluster catalogs is exactly the same as it is for a table or view. A materialized view is a relation, just like a table or a view. When a materialized view is referenced in a query, the data is returned directly from the materialized view, just like from a table. The query in the materialized view definition is only used for populating the materialized view.

If you can tolerate periodic updates of materialized view data, the performance benefit can be substantial.

One use of a materialized view is to allow faster access to data brought in from an external data source such as external table or a foreign data wrapper. Also, you can define indexes on a materialized view, whereas foreign data wrappers do not support indexes; this advantage might not apply for other types of external data access.

If a subquery is associated with a single query, consider using the `WITH` clause of the `SELECT` command instead of creating a seldom-used materialized view.

Parent topic: DDL: Defining Database Objects

Creating Materialized Views

The `CREATE MATERIALIZED VIEW` command defines a materialized view based on a query.

```
CREATE MATERIALIZED VIEW us_users AS SELECT u.id, u.name, a.zone FROM users u, address a WHERE a.country = 'USA';
```

If a materialized view query contains an `ORDER BY` or `SORT` clause, the clause is ignored when a `SELECT` is performed on the materialized query.

Refreshing or Deactivating Materialized Views

The `REFRESH MATERIALIZED VIEW` command updates the materialized view data.

```
REFRESH MATERIALIZED VIEW us_users;
```

With the `WITH NO DATA` clause, the current data is removed, no new data is generated, and the materialized view is left in an unscannable state. An error is returned if a query attempts to access an unscannable materialized view.

```
REFRESH MATERIALIZED VIEW us_users WITH NO DATA;
```

Dropping Materialized Views

The `DROP MATERIALIZED VIEW` command removes a materialized view definition and data. For example:

```
DROP MATERIALIZED VIEW us_users;
```

The `DROP MATERIALIZED VIEW ... CASCADE` command also removes all dependent objects. For example, if another materialized view depends on the materialized view which is about to be dropped, the other materialized view will be dropped as well. Without the `CASCADE` option, the `DROP MATERIALIZED VIEW` command fails.

4.5 DML: Inserting, Updating and Deleting

This section provides information about manipulating data and concurrent access in WarehousePG.

This topic includes the following subtopics:

- About Concurrency Control in WarehousePG
- Inserting Rows
- Updating Existing Rows
- Deleting Rows
- Working With Transactions
- Global Deadlock Detector
- Vacuuming the Database
- Running Out of Locks

Parent topic: WarehousePG Administrator Guide

About Concurrency Control in WarehousePG

WarehousePG and PostgreSQL do not use locks for concurrency control. They maintain data consistency using a multiversion model, Multiversion Concurrency Control (MVCC). MVCC achieves transaction isolation for each database session, and each query transaction sees a snapshot of data. This ensures the transaction sees consistent data that is not affected by other concurrent transactions.

Because MVCC does not use explicit locks for concurrency control, lock contention is minimized and WarehousePG maintains reasonable performance in multiuser environments. Locks acquired for querying (reading) data do not conflict with locks acquired for writing data.

WarehousePG provides multiple lock modes to control concurrent access to data in tables. Most WarehousePG SQL commands automatically acquire the appropriate locks to ensure that referenced tables are not dropped or modified in incompatible ways while a command runs. For applications that cannot adapt easily to MVCC behavior, you can use the `LOCK` command to acquire explicit locks. However, proper use of MVCC generally provides better performance.

Lock Mode	Associated SQL Commands	Conflicts With
ACCESS SHARE	`SELECT`	ACCESS EXCLUSIVE
ROW SHARE	`SELECT...FOR lock_strength`	EXCLUSIVE, ACCESS EXCLUSIVE
ROW EXCLUSIVE	`INSERT`, `COPY`	SHARE, SHARE ROW EXCLUSIVE, EXCLUSIVE, ACCESS EXCLUSIVE
SHARE UPDATE EXCLUSIVE	`VACUUM` (without `FULL`), `ANALYZE`	SHARE UPDATE EXCLUSIVE, SHARE, SHARE ROW EXCLUSIVE, EXCLUSIVE, ACCESS EXCLUSIVE
SHARE	`CREATE INDEX`	ROW EXCLUSIVE, SHARE UPDATE EXCLUSIVE, SHARE ROW EXCLUSIVE, EXCLUSIVE, ACCESS EXCLUSIVE
SHARE ROW EXCLUSIVE		ROW EXCLUSIVE, SHARE UPDATE EXCLUSIVE, SHARE, SHARE ROW EXCLUSIVE, EXCLUSIVE, ACCESS EXCLUSIVE
EXCLUSIVE	`DELETE`, `UPDATE`, `SELECT...FOR lock_strength`, `REFRESH MATERIALIZED VIEW CONCURRENTLY`	ROW SHARE, ROW EXCLUSIVE, SHARE UPDATE EXCLUSIVE, SHARE, SHARE ROW EXCLUSIVE, EXCLUSIVE, ACCESS EXCLUSIVE
ACCESS EXCLUSIVE	`ALTER TABLE`, `DROP TABLE`, `TRUNCATE`, `REINDEX`, `CLUSTER`, `REFRESH MATERIALIZED VIEW` (without `CONCURRENTLY`), `VACUUM FULL`	ACCESS SHARE, ROW SHARE, ROW EXCLUSIVE, SHARE UPDATE EXCLUSIVE, SHARE, SHARE ROW EXCLUSIVE, EXCLUSIVE, ACCESS EXCLUSIVE

> **Note** By default, the Global Deadlock Detector is deactivated, and WarehousePG acquires the more restrictive `EXCLUSIVE` lock (rather than `ROW EXCLUSIVE` in PostgreSQL) for `UPDATE`, `DELETE`, and `SELECT` queries with a locking clause (`FOR lock_strength`).

When the Global Deadlock Detector is enabled:

- The lock mode for some `DELETE` and `UPDATE` operations on heap tables is `ROW EXCLUSIVE`. See Global Deadlock Detector.
- The lock mode for some queries with a locking clause (`SELECT...FOR lock_strength`) is `ROW SHARE`. See "The Locking Clause" in SELECT.

Inserting Rows

Use the `INSERT` command to create rows in a table. This command requires the table name and a value for each column in the table; you may optionally specify the column names in any order. If you do not specify column names, list the data values in the order of the columns in the table, separated by commas.

For example, to specify the column names and the values to insert:

```
INSERT INTO products (name, price, product_no) VALUES ('Cheese', 9.99, 1);
```

To specify only the values to insert:

```
INSERT INTO products VALUES (1, 'Cheese', 9.99);
```

Usually, the data values are literals (constants), but you can also use scalar expressions. For example:

```
INSERT INTO films SELECT * FROM tmp_films WHERE date_prod <
'2016-05-07';
```

You can insert multiple rows in a single command. For example:

```
INSERT INTO products (product_no, name, price) VALUES
    (1, 'Cheese', 9.99),
    (2, 'Bread', 1.99),
    (3, 'Milk', 2.99);
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

To insert data into a partitioned table, you specify the root partitioned table, which is the table created with the `CREATE TABLE` command. You also can specify a leaf partition in an `INSERT` command. An error is returned if the data is not valid for the specified leaf partition. Specifying a table that is not a leaf partition in the `INSERT` command is not supported.

To insert large amounts of data, use external tables or the `COPY` command. These load mechanisms are more efficient than `INSERT` for inserting large quantities of rows. See Loading and Unloading Data for more information about bulk data loading.

The storage model of append-optimized tables is optimized for bulk data loading. WarehousePG does not recommend single row `INSERT` statements for append-optimized tables. For append-optimized tables, WarehousePG supports a maximum of 127 concurrent `INSERT` transactions into a single append-optimized table.

Updating Existing Rows

The `UPDATE` command updates rows in a table. You can update all rows, a subset of all rows, or individual rows in a table. You can update each column separately without affecting other columns.

To perform an update, you need:

- The name of the table and columns to update
- The new values of the columns
- One or more conditions specifying the row or rows to be updated.

For example, the following command updates all products that have a price of *5* to have a price of *10*:

```
UPDATE products SET price = 10 WHERE price = 5;
```

Using `UPDATE` in WarehousePG has the following restrictions:

- While GPORCA supports updates to WarehousePG distribution key columns, the Postgres-based planner does not.
- If mirrors are enabled, you cannot use `STABLE` or `VOLATILE` functions in an `UPDATE` statement.
- WarehousePG partitioning columns cannot be updated.

Deleting Rows

The `DELETE` command deletes rows from a table. Specify a `WHERE` clause to delete rows that match certain criteria. If you do not specify a `WHERE` clause, all rows in the table are deleted. The result is a valid, but empty, table. For example, to remove all rows from the products table that have a price of *10*:

```
DELETE FROM products WHERE price = 10;
```

To delete all rows from a table:

```
DELETE FROM products;
```

Using `DELETE` in WarehousePG has similar restrictions to using `UPDATE`:

- If mirrors are enabled, you cannot use `STABLE` or `VOLATILE` functions in an `UPDATE` statement.

Truncating a Table

Use the `TRUNCATE` command to quickly remove all rows in a table. For example:

```
TRUNCATE mytable;
```

This command empties a table of all rows in one operation. Note that `TRUNCATE` does not scan the table, therefore it does not process inherited child tables or `ON DELETE` rewrite rules. The command truncates only rows in the named table.

Working With Transactions

Transactions allow you to bundle multiple SQL statements in one all-or-nothing operation.

The following are the WarehousePG SQL transaction commands:

- `BEGIN` or `START TRANSACTION` starts a transaction block.
- `END` or `COMMIT` commits the results of a transaction.
- `ROLLBACK` abandons a transaction without making any changes.
- `SAVEPOINT` marks a place in a transaction and enables partial rollback. You can roll back commands run after a savepoint while maintaining commands run before the savepoint.
- `ROLLBACK TO SAVEPOINT` rolls back a transaction to a savepoint.
- `RELEASE SAVEPOINT` destroys a savepoint within a transaction.

Transaction Isolation Levels

WarehousePG accepts the standard SQL transaction levels as follows:

- `READ UNCOMMITTED` and `READ COMMITTED` behave like the standard `READ COMMITTED`.
- `REPEATABLE READ` and `SERIALIZABLE` behave like `REPEATABLE READ`.

The following information describes the behavior of the WarehousePG transaction levels.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Read Uncommitted and Read Committed

WarehousePG does not allow any command to see an uncommitted update in another concurrent transaction, so `READ UNCOMMITTED` behaves the same as `READ COMMITTED`. `READ COMMITTED` provides fast, simple, partial transaction isolation. `SELECT`, `UPDATE`, and `DELETE` commands operate on a snapshot of the database taken when the query started.

A `SELECT` query:

- Sees data committed before the query starts.
- Sees updates run within the transaction.
- Does not see uncommitted data outside the transaction.
- Can possibly see changes that concurrent transactions made if the concurrent transaction is committed after the initial read in its own transaction.

Successive `SELECT` queries in the same transaction can see different data if other concurrent transactions commit changes between the successive queries. `UPDATE` and `DELETE` commands find only rows committed before the commands started.

`READ COMMITTED` transaction isolation allows concurrent transactions to modify or lock a row before `UPDATE` or `DELETE` find the row. `READ COMMITTED` transaction isolation may be inadequate for applications that perform complex queries and updates and require a consistent view of the database.

Repeatable Read and Serializable

`SERIALIZABLE` transaction isolation, as defined by the SQL standard, ensures that transactions that run concurrently produce the same results as if they were run one after another. If you specify `SERIALIZABLE` WarehousePG falls back to `REPEATABLE READ`. `REPEATABLE READ` transactions prevent dirty reads, non-repeatable reads, and phantom reads without expensive locking, but WarehousePG does not detect all serializability interactions that can occur during concurrent transaction execution. Concurrent transactions should be examined to identify interactions that are not prevented by disallowing concurrent updates of the same data. You can prevent these interactions by using explicit table locks or by requiring the conflicting transactions to update a dummy row introduced to represent the conflict.

With `REPEATABLE READ` transactions, a `SELECT` query:

- Sees a snapshot of the data as of the start of the transaction (not as of the start of the current query within the transaction).
- Sees only data committed before the query starts.
- Sees updates run within the transaction.
- Does not see uncommitted data outside the transaction.
- Does not see changes that concurrent transactions make.
- Successive `SELECT` commands within a single transaction always see the same data.
- `UPDATE`, `DELETE`, `SELECT FOR UPDATE`, and `SELECT FOR SHARE` commands find only rows committed before the command started. If a concurrent transaction has updated, deleted, or locked a target row, the `REPEATABLE READ` transaction waits for the concurrent transaction to commit or roll back the change. If the concurrent transaction commits the change, the `REPEATABLE READ` transaction rolls back. If the concurrent transaction rolls back its change, the `REPEATABLE READ` transaction can commit its changes.

The default transaction isolation level in WarehousePG is `READ COMMITTED`. To change the isolation level for a transaction, declare the isolation level when you `BEGIN` the transaction or use the `SET TRANSACTION` command after the transaction starts.

Global Deadlock Detector

The WarehousePG Global Deadlock Detector background worker process collects lock information on all segments and uses a directed algorithm to detect the existence of local and global deadlocks. This algorithm allows WarehousePG to relax concurrent update and delete restrictions on heap tables. (WarehousePG still employs table-level locking on AO/CO tables, restricting concurrent `UPDATE`, `DELETE`, and `SELECT...FOR lock_strength` operations.)

By default, the Global Deadlock Detector is deactivated and WarehousePG runs the concurrent `UPDATE` and `DELETE` operations on a heap table serially. You can activate these concurrent updates and have the Global Deadlock Detector determine when a deadlock exists by setting the server configuration parameter `gp_enable_global_deadlock_detector`.

When the Global Deadlock Detector is enabled, the background worker process is automatically started on the coordinator host when you start WarehousePG. You configure the interval at which the Global Deadlock Detector collects and analyzes lock waiting data via the gp_global_deadlock_detector_period server configuration parameter.

If the Global Deadlock Detector determines that deadlock exists, it breaks the deadlock by cancelling one or more backend processes associated with the youngest transaction(s) involved.

When the Global Deadlock Detector determines a deadlock exists for the following types of transactions, only one of the transactions will succeed. The other transactions will fail with an error indicating that concurrent updates to the same row is not allowed.

- Concurrent transactions on the same row of a heap table where the first transaction is an update operation and a later transaction runs an update or delete and the query plan contains a motion operator.
- Concurrent update transactions on the same distribution key of a heap table that are run by the Postgres-based planner.
- Concurrent update transactions on the same row of a hash table that are run by the GPORCA optimizer.

> **Note** WarehousePG uses the interval specified in the deadlock_timeout server configuration parameter for local deadlock detection. Because the local and global deadlock detection algorithms differ, the cancelled process(es) may differ depending upon which detector (local or global) WarehousePG triggers first.

> **Note** If the lock_timeout server configuration parameter is turned on and set to a value smaller than `deadlock_timeout` and `gp_global_deadlock_detector_period`, WarehousePG will cancel a statement before it would ever trigger a deadlock check in that session.

To view lock waiting information for all segments, run the `gp_dist_wait_status()` user-defined function. You can use the output of this function to determine which transactions are waiting on locks, which transactions are holding locks, the lock types and mode, the waiter and holder session identifiers, and which segments are running the transactions. Sample output of the `gp_dist_wait_status()` function follows:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
SELECT * FROM pg_catalog.gp_dist_wait_status();
-[ RECORD 1 ]----+--------------
segid            | 0
waiter_dxid      | 11
holder_dxid      | 12
holdTillEndXact  | t
waiter_lpid      | 31249
holder_lpid      | 31458
waiter_lockmode  | ShareLock
waiter_locktype  | transactionid
waiter_sessionid | 8
holder_sessionid | 9
-[ RECORD 2 ]----+--------------
segid            | 1
waiter_dxid      | 12
holder_dxid      | 11
holdTillEndXact  | t
waiter_lpid      | 31467
holder_lpid      | 31250
waiter_lockmode  | ShareLock
waiter_locktype  | transactionid
waiter_sessionid | 9
holder_sessionid | 8
```

When it cancels a transaction to break a deadlock, the Global Deadlock Detector reports the following error message:

```
ERROR:  canceling statement due to user request: "cancelled by global deadlock detector"
```

Global Deadlock Detector UPDATE and DELETE Compatibility

The Global Deadlock Detector can manage concurrent updates for these types of `UPDATE` and `DELETE` commands on heap tables:

- Simple `UPDATE` of a single table. Update a non-distribution key with the Postgres-based planner. The command does not contain a `FROM` clause, or a sub-query in the `WHERE` clause.

  ```
  UPDATE t SET c2 = c2 + 1 WHERE c1 > 10;
  ```

- Simple `DELETE` of a single table. The command does not contain a sub-query in the `FROM` or `WHERE` clauses.

  ```
  DELETE FROM t WHERE c1 > 10;
  ```

- Split `UPDATE`. For the Postgres-based planner, the `UPDATE` command updates a distribution key.

  ```
  UPDATE t SET c = c + 1; -- c is a distribution key
  ```

  For GPORCA, the `UPDATE` command updates a distribution key or references a distribution key.

  ```
  UPDATE t SET b = b + 1 WHERE c = 10; -- c is a distribution key
  ```

- Complex `UPDATE`. The `UPDATE` command includes multiple table joins.

  ```
  UPDATE t1 SET c = t1.c+1 FROM t2 WHERE t1.c = t2.c;
  ```

  Or the command contains a sub-query in the `WHERE` clause.

  ```
  UPDATE t SET c = c + 1 WHERE c > ALL(SELECT * FROM t1);
  ```

- Complex `DELETE`. A complex `DELETE` command is similar to a complex `UPDATE`, and involves multiple table joins or a sub-query.

  ```
  DELETE FROM t USING t1 WHERE t.c > t1.c;
  ```

The following table shows the concurrent `UPDATE` or `DELETE` commands that are managed by the Global Deadlock Detector. For example, concurrent simple `UPDATE` commands on the same table row are managed by the Global Deadlock Detector. For a concurrent complex `UPDATE` and a simple `UPDATE`, only one `UPDATE` is performed, and an error is returned for the other `UPDATE`.

Command	Simple `UPDATE`	Simple `DELETE`	Split `UPDATE`	Complex `UPDATE`	Complex `DELETE`
Simple `UPDATE`	YES	YES	NO	NO	NO
Simple `DELETE`	YES	YES	NO	YES	YES
Split `UPDATE`	NO	NO	NO	NO	NO
Complex `UPDATE`	NO	YES	NO	NO	NO
Complex `DELETE`	NO	YES	NO	NO	YES

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Vacuuming the Database

Deleted or updated data rows occupy physical space on disk even though new transactions cannot see them. Periodically running the `VACUUM` command removes these expired rows. For example:

```
VACUUM mytable;
```

The `VACUUM` command collects table-level statistics such as the number of rows and pages. Vacuum all tables after loading data, including append-optimized tables. For information about recommended routine vacuum operations, see Routine Vacuum and Analyze.

> **Important** The `VACUUM`, `VACUUM FULL`, and `VACUUM ANALYZE` commands should be used to maintain the data in a WarehousePG especially if updates and deletes are frequently performed on your database data. See the `VACUUM` command in the *WarehousePG Reference Guide* for information about using the command.

Running Out of Locks

WarehousePG can potentially run out of locks when a database operation accesses multiple tables in a single transaction. Backup and restore are examples of such operations.

When WarehousePG runs out of locks, the error message that you may observe references a shared memory error:

```
... "WARNING","53200","out of shared memory",,,,,,"LOCK TABLE ...
... "ERROR","53200","out of shared memory",,"You might need to increase max_locks_per_transaction.",,,,"LOCK TABLE ...
```

> **Note** "shared memory" in this context refers to the shared memory of the internal object: the lock slots. "Out of shared memory" does *not* refer to exhaustion of system- or WarehousePG-level memory resources.

As the hint describes, consider increasing the `max_locks_per_transaction` server configuration parameter when you encounter this error.

4.6 Querying Data

This topic provides information about using SQL in WarehousePGs.

You enter SQL statements called queries to view, change, and analyze data in a database using the `psql` interactive SQL client and other client tools.

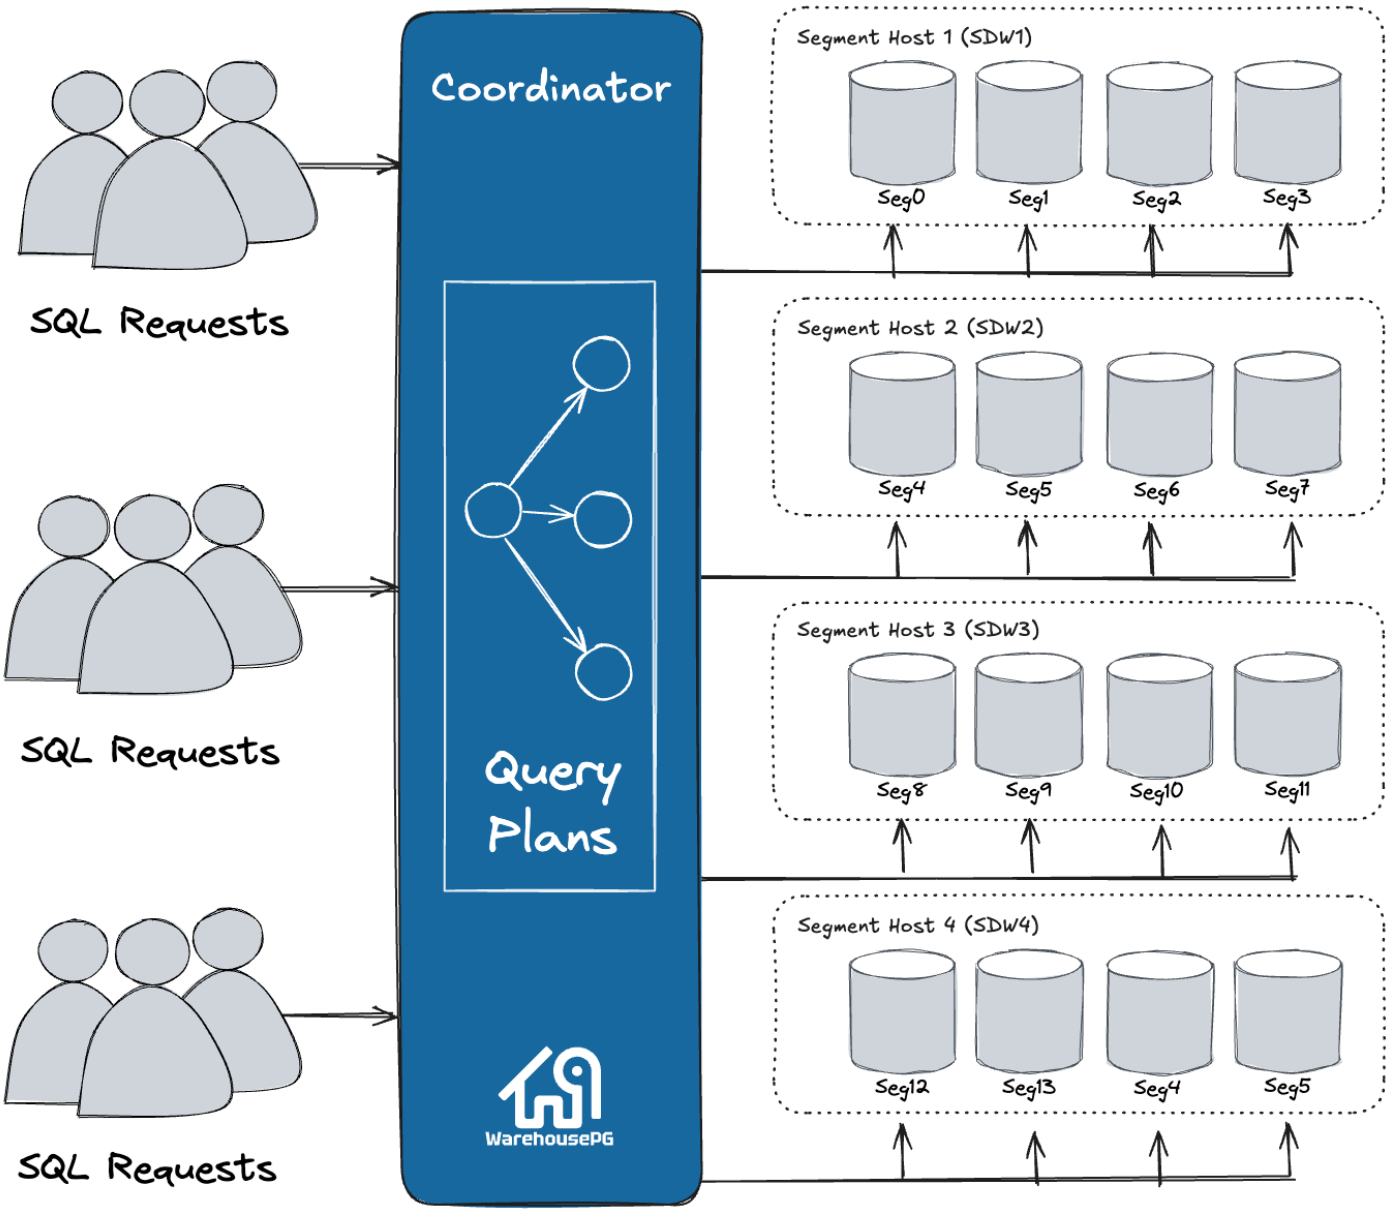
- About WarehousePG Query Processing
  This topic provides an overview of how WarehousePG processes queries. Understanding this process can be useful when writing and tuning queries.
- About GPORCA
  In WarehousePG, the default GPORCA optimizer co-exists with the Postgres-based planner.
- Defining Queries
  WarehousePG is based on the PostgreSQL implementation of the SQL standard.
- WITH Queries (Common Table Expressions)
  The `WITH` clause provides a way to use subqueries or perform a data modifying operation in a larger `SELECT` query. You can also use the `WITH` clause in an `INSERT`, `UPDATE`, or `DELETE` command.
- Using Functions and Operators
  Description of user-defined and built-in functions and operators in WarehousePG.
- Working with JSON Data
  WarehousePG supports the `json` and `jsonb` data types that store JSON (JavaScript Object Notation) data.
- Working with XML Data
  WarehousePG supports the `xml` data type that stores XML data.
- Using Full Text Search
  WarehousePG provides data types, functions, operators, index types, and configurations for querying natural language documents.
- Query Performance
  WarehousePG dynamically eliminates irrelevant partitions in a table and optimally allocates memory for different operators in a query.
- Managing Spill Files Generated by Queries
  WarehousePG creates spill files, also known as workfiles, on disk if it does not have sufficient memory to run an SQL query in memory.
- Query Profiling
  Examine the query plans of poorly performing queries to identify possible performance tuning opportunities.
- Just-in-Time Compilation (JIT) WarehousePG supports Just-in-Time compilation for long-running CPU-bound queries.

Parent topic: WarehousePG Administrator Guide

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.6.1 About WarehousePG Query Processing

This topic provides an overview of how WarehousePG processes queries. Understanding this process can be useful when writing and tuning queries.

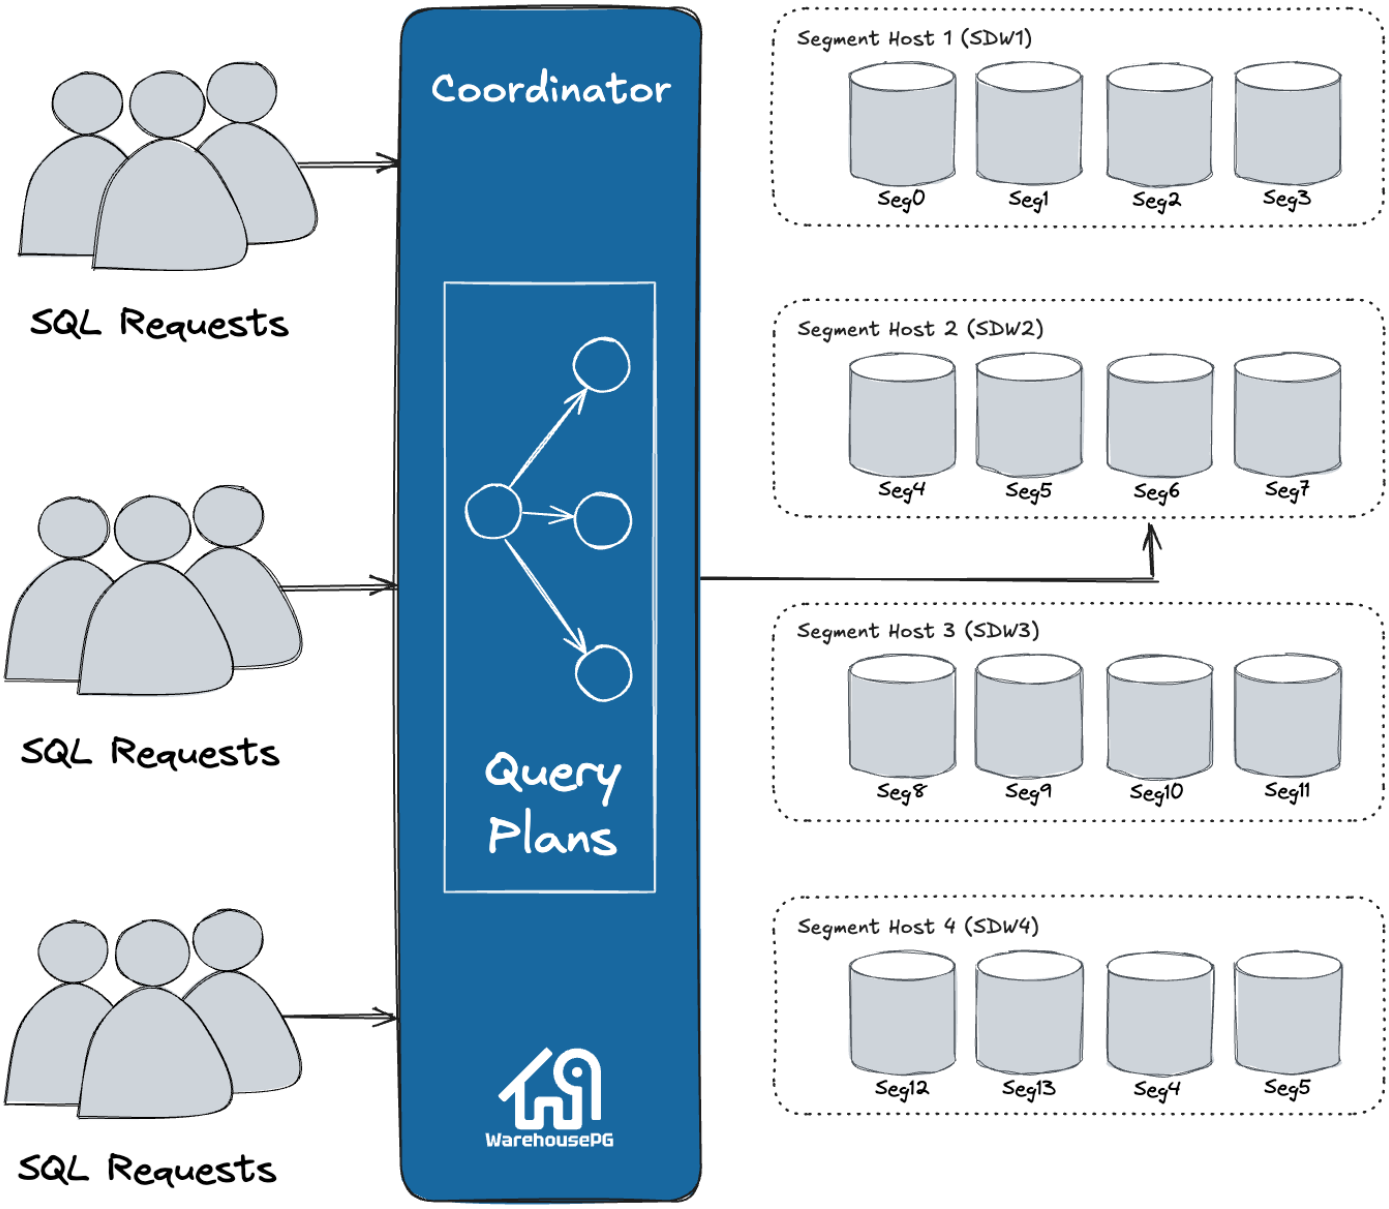


Users issue queries to WarehousePG as they would to any database management system. They connect to the database instance on the WarehousePG coordinator host using a client application such as `psql` and submit SQL statements.

Parent topic: Querying Data

Understanding Query Planning and Dispatch

The coordinator receives, parses, and optimizes the query. The resulting query plan is either parallel or targeted. The coordinator dispatches parallel query plans to all data segments.



Dispatched Parallel Query Plan

The coordinator dispatches targeted query plans to a single segment. Each segment is responsible for running local database operations on its own set of data. Most database operations—such as table scans, joins, aggregations, and sorts—run across all segments in parallel. Each operation is performed on a segment database independent of the data stored in the other segment databases.

Dispatched Targeted Query Plan

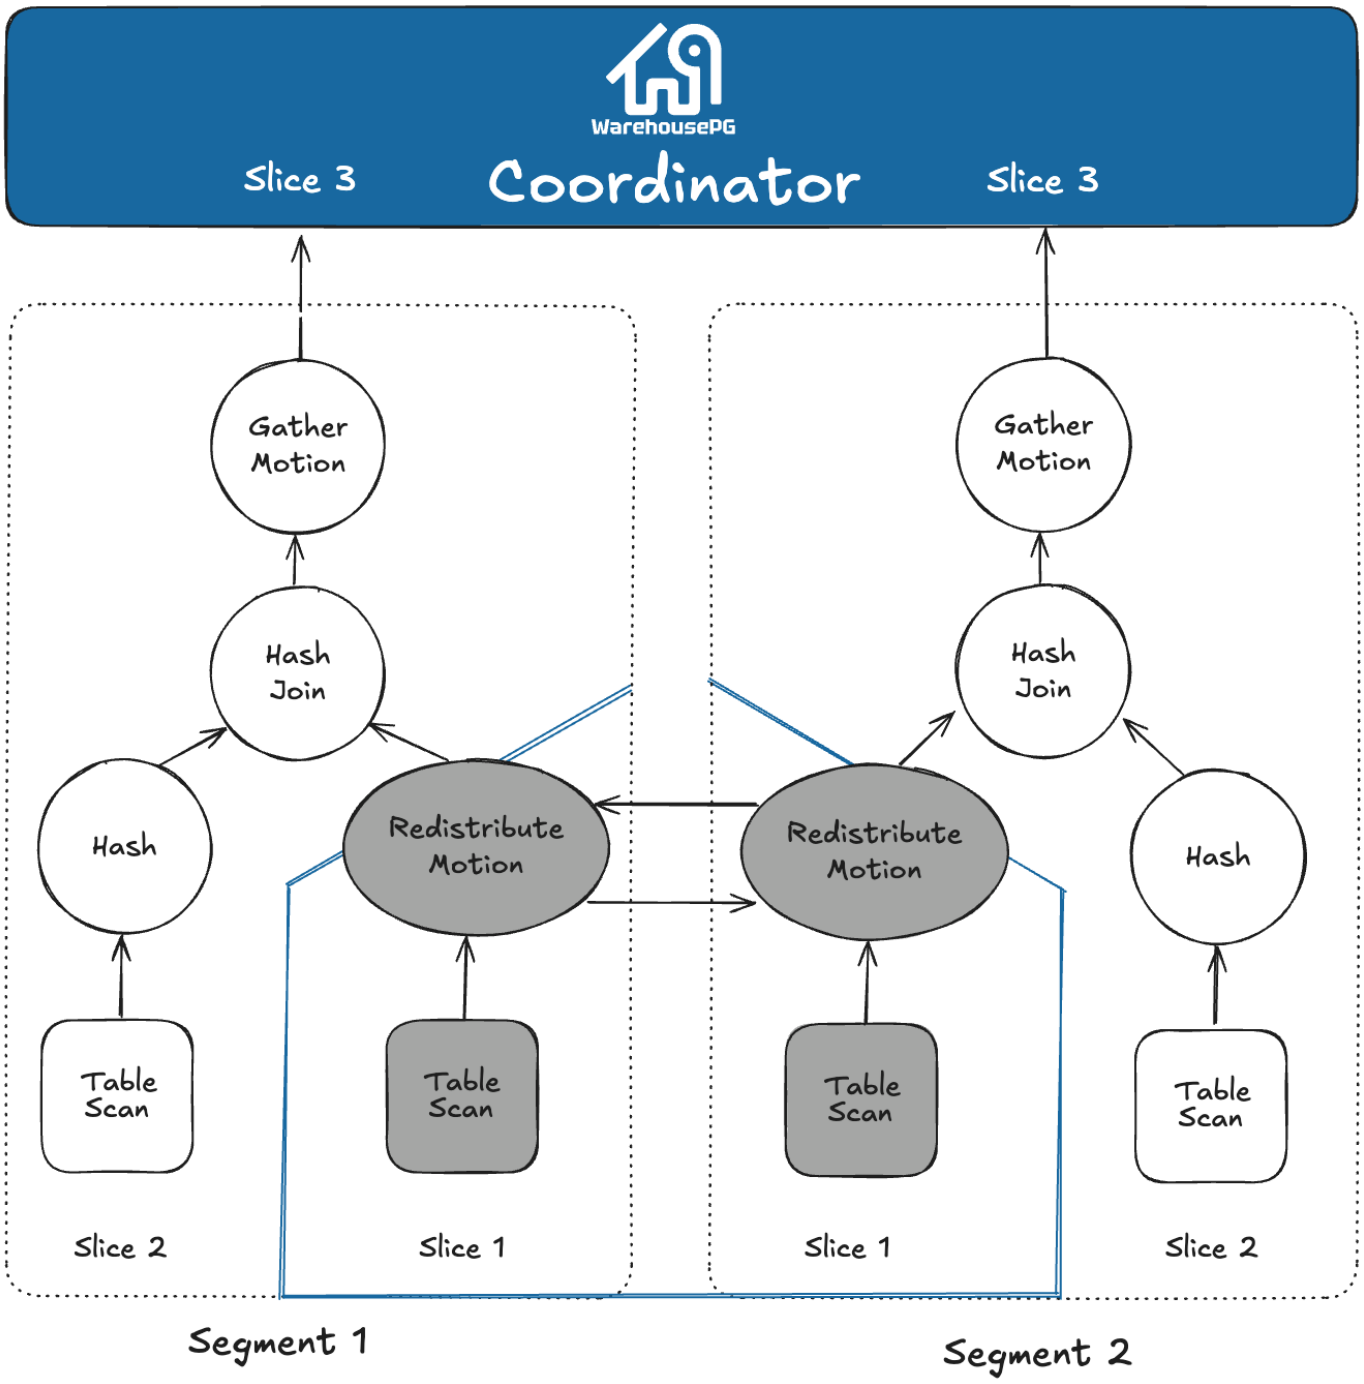
Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Certain queries may access only data on a single segment, such as single-row `INSERT`, `UPDATE`, `DELETE`, or `SELECT` operations or queries that filter on the table distribution key column(s). In queries such as these, the query plan is not dispatched to all segments, but is targeted at the segment that contains the affected or relevant row(s).

Understanding WarehousePG Query Plans

A query plan is the set of operations WarehousePG will perform to produce the answer to a query. Each *node* or step in the plan represents a database operation such as a table scan, join, aggregation, or sort. Plans are read and run from bottom to top.

In addition to common database operations such as table scans, joins, and so on, WarehousePG has an additional operation type called *motion*. A motion operation involves moving tuples between the segments during query processing. Note that not every query requires a motion. For example, a targeted query plan does not require data to move across the interconnect.



To achieve maximum parallelism during query runtime, WarehousePG divides the work of the query plan into *slices*. A slice is a portion of the plan that segments can work on independently. A query plan is sliced wherever a *motion* operation occurs in the plan, with one slice on each side of the motion.

For example, consider the following simple query involving a join between two tables:

```
SELECT customer, amount
FROM ww_sales JOIN customer USING (cust_id)
WHERE dateCol = '04-30-2025';
```

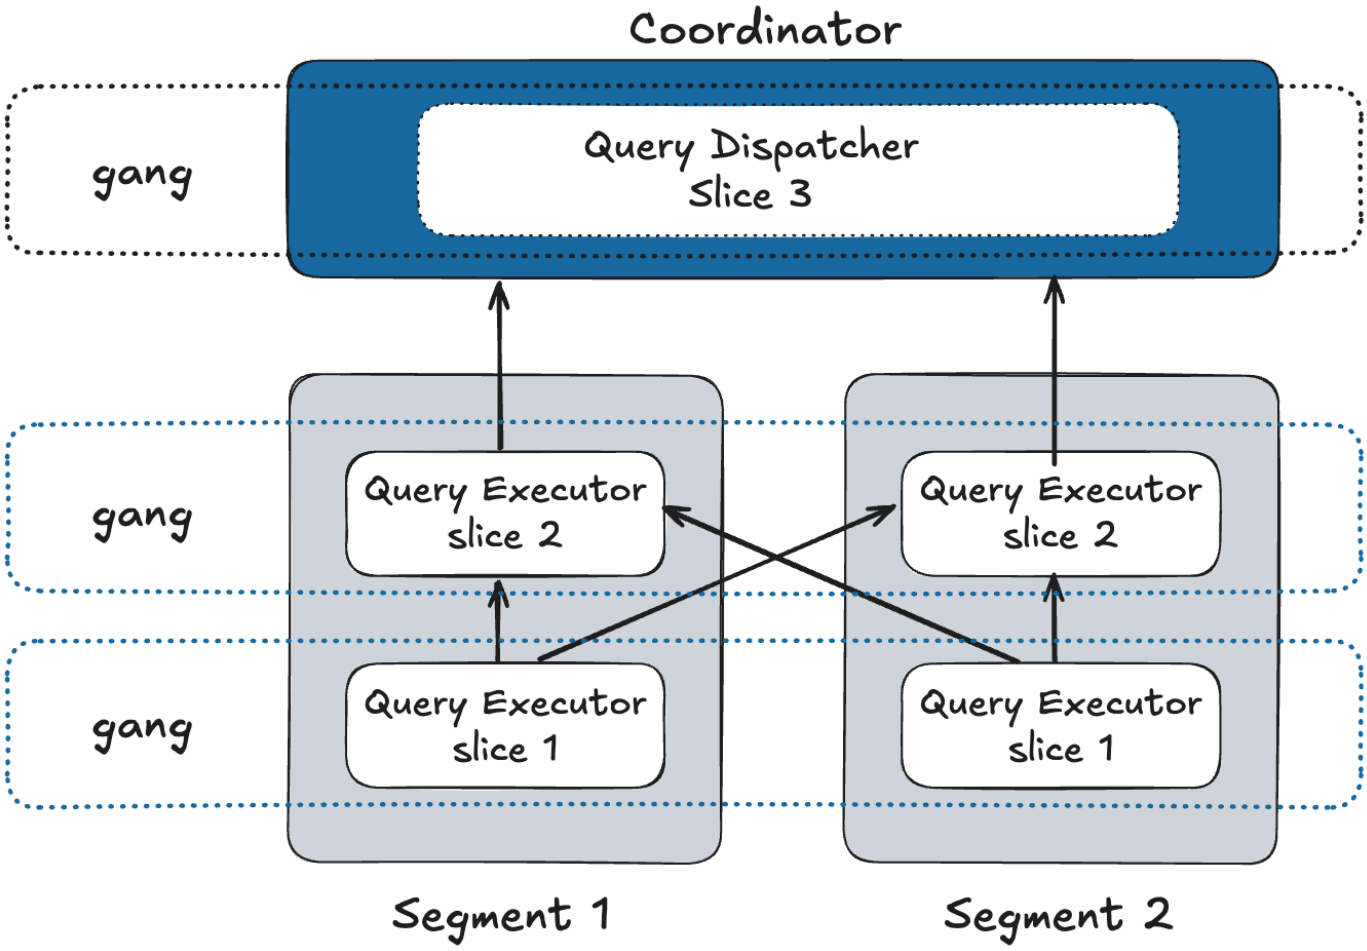
The following figure shows the query plan. Each segment receives a copy of the query plan and works on it in parallel.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

The query plan for this example has a *redistribute motion* that moves tuples between the segments to complete the join. The redistribute motion is necessary because the customer table is distributed across the segments by `cust_id`, but the sales table is distributed across the segments by `sale_id`. To perform the join, the `sales` tuples must be redistributed by `cust_id`. The plan is sliced on either side of the redistribute motion, creating *slice 1* and *slice 2*.

This query plan has another type of motion operation called a *gather motion*. A gather motion is when the segments send results back up to the coordinator for presentation to the client. Because a query plan is always sliced wherever a motion occurs, this plan also has an implicit slice at the very top of the plan (*slice 3*). Not all query plans involve a gather motion. For example, a `CREATE TABLE x AS SELECT...` statement would not have a gather motion because tuples are sent to the newly created table, not to the coordinator.

Understanding Parallel Query Execution



WarehousePG creates a number of database processes to handle the work of a query. On the coordinator, the query worker process is called the *query dispatcher* (QD). The QD is responsible for creating and dispatching the query plan. It also accumulates and presents the final results. On the segments, a query worker process is called a *query executor* (QE). A QE is responsible for completing its portion of work and communicating its intermediate results to the other worker processes.

There is at least one worker process assigned to each *slice* of the query plan. A worker process works on its assigned portion of the query plan independently. During query runtime, each segment will have a number of processes working on the query in parallel.

Related processes that are working on the same slice of the query plan but on different segments are called *gangs*. As a portion of work is completed, tuples flow up the query plan from one gang of processes to the next. This inter-process communication between the segments is referred to as the *interconnect* component of WarehousePG.

The following figure shows the query worker processes on the coordinator and two segment instances for previous query plan.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.6.2 About GPORCA

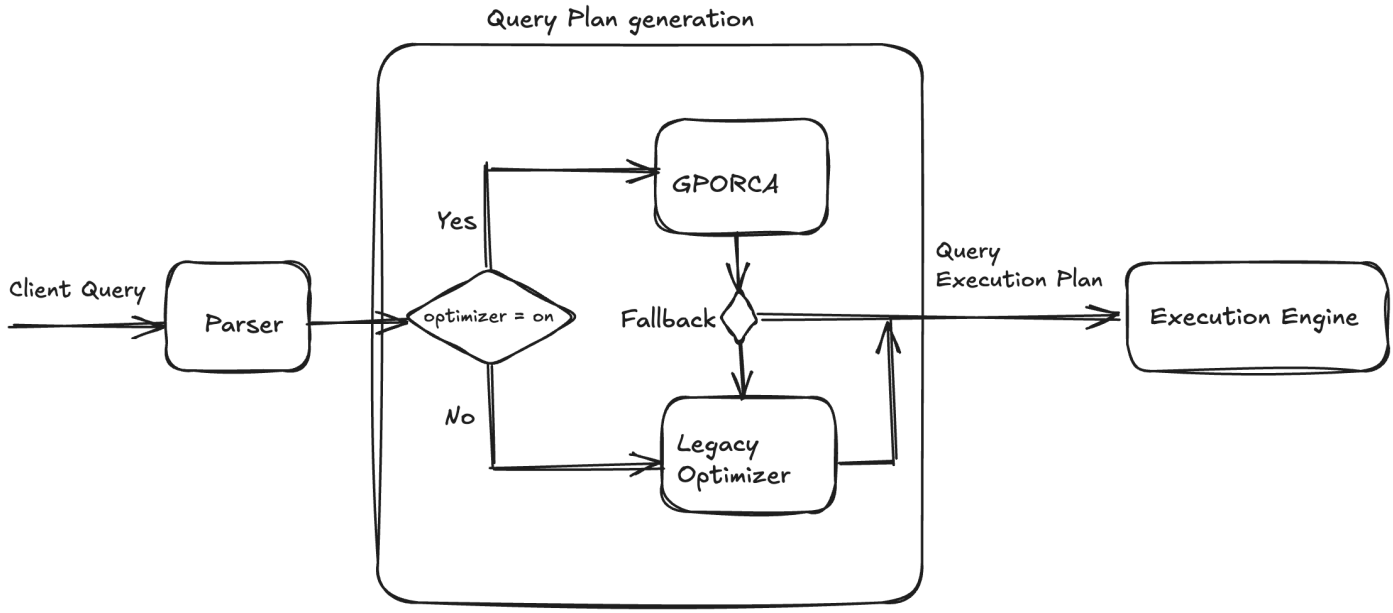
In WarehousePG, the default GPORCA optimizer co-exists with the Postgres-based planner.

- **Overview of GPORCA**
  GPORCA extends the planning and optimization capabilities of the Postgres-based planner.
- **Activating and Deactivating GPORCA**
  By default, WarehousePG uses GPORCA instead of the Postgres-based planner. Server configuration parameters activate or deactivate GPORCA.
- **Collecting Root Partition Statistics**
  For a partitioned table, GPORCA uses statistics of the table root partition to generate query plans. These statistics are used for determining the join order, for splitting and joining aggregate nodes, and for costing the query steps. In contrast, the Postgres-based planner uses the statistics of each leaf partition.
- **Considerations when Using GPORCA**
  To run queries optimally with GPORCA, consider the query criteria closely.
- **GPORCA Features and Enhancements**
  GPORCA, the WarehousePG next generation query optimizer, includes enhancements for specific types of queries and operations:
- **Changed Behavior with GPORCA**
  There are changes to WarehousePG behavior with the GPORCA optimizer enabled (the default) as compared to the Postgres-based planner.
- **GPORCA Limitations**
  There are limitations in WarehousePG when using the default GPORCA optimizer. GPORCA and the Postgres-based planner currently coexist in WarehousePG because GPORCA does not support all WarehousePG features.
- **Determining the Query Optimizer that is Used**
  When GPORCA is enabled (the default), you can determine if WarehousePG is using GPORCA or is falling back to the Postgres-based planner.

Parent topic: Querying Data

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.6.2.1 Overview of GPORCA



GPORCA extends the planning and optimization capabilities of the Postgres-based planner.GPORCA is extensible and achieves better optimization in multi-core architecture environments. WarehousePG uses GPORCA by default to generate an execution plan for a query when possible.

GPORCA also enhances WarehousePG query performance tuning in the following areas:

- Queries against partitioned tables
- Queries that contain a common table expression (CTE)
- Queries that contain subqueries

In WarehousePG, GPORCA co-exists with the Postgres-based planner. By default, WarehousePG uses GPORCA. If GPORCA cannot be used, then the Postgres-based planner is used.

The following figure shows how GPORCA fits into the query planning architecture.

Note All Postgres-based planner server configuration parameters are ignored by GPORCA. However, if WarehousePG falls back to the Postgres-based planner, the planner server configuration parameters will impact the query plan generation. For a list of Postgres-based planner server configuration parameters, see Query Tuning Parameters.

Parent topic: About GPORCA

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.6.2.2 Activating and Deactivating GPORCA

By default, WarehousePG uses GPORCA instead of the Postgres-based planner. Server configuration parameters activate or deactivate GPORCA.

Although GPORCA is on by default, you can configure GPORCA usage at the system, database, session, or query level using the optimizer parameter. Refer to one of the following sections if you want to change the default behavior:

- Enabling GPORCA for a System
- Enabling GPORCA for a Database
- Enabling GPORCA for a Session or a Query

> **Note** You can deactivate the ability to activate or deactivate GPORCA with the server configuration parameter optimizer_control. For information about the server configuration parameters, see the *WarehousePG Reference Guide*.

Parent topic: About GPORCA

Enabling GPORCA for a System

Set the server configuration parameter optimizer for the WarehousePG cluster.

1. Log into the WarehousePG coordinator host as `gpadmin`, the WarehousePG administrator.
2. Set the values of the server configuration parameters. These WarehousePG gpconfig utility commands sets the value of the parameters to `on`:

   ```
   $ gpconfig -c optimizer -v on --coordinatoronly
   ```

3. Restart WarehousePG. This WarehousePG gpstop utility command reloads the `postgresql.conf` files of the coordinator and segments without shutting down WarehousePG.

   ```
   gpstop -u
   ```

Enabling GPORCA for a Database

Set the server configuration parameter optimizer for individual WarehousePGs with the ALTER DATABASE command. For example, this command enables GPORCA for the database *test_db*.

```
> ALTER DATABASE test_db SET OPTIMIZER = ON ;
```

Enabling GPORCA for a Session or a Query

You can use the SET command to set optimizer server configuration parameter for a session. For example, after you use the psql utility to connect to WarehousePG, this SET command enables GPORCA:

```
> set optimizer = on ;
```

To set the parameter for a specific query, include the SET command prior to running the query.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.6.2.3 Collecting Root Partition Statistics

For a partitioned table, GPORCA uses statistics of the table root partition to generate query plans. These statistics are used for determining the join order, for splitting and joining aggregate nodes, and for costing the query steps. In contrast, the Postgres-based planner uses the statistics of each leaf partition.

If you run queries on partitioned tables, you should collect statistics on the root partition and periodically update those statistics to ensure that GPORCA can generate optimal query plans. If the root partition statistics are not up-to-date or do not exist, GPORCA still performs dynamic partition elimination for queries against the table. However, the query plan might not be optimal.

Parent topic: About GPORCA

Running ANALYZE

By default, running the `ANALYZE` command on a root partitioned table samples the leaf partition data in the table, and stores the statistics for the root partition. `ANALYZE` collects statistics on the root and leaf partitions, including HyperLogLog (HLL) statistics on the leaf partitions. `ANALYZE ROOTPARTITION` collects statistics only on the root partition. The server configuration parameter optimizer_analyze_root_partition controls whether the `ROOTPARTITION` keyword is required to collect root statistics for a root partitioned table. See the ANALYZE command for information about collecting statistics on partitioned tables.

Keep in mind that `ANALYZE` always scans the entire table before updating the root partition statistics. If your table is very large, this operation can take a significant amount of time. `ANALYZE ROOTPARTITION` also uses an `ACCESS SHARE` lock that prevents certain operations, such as `TRUNCATE` and `VACUUM` operations, during runtime. For these reasons, you should schedule `ANALYZE` operations periodically, or when there are significant changes to leaf partition data.

Follow these best practices for running `ANALYZE` or `ANALYZE ROOTPARTITION` on partitioned tables in your system:

- Run `ANALYZE <root_partition_table_name>` on a new partitioned table after adding initial data. Run `ANALYZE <leaf_partition_table_name>` on a new leaf partition or a leaf partition where data has changed. By default, running the command on a leaf partition updates the root partition statistics if the other leaf partitions have statistics.
- Update root partition statistics when you observe query performance regression in `EXPLAIN` plans against the table, or after significant changes to leaf partition data. For example, if you add a new leaf partition at some point after generating root partition statistics, consider running `ANALYZE` or `ANALYZE ROOTPARTITION` to update root partition statistics with the new tuples inserted from the new leaf partition.
- For very large tables, run `ANALYZE` or `ANALYZE ROOTPARTITION` only weekly, or at some interval longer than daily.
- Avoid running `ANALYZE` with no arguments, because doing so runs the command on all database tables including partitioned tables. With large databases, these global `ANALYZE` operations are difficult to monitor, and it can be difficult to predict the time needed for completion.
- Consider running multiple `ANALYZE <table_name>` or `ANALYZE ROOTPARTITION <table_name>` operations in parallel to speed the operation of statistics collection, if your I/O throughput can support the load.
- You can also use the WarehousePG utility `analyzedb` to update table statistics. Using `analyzedb` ensures that tables that were previously analyzed are not re-analyzed if no modifications were made to the leaf partition.

GPORCA and Leaf Partition Statistics

Although creating and maintaining root partition statistics is crucial for GPORCA query performance with partitioned tables, maintaining leaf partition statistics is also important. If GPORCA cannot generate a plan for a query against a partitioned table, then the Postgres-based planner is used and leaf partition statistics are needed to produce the optimal plan for that query.

GPORCA itself also uses leaf partition statistics for any queries that access leaf partitions directly, instead of using the root partition with predicates to eliminate partitions. For example, if you know which partitions hold necessary tuples for a query, you can directly query the leaf partition itself; in this case GPORCA uses the leaf partition statistics.

Deactivating Automatic Root Partition Statistics Collection

If you do not intend to run queries on partitioned tables with GPORCA (setting the server configuration parameter optimizer to `off`), then you can deactivate the automatic collection of statistics on the root partition of the partitioned table. The server configuration parameter optimizer_analyze_root_partition controls whether the `ROOTPARTITION` keyword is required to collect root statistics for a root partitioned table. The default setting for the parameter is `on`, the `ANALYZE` command can collect root partition statistics without the `ROOTPARTITION` keyword. You can deactivate automatic collection of root partition statistics by setting the parameter to `off`. When the value is `off`, you must run `ANALZYE ROOTPARTITION` to collect root partition statistics.

1. Log into the WarehousePG coordinator host as `gpadmin`, the WarehousePG administrator.
2. Set the values of the server configuration parameters. These WarehousePG `gpconfig` utility commands sets the value of the parameters to `off`:

   ```
   $ gpconfig -c optimizer_analyze_root_partition -v off --coordinatoronly
   ```

3. Restart WarehousePG. This WarehousePG `gpstop` utility command reloads the `postgresql.conf` files of the coordinator and segments without shutting down WarehousePG.

   ```
   gpstop -u
   ```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.6.2.4 Considerations when Using GPORCA

To run queries optimally with GPORCA, consider the query criteria closely.

Ensure the following criteria are met:

- The table does not contain multi-column partition keys.
- The server configuration parameter `optimizer_enable_coordinator_only_queries` is set to `on` when running against coordinator only tables such as the system table *pg_attribute*. For information about the parameter, see the *WarehousePG Reference Guide*.

  > **Note** Enabling this parameter decreases performance of short running catalog queries. To avoid this issue, set this parameter only for a session or a query.

- Statistics have been collected on the root partitioned table.

If the partitioned table contains more than 20,000 partitions, consider a redesign of the table schema.

These server configuration parameters affect GPORCA query processing.

- `optimizer_cte_inlining_bound` controls the amount of inlining performed for common table expression (CTE) queries (queries that contain a `WITH` clause).
- `optimizer_force_comprehensive_join_implementation` affects GPORCA's consideration of nested loop join and hash join alternatives. When the value is `false` (the default), GPORCA does not consider nested loop join alternatives when a hash join is available.
- `optimizer_force_multistage_agg` forces GPORCA to choose a multi-stage aggregate plan for a scalar distinct qualified aggregate. When the value is `off` (the default), GPORCA chooses between a one-stage and two-stage aggregate plan based on cost.
- `optimizer_force_three_stage_scalar_dqa` forces GPORCA to choose a plan with multistage aggregates when such a plan alternative is generated.
- `optimizer_join_order` sets the query optimization level for join ordering by specifying which types of join ordering alternatives to evaluate.
- `optimizer_join_order_threshold` specifies the maximum number of join children for which GPORCA uses the dynamic programming-based join ordering algorithm.
- `optimizer_nestloop_factor` controls nested loop join cost factor to apply to during query optimization.
- `optimizer_parallel_union` controls the amount of parallelization that occurs for queries that contain a `UNION` or `UNION ALL` clause. When the value is `on`, GPORCA can generate a query plan of the child operations of a `UNION` or `UNION ALL` operation run in parallel on segment instances.
- `optimizer_sort_factor` controls the cost factor that GPORCA applies to sorting operations during query optimization. The cost factor can be adjusted for queries when data skew is present.
- `gp_enable_relsize_collection` controls how GPORCA (and the Postgres-based planner) handle a table without statistics. By default, GPORCA uses a default value to estimate the number of rows if statistics are not available. When this value is `on`, GPORCA uses the estimated size of a table if there are no statistics for the table.

  This parameter is ignored for a root partitioned table. If the root partition does not have statistics, GPORCA always uses the default value. You can use `ANALZYE ROOTPARTITION` to collect statistics on the root partition. See ANALYZE.

These server configuration parameters control the display and logging of information.

- `optimizer_print_missing_stats` controls the display of column information about columns with missing statistics for a query (default is `true`)
- `optimizer_print_optimization_stats` controls the logging of GPORCA query optimization metrics for a query (default is `off`)

For information about the parameters, see the *WarehousePG Reference Guide*.

GPORCA generates minidumps to describe the optimization context for a given query. The minidump files are used by support to analyze WarehousePG issues. The information in the file is not in a format that can be easily used for debugging or troubleshooting. The minidump file is located under the coordinator data directory and uses the following naming format:

```
Minidump_date_time.mdp
```

For information about the minidump file, see the server configuration parameter `optimizer_minidump` in the *WarehousePG Reference Guide*.

When the `EXPLAIN ANALYZE` command uses GPORCA, the `EXPLAIN` plan shows only the number of partitions that are being eliminated. The scanned partitions are not shown. To show the name of the scanned partitions in the segment logs set the server configuration parameter `gp_log_dynamic_partition_pruning` to `on`. This example `SET` command enables the parameter.

```
SET gp_log_dynamic_partition_pruning = on;
```

Parent topic: About GPORCA

4.6.2.5 GPORCA Features and Enhancements

GPORCA, the WarehousePG next generation query optimizer, includes enhancements for specific types of queries and operations:

- Queries Against Partitioned Tables
- Queries that Contain Subqueries
- Queries that Contain Common Table Expressions
- DML Operation Enhancements with GPORCA

GPORCA also includes these optimization enhancements:

- Improved join ordering
- Join-Aggregate reordering
- Sort order optimization
- Data skew estimates included in query optimization

Parent topic: About GPORCA

Queries Against Partitioned Tables

GPORCA includes these enhancements for queries against partitioned tables:

- Partition elimination is improved.
- Query plan can contain the Partition selector operator.
- Partitions are not enumerated in EXPLAIN plans.

  For queries that involve static partition selection where the partitioning key is compared to a constant, GPORCA lists the number of partitions to be scanned in the `EXPLAIN` output under the Partition Selector operator. This example Partition Selector operator shows the filter and number of partitions selected:

  ```
  Partition Selector for Part_Table (dynamic scan id: 1)
         Filter: a > 10
         Partitions selected:  1 (out of 3)
  ```

  For queries that involve dynamic partition selection where the partitioning key is compared to a variable, the number of partitions that are scanned will be known only during query execution. The partitions selected are not shown in the `EXPLAIN` output.
- Plan size is independent of number of partitions.
- Out of memory errors caused by number of partitions are reduced.

This example CREATE TABLE command creates a range partitioned table.

```
CREATE TABLE sales(order_id int, item_id int, amount numeric(15,2),
      date date, yr_qtr int)
   PARTITION BY RANGE (yr_qtr) (start (201501) INCLUSIVE end (201504) INCLUSIVE,
   start (201601) INCLUSIVE end (201604) INCLUSIVE,
   start (201701) INCLUSIVE end (201704) INCLUSIVE,
   start (201801) INCLUSIVE end (201804) INCLUSIVE,
   start (201901) INCLUSIVE end (201904) INCLUSIVE,
   start (202001) INCLUSIVE end (202004) INCLUSIVE);
```

GPORCA improves on these types of queries against partitioned tables:

- Full table scan. Partitions are not enumerated in plans.

  ```
  SELECT * FROM sales;
  ```
- Query with a constant filter predicate. Partition elimination is performed.

  ```
  SELECT * FROM sales WHERE yr_qtr = 201501;
  ```
- Range selection. Partition elimination is performed.

  ```
  SELECT * FROM sales WHERE yr_qtr BETWEEN 201601 AND 201704 ;
  ```
- Joins involving partitioned tables. In this example, the partitioned dimension table *date_dim* is joined with fact table *catalog_sales*:

  ```
  SELECT * FROM catalog_sales
     WHERE date_id IN (SELECT id FROM date_dim WHERE month=12);
  ```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Queries that Contain Subqueries

GPORCA handles subqueries more efficiently. A subquery is query that is nested inside an outer query block. In the following query, the SELECT in the WHERE clause is a subquery.

```
SELECT * FROM part
  WHERE price > (SELECT avg(price) FROM part);
```

GPORCA also handles queries that contain a correlated subquery (CSQ) more efficiently. A correlated subquery is a subquery that uses values from the outer query. In the following query, the `price` column is used in both the outer query and the subquery.

```
SELECT * FROM part p1 WHERE price > (SELECT avg(price) FROM part p2 WHERE p2.brand = p1.brand);
```

GPORCA generates more efficient plans for the following types of subqueries:

- CSQ in the SELECT list.

  ```
  SELECT *,
   (SELECT min(price) FROM part p2 WHERE p1.brand = p2.brand)
   AS foo
  FROM part p1;
  ```

- CSQ in disjunctive (OR) filters.

  ```
  SELECT FROM part p1 WHERE p_size > 40 OR
        p_retailprice >
        (SELECT avg(p_retailprice)
            FROM part p2
            WHERE p2.p_brand = p1.p_brand)
  ```

- Nested CSQ with skip level correlations

  ```
  SELECT * FROM part p1 WHERE p1.p_partkey
  IN (SELECT p_partkey FROM part p2 WHERE p2.p_retailprice =
       (SELECT min(p_retailprice)
         FROM part p3
         WHERE p3.p_brand = p1.p_brand)
  );
  ```

  Note Nested CSQ with skip level correlations are not supported by the Postgres-based planner.

- CSQ with aggregate and inequality. This example contains a CSQ with an inequality.

  ```
  SELECT * FROM part p1 WHERE p1.p_retailprice =
   (SELECT min(p_retailprice) FROM part p2 WHERE p2.p_brand <> p1.p_brand);
  ```

- CSQ that must return one row.

  ```
  SELECT p_partkey,
    (SELECT p_retailprice FROM part p2 WHERE p2.p_brand = p1.p_brand )
  FROM part p1;
  ```

Queries that Contain Common Table Expressions

GPORCA handles queries that contain the WITH clause. The WITH clause, also known as a common table expression (CTE), generates temporary tables that exist only for the query. This example query contains a CTE.

```
WITH v AS (SELECT a, sum(b) as s FROM T where c < 10 GROUP BY a)
  SELECT *FROM  v AS v1 ,  v AS v2
  WHERE v1.a <> v2.a AND v1.s < v2.s;
```

As part of query optimization, GPORCA can push down predicates into a CTE. For example query, GPORCA pushes the equality predicates to the CTE.

```
WITH v AS (SELECT a, sum(b) as s FROM T GROUP BY a)
  SELECT *
  FROM v as v1, v as v2, v as v3
  WHERE v1.a < v2.a
    AND v1.s < v3.s
    AND v1.a = 10
    AND v2.a = 20
    AND v3.a = 30;
```

GPORCA can handle these types of CTEs:

- CTE that defines one or multiple tables. In this query, the CTE defines two tables.

  ```
  WITH cte1 AS (SELECT a, sum(b) as s FROM T
                where c < 10 GROUP BY a),
       cte2 AS (SELECT a, s FROM cte1 where s > 1000)
    SELECT *
    FROM cte1 as v1, cte2 as v2, cte2 as v3
    WHERE v1.a < v2.a AND v1.s < v3.s;
  ```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

- Nested CTEs.

```
WITH v AS (WITH w AS (SELECT a, b FROM foo
                      WHERE b < 5)
           SELECT w1.a, w2.b
           FROM w AS w1, w AS w2
           WHERE w1.a = w2.a AND w1.a > 2)
  SELECT v1.a, v2.a, v2.b
  FROM v as v1, v as v2
  WHERE v1.a < v2.a;
```

DML Operation Enhancements with GPORCA

GPORCA contains enhancements for DML operations such as INSERT, UPDATE, and DELETE.

- A DML node in a query plan is a query plan operator.
    - Can appear anywhere in the plan, as a regular node (top slice only for now)
    - Can have consumers
- UPDATE operations use the query plan operator Split and supports these operations:
    - UPDATE operations on the table distribution key columns.
    - UPDATE operations on the table on the partition key column. This example plan shows the Split operator.

```
QUERY PLAN
------------------------------------------------------------------
Update  (cost=0.00..5.46 rows=1 width=1)
   ->  Redistribute Motion 2:2  (slice1; segments: 2)
         Hash Key: a
         ->  Result  (cost=0.00..3.23 rows=1 width=48)
               ->  Split  (cost=0.00..2.13 rows=1 width=40)
                     ->  Result  (cost=0.00..1.05 rows=1 width=40)
                           ->  Seq Scan on dmltest
```

- New query plan operator Assert is used for constraints checking.

  This example plan shows the Assert operator.

```
QUERY PLAN
------------------------------------------------------------------
 Insert  (cost=0.00..4.61 rows=3 width=8)
   ->  Assert  (cost=0.00..3.37 rows=3 width=24)
         Assert Cond: (dmlsource.a > 2) IS DISTINCT FROM
false
         ->  Assert  (cost=0.00..2.25 rows=3 width=24)
               Assert Cond: NOT dmlsource.b IS NULL
               ->  Result  (cost=0.00..1.14 rows=3 width=24)
                     ->  Seq Scan on dmlsource
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.6.2.6 Changed Behavior with GPORCA

There are changes to WarehousePG behavior with the GPORCA optimizer enabled (the default) as compared to the Postgres-based planner.

- UPDATE operations on distribution keys are allowed.
- UPDATE operations on partitioned keys are allowed.
- Queries against uniform partitioned tables are supported.
- The command CREATE TABLE AS distributes table data randomly if the DISTRIBUTED BY clause is not specified and no primary or unique keys are specified.
- Non-deterministic updates not allowed. The following UPDATE command returns an error.

```
update r set b =  r.b  + 1 from s where  r.a  in (select a from s);
```

- Statistics are required on the root table of a partitioned table. The ANALYZE command generates statistics on both the root partitioned table and individual leaf partitions. See the ROOTPARTITION clause for ANALYZE command.
- Additional Result nodes in the query plan:
    - Query plan Assert operator.
    - Query plan Partition selector operator.
    - Query plan Split operator.
- When running EXPLAIN, the query plan generated by GPORCA is different than the plan generated by the Postgres-based planner.
- WarehousePG adds the log file message `Planner produced plan` when GPORCA is enabled and WarehousePG falls back to the Postgres-based planner to generate the query plan.
- WarehousePG issues a warning when statistics are missing from one or more table columns. When running an SQL command with GPORCA, WarehousePG issues a warning if the command performance could be improved by collecting statistics on a column or set of columns referenced by the command. The warning is issued on the command line and information is added to the WarehousePG log file. For information about collecting statistics on table columns, see the ANALYZE command in the *WarehousePG Reference Guide*.

Parent topic: About GPORCA

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.6.2.7 GPORCA Limitations

There are limitations in WarehousePG when using the default GPORCA optimizer. GPORCA and the Postgres-based planner currently coexist in WarehousePG because GPORCA does not support all WarehousePG features.

This section describes the limitations.

- Unsupported SQL Query Features
- Performance Regressions

Parent topic: About GPORCA

Unsupported SQL Query Features

Certain query features are not supported with the default GPORCA optimizer. When an unsupported query is run, WarehousePG logs this notice along with the query text:

```
Falling back to Postgres-based planner because GPORCA does not support the following feature: UTILITY command
```

These features are unsupported when GPORCA is enabled (the default):

- SP-GiST indexing method. GPORCA supports only B-tree, bitmap, GIN, and GiST indexes. GPORCA ignores indexes created with unsupported methods.
- The `SELECT` command's `TABLESAMPLE` clause.
- The optional `WITH ORDINALITY` clause of a function call inside the `FROM` clause of a `SELECT` command.
- Multi-level partitioned tables.
- Non-uniform partitioned tables.
- SortMergeJoin (SMJ).
- Ordered aggregations.
- Multi-argument `DISTINCT` qualified aggregates, for example `SELECT corr(DISTINCT a, b) FROM tbl1;`.
- Multiple grouping sets specified using a duplicate alias in a null-producing grouping set spec. Such queries fall back to the Postgres-based planner unless you directly coerce the alias to a separate variable as shown in the example below:

  ```
  CREATE TEMP TABLE tempt AS SELECT i AS ai1, i AS ai2 FROM generate_series(1,
  3)i;
  SELECT ai1, ai2 FROM tempt GROUP BY ai2, ROLLUP(ai1) ORDER BY ai1,
  ai2;
  ```

- These scalar operators:
  - ROW
  - ROWCOMPARE
  - FIELDSELECT
- Aggregate functions that take set operators as input arguments.
- Multiple Distinct Qualified Aggregates, such as `SELECT count(DISTINCT a), sum(DISTINCT b) FROM foo`, are not supported by default. They can be enabled with the `optimizer_enable_multiple_distinct_aggs` Configuration Parameter.
- percentile_* window functions (ordered-set aggregate functions).
- Inverse distribution functions.
- Queries that run functions that are defined with the `ON COORDINATOR` or `ON ALL SEGMENTS` attribute.
- Queries that contain UNICODE characters in metadata names, such as table names, and the characters are not compatible with the host system locale.
- `SELECT`, `UPDATE`, and `DELETE` commands where a table name is qualified by the `ONLY` keyword.
- Per-column collation. GPORCA supports collation only when all columns in the query use the same collation. If columns in the query use different collations, then WarehousePG uses the Postgres-based planner.
- DML and `COPY ... FROM` operations on foreign tables.
- Unsupported index-related features include:
  - Index scan on AO tables
  - Partial dynamic index scan
  - Partial indexes
  - Forward and backward dynamic index and dynamic index-only scans on partitioned tables
  - Indexed expressions (an index defined as an expression based on one or more columns of the table)
  - Combined indexes

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Performance Regressions

The following features are known performance regressions that occur with GPORCA enabled:

- Short running queries - For GPORCA, short running queries might encounter additional overhead due to GPORCA enhancements for determining an optimal query execution plan.
- ANALYZE - For GPORCA, the ANALYZE command generates root partition statistics for partitioned tables. For the Postgres-based planner, these statistics are not generated.
- DML operations - For GPORCA, DML enhancements including the support of updates on partition and distribution keys might require additional overhead.

Also, enhanced functionality of the features from previous versions could result in additional time required when GPORCA runs SQL statements with the features.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.6.2.8 Determining the Query Optimizer that is Used

When GPORCA is enabled (the default), you can determine if WarehousePG is using GPORCA or is falling back to the Postgres-based planner.

You can examine the `EXPLAIN` query plan for the query to determine which query optimizer was used by WarehousePG to run the query:

- The optimizer is listed at the end of the query plan. For example, when GPORCA generates the query plan, the query plan ends with:

  ```
  Optimizer: GPORCA
  ```

  When WarehousePG falls back to the Postgres-based planner to generate the plan, the query plan ends with:

  ```
  Optimizer: Postgres-based planner
  ```

- These plan items appear only in the `EXPLAIN` plan output generated by GPORCA. The items are not supported in a Postgres-based planner query plan.

  - Assert operator
  - Sequence operator
  - Dynamic Index Scan
  - Dynamic Seq Scan

- When a query against a partitioned table is generated by GPORCA, the `EXPLAIN` plan displays only the number of partitions that are being eliminated is listed. The scanned partitions are not shown. The `EXPLAIN` plan generated by the Postgres-based planner lists the scanned partitions.

The log file contains messages that indicate which query optimizer was used. If WarehousePG falls back to the Postgres-based planner, a message with `NOTICE` information is added to the log file that indicates the unsupported feature. Also, the label `Planner produced plan:` appears before the query in the query execution log message when WarehousePG falls back to the Postgres optimizer.

> **Note** You can configure WarehousePG to display log messages on the psql command line by setting the WarehousePG server configuration parameter `client_min_messages` to `LOG`. See the *WarehousePG Reference Guide* for information about the parameter.

Parent topic: About GPORCA

Examples

This example shows the differences for a query that is run against partitioned tables when GPORCA is enabled.

This `CREATE TABLE` statement creates a table with single level partitions:

```
CREATE TABLE sales (trans_id int, date date,
    amount decimal(9,2), region text)
   DISTRIBUTED BY (trans_id)
   PARTITION BY RANGE (date)
      (START (date '20160101')
       INCLUSIVE END (date '20170101')
       EXCLUSIVE EVERY (INTERVAL '1 month'),
   DEFAULT PARTITION outlying_dates );
```

This query against the table is supported by GPORCA and does not generate errors in the log file:

```
select * from sales ;
```

The `EXPLAIN` plan output lists only the number of selected partitions.

```
 ->  Partition Selector for sales (dynamic scan id: 1)  (cost=10.00..100.00 rows=50 width=4)
       Partitions selected:  13 (out of 13)
```

If a query against a partitioned table is not supported by GPORCA. WarehousePG falls back to the Postgres-based planner. The `EXPLAIN` plan generated by the Postgres-based planner lists the selected partitions. This example shows a part of the explain plan that lists some selected partitions.

```
 ->  Append  (cost=0.00..0.00 rows=26 width=53)
     ->  Seq Scan on sales2_1_prt_7_2_prt_usa sales2  (cost=0.00..0.00 rows=1 width=53)
     ->  Seq Scan on sales2_1_prt_7_2_prt_asia sales2  (cost=0.00..0.00 rows=1 width=53)
     ...
```

This example shows the log output when the WarehousePG falls back to the Postgres-based planner from GPORCA.

When this query is run, WarehousePG falls back to the Postgres-based planner.

```
explain select * from pg_class;
```

A message is added to the log file. The message contains this `NOTICE` information that indicates the reason GPORCA did not run the query:

```
NOTICE,""Falling back to Postgres-based planner because GPORCA does not support the following feature: Queries on coordinator-only tables"
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.6.3 Defining Queries

WarehousePG is based on the PostgreSQL implementation of the SQL standard.

This topic describes how to construct SQL queries in WarehousePG.

- SQL Lexicon
- SQL Value Expressions

Parent topic: SQL: Querying Data

SQL Lexicon

SQL is a standard language for accessing databases. The language consists of elements that enable data storage, retrieval, analysis, viewing, manipulation, and so on. You use SQL commands to construct queries and commands that the WarehousePG engine understands. SQL queries consist of a sequence of commands. Commands consist of a sequence of valid tokens in correct syntax order, terminated by a semicolon (`;`).

For more information about SQL commands, see SQL Command Reference.

WarehousePG uses PostgreSQL's structure and syntax, with some exceptions. For more information about SQL rules and concepts in PostgreSQL, see "SQL Syntax" in the PostgreSQL documentation.

SQL Value Expressions

SQL value expressions consist of one or more values, symbols, operators, SQL functions, and data. The expressions compare data or perform calculations and return a value as the result. Calculations include logical, arithmetic, and set operations.

The following are value expressions:

- An aggregate expression
- An array constructor
- A column reference
- A constant or literal value
- A correlated subquery
- A field selection expression
- A function call
- A new column value in an `INSERT` or `UPDATE`
- An operator invocation column reference
- A positional parameter reference, in the body of a function definition or prepared statement
- A row constructor
- A scalar subquery
- A search condition in a `WHERE` clause
- A target list of a `SELECT` command
- A type cast
- A value expression in parentheses, useful to group sub-expressions and override precedence
- A window expression

SQL constructs such as functions and operators are expressions but do not follow any general syntax rules. For more information about these constructs, see Using Functions and Operators.

Column References

A column reference has the form:

```
<correlation>.<columnname>
```

Here, `<correlation>` is the name of a table (possibly qualified with a schema name) or an alias for a table defined with a `FROM` clause or one of the keywords `NEW` or `OLD`. `NEW` and `OLD` can appear only in rewrite rules, but you can use other correlation names in any SQL statement. If the column name is unique across all tables in the query, you can omit the `<correlation>` part of the column reference.

Positional Parameters

Positional parameters are arguments to SQL statements or functions that you reference by their positions in a series of arguments. For example, `$1` refers to the first argument, `$2` to the second argument, and so on. The values of positional parameters are set from arguments external to the SQL statement or supplied when SQL functions are invoked. Some client libraries support specifying data values separately from the SQL command, in which case parameters refer to the out-of-line data values. A parameter reference has the form:

```
$number
```

For example:

```
CREATE FUNCTION dept(text) RETURNS dept
    AS $$ SELECT * FROM dept WHERE name = $1 $$
    LANGUAGE SQL;
```

Here, the `$1` references the value of the first function argument whenever the function is invoked.

Subscripts

If an expression yields a value of an array type, you can extract a specific element of the array value as follows:

```
<expression>[<subscript>]
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

You can extract multiple adjacent elements, called an array slice, as follows (including the brackets):

```
<expression>[<lower_subscript>:<upper_subscript>]
```

Each subscript is an expression and yields an integer value.

Array expressions usually must be in parentheses, but you can omit the parentheses when the expression to be subscripted is a column reference or positional parameter. You can concatenate multiple subscripts when the original array is multidimensional. For example (including the parentheses):

```
mytable.arraycolumn[4]
```

```
mytable.two_d_column[17][34]
```

```
$1[10:42]
```

```
(arrayfunction(a,b))[42]
```

Field Selection

If an expression yields a value of a composite type (row type), you can extract a specific field of the row as follows:

```
<expression>.<fieldname>
```

The row expression usually must be in parentheses, but you can omit these parentheses when the expression to be selected from is a table reference or positional parameter. For example:

```
mytable.mycolumn
```

```
$1.somecolumn
```

```
(rowfunction(a,b)).col3
```

A qualified column reference is a special case of field selection syntax.

Operator Invocations

Operator invocations have the following possible syntaxes:

```
<expression operator expression>(binary infix operator)
```

```
<operator expression>(unary prefix operator)
```

```
<expression operator>(unary postfix operator)
```

Where `operator` is an operator token, one of the key words `AND`, `OR`, or `NOT`, or qualified operator name in the form:

```
OPERATOR(<schema>.<operatorname>)
```

Available operators and whether they are unary or binary depends on the operators that the system or user defines. For more information about built-in operators, see Built-in Functions and Operators.

Function Calls

The syntax for a function call is the name of a function (possibly qualified with a schema name), followed by its argument list enclosed in parentheses:

```
function ([expression [, expression ... ]])
```

For example, the following function call computes the square root of 2:

```
sqrt(2)
```

See Summary of Built-in Functions for lists of the built-in functions by category. You can add custom functions, too.

Aggregate Expressions

An aggregate expression applies an aggregate function across the rows that a query selects. An aggregate function performs a calculation on a set of values and returns a single value, such as the sum or average of the set of values. The syntax of an aggregate expression is one of the following:

- `aggregate_name(expression [ , ... ] ) [ FILTER ( WHERE filter_clause ) ]` — operates across all input rows for which the expected result value is non-null. `ALL` is the default.
- `aggregate_name(ALL expression [ , ... ] ) [ FILTER ( WHERE filter_clause ) ]` — operates identically to the first form because `ALL` is the default.
- `aggregate_name(DISTINCT expression [ , ... ] ) [ FILTER ( WHERE filter_clause ) ]` — operates across all distinct non-null values of input rows.
- `aggregate_name(*) [ FILTER ( WHERE filter_clause ) ]` — operates on all rows with values both null and non-null. Generally, this form is most useful for the `count(*)` aggregate function.

Where `aggregate_name` is a previously defined aggregate (possibly schema-qualified) and `expression` is any value expression that does not contain an aggregate expression.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

For example, `count(*)` yields the total number of input rows, `count(f1)` yields the number of input rows in which `f1` is non-null, and `count(distinct f1)` yields the number of distinct non-null values of `f1`.

If `FILTER` is specified, then only the input rows for which the `filter_clause` evaluates to true are fed to the aggregate function; other rows are discarded. For example:

```
SELECT
    count(*) AS unfiltered,
    count(*) FILTER (WHERE i < 5) AS filtered
FROM generate_series(1,10) AS s(i);
 unfiltered | filtered
------------+----------
         10 |        4
(1 row)
```

For predefined aggregate functions, see Built-in Functions and Operators. You can also add custom aggregate functions.

WarehousePG provides the `MEDIAN` aggregate function, which returns the fiftieth percentile of the `PERCENTILE_CONT` result and special aggregate expressions for inverse distribution functions as follows:

```
PERCENTILE_CONT(<percentage>) WITHIN GROUP (ORDER BY <expression>)
```

```
PERCENTILE_DISC(<percentage>) WITHIN GROUP (ORDER BY <expression>)
```

Currently you can use only these two expressions with the keyword `WITHIN GROUP`.

Limitations of Aggregate Expressions

The following are current limitations of the aggregate expressions:

- WarehousePG does not support the following keywords: `ALL`, `DISTINCT`, and `OVER`. See Table 5 for more details.
- An aggregate expression can appear only in the result list or `HAVING` clause of a `SELECT` command. It is forbidden in other clauses, such as `WHERE`, because those clauses are logically evaluated before the results of aggregates form. This restriction applies to the query level to which the aggregate belongs.
- When an aggregate expression appears in a subquery, the aggregate is normally evaluated over the rows of the subquery. If the aggregate's arguments (and `filter_clause` if any) contain only outer-level variables, the aggregate belongs to the nearest such outer level and evaluates over the rows of that query. The aggregate expression as a whole is then an outer reference for the subquery in which it appears, and the aggregate expression acts as a constant over any one evaluation of that subquery. The restriction about appearing only in the result list or `HAVING` clause applies with respect to the query level at which the aggregate appears. See Scalar Subqueries and Table 3.
- WarehousePG does not support specifying an aggregate function as an argument to another aggregate function.
- WarehousePG does not support specifying a window function as an argument to an aggregate function.

Window Expressions

Window expressions allow application developers to more easily compose complex online analytical processing (OLAP) queries using standard SQL commands. For example, with window expressions, users can calculate moving averages or sums over various intervals, reset aggregations and ranks as selected column values change, and express complex ratios in simple terms.

A window expression represents the application of a `<window function>` to a `<window frame>`, which is defined with an `OVER()` clause. This is comparable to the type of calculation that can be done with an aggregate function and a `GROUP BY` clause. Unlike aggregate functions, which return a single result value for each group of rows, window functions return a result value for every row, but that value is calculated with respect to the set of rows in the window frame to which the row belongs. The `OVER()` clause allows dividing the rows into *partitions* and then further restricting the window frame by specifying which rows preceding or following the current row within its partition to include in the calculation.

WarehousePG does not support specifying a window function as an argument to another window function.

The syntax of a window expression is:

```
<window_function> ( [<expression> [, ...]] ) [ FILTER ( WHERE <filter_clause> ) ] OVER ( <window_specification> )
```

Where `<window_function>` is one of the functions listed in Table 4 or a user-defined window function, `<expression>` is any value expression that does not contain a window expression, and `<window_specification>` is:

```
[<window_name>]
[PARTITION BY <expression> [, ...]]
[[ORDER BY <expression> [ASC | DESC | USING operator] [NULLS {FIRST | LAST}] [, ...]
[ <frame_clause> ]
```

The optional `<frame_clause>` can be one of the following:

```
{ RANGE | ROWS | GROUPS } <frame_start> [ <frame_exclusion> ]
{ RANGE | ROWS | GROUPS } BETWEEN <frame_start> AND <frame_end> [ <frame_exclusion> ]
```

Where `<frame_start>` and `<frame_end>` can be one of the following:

```
UNBOUNDED PRECEDING
<offset> PRECEDING
CURRENT ROW
<offset> FOLLOWING
UNBOUNDED FOLLOWING
```

and `<frame_exclusion>` can be one of the following:

```
EXCLUDE CURRENT ROW
EXCLUDE GROUP
EXCLUDE TIES
EXCLUDE NO OTHERS
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

A window expression can appear only in the select list of a `SELECT` command. For example:

```
SELECT count(*) OVER(PARTITION BY customer_id), * FROM sales;
```

If `FILTER` is specified, then only the input rows for which the `<filter_clause>` evaluates to true are fed to the window function; other rows are discarded. In a window expression, a `FILTER` clause can be used only with a `<window_function>` that is an aggregate function.

In a window expression, the expression must contain an `OVER` clause. The `OVER` clause specifies the window frame—the rows to be processed by the window function. This syntactically distinguishes the function from a regular or aggregate function.

In a window aggregate function that is used in a window expression, WarehousePG does not support a `DISTINCT` clause with multiple input expressions.

A window specification has the following characteristics:

- The `PARTITION BY` clause defines the window partitions to which the window function is applied. If omitted, the entire result set is treated as one partition.
- The `ORDER BY` clause defines the expression(s) for sorting rows within a window partition. The `ORDER BY` clause of a window specification is separate and distinct from the `ORDER BY` clause of a regular query expression. The `ORDER BY` clause is required for the window functions that calculate rankings, as it identifies the measure(s) for the ranking values. For OLAP aggregations, the `ORDER BY` clause is required to use window frames (the `ROWS`, `RANGE` or `GROUPS` clause).

> **Note** Columns of data types without a coherent ordering, such as `time`, are not good candidates for use in the `ORDER BY` clause of a window specification. `Time`, with or without a specified time zone, lacks a coherent ordering because addition and subtraction do not have the expected effects. For example, the following is not generally true: `x::time < x::time + '2 hour'::interval`

- The `<frame_clause>` specifies the set of rows constituting the `<window frame>`, which is a subset of the current partition, for those window functions that act on the frame instead of the whole partition. The set of rows in the frame can vary depending on which row is the current row. The frame can be specified in `RANGE`, `ROWS` or `GROUPS` mode; in each case, it runs from the `<frame_start>` to the `<frame_end>`. If `<frame_end>` is omitted, the end defaults to `CURRENT ROW`.

- A `<frame_start>` of `UNBOUNDED PRECEDING` means that the frame starts with the first row of the partition, and similarly a `<frame_end>` of `UNBOUNDED FOLLOWING` means that the frame ends with the last row of the partition.

- In `RANGE` or `GROUPS` mode, a `<frame_start>` of `CURRENT ROW` means the frame starts with the current row's first peer row (a row that the window's `ORDER BY` clause sorts as equivalent to the current row), while a `<frame_end>` of `CURRENT ROW` means the frame ends with the current row's last peer row. In `ROWS` mode, `CURRENT ROW` simply means the current row.

- In the `<offset> PRECEDING` and `<offset> FOLLOWING` frame options, the `<offset>` must be an expression not containing any variables, aggregate functions, or window functions. The meaning of the `<offset>` depends on the frame mode:

    - In `ROWS` mode, the `<offset>` must yield a non-null, non-negative integer, and the option means that the frame starts or ends the specified number of rows before or after the current row.

    - In `GROUPS` mode, the `<offset>` again must yield a non-null, non-negative integer, and the option means that the frame starts or ends the specified number of peer groups before or after the current row's peer group, where a peer group is a set of rows that are equivalent in the `ORDER BY` ordering. (There must be an `ORDER BY` clause in the window definition to use `GROUPS` mode).

    - In `RANGE` mode, these options require that the `ORDER BY` clause specifies exactly one column. The `<offset>` specifies the maximum difference between the value of that column in the current row and its value in preceding or following rows of the frame. The data type of the `<offset>` expression varies depending on the data type of the ordering column. For numeric ordering columns it is typically of the same type as the ordering column, but for datetime ordering columns it is an `interval`. For example, if the ordering column is of type `date` or `timestamp`, one could write `RANGE BETWEEN '1 day' PRECEDING AND '10 days' FOLLOWING`. The `<offset>` is still required to be non-null and non-negative, though the meaning of "non-negative" depends on its data type.

      In any case, the distance to the end of the frame is limited by the distance to the end of the partition, so that for rows near the partition ends the frame might contain fewer rows than elsewhere.

- Notice that in both `ROWS` and `GROUPS` mode, `0 PRECEDING` and `0 FOLLOWING` are equivalent to `CURRENT ROW`. This normally holds in `RANGE` mode as well, for an appropriate data-type-specific meaning of "zero".

- The `<frame_exclusion>` option allows rows around the current row to be excluded from the frame, even if they would be included according to the frame start and frame end options. `EXCLUDE CURRENT ROW` excludes the current row from the frame. `EXCLUDE GROUP` excludes the current row and its ordering peers from the frame. `EXCLUDE TIES` excludes any peers of the current row from the frame, but not the current row itself. `EXCLUDE NO OTHERS` simply specifies explicitly the default behavior of not excluding the current row or its peers.

- The default framing option is `RANGE UNBOUNDED PRECEDING`, which is the same as `RANGE BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW`. With `ORDER BY`, this sets the frame to be all rows from the partition start up through the current row's last `ORDER BY` peer. Without `ORDER BY`, this means all rows of the partition are included in the window frame, since all rows become peers of the current row.

- Restrictions are that `<frame_start>` cannot be `UNBOUNDED FOLLOWING`, `<frame_end>` cannot be `UNBOUNDED PRECEDING`, and the `<frame_end>` choice cannot appear earlier in the above list than the `<frame_start>` choice. for example `RANGE BETWEEN CURRENT ROW AND value PRECEDING` is not allowed.

Window Examples

The following examples demonstrate using window functions with partitions and window frames.

Example 1 – Aggregate Window Function Over a Partition

The `PARTITION BY` list in the `OVER` clause divides the rows into groups, or partitions, that have the same values as the specified expressions.

This example compares employees' salaries with the average salaries for their departments:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
SELECT depname, empno, salary, avg(salary) OVER(PARTITION BY depname)
FROM empsalary;
  depname  | empno | salary |          avg
-----------+-------+--------+-----------------------
 develop   |     9 |   4500 | 5020.0000000000000000
 develop   |    10 |   5200 | 5020.0000000000000000
 develop   |    11 |   5200 | 5020.0000000000000000
 develop   |     7 |   4200 | 5020.0000000000000000
 develop   |     8 |   6000 | 5020.0000000000000000
 personnel |     5 |   3500 | 3700.0000000000000000
 personnel |     2 |   3900 | 3700.0000000000000000
 sales     |     1 |   5000 | 4866.6666666666666667
 sales     |     3 |   4800 | 4866.6666666666666667
 sales     |     4 |   4800 | 4866.6666666666666667
(10 rows)
```

The first three output columns come from the table `empsalary`, and there is one output row for each row in the table. The fourth column is the average calculated on all rows that have the same `depname` value as the current row. Rows that share the same `depname` value constitute a partition, and there are three partitions in this example. The `avg` function is the same as the regular `avg` aggregate function, but the `OVER` clause causes it to be applied as a window function.

You can also put the window specification in a `WINDOW` clause and reference it in the select list. This example is equivalent to the previous query:

```
SELECT depname, empno, salary, avg(salary) OVER(mywindow)
FROM empsalary
WINDOW mywindow AS (PARTITION BY depname);
```

Defining a named window is useful when the select list has multiple window functions using the same window specification.

Example 2 – Ranking Window Function With an ORDER BY Clause

An `ORDER BY` clause within the `OVER` clause controls the order in which rows are processed by window functions. The `ORDER BY` list for the window function does not have to match the output order of the query. This example uses the `rank()` window function to rank employees' salaries within their departments:

```
SELECT depname, empno, salary,
    rank() OVER (PARTITION BY depname ORDER BY salary DESC)
FROM empsalary;
  depname  | empno | salary | rank
-----------+-------+--------+------
 develop   |     8 |   6000 |    1
 develop   |    11 |   5200 |    2
 develop   |    10 |   5200 |    2
 develop   |     9 |   4500 |    4
 develop   |     7 |   4200 |    5
 personnel |     2 |   3900 |    1
 personnel |     5 |   3500 |    2
 sales     |     1 |   5000 |    1
 sales     |     4 |   4800 |    2
 sales     |     3 |   4800 |    2
(10 rows)
```

Example 3 – Aggregate Function over a Row Window Frame

A `RANGE`, `ROWS` or `GROUPS` clause defines the window frame—a set of rows within a partition—that the window function includes in the calculation. `ROWS` specifies a physical set of rows to process, for example all rows from the beginning of the partition to the current row.

This example calculates a running total of employee's salaries by department using the `sum()` function to total rows from the start of the partition to the current row:

```
SELECT depname, empno, salary,
    sum(salary) OVER (PARTITION BY depname ORDER BY salary
        ROWS between UNBOUNDED PRECEDING AND CURRENT ROW)
FROM empsalary ORDER BY depname, sum;
  depname  | empno | salary |  sum
-----------+-------+--------+-------
 develop   |     7 |   4200 |  4200
 develop   |     9 |   4500 |  8700
 develop   |    11 |   5200 | 13900
 develop   |    10 |   5200 | 19100
 develop   |     8 |   6000 | 25100
 personnel |     5 |   3500 |  3500
 personnel |     2 |   3900 |  7400
 sales     |     4 |   4800 |  4800
 sales     |     3 |   4800 |  9600
 sales     |     1 |   5000 | 14600
(10 rows)
```

Example 4 – Aggregate Function for a Range or Groups Window Frame

`RANGE` and `GROUPS` modes specify logical values based on values of the `ORDER BY` expression in the `OVER` clause. This example demonstrates the difference between `ROWS` and `RANGE` or `GROUPS`. The frame contains all rows with salary values less than or equal to the current row. Unlike the previous example, for employees with the same salary, the sum is the same and includes the salaries of all of those employees.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
SELECT depname, empno, salary,
    sum(salary) OVER (PARTITION BY depname ORDER BY salary
        RANGE between UNBOUNDED PRECEDING AND CURRENT ROW)
FROM empsalary ORDER BY depname, sum;
  depname  | empno | salary |  sum
-----------+-------+--------+-------
 develop   |     7 |   4200 |  4200
 develop   |     9 |   4500 |  8700
 develop   |    11 |   5200 | 19100
 develop   |    10 |   5200 | 19100
 develop   |     8 |   6000 | 25100
 personnel |     5 |   3500 |  3500
 personnel |     2 |   3900 |  7400
 sales     |     4 |   4800 |  9600
 sales     |     3 |   4800 |  9600
 sales     |     1 |   5000 | 14600
(10 rows)
```

In this example, since the `<frame_start>` and `<frame_end>` are not using an `<offset>`, `RANGE` and `GROUPS` mode provide identical results:

```
SELECT depname, empno, salary,
    sum(salary) OVER (PARTITION BY depname ORDER BY salary
        GROUPS between UNBOUNDED PRECEDING AND CURRENT ROW)
FROM empsalary ORDER BY depname, sum;
  depname  | empno | salary |  sum
-----------+-------+--------+-------
 develop   |     7 |   4200 |  4200
 develop   |     9 |   4500 |  8700
 develop   |    11 |   5200 | 19100
 develop   |    10 |   5200 | 19100
 develop   |     8 |   6000 | 25100
 personnel |     5 |   3500 |  3500
 personnel |     2 |   3900 |  7400
 sales     |     4 |   4800 |  9600
 sales     |     3 |   4800 |  9600
 sales     |     1 |   5000 | 14600
(10 rows)
```

Example 5 – Aggregate Function for a Range and a Groups Window Frame

This example demonstrates the difference between `RANGE` and `GROUPS`. The table `sales` lists the sales a company's two shops during a period of four days.

When using `GROUPS` mode, the value of `<offset>` indicates the number of peer groups before the current row's peer group. The different peer groups are set by the `ORDER BY` clause, in this case the date. Since the query does not specify a value for `<frame_end>`, the end defaults to `CURRENT ROW`.

```
SELECT date, shop, total, sum(total) OVER (PARTITION BY shop ORDER BY date asc GROUPS 2 PRECEDING)
FROM sales ORDER BY shop, date;
    date    |  shop  |  total  |   sum
------------+--------+---------+----------
 2022-01-07 | Shop 1 | 3000.00 |  3000.00
 2022-01-08 | Shop 1 | 1000.00 |  4000.00
 2022-01-09 | Shop 1 | 5000.00 | 11000.00
 2022-01-09 | Shop 1 | 2000.00 | 11000.00
 2022-01-07 | Shop 2 | 4000.00 | 10000.00
 2022-01-07 | Shop 2 | 6000.00 | 10000.00
 2022-01-09 | Shop 2 | 7000.00 | 21000.00
 2022-01-09 | Shop 2 | 4000.00 | 21000.00
 2022-01-10 | Shop 2 | 2000.00 | 23000.00
(9 rows)
```

In order to get the equivalent result when using the `RANGE` mode, the `<frame_clause>` must specify an `<offset>` using the same data type as the ordering column, in this case `date`. Using the numberic value `2` will return an error.

```
SELECT date, shop, total, sum(total) OVER (PARTITION BY shop ORDER BY date asc RANGE '2 days' PRECEDING)
FROM sales ORDER BY shop, date;
    date    |  shop  |  total  |   sum
------------+--------+---------+----------
 2022-01-07 | Shop 1 | 3000.00 |  3000.00
 2022-01-08 | Shop 1 | 1000.00 |  4000.00
 2022-01-09 | Shop 1 | 5000.00 | 11000.00
 2022-01-09 | Shop 1 | 2000.00 | 11000.00
 2022-01-07 | Shop 2 | 4000.00 | 10000.00
 2022-01-07 | Shop 2 | 6000.00 | 10000.00
 2022-01-09 | Shop 2 | 7000.00 | 21000.00
 2022-01-09 | Shop 2 | 4000.00 | 21000.00
 2022-01-10 | Shop 2 | 2000.00 | 13000.00
(9 rows)
```

Note that the above outputs differ in the last row because `RANGE` mode uses the entries from the previous two days and there is no entry for `2022-01-08` for Shop 2, but `GROUPS` mode uses the previous two peer groups, which are `2022-01-07` and `2022-01-09`.

Type Casts

A type cast specifies a conversion from one data type to another. A cast applied to a value expression of a known type is a run-time type conversion. The cast succeeds only if a suitable type conversion is defined. This differs from the use of casts with constants. A cast applied to a string literal represents the initial assignment of a type to a literal constant value, so it succeeds for any type if the contents of the string literal are acceptable input syntax for the data type.

WarehousePG supports three types of casts applied to a value expression:

- *Explicit cast* - WarehousePG applies a cast when you explicitly specify a cast between two data types. WarehousePG accepts two equivalent syntaxes for explicit type casts:

  ```
  CAST ( expression AS type )
  expression::type
  ```

  The `CAST` syntax conforms to SQL; the syntax using `::` is historical PostgreSQL usage.

- *Assignment cast* - WarehousePG implicitly invokes a cast in assignment contexts, when assigning a value to a column of the target data type. For example, a`CREATE CAST` command with the `AS ASSIGNMENT` clause creates a cast that is applied implicitly in the assignment context. This example assignment cast assumes that `tbl1.f1` is a column of type `text`. The `INSERT` command is allowed because the value is implicitly cast from the `integer` to `text` type.

  ```
  INSERT INTO tbl1 (f1) VALUES (42);
  ```

- *Implicit cast* - WarehousePG implicitly invokes a cast in assignment or expression contexts. For example, a `CREATE CAST` command with the `AS IMPLICIT` clause creates an implicit cast, a cast that is applied implicitly in both the assignment and expression context. This example implicit cast assumes that `tbl1.c1` is a column of type `int`. For the calculation in the predicate, the value of `c1` is implicitly cast from `int` to a `decimal` type.

  ```
  SELECT * FROM tbl1 WHERE tbl1.c2 = (4.3 + tbl1.c1) ;
  ```

You can usually omit an explicit type cast if there is no ambiguity about the type a value expression must produce (for example, when it is assigned to a table column); the system automatically applies a type cast. WarehousePG implicitly applies casts only to casts defined with a cast context of assignment or explicit in the system catalogs. Other casts must be invoked with explicit casting syntax to prevent unexpected conversions from being applied without the user's knowledge.

You can display cast information with the `psql` meta-command `\dC`. Cast information is stored in the catalog table `pg_cast`, and type information is stored in the catalog table `pg_type`.

Scalar Subqueries

A scalar subquery is a `SELECT` query in parentheses that returns exactly one row with one column. Do not use a `SELECT` query that returns multiple rows or columns as a scalar subquery. The query runs and uses the returned value in the surrounding value expression. A correlated scalar subquery contains references to the outer query block.

Correlated Subqueries

A correlated subquery (CSQ) is a `SELECT` query with a `WHERE` clause or target list that contains references to the parent outer clause. CSQs efficiently express results in terms of results of another query. WarehousePG supports correlated subqueries that provide compatibility with many existing applications. A CSQ is a scalar or table subquery, depending on whether it returns one or multiple rows. WarehousePG does not support correlated subqueries with skip-level correlations.

Correlated Subquery Examples

Example 1 – Scalar correlated subquery

```
SELECT * FROM t1 WHERE t1.x
           > (SELECT MAX(t2.x) FROM t2 WHERE t2.y = t1.y);
```

Example 2 – Correlated EXISTS subquery

```
SELECT * FROM t1 WHERE
EXISTS (SELECT 1 FROM t2 WHERE t2.x = t1.x);
```

WarehousePG uses one of the following methods to run CSQs:

- Unnest the CSQ into join operations – This method is most efficient, and it is how WarehousePG runs most CSQs, including queries from the TPC-H benchmark.
- Run the CSQ on every row of the outer query – This method is relatively inefficient, and it is how WarehousePG runs queries that contain CSQs in the `SELECT` list or are connected by `OR` conditions.

The following examples illustrate how to rewrite some of these types of queries to improve performance.

Example 3 - CSQ in the Select List

Original Query

```
SELECT T1.a,
      (SELECT COUNT(DISTINCT T2.z) FROM t2 WHERE t1.x = t2.y) dt2
FROM t1;
```

Rewrite this query to perform an inner join with `t1` first and then perform a left join with `t1` again. The rewrite applies for only an equijoin in the correlated condition.

Rewritten Query

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
SELECT t1.a, dt2 FROM t1
       LEFT JOIN
        (SELECT t2.y AS csq_y, COUNT(DISTINCT t2.z) AS dt2
              FROM t1, t2 WHERE t1.x = t2.y
              GROUP BY t1.x)
       ON (t1.x = csq_y);
```

Example 4 - CSQs connected by OR Clauses

Original Query

```
SELECT * FROM t1
WHERE
x > (SELECT COUNT(*) FROM t2 WHERE t1.x = t2.x)
OR x < (SELECT COUNT(*) FROM t3 WHERE t1.y = t3.y)
```

Rewrite this query to separate it into two parts with a union on the `OR` conditions.

Rewritten Query

```
SELECT * FROM t1
WHERE x > (SELECT count(*) FROM t2 WHERE t1.x = t2.x)
UNION
SELECT * FROM t1
WHERE x < (SELECT count(*) FROM t3 WHERE t1.y = t3.y)
```

To view the query plan, use `EXPLAIN SELECT` or `EXPLAIN ANALYZE SELECT`. Subplan nodes in the query plan indicate that the query will run on every row of the outer query, and the query is a candidate for rewriting. For more information about these statements, see Query Profiling.

Array Constructors

An array constructor is an expression that builds an array value from values for its member elements. A simple array constructor consists of the key word `ARRAY`, a left square bracket `[`, one or more expressions separated by commas for the array element values, and a right square bracket `]`. For example,

```
SELECT ARRAY[1,2,3+4];
  array
---------
 {1,2,7}
```

The array element type is the common type of its member expressions, determined using the same rules as for `UNION` or `CASE` constructs.

You can build multidimensional array values by nesting array constructors. In the inner constructors, you can omit the keyword `ARRAY`. For example, the following two `SELECT` statements produce the same result:

```
SELECT ARRAY[ARRAY[1,2], ARRAY[3,4]];
SELECT ARRAY[[1,2],[3,4]];
     array
---------------
 {{1,2},{3,4}}
```

Since multidimensional arrays must be rectangular, inner constructors at the same level must produce sub-arrays of identical dimensions.

Multidimensional array constructor elements are not limited to a sub-`ARRAY` construct; they are anything that produces an array of the proper kind. For example:

```
CREATE TABLE arr(f1 int[], f2 int[]);
INSERT INTO arr VALUES (ARRAY[[1,2],[3,4]],
ARRAY[[5,6],[7,8]]);
SELECT ARRAY[f1, f2, '{{9,10},{11,12}}'::int[]] FROM arr;
                     array
-----------------------------------------------
 {{{1,2},{3,4}},{{5,6},{7,8}},{{9,10},{11,12}}}
```

You can construct an array from the results of a subquery. Write the array constructor with the keyword `ARRAY` followed by a subquery in parentheses. For example:

```
SELECT ARRAY(SELECT oid FROM pg_proc WHERE proname LIKE 'bytea%');
                          ?column?
------------------------------------------------------------
 {2011,1954,1948,1952,1951,1244,1950,2005,1949,1953,2006,31}
```

The subquery must return a single column. The resulting one-dimensional array has an element for each row in the subquery result, with an element type matching that of the subquery's output column. The subscripts of an array value built with `ARRAY` always begin with `1`.

Row Constructors

A row constructor is an expression that builds a row value (also called a composite value) from values for its member fields. For example,

```
SELECT ROW(1,2.5,'this is a test');
```

Row constructors have the syntax `rowvalue.*`, which expands to a list of the elements of the row value, as when you use the syntax `.*` at the top level of a `SELECT` list. For example, if table `t` has columns `f1` and `f2`, the following queries are the same:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
SELECT ROW(t.*, 42) FROM t;
SELECT ROW(t.f1, t.f2, 42) FROM t;
```

By default, the value created by a `ROW` expression has an anonymous record type. If necessary, it can be cast to a named composite type — either the row type of a table, or a composite type created with `CREATE TYPE AS`. To avoid ambiguity, you can explicitly cast the value if necessary. For example:

```
CREATE TABLE mytable(f1 int, f2 float, f3 text);
CREATE FUNCTION getf1(mytable) RETURNS int AS 'SELECT $1.f1'
LANGUAGE SQL;
```

In the following query, you do not need to cast the value because there is only one `getf1()` function and therefore no ambiguity:

```
SELECT getf1(ROW(1,2.5,'this is a test'));
 getf1
-------
     1
CREATE TYPE myrowtype AS (f1 int, f2 text, f3 numeric);
CREATE FUNCTION getf1(myrowtype) RETURNS int AS 'SELECT
$1.f1' LANGUAGE SQL;
```

Now we need a cast to indicate which function to call:

```
SELECT getf1(ROW(1,2.5,'this is a test'));
ERROR:  function getf1(record) is not unique
```

```
SELECT getf1(ROW(1,2.5,'this is a test')::mytable);
 getf1
-------
     1
SELECT getf1(CAST(ROW(11,'this is a test',2.5) AS
myrowtype));
 getf1
-------
    11
```

You can use row constructors to build composite values to be stored in a composite-type table column or to be passed to a function that accepts a composite parameter.

Expression Evaluation Rules

The order of evaluation of subexpressions is undefined. The inputs of an operator or function are not necessarily evaluated left-to-right or in any other fixed order.

If you can determine the result of an expression by evaluating only some parts of the expression, then other subexpressions might not be evaluated at all. For example, in the following expression:

```
SELECT true OR somefunc();
```

`somefunc()` would probably not be called at all. The same is true in the following expression:

```
SELECT somefunc() OR true;
```

This is not the same as the left-to-right evaluation order that Boolean operators enforce in some programming languages.

Do not use functions with side effects as part of complex expressions, especially in `WHERE` and `HAVING` clauses, because those clauses are extensively reprocessed when developing an execution plan. Boolean expressions (`AND` / `OR` / `NOT` combinations) in those clauses can be reorganized in any manner that Boolean algebra laws allow.

Use a `CASE` construct to force evaluation order. The following example is an untrustworthy way to avoid division by zero in a `WHERE` clause:

```
SELECT ... WHERE x <> 0 AND y/x > 1.5;
```

The following example shows a trustworthy evaluation order:

```
SELECT ... WHERE CASE WHEN x <> 0 THEN y/x > 1.5 ELSE false
END;
```

This `CASE` construct usage defeats optimization attempts; use it only when necessary.

4.6.4 WITH Queries (Common Table Expressions)

The `WITH` clause provides a way to write auxiliary statements for use in a larger query. These statements, which are often referred to as Common Table Expressions or CTEs, can be thought of as defining temporary tables that exist just for one query.

> **Note** Limitations when using a `WITH` clause in WarehousePG include:
>
> - For a `SELECT` command that includes a `WITH` clause, the clause can contain at most a single clause that modifies table data (`INSERT`, `UPDATE`, or `DELETE` command).
> - For a data-modifying command (`INSERT`, `UPDATE`, or `DELETE`) that includes a `WITH` clause, the clause can only contain a `SELECT` command; it cannot contain a data-modifying command.

By default, WarehousePG enables the `RECURSIVE` keyword for the `WITH` clause. `RECURSIVE` can be deactivated by setting the server configuration parameter gp_recursive_cte to `false`.

Parent topic: SQL: Querying Data

SELECT in a WITH Clause

One use of CTEs is to break down complicated queries into simpler parts. The examples in this section show the `WITH` clause being used with a `SELECT` command. The example `WITH` clauses can be used the same manner with `INSERT`, `UPDATE`, or `DELETE`.

A `SELECT` command in the `WITH` clause is evaluated only once per execution of the parent query, even if it is referred to more than once by the parent query or sibling `WITH` clauses. Thus, expensive calculations that are needed in multiple places can be placed within a `WITH` clause to avoid redundant work. Another possible application is to prevent unwanted multiple evaluations of functions with side-effects. However, the other side of this coin is that the optimizer is less able to push restrictions from the parent query down into a `WITH` query than an ordinary sub-query. The `WITH` query will generally be evaluated as written, without suppression of rows that the parent query might discard afterwards. However, evaluation might stop early if the references to the query demand only a limited number of rows.

The following example query displays per-product sales totals in only the top sales regions:

```
WITH regional_sales AS (
     SELECT region, SUM(amount) AS total_sales
     FROM orders
     GROUP BY region
  ), top_regions AS (
     SELECT region
     FROM regional_sales
     WHERE total_sales > (SELECT SUM(total_sales)/10 FROM regional_sales)
  )
SELECT region,
    product,
    SUM(quantity) AS product_units,
    SUM(amount) AS product_sales
FROM orders
WHERE region IN (SELECT region FROM top_regions)
GROUP BY region, product;
```

The `WITH` clause defines two auxiliary statements named `regional_sales` and `top_regions`, where the output of `regional_sales` is used in `top_regions` and the output of `top_regions` is used in the primary `SELECT` query. The query could have been written without the `WITH` clause, but would have required two levels of nested sub- `SELECT`s.

When you specify the optional `RECURSIVE` keyword, the `WITH` clause can accomplish operations not otherwise possible in standard SQL. Using `RECURSIVE`, a `WITH` query can refer to its own output. This simple example computes the sum of integers from 1 through 100:

```
WITH RECURSIVE t(n) AS (
    VALUES (1)
  UNION ALL
    SELECT n+1 FROM t WHERE n < 100
)
SELECT sum(n) FROM t;
```

The general form of a recursive `WITH` query always follows the pattern of: a *non-recursive term*, followed by a `UNION` (or `UNION ALL`), and then a *recursive term*, where only the *recursive term* can contain a reference to the query output.

```
<non_recursive_term> UNION [ ALL ] <recursive_term>
```

A recursive `WITH` query that contains a `UNION [ ALL ]` is evaluated as follows:

1. Evaluate the non-recursive term. For `UNION` (but not `UNION ALL`), discard duplicate rows. Include all remaining rows in the result of the recursive query, and also place them in a temporary *working table*.
2. As long as the working table is not empty, repeat these steps:
    1. Evaluate the recursive term, substituting the current contents of the working table for the recursive self-reference. For `UNION` (but not `UNION ALL`), discard duplicate rows and rows that duplicate any previous result row. Include all remaining rows in the result of the recursive query, and also place them in a temporary *intermediate table*.
    2. Replace the contents of the *working table* with the contents of the *intermediate table*, then empty the *intermediate table*.

> **Note** While `RECURSIVE` allows queries to be specified recursively, WarehousePG evaluates such queries iteratively internally.

In the example above, the working table has just a single row in each step, and it takes on the values from 1 through 100 in successive steps. In the 100th step, there is no output because of the `WHERE` clause, and so the query terminates.

Recursive `WITH` queries are typically used to deal with hierarchical or tree-structured data. For example, this query locates all of the direct and indirect sub-parts of a product, given only a table that shows immediate inclusions:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
WITH RECURSIVE included_parts(sub_part, part, quantity) AS (
    SELECT sub_part, part, quantity FROM parts WHERE part = 'our_product'
  UNION ALL
    SELECT p.sub_part, p.part, p.quantity * pr.quantity
    FROM included_parts pr, parts p
    WHERE p.part = pr.sub_part
)
SELECT sub_part, SUM(quantity) as total_quantity
FROM included_parts
GROUP BY sub_part;
```

When working with recursive `WITH` queries, you must ensure that the recursive part of the query eventually returns no tuples, or else the query loops indefinitely.

For some queries, using `UNION` instead of `UNION ALL` can ensure that the recursive part of the query eventually returns no tuples by discarding rows that duplicate previous output rows. However, often a cycle does not involve output rows that are complete duplicates: it might be sufficient to check just one or a few fields to see if the same point has been reached before. The standard method for handling such situations is to compute an array of the visited values. For example, consider the following query that searches a table `graph` using a `link` field:

```
WITH RECURSIVE search_graph(id, link, data, depth) AS (
    SELECT g.id, g.link, g.data, 1
    FROM graph g
  UNION ALL
    SELECT g.id, g.link, g.data, sg.depth + 1
    FROM graph g, search_graph sg
    WHERE g.id = sg.link
)
SELECT * FROM search_graph;
```

This query loops if the `link` relationships contain cycles. Because the query requires a `depth` output, changing `UNION ALL` to `UNION` does not eliminate the looping. Instead the query needs to recognize whether it has reached the same row again while following a particular path of links. This modified query adds two columns, `path` and `cycle`, to the loop-prone query:

```
WITH RECURSIVE search_graph(id, link, data, depth, path, cycle) AS (
    SELECT g.id, g.link, g.data, 1,
      ARRAY[g.id],
      false
    FROM graph g
  UNION ALL
    SELECT g.id, g.link, g.data, sg.depth + 1,
      path || g.id,
      g.id = ANY(path)
    FROM graph g, search_graph sg
    WHERE g.id = sg.link AND NOT cycle
)
SELECT * FROM search_graph;
```

Aside from detecting cycles, the array value is useful in its own right since it represents the "path" taken to reach any particular row.

In the general case where more than one field needs to be checked to recognize a cycle, use an array of rows. For example, if we needed to compare fields `f1` and `f2`:

```
WITH RECURSIVE search_graph(id, link, data, depth, path, cycle) AS (
    SELECT g.id, g.link, g.data, 1,
      ARRAY[ROW(g.f1, g.f2)],
      false
    FROM graph g
  UNION ALL
    SELECT g.id, g.link, g.data, sg.depth + 1,
      path || ROW(g.f1, g.f2),
      ROW(g.f1, g.f2) = ANY(path)
    FROM graph g, search_graph sg
    WHERE g.id = sg.link AND NOT cycle
)
SELECT * FROM search_graph;
```

Tip: Omit the `ROW()` syntax in the case where only one field must be checked to recognize a cycle. This uses a simple array rather than a composite-type array, gaining efficiency.

Tip: The recursive query evaluation algorithm produces its output in breadth-first search order. You can display the results in depth-first search order by making the outer query `ORDER BY` a "path" column constructed in this way.

A helpful technique for testing a query when you are not certain if it might loop indefinitely is to place a `LIMIT` in the parent query. For example, the following query would loop forever without the `LIMIT` clause:

```
WITH RECURSIVE t(n) AS (
    SELECT 1
  UNION ALL
    SELECT n+1 FROM t
)
SELECT n FROM t LIMIT 100;
```

This technique works because WarehousePG evaluates only as many rows of a `WITH` query as are actually fetched by the parent query. *Using this technique in production environments is not recommended*, because other systems might work differently. Also, the technique might not work if the outer query sorts the recursive `WITH` results or joins the results to another table, because in such cases the outer query will usually try to fetch all of the `WITH` query's output anyway.

A useful property of `WITH` queries is that they are normally evaluated only once per execution of the parent query, even if they are referred to more than once by the parent query or sibling `WITH` queries. Thus, expensive calculations that are needed in multiple places can be placed within a `WITH` query to avoid redundant work. Another possible application is to prevent unwanted multiple evaluations of functions with side-effects. However, the other side of this coin is that the optimizer is not able to push restrictions from the parent query down into a multiply-referenced `WITH` query, since that might affect all uses of the `WITH` query's output when it should affect only one. WarehousePG evalues the multiply-referenced `WITH` query as written, without suppression of rows that the parent query might discard afterwards. (But, as mentioned above, evaluation might stop early if the reference(s) to the query demand only a limited number of rows.)

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

If a `WITH` query is non-recursive and side-effect-free (that is, it is a `SELECT` containing no volatile functions) then it can be folded into the parent query, allowing joint optimization of the two query levels. By default, this happens if the parent query references the `WITH` query just once, but not if it references the `WITH` query more than once. You can override that decision by specifying `MATERIALIZED` to force separate calculation of the `WITH` query, or by specifying `NOT MATERIALIZED` to force it to be merged into the parent query. The latter choice risks duplicate computation of the `WITH` query, but it can still give a net savings if each usage of the `WITH` query needs only a small part of the `WITH` query's full output.

A simple example of these rules follows:

```
WITH w AS
(
    SELECT * FROM big_table
)
SELECT * FROM w WHERE key =
123;
```

This `WITH` query will be folded, producing the same execution plan as:

```
SELECT * FROM big_table WHERE key = 123;
```

In particular, if there's an index on `key`, WarehousePG uses it to fetch just the rows having `key = 123`. On the other hand, in:

```
WITH w AS
(
    SELECT * FROM big_table
)
SELECT * FROM w AS w1 JOIN w AS w2 ON w1.key =
w2.ref
WHERE w2.key =
123;
```

the `WITH` query will be materialized, producing a temporary copy of `big_table` that is then joined with itself — without benefit of any index. This query will run much more efficiently if written as:

```
WITH w AS NOT MATERIALIZED
(
    SELECT * FROM big_table
)
SELECT * FROM w AS w1 JOIN w AS w2 ON w1.key =
w2.ref
WHERE w2.key =
123;
```

so that the parent query's restrictions can be applied directly to scans of `big_table`.

An example where `NOT MATERIALIZED` could be undesirable is:

```
WITH w AS
(
    SELECT key, very_expensive_function(val) as f FROM
some_table
)
SELECT * FROM w AS w1 JOIN w AS w2 ON w1.f =
w2.f;
```

Here, materialization of the `WITH` query ensures that WarehousePG evaluations `very_expensive_function` only once per table row, not twice.

Data-Modifying Statements in a WITH clause

For a `SELECT` command, you can use the data-modifying commands `INSERT`, `UPDATE`, or `DELETE` in a `WITH` clause. This allows you to perform several different operations in the same query.

A data-modifying statement in a `WITH` clause is run exactly once, and always to completion, independently of whether the primary query reads all (or indeed any) of the output. This is different from the rule when using `SELECT` in a `WITH` clause, the execution of a `SELECT` continues only as long as the primary query demands its output.

This simple CTE query deletes rows from `products`. The `DELETE` in the `WITH` clause deletes the specified rows from products, returning their contents by means of its `RETURNING` clause.

```
WITH deleted_rows AS (
    DELETE FROM products
    WHERE
        "date" >= '2010-10-01' AND
        "date" < '2010-11-01'
    RETURNING *
)
SELECT * FROM deleted_rows;
```

Data-modifying statements in a `WITH` clause must have `RETURNING` clauses, as shown in the previous example. It is the output of the `RETURNING` clause, *not* the target table of the data-modifying statement, that forms the temporary table that can be referred to by the rest of the query. If a data-modifying statement in a `WITH` lacks a `RETURNING` clause, then it forms no temporary table and cannot be referred to in the rest of the query. WarehousePG runs such a statement nonetheless.

If the optional `RECURSIVE` keyword is enabled, recursive self-references in data-modifying statements are not allowed. In some cases it is possible to work around this limitation by referring to the output of a recursive `WITH`. For example, this query would remove all direct and indirect subparts of a product:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
WITH RECURSIVE included_parts(sub_part, part) AS (
    SELECT sub_part, part FROM parts WHERE part = 'our_product'
  UNION ALL
    SELECT p.sub_part, p.part
    FROM included_parts pr, parts p
    WHERE p.part = pr.sub_part
  )
DELETE FROM parts
  WHERE part IN (SELECT part FROM included_parts);
```

The sub-statements in a `WITH` clause are run concurrently with each other and with the main query. Therefore, when using a data-modifying statement in a `WITH` , the order in which the specified updates actually happen is unpredictable. All of the statements are run wth the same *snapshot*. The effects of the statement are not visible on the target tables. This alleviates the effects of the unpredictability of the actual order of row updates, and means thats the `RETURNING` data is the only way to communicate changes between different `WITH` sub-statements and the main query.

In this example, the outer `SELECT` returns the original prices before the action of the `UPDATE` in the `WITH` clause:

```
WITH t AS (
    UPDATE products SET price = price * 1.05
    RETURNING *
)
SELECT * FROM products;
```

In this example, the outer `SELECT` returns the updated data:

```
WITH t AS (
    UPDATE products SET price = price * 1.05
    RETURNING *
)
SELECT * FROM t;
```

Updating the same row twice in a single statement is not supported. The effects of such a statement will not be predictable. Only one of the modifications takes place, but it is not easy (and sometimes not possible) to predict which modification occurs.

Any table used as the target of a data-modifying statement in a `WITH` clause must not have a conditional rule, nor an `ALSO` rule, nor an `INSTEAD` rule that expands to multiple statements.

Considerations

When constructing `WITH` queries, keep the following in mind:

- `SELECT FOR UPDATE` cannot be inlined.
- WarehousePG inlines multiply-referenced CTEs only when requested (by specifying `NOT MATERIALIZED`).
- Multiply-referenced CTEs cannot be inlined if they contain outer self-references.
- WarehousePG does not inline when the CTE includes a volatile function.
- An `ORDER BY` in the subquery or CTE does not force an ordering for the whole query.
- WarehousePG always materializes a CTE term in a query. Due to this:
    - A query that should touch a small amount of data may instead read a whole table, and possibly spill to a temporary file.
    - `UPDATE` or `DELETE FROM` statements are not permitted in a CTE term, as it acts more like a read-only temporary table than a dynamic view.
- While inlining is generally a huge win, there are certain boundary cases where it is not; for example, when a non-trivial expression will be inlined in multiple places.
- The GPORCA query optimizer does not support `[NOT] MATERIALIZED`.

4.6.5 Using Functions and Operators

Description of user-defined and built-in functions and operators in WarehousePG.

- Using Functions in WarehousePG
- User-Defined Functions
- User-Defined Procedures
- Built-in Functions and Operators
- Window Functions
- Advanced Aggregate Functions

Parent topic: SQL: Querying Data

Using Functions in WarehousePG

When you invoke a function in WarehousePG, function attributes control the execution of the function. The volatility attributes (`IMMUTABLE`, `STABLE`, `VOLATILE`) and the `EXECUTE ON` attributes control two different aspects of function execution. In general, volatility indicates when the function is run, and `EXECUTE ON` indicates where it is run. The volatility attributes are PostgreSQL based attributes, the `EXECUTE ON` attributes are WarehousePG attributes.

For example, a function defined with the `IMMUTABLE` attribute can be run at query planning time, while a function with the `VOLATILE` attribute must be run for every row in the query. A function with the `EXECUTE ON COORDINATOR` attribute runs only on the coordinator instance, and a function with the `EXECUTE ON ALL SEGMENTS` attribute runs on all primary segment instances (not the coordinator).

These tables summarize what WarehousePG assumes about function execution based on the attribute.

Function Attribute	WarehousePG Support	Description	Comments
IMMUTABLE	Yes	Relies only on information directly in its argument list. Given the same argument values, always returns the same result.	
STABLE	Yes, in most cases	Within a single table scan, returns the same result for same argument values, but results change across SQL statements.	Results depend on database lookups or parameter values. `current_timestamp` family of functions is `STABLE`; values do not change within an execution.
VOLATILE	Restricted	Function values can change within a single table scan. For example: `random()`, `timeofday()`. This is the default attribute.	Any function with side effects is volatile, even if its result is predictable. For example: `setval()`.

Function Attribute	Description	Comments
EXECUTE ON ANY	Indicates that the function can be run on the coordinator, or any segment instance, and it returns the same result regardless of where it runs. This is the default attribute.	WarehousePG determines where the function runs.
EXECUTE ON COORDINATOR	Indicates that the function must be run on the coordinator instance.	Specify this attribute if the user-defined function runs queries to access tables.
EXECUTE ON ALL SEGMENTS	Indicates that for each invocation, the function must be run on all primary segment instances, but not the coordinator.	
EXECUTE ON INITPLAN	Indicates that the function contains an SQL command that dispatches queries to the segment instances and requires special processing on the coordinator instance by WarehousePG when possible.	

You can display the function volatility and `EXECUTE ON` attribute information with the psql `\df+ function` command.

Refer to the PostgreSQL Function Volatility Categories documentation for additional information about the WarehousePG function volatility classifications.

For more information about `EXECUTE ON` attributes, see CREATE FUNCTION.

In WarehousePG, data is divided up across segments — each segment is a distinct PostgreSQL database. To prevent inconsistent or unexpected results, do not run functions classified as `VOLATILE` at the segment level if they contain SQL commands or modify the database in any way. For example, functions such as `setval()` are not allowed to run on distributed data in WarehousePG because they can cause inconsistent data between segment instances.

A function can run read-only queries on replicated tables (`DISTRIBUTED REPLICATED`) on the segments, but any SQL command that modifies data must run on the coordinator instance.

> **Note** The hidden system columns (`ctid`, `cmin`, `cmax`, `xmin`, `xmax`, and `gp_segment_id`) cannot be referenced in user queries on replicated tables because they have no single, unambiguous value. WarehousePG returns a `column does not exist` error for the query.

To ensure data consistency, you can safely use `VOLATILE` and `STABLE` functions in statements that are evaluated on and run from the coordinator. For example, the following statements run on the coordinator (statements without a `FROM` clause):

```
SELECT setval('myseq', 201);
SELECT foo();
```

If a statement has a `FROM` clause containing a distributed table *and* the function in the `FROM` clause returns a set of rows, the statement can run on the segments:

```
SELECT * from foo();
```

WarehousePG does not support functions that return a table reference (`rangeFuncs`) or functions that use the `refCursor` data type.

Function Volatility and Plan Caching

There is relatively little difference between the `STABLE` and `IMMUTABLE` function volatility categories for simple interactive queries that are planned and immediately run. It does not matter much whether a function is run once during planning or once during query execution start up. But there is a big difference when you save the plan and reuse it later. If you mislabel a function `IMMUTABLE`, WarehousePG may prematurely fold it to a constant during planning, possibly reusing a stale value during subsequent execution of the plan. You may run into this hazard when using `PREPARE`d statements, or when using languages such as PL/pgSQL that cache plans.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

User-Defined Functions

WarehousePG supports user-defined functions. See Extending SQL in the PostgreSQL documentation for more information.

Use the `CREATE FUNCTION` statement to register user-defined functions that are used as described in Using Functions in WarehousePG. By default, user-defined functions are declared as `VOLATILE`, so if your user-defined function is `IMMUTABLE` or `STABLE`, you must specify the correct volatility level when you register your function.

By default, user-defined functions are declared as `EXECUTE ON ANY`. A function that runs queries to access tables is supported only when the function runs on the coordinator instance, except that a function can run `SELECT` commands that access only replicated tables on the segment instances. A function that accesses hash-distributed or randomly distributed tables must be defined with the `EXECUTE ON COORDINATOR` attribute. Otherwise, the function might return incorrect results when the function is used in a complicated query. Without the attribute, planner optimization might determine it would be beneficial to push the function invocation to segment instances.

When you create user-defined functions, avoid using fatal errors or destructive calls. WarehousePG may respond to such errors with a sudden shutdown or restart.

In WarehousePG, the shared library files for user-created functions must reside in the same library path location on every host in the WarehousePG cluster (coordinators, segments, and mirrors).

You can also create and run anonymous code blocks that are written in a WarehousePG procedural language such as PL/pgSQL. The anonymous blocks run as transient anonymous functions. For information about creating and running anonymous blocks, see the `DO` command.

User-Defined Procedures

A procedure is a database object similar to a function. The key differences are:

- You define a procedure with the CREATE PROCEDURE command, not `CREATE FUNCTION`.
- Procedures do not return a function value; hence `CREATE PROCEDURE` lacks a `RETURNS` clause. However, procedures can instead return data to their callers via output parameters.
- While a function is called as part of a query or DML command, you call a procedure in isolation using the CALL command.
- A procedure can commit or roll back transactions during its execution (then automatically beginning a new transaction), so long as the invoking `CALL` command is not part of an explicit transaction block. A function cannot do that.
- Certain function attributes, such as strictness, don't apply to procedures. Those attributes control how the function is used in a query, which isn't relevant to procedures.

Collectively, functions and procedures are also known as routines. There are commands such as ALTER ROUTINE and DROP ROUTINE that can operate on functions and procedures without having to know which kind it is. Note, however, that there is no `CREATE ROUTINE` command.

Built-in Functions and Operators

The following table lists the categories of built-in functions and operators supported by PostgreSQL. All functions and operators are supported in WarehousePG as in PostgreSQL with the exception of `STABLE` and `VOLATILE` functions, which are subject to the restrictions noted in Using Functions in WarehousePG. See the Functions and Operators section of the PostgreSQL documentation for more information about these built-in functions and operators.

WarehousePG includes JSON processing functions that manipulate values the `json` data type. For information about JSON data, see Working with JSON Data.

Table 3. Built-in functions and operators

Operator/Function Category	VOLATILE Functions	STABLE Functions	Restrictions
Logical Operators			
Comparison Operators			
Mathematical Functions and Operators	random setseed		
String Functions and Operators	*All built-in conversion functions*	convert pg_client_encoding	
Binary String Functions and Operators			
Bit String Functions and Operators			
Pattern Matching			
Data Type Formatting Functions		to_char to_timestamp	
Date/Time Functions and Operators	timeofday	age current_date current_time current_timestamp localtime localtimestamp now	
Enum Support Functions

XML Functions and function-like expressions		table_to_xml_and_xmlschema(tbl regclass, nulls boolean, tableforest boolean, targetns text) xmlagg(xml) xmlconcat(xml[, ...]) xmlelement(name name [, xmlattributes(value [AS attname] [, ...])] [, content, ...]) xmlexists(text, xml) xmlforest(content [AS name] [, ...]) xml_is_well_formed(text) xml_is_well_formed_document(text) xml_is_well_formed_content(text) xmlparse ({ DOCUMENT | CONTENT } value) xpath(text, xml) xpath(text, xml, text[]) xpath_exists(text, xml) xpath_exists(text, xml, text[]) xmlpi(name target [, content]) xmlroot(xml, version text | no value [, standalone yes|no|no value]) xmlserialize ({ DOCUMENT | CONTENT } value AS type) xml(text) text(xml) xmlcomment(xml) xmlconcat2(xml, xml)	

Window Functions

The following built-in window functions are WarehousePG extensions to the PostgreSQL database. All window functions are *immutable*. For more information about window functions, see Window Expressions.

Table 4. Window functions

Function	Return Type	Full Syntax	Description
`cume_dist()`	`double precision`	`CUME_DIST() OVER ( [PARTITION BY` expr `] ORDER BY` expr `)`	Calculates the cumulative distribution of a value in a group of values. Rows with equal values always evaluate to the same cumulative distribution value.
`dense_rank()`	`bigint`	`DENSE_RANK () OVER ( [PARTITION BY` expr `] ORDER BY` expr `)`	Computes the rank of a row in an ordered group of rows without skipping rank values. Rows with equal values are given the same rank value.
`first_value(`*`expr`*`)`	same as input expr type	`FIRST_VALUE(` expr `) OVER ( [PARTITION BY` expr `] ORDER BY` expr `[ROWS|RANGE|GROUPS` frame_expr `] )`	Returns the first value in an ordered set of values.
`lag(`*`expr`* `[,`*`offset`*`] [,`*`default`*`])`	same as input *expr* type	`LAG(` *expr* `[,` *offset* `] [,` *default* `]) OVER ( [PARTITION BY` *expr* `] ORDER BY` *expr* `)`	Provides access to more than one row of the same table without doing a self join. Given a series of rows returned from a query and a position of the cursor, `LAG` provides access to a row at a given physical offset prior to that position. The default `offset` is 1. *default* sets the value that is returned if the offset goes beyond the scope of the window. If *default* is not specified, the default value is null.
`last_value(`*`expr`*`)`	same as input *expr* type	`LAST_VALUE(`*`expr`*`) OVER ( [PARTITION BY` *expr*`] ORDER BY` *expr* `[ROWS|RANGE|GROUPS` *frame_expr*`] )`	Returns the last value in an ordered set of values.
`lead(`*`expr`* `[,`*`offset`*`] [,`*`default`*`])`	same as input *expr* type	`LEAD(`*`expr`* `[,`*`offset`*`] [,`*`exprdefault`*`]) OVER ( [PARTITION BY` *expr*`] ORDER BY` *expr* `)`	Provides access to more than one row of the same table without doing a self join. Given a series of rows returned from a query and a position of the cursor, `lead` provides access to a row at a given physical offset after that position. If *offset* is not specified, the default offset is 1. *default* sets the value that is returned if the offset goes beyond the scope of the window. If *default* is not specified, the default value is null.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Function	Return Type	Full Syntax	Description
`nth_value(expr)`	same as input *expr* type	`NTH_VALUE(expr) OVER ( [PARTITION BY expr] ORDER BY expr [ROWS|RANGE|GROUPS frame_expr] )`	Returns the value evaluated at the row that is the *nth* row of the window frame (counting from 1); null if no such row.
`ntile(expr)`	`bigint`	`NTILE(expr) OVER ( [PARTITION BY expr] ORDER BY expr )`	Divides an ordered data set into a number of buckets (as defined by *expr*) and assigns a bucket number to each row.
`percent_rank()`	`double precision`	`PERCENT_RANK () OVER ( [PARTITION BY expr] ORDER BY expr )`	Calculates the rank of a hypothetical row `R` minus 1, divided by 1 less than the number of rows being evaluated (within a window partition).
`rank()`	`bigint`	`RANK () OVER ( [PARTITION BY expr] ORDER BY expr )`	Calculates the rank of a row in an ordered group of values. Rows with equal values for the ranking criteria receive the same rank. The number of tied rows are added to the rank number to calculate the next rank value. Ranks may not be consecutive numbers in this case.
`row_number()`	`bigint`	`ROW_NUMBER () OVER ( [PARTITION BY expr] ORDER BY expr )`	Assigns a unique number to each row to which it is applied (either each row in a window partition or each row of the query).

Advanced Aggregate Functions

The following built-in advanced aggregate functions are WarehousePG extensions of the PostgreSQL database. These functions are *immutable*.

> **Note** The WarehousePG MADlib Extension for Analytics provides additional advanced functions to perform statistical analysis and machine learning with WarehousePG data. See WarehousePG MADlib Extension for Analytics in the *WarehousePG Reference Guide*.

Table 5. Advanced Aggregate Functions

Function	Return Type	Full Syntax	Description

`MEDIAN (expr)`	`timestamp, timestamptz, interval, float`	`MEDIAN (expression)`
		Example:
		`SELECT departmzent_id, MEDIAN(salary) FROM employees GROUP BY department_id;`
			Can take a two-dimensional array as input. Treats such arrays as matrices.

`sum(array[])`	`smallint[], int[], bigint[], float[]`	`sum(array[[1,2],[3,4]])`
		Example:
		`CREATE TABLE mymatrix (myvalue int[]); INSERT INTO mymatrix VALUES (array[[1,2],[3,4]]); INSERT INTO mymatrix VALUES (array[[0,1],[1,0]]); SELECT sum(myvalue) FROM mymatrix; sum \-\-\-\-\-\-\-\-\-\-\-\-\-\-\-\-\-\-\-\-\-\-\- {1,3},{4,4}`
			Performs matrix summation. Can take as input a two-dimensional array that is treated as a matrix.

`pivot_sum (label[], label, expr)`	`int[], bigint[], float[]`	`pivot_sum( array['A1','A2'], attr, value)`	A pivot aggregation using sum to resolve duplicate entries.
`unnest (array[])`	set of `anyelement`	`unnest( array['one', 'row', 'per', 'item'])`	Transforms a one dimensional array into rows. Returns a set of `anyelement`, a polymorphic pseudo-type in PostgreSQL.

4.6.6 Working with JSON Data

WarehousePG supports JSON as specified in the RFC 7159 document and enforces data validity according to the JSON rules. There are also JSON-specific functions and operators available for the `json` and `jsonb` data types. See JSON Functions and Operators.

WarehousePG offers two types for storing JSON (JavaScript Object Notation) data: `json` and `jsonb`. To implement efficient query mechanisms for these data types, WarehousePG also provides the `jsonpath` data type described in jsonpath Type later in this topic.

This section contains the following topics:

- About JSON Data
- JSON Input and Output Syntax
- Designing JSON documents
- jsonb Containment and Existence
- jsonb Indexing
- Transforms
- jsonpath Type

Parent topic: SQL: Querying Data

About JSON Data

The `json` and `jsonb` data types accept *almost* identical sets of values as input. The major difference is one of efficiency.

- The `json` data type stores an exact copy of the input text. This requires JSON processing functions to reparse `json` data on each execution. The `json` data type does not alter the input text.
    - Semantically-insignificant white space between tokens is preserved, as well as the order of keys within JSON objects.
    - All key/value pairs are kept even if a JSON object contains duplicate keys. For duplicate keys, JSON processing functions consider the last value as the operative one.
- The `jsonb` data type stores a decomposed binary format of the input text. The conversion overhead makes data input slightly slower than the `json` data type. However, The JSON processing functions are significantly faster because reparsing `jsonb` data is not required. The `jsonb` data type alters the input text.
    - White space is not preserved.
    - The order of object keys is not preserved.
    - Duplicate object keys are not kept. If the input includes duplicate keys, only the last value is kept.
- The `jsonb` data type supports indexing. See jsonb Indexing.

In general, JSON data should be stored as the `jsonb` data type unless there are specialized needs, such as legacy assumptions about ordering of object keys.

WarehousePG allows only one character set encoding per database. It is therefore not possible for the JSON types to conform rigidly to the JSON specification unless the database encoding is UTF8. Attempts to directly include characters that cannot be represented in the database encoding will fail; conversely, characters that can be represented in the database encoding but not in UTF8 are allowed.

About Unicode Characters in JSON Data

The RFC 7159 document permits JSON strings to contain Unicode escape sequences denoted by `\uXXXX`.

- The WarehousePG input function for the `json` data type allows Unicode escapes regardless of the database encoding and checks Unicode escapes only for syntactic correctness (a `\u` followed by four hex digits).
- The WarehousePG input function for the `jsonb` data type is more strict. It does not allow Unicode escapes for non-ASCII characters (those above `U+007F`) unless the database encoding is UTF8. The `jsonb` type also rejects `\u0000`, which cannot be represented in the WarehousePG `text` type, and it requires that any use of Unicode surrogate pairs to designate characters outside the Unicode Basic Multilingual Plane be correct. Valid Unicode escapes, except for `\u0000`, are converted to the equivalent ASCII or UTF8 character for storage; this includes folding surrogate pairs into a single character.

> **Note** Many of the JSON processing functions described in JSON Functions and Operators convert Unicode escapes to regular characters and will therefore throw the same types of errors just described even if their input is of type `json` not `jsonb`. The fact that the `json` input function does not make these checks may be considered a historical artifact, although it does allow for simple storage (without processing) of JSON Unicode escapes in a non-UTF8 database encoding. In general, it is best to avoid mixing Unicode escapes in JSON with a non-UTF8 database encoding, if possible.

Mapping JSON Data Types to WarehousePG Data Types

When converting JSON text input into `jsonb` data, the primitive data types described by RFC 7159 are effectively mapped onto native WarehousePG data types, as shown in the following table.

JSON primitive data type	WarehousePG data type	Notes
`string`	`text`	`\u0000` is not allowed. Non-ASCII Unicode escapes are allowed only if database encoding is UTF8
`number`	`numeric`	`NaN` and `infinity` values are disallowed
`boolean`	`boolean`	Only lowercase `true` and `false` spellings are accepted
`null`	(none)	The JSON `null` primitive type is different than the SQL `NULL`

There are some minor constraints on what constitutes valid `jsonb` data that do not apply to the `json` data type, nor to JSON in the abstract, corresponding to limits on what can be represented by the underlying data type. Notably, when converting data to the `jsonb` data type, numbers that are outside the range of the WarehousePG `numeric` data type are rejected, while the `json` data type does not reject such numbers.

Such implementation-defined restrictions are permitted by RFC 7159. However, in practice such problems might occur in other implementations, as it is common to represent the JSON `number` primitive type as IEEE 754 double precision floating point (which RFC 7159 explicitly anticipates and allows for).

When using JSON as an interchange format with other systems, be aware of the possibility of losing numeric precision compared to data originally stored by WarehousePG.

Also, as noted in the previous table, there are some minor restrictions on the input format of JSON primitive types that do not apply to the corresponding WarehousePG data types.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

JSON Input and Output Syntax

The input and output syntax for the `json` data type is as specified in RFC 7159.

The following are all valid `json` (or `jsonb`) expressions:

```
-- Simple scalar/primitive value
-- Primitive values can be numbers, quoted strings, true, false, or null
SELECT '5'::json;

-- Array of zero or more elements (elements need not be of same type)
SELECT '[1, 2, "foo", null]'::json;

-- Object containing pairs of keys and values
-- Note that object keys must always be quoted strings
SELECT '{"bar": "baz", "balance": 7.77, "active": false}'::json;

-- Arrays and objects can be nested arbitrarily
SELECT '{"foo": [true, "bar"], "tags": {"a": 1, "b": null}}'::json;
```

As previously stated, when a JSON value is input and then printed without any additional processing, the `json` data type outputs the same text that was input, while the `jsonb` data type does not preserve semantically-insignificant details such as whitespace. For example, note the differences here:

```
SELECT '{"bar": "baz", "balance": 7.77, "active":false}'::json;
                      json
-------------------------------------------------
 {"bar": "baz", "balance": 7.77, "active":false}
(1 row)

SELECT '{"bar": "baz", "balance": 7.77, "active":false}'::jsonb;
                      jsonb
-------------------------------------------------
 {"bar": "baz", "active": false, "balance": 7.77}
(1 row)
```

One semantically-insignificant detail worth noting is that with the `jsonb` data type, numbers will be printed according to the behavior of the underlying `numeric` type. In practice, this means that numbers entered with `E` notation will be printed without it, for example:

```
SELECT '{"reading": 1.230e-5}'::json, '{"reading": 1.230e-5}'::jsonb;
         json          |          jsonb
-----------------------+-------------------------
 {"reading": 1.230e-5} | {"reading": 0.00001230}
(1 row)
```

However, the `jsonb` data type preserves trailing fractional zeroes, as seen in previous example, even though those are semantically insignificant for purposes such as equality checks.

Designing JSON documents

Representing data as JSON can be considerably more flexible than the traditional relational data model, which is compelling in environments where requirements are fluid. It is quite possible for both approaches to co-exist and complement each other within the same application. However, even for applications where maximal flexibility is desired, it is still recommended that JSON documents have a somewhat fixed structure. The structure is typically unenforced (though enforcing some business rules declaratively is possible), but having a predictable structure makes it easier to write queries that usefully summarize a set of JSON documents (datums) in a table.

JSON data is subject to the same concurrency-control considerations as any other data type when stored in a table. Although storing large documents is practicable, keep in mind that any update acquires a row-level lock on the whole row. Consider limiting JSON documents to a manageable size in order to decrease lock contention among updating transactions. Ideally, JSON documents should each represent an atomic datum that business rules dictate cannot reasonably be further subdivided into smaller datums that could be modified independently.

jsonb Containment and Existence

Testing *containment* is an important capability of `jsonb`. There is no parallel set of facilities for the `json` type. Containment tests whether one `jsonb` document has contained within it another one. These examples return `true` except as noted:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
-- Simple scalar/primitive values contain only the identical value:
SELECT '"foo"'::jsonb @> '"foo"'::jsonb;

-- The array on the right side is contained within the one on the left:
SELECT '[1, 2, 3]'::jsonb @> '[1, 3]'::jsonb;

-- Order of array elements is not significant, so this is also true:
SELECT '[1, 2, 3]'::jsonb @> '[3, 1]'::jsonb;

-- Duplicate array elements don't matter either:
SELECT '[1, 2, 3]'::jsonb @> '[1, 2, 2]'::jsonb;

-- The object with a single pair on the right side is contained
-- within the object on the left side:
SELECT '{"product": "WarehousePG", "version": "7.0.0", "jsonb":true}'::jsonb @> '{"version":"7.0.0"}'::jsonb;

-- The array on the right side is not considered contained within the
-- array on the left, even though a similar array is nested within it:
SELECT '[1, 2, [1, 3]]'::jsonb @> '[1, 3]'::jsonb;  -- yields false

-- But with a layer of nesting, it is contained:
SELECT '[1, 2, [1, 3]]'::jsonb @> '[[1, 3]]'::jsonb;

-- Similarly, containment is not reported here:
SELECT '{"foo": {"bar": "baz"}}'::jsonb @> '{"bar": "baz"}'::jsonb; -- yields false

-- But with a layer of nesting, it is contained:
SELECT '{"foo": {"bar": "baz"}}'::jsonb @> '{"foo": {}}'::jsonb;
```

The general principle is that the contained object must match the containing object as to structure and data contents, possibly after discarding some non-matching array elements or object key/value pairs from the containing object. For containment, the order of array elements is not significant when doing a containment match, and duplicate array elements are effectively considered only once.

As an exception to the general principle that the structures must match, an array may contain a primitive value:

```
-- This array contains the primitive string value:
SELECT '["foo", "bar"]'::jsonb @> '"bar"'::jsonb;

-- This exception is not reciprocal -- non-containment is reported here:
SELECT '"bar"'::jsonb @> '["bar"]'::jsonb;  -- yields false
```

`jsonb` also has an *existence* operator, which is a variation on the theme of containment: it tests whether a string (given as a `text` value) appears as an object key or array element at the top level of the `jsonb` value. These examples return `true` except as noted:

```
-- String exists as array element:
SELECT '["foo", "bar", "baz"]'::jsonb ? 'bar';

-- String exists as object key:
SELECT '{"foo": "bar"}'::jsonb ? 'foo';

-- Object values are not considered:
SELECT '{"foo": "bar"}'::jsonb ? 'bar';  -- yields false

-- As with containment, existence must match at the top level:
SELECT '{"foo": {"bar": "baz"}}'::jsonb ? 'bar'; -- yields false

-- A string is considered to exist if it matches a primitive JSON string:
SELECT '"foo"'::jsonb ? 'foo';
```

JSON objects are better suited than arrays for testing containment or existence when there are many keys or elements involved, because unlike arrays they are internally optimized for searching, and do not need to be searched linearly.

Because JSON containment is nested, an appropriate query can skip explicit selection of sub-objects. As an example, suppose that we have a `doc` column containing objects at the top level, with most objects containing `tags` fields that contain arrays of sub-objects. This query finds entries in which sub-objects containing both `"term":"paris"` and `"term":"food"` appear, while ignoring any such keys outside the `tags` array:

```
SELECT doc->'site_name' FROM websites
  WHERE doc @> '{"tags":[{"term":"paris"}, {"term":"food"}]}';
```

The query with this predicate could accomplish the same thing:

```
SELECT doc->'site_name' FROM websites
  WHERE doc->'tags' @> '[{"term":"paris"}, {"term":"food"}]';
```

However, the second approach is less flexible and is often less efficient as well.

On the other hand, the JSON existence operator is not nested: it will only look for the specified key or array element at top level of the JSON value.

The various containment and existence operators, along with all other JSON operators and functions are documented in JSON Functions and Operators.

jsonb Indexing

The WarehousePG `jsonb` data type, supports GIN, btree, and hash indexes.

- GIN Indexes on jsonb Data
- Btree and Hash Indexes on jsonb Data

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

GIN Indexes on jsonb Data

GIN indexes can be used to efficiently search for keys or key/value pairs occurring within a large number of `jsonb` documents (datums). Two GIN operator classes are provided, offering different performance and flexibility trade-offs.

The default GIN operator class for jsonb supports queries with the `@>`, `?`, `?&` and `?|` operators. (For details of the semantics that these operators implement, see JSON Operators.) An example of creating an index with this operator class is:

```
CREATE INDEX idxgin ON api USING GIN (jdoc);
```

The non-default GIN operator class `jsonb_path_ops` does not support the key-exists operators, but it does support `@>`, `@?`, and `@@`. An example of creating an index with this operator class is:

```
CREATE INDEX idxginp ON api USING GIN (jdoc jsonb_path_ops);
```

Consider the example of a table that stores JSON documents retrieved from a third-party web service, with a documented schema definition. This is a typical document:

```
{
    "guid": "9c36adc1-7fb5-4d5b-83b4-90356a46061a",
    "name": "Angela Barton",
    "is_active": true,
    "company": "Magnafone",
    "address": "178 Howard Place, Gulf, Washington, 702",
    "registered": "2009-11-07T08:53:22 +08:00",
    "latitude": 19.793713,
    "longitude": 86.513373,
    "tags": [
        "enim",
        "aliquip",
        "qui"
    ]
}
```

The JSON documents are stored a table named `api`, in a `jsonb` column named `jdoc`. If a GIN index is created on this column, queries like the following can make use of the index:

```
-- Find documents in which the key "company" has value "Magnafone"
SELECT jdoc->'guid', jdoc->'name' FROM api WHERE jdoc @> '{"company": "Magnafone"}';
```

However, the index could not be used for queries like the following. The operator `?` is indexable, however, the comparison is not applied directly to the indexed column `jdoc`:

```
-- Find documents in which the key "tags" contains key or array element "qui"
SELECT jdoc->'guid', jdoc->'name' FROM api WHERE jdoc -> 'tags' ? 'qui';
```

With appropriate use of expression indexes, the above query can use an index. If querying for particular items within the `tags` key is common, defining an index like this might be worthwhile:

```
CREATE INDEX idxgintags ON api USING GIN ((jdoc -> 'tags'));
```

Now, the `WHERE` clause `jdoc -> 'tags' ? 'qui'` is recognized as an application of the indexable operator `?` to the indexed expression `jdoc -> 'tags'`. For information about expression indexes, see Indexes on Expressions.

Another approach to querying JSON documents is to exploit containment, for example:

```
-- Find documents in which the key "tags" contains array element "qui"
SELECT jdoc->'guid', jdoc->'name' FROM api WHERE jdoc @> '{"tags": ["qui"]}';
```

A simple GIN index on the `jdoc` column can support this query. However, the index will store copies of every key and value in the `jdoc` column, whereas the expression index of the previous example stores only data found under the `tags` key. While the simple-index approach is far more flexible (since it supports queries about any key), targeted expression indexes are likely to be smaller and faster to search than a simple index.

GIN indexes also support the `@?` and `@@` operators, which perform `jsonpath` matching. Examples are:

```
SELECT jdoc->'guid', jdoc->'name' FROM api WHERE jdoc @? '$.tags[*] ? (@ == "qui")';
```

```
SELECT jdoc->'guid', jdoc->'name' FROM api WHERE jdoc @@ '$.tags[*] == "qui"';
```

For these operators, a GIN index extracts clauses of the form `accessors_chain = constant` out of the `jsonpath` pattern, and does the index search based on the keys and values mentioned in these clauses. The accessors chain may include `.key`, `[*]`, and `[index]` accessors. The `jsonb_ops` operator class also supports `.*` and `.**` accessors, but the `jsonb_path_ops` operator class does not.

Although the `jsonb_path_ops` operator class supports only queries with the `@>`, `@?` and `@@` operators, it has notable performance advantages over the default operator class `jsonb_ops`. A `jsonb_path_ops` index is usually much smaller than a `jsonb_ops` index over the same data, and the specificity of searches is better, particularly when queries contain keys that appear frequently in the data. Therefore search operations typically perform better than with the default operator class.

The technical difference between a `jsonb_ops` and a `jsonb_path_ops` GIN index is that the former creates independent index items for each key and value in the data, while the latter creates index items only for each value in the data.

> **Note** For this discussion, the term *value* includes array elements, though JSON terminology sometimes considers array elements distinct from values within objects.

Basically, each `jsonb_path_ops` index item is a hash of the value and the key(s) leading to it; for example to index `{"foo": {"bar": "baz"}}`, a single index item would be created incorporating all three of `foo`, `bar`, and `baz` into the hash value. Thus a containment query looking for this structure would result in an extremely specific index search; but there is no way at all to find out whether `foo` appears as a key. On the other hand, a `jsonb_ops` index would create three index items representing `foo`, `bar`, and `baz` separately; then to do the containment query, it would look for rows containing all three of these items. While GIN indexes can perform such an `AND` search fairly efficiently, it will still be less specific and slower than the equivalent `jsonb_path_ops` search, especially if there are a very large number of rows containing any single one of the three index items.

A disadvantage of the `jsonb_path_ops` approach is that it produces no index entries for JSON structures not containing any values, such as `{"a": {}}`. If a search for documents containing such a structure is requested, it will require a full-index scan, which is quite slow. `jsonb_path_ops` is ill-suited for applications that often perform such searches.

Btree and Hash Indexes on jsonb Data

`jsonb` also supports `btree` and `hash` indexes. These are usually useful only when it is important to check the equality of complete JSON documents.

For completeness, the `btree` ordering for `jsonb` datums is:

```
Object > Array > Boolean > Number > String > Null

Object with n pairs > object with n - 1 pairs

Array with n elements > array with n - 1 elements
```

Objects with equal numbers of pairs are compared in the order:

```
key-1, value-1, key-2 ...
```

Object keys are compared in their storage order. In particular, since shorter keys are stored before longer keys, this can lead to orderings that might not be intuitive, such as:

```
{ "aa": 1, "c": 1} > {"b": 1, "d": 1}
```

Similarly, arrays with equal numbers of elements are compared in the order:

```
element-1, element-2 ...
```

Primitive JSON values are compared using the same comparison rules as for the underlying WarehousePG data type. Strings are compared using the default database collation.

Transforms

Additional extensions are available that implement transforms for the `jsonb` type for different procedural languages.

The extensions for PL/Perl are called `jsonb_plperl` and j `sonb_plperlu` . If you use them, `jsonb` values are mapped to Perl arrays, hashes, and scalars, as appropriate.

The extension for PL/Python is called `jsonb_plpython3u` . If you use it, `jsonb` values are mapped to Python dictionaries, lists, and scalars, as appropriate.

jsonpath Type

The `jsonpath` type implements support for the SQL/JSON path language in WarehousePG to efficiently query JSON data. It provides a binary representation of the parsed SQL/JSON path expression that specifies the items to be retrieved by the path engine from the JSON data for further processing with the SQL/JSON query functions.

The semantics of SQL/JSON path predicates and operators generally follow SQL. At the same time, to provide a most natural way of working with JSON data, SQL/JSON path syntax uses some of the JavaScript conventions:

- Dot (`.`) is used for member access.
- Square brackets (`[]`) are used for array access.
- SQL/JSON arrays are 0-relative, unlike regular SQL arrays that start from 1.

An SQL/JSON path expression is typically written in an SQL query as an SQL character string literal, so it must be enclosed in single quotes, and any single quotes desired within the value must be doubled. Some forms of path expressions require string literals within them. These embedded string literals follow JavaScript/ECMAScript conventions: they must be surrounded by double quotes, and backslash escapes may be used within them to represent otherwise-hard-to-type characters. In particular, the way to write a double quote within an embedded string literal is `\"` , and to write a backslash itself, you must write `\\` . Other special backslash sequences include those recognized in JSON strings: `\b` , `\f` , `\n` , `\r` , `\t` , `\v` for various ASCII control characters, and `\uNNNN` for a Unicode character identified by its 4-hex-digit code point. The backslash syntax also includes two cases not allowed by JSON: `\xNN` for a character code written with only two hex digits, and `\u{N...}` for a character code written with 1 to 6 hex digits.

A path expression consists of a sequence of path elements, which can be the following:

- Path literals of JSON primitive types: Unicode text, numeric, true, false, or null.
- Path variables listed in the **jsonpath Variables** table below.
- Accessor operators listed in the **jsonpath Accessors** table below.
- `jsonpath` operators and methods listed in SQL/JSON Path Operators and Methods.
- Parentheses, which can be used to provide filter expressions or define the order of path evaluation.

For details on using `jsonpath` expressions with SQL/JSON query functions, see SQL/JSON Filter Expression Elements.

`jsonpath` Variables

Variable	Description
`$`	A variable representing the JSON text to be queried (the *context item*).
`$varname`	A named variable. Its value can be set by the parameter `vars` of several JSON processing functions. See JSON Processing Functions and its notes for details.
`@`	A variable representing the result of path evaluation in filter expressions.

`jsonpath` Accessors

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Accessor Operator	Description

`. key`
 	
`."$ varname "`
	Member accessor that returns an object member with the specified key. If the key name is a named variable starting with `$` or does not meet the JavaScript rules of an identifier, it must be enclosed in double quotes as a character string literal.

`.*`	Wildcard member accessor that returns the values of all members located at the top level of the current object.
`.**`	Recursive wildcard member accessor that processes all levels of the JSON hierarchy of the current object and returns all the member values, regardless of their nesting level. This is a WarehousePG extension of the SQL/JSON standard.

`.**{ level }`
 	
`.**{ start_level to end_level }`
	Same as `.**`, but with a filter over nesting levels of JSON hierarchy. Nesting levels are specified as integers. Zero level corresponds to the current object. To access the lowest nesting level, you can use the `last` keyword. This is a WarehousePG extension of the SQL/JSON standard.

`[ subscript , ...]`	Array element accessor. `subscript` can be given in two forms: `index` or `start_index to end_index`. The first form returns a single array element by its index. The second form returns an array slice by the range of indexes, including the elements that correspond to the provided `start_index` and `end_index`. The specified `index` can be an integer, as well as an expression returning a single numeric value, which is automatically cast to integer. Zero index corresponds to the first array element. You can also use the `last` keyword to denote the last array element, which is useful for handling arrays of unknown length.
`[*]`	Wildcard array element accessor that returns all array elements.

4.6.7 Working with XML Data

WarehousePG supports the `xml` data type that stores XML data.

The `xml` data type checks the input values for well-formedness, providing an advantage over simply storing XML data in a text field. Additionally, support functions allow you to perform type-safe operations on this data; refer toXML Function Reference, below.

Use of this data type requires the installation to have been built with `configure --with-libxml`. This is enabled by default for WarehousePG builds.

The `xml` type can store well-formed "documents", as defined by the XML standard, as well as "content" fragments, which are defined by reference to the more permissivedocument node of the XQuery and XPath model. Roughly, this means that content fragments can have more than one top-level element or character node. The expression `xmlvalue IS DOCUMENT` can be used to evaluate whether a particular `xml` value is a full document or only a content fragment.

This section contains the following topics:

- Creating XML Values
- Encoding Handling
- Accessing XML Values
- Processing XML
- Mapping Tables to XML
- Using XML Functions and Expressions

Parent topic: SQL: Querying Data

Creating XML Values

To produce a value of type `xml` from character data, use the function `xmlparse`:

```
xmlparse ( { DOCUMENT | CONTENT } value)
```

For example:

```
XMLPARSE (DOCUMENT '<?xml version="1.0"?><book><title>Manual</title><chapter>...</chapter></book>')
XMLPARSE (CONTENT 'abc<foo>bar</foo><bar>foo</bar>')
```

The above method converts character strings into XML values according to the SQL standard, but you can also use WarehousePG syntax like the following:

```
xml '<foo>bar</foo>'
'<foo>bar</foo>'::xml
```

The `xml` type does not validate input values against a document type declaration (DTD), even when the input value specifies a DTD. There is also currently no built-in support for validating against other XML schema languages such as XML schema.

The inverse operation, producing a character string value from `xml`, uses the function `xmlserialize`:

```
xmlserialize ( { DOCUMENT | CONTENT } <value> AS <type> )
```

type can be `character`, `character varying`, or `text` (or an alias for one of those). Again, according to the SQL standard, this is the only way to convert between type `xml` and character types, but WarehousePG also allows you to simply cast the value.

When a character string value is cast to or from type `xml` without going through `XMLPARSE` or `XMLSERIALIZE`, respectively, the choice of `DOCUMENT` versus `CONTENT` is determined by the `XML OPTION` session configuration parameter, which can be set using the standard command:

```
SET XML OPTION { DOCUMENT | CONTENT };
```

or simply like WarehousePG:

```
SET XML OPTION TO { DOCUMENT | CONTENT };
```

The default is CONTENT, so all forms of XML data are allowed.

Encoding Handling

Be careful when dealing with multiple character encodings on the client, server, and in the XML data passed through them. When using the text mode to pass queries to the server and query results to the client (which is the normal mode), WarehousePG converts all character data passed between the client and the server, and vice versa, to the character encoding of the respective endpoint; see Character Set Support. This includes string representations of XML values, such as in the above examples. Ordinarily, this means that encoding declarations contained in XML data can become invalid, as the character data is converted to other encodings while travelling between client and server, because the embedded encoding declaration is not changed. To cope with this behavior, encoding declarations contained in character strings presented for input to the `xml` type are ignored, and content is assumed to be in the current server encoding. Consequently, for correct processing, character strings of XML data must be sent from the client in the current client encoding. It is the responsibility of the client to either convert documents to the current client encoding before sending them to the server, or to adjust the client encoding appropriately. On output, values of type `xml` will not have an encoding declaration, and clients should assume all data is in the current client encoding.

When using binary mode to pass query parameters to the server and query results back to the client, no character set conversion is performed, so the situation is different. In this case, an encoding declaration in the XML data will be observed, and if it is absent, the data will be assumed to be in UTF-8 (as required by the XML standard; note that WarehousePG does not support UTF-16). On output, data will have an encoding declaration specifying the client encoding, unless the client encoding is UTF-8, in which case it will be omitted.

> **Note** Processing XML data with WarehousePG will be less error-prone and more efficient if the XML data encoding, client encoding, and server encoding are the same. Because XML data is internally processed in UTF-8, computations will be most efficient if the server encoding is also UTF-8.

Accessing XML Values

The `xml` data type is unusual in that it does not provide any comparison operators. This is because there is no well-defined and universally useful comparison algorithm for XML data. One consequence of this is that you cannot retrieve rows by comparing an `xml` column against a search value. XML values should therefore typically be accompanied by a separate key field such as an ID. An alternative solution for comparing XML values is to convert them to character strings first, but note that character string comparison has little to do with a useful XML comparison method.

Because there are no comparison operators for the `xml` data type, it is not possible to create an index directly on a column of this type. If speedy searches in XML data are desired, possible workarounds include casting the expression to a character string type and indexing that, or indexing an XPath expression. Of course, the actual query would have to be adjusted to search by the indexed expression.

Processing XML

To process values of data type `xml`, WarehousePG offers the functions `xpath` and `xpath_exists`, which evaluate XPath 1.0 expressions.

```
xpath(<xpath>, <xml> [, <nsarray>])
```

The function `xpath` evaluates the XPath expression `xpath` (a text value) against the XML value `xml`. It returns an array of XML values corresponding to the node set produced by the XPath expression.

The second argument must be a well formed XML document. In particular, it must have a single root node element.

The optional third argument of the function is an array of namespace mappings. This array should be a two-dimensional text array with the length of the second axis being equal to 2 (i.e., it should be an array of arrays, each of which consists of exactly 2 elements). The first element of each array entry is the namespace name (alias), the second the namespace URI. It is not required that aliases provided in this array be the same as those being used in the XML document itself (in other words, both in the XML document and in the `xpath` function context, aliases are local).

Example:

```
SELECT xpath('/my:a/<text>()', '<my:a xmlns:my="http://example.com">test</my:a>',
            ARRAY[ARRAY['my', 'http://example.com']]);

 xpath
--------
 {test}
(1 row)
```

To deal with default (anonymous) namespaces, do something like this:

```
SELECT xpath('//mydefns:b/<text>()', '<a xmlns="http://example.com"><b>test</b></a>',
            ARRAY[ARRAY['mydefns', 'http://example.com']]);

 xpath
--------
 {test}
(1 row)
```

```
xpath_exists(<xpath>, <xml> [, <nsarray>])
```

The function `xpath_exists` is a specialized form of the `xpath` function. Instead of returning the individual XML values that satisfy the XPath, this function returns a Boolean indicating whether the query was satisfied or not. This function is equivalent to the standard `XMLEXISTS` predicate, except that it also offers support for a namespace mapping argument.

Example:

```
SELECT xpath_exists('/my:a/<text>()', '<my:a xmlns:my="http://example.com">test</my:a>',
                    ARRAY[ARRAY['my', 'http://example.com']]);

 xpath_exists
--------------
 t
(1 row)
```

Mapping Tables to XML

The following functions map the contents of relational tables to XML values. They can be thought of as XML export functionality:

```
table_to_xml(tbl regclass, nulls boolean, tableforest boolean, targetns text)
query_to_xml(query <text>, nulls boolean, tableforest boolean, targetns text)
cursor_to_xml(cursor refcursor, count int, nulls boolean,
              tableforest boolean, targetns text)
```

The return type of each function is `xml`.

`table_to_xml` maps the content of the named table, passed as parameter `tbl`. The `regclass` type accepts strings identifying tables using the usual notation, including optional schema qualifications and double quotes. `query_to_xml` runs the query whose text is passed as parameter query and maps the result set. `cursor_to_xml` fetches the indicated number of rows from the cursor specified by the parameter cursor. This variant is recommended if large tables have to be mapped, because the result value is built up in memory by each function.

If `tableforest` is false, then the resulting XML document looks like this:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
<tablename>
  <row>
    <columnname1>data</columnname1>
    <columnname2>data</columnname2>
  </row>

  <row>
    ...
  </row>

  ...
</tablename>
```

If `tableforest` is true, the result is an XML content fragment that looks like this:

```
<tablename>
  <columnname1>data</columnname1>
  <columnname2>data</columnname2>
</tablename>

<tablename>
  ...
</tablename>

...
```

If no table name is available, that is, when mapping a query or a cursor, the string `table` is used in the first format, `row` in the second format.

The choice between these formats is up to the user. The first format is a proper XML document, which will be important in many applications. The second format tends to be more useful in the `cursor_to_xml` function if the result values are to be later reassembled into one document. The functions for producing XML content discussed above, in particular `xmlelement`, can be used to alter the results as desired.

The data values are mapped in the same way as described for the function `xmlelement`, above.

The parameter nulls determines whether null values should be included in the output. If true, null values in columns are represented as:

```
<columnname xsi:nil="true"/>
```

where `xsi` is the XML namespace prefix for XML schema Instance. An appropriate namespace declaration will be added to the result value. If false, columns containing null values are simply omitted from the output.

The parameter `targetns` specifies the desired XML namespace of the result. If no particular namespace is wanted, an empty string should be passed.

The following functions return XML schema documents describing the mappings performed by the corresponding functions above:

```
able_to_xmlschema(tbl regclass, nulls boolean, tableforest boolean, targetns text)
query_to_xmlschema(query <text>, nulls boolean, tableforest boolean, targetns text)
cursor_to_xmlschema(cursor refcursor, nulls boolean, tableforest boolean, targetns text)
```

It is essential that the same parameters are passed in order to obtain matching XML data mappings and XML schema documents.

The following functions produce XML data mappings and the corresponding XML schema in one document (or `forest`), linked together. They can be useful where self-contained and self-describing results are desired:

```
table_to_xml_and_xmlschema(tbl regclass, nulls boolean, tableforest boolean, targetns text)
query_to_xml_and_xmlschema(query <text>, nulls boolean, tableforest boolean, targetns text)
```

In addition, the following functions are available to produce analogous mappings of entire schemas or the entire current database:

```
schema_to_xml(schema name, nulls boolean, tableforest boolean, targetns text)
schema_to_xmlschema(schema name, nulls boolean, tableforest boolean, targetns text)
schema_to_xml_and_xmlschema(schema name, nulls boolean, tableforest boolean, targetns text)

database_to_xml(nulls boolean, tableforest boolean, targetns text)
database_to_xmlschema(nulls boolean, tableforest boolean, targetns text)
database_to_xml_and_xmlschema(nulls boolean, tableforest boolean, targetns text)
```

Note that these potentially produce large amounts of data, which needs to be built up in memory. When requesting content mappings of large schemas or databases, consider mapping the tables separately instead, possibly even through a cursor.

The result of a schema content mapping looks like this:

```
<schemaname>

table1-mapping

table2-mapping

...

</schemaname>
```

where the format of a table mapping depends on the `tableforest` parameter, as explained above.

The result of a database content mapping looks like this:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
<dbname>

<schema1name>
  ...
</schema1name>

<schema2name>
  ...
</schema2name>

...

</dbname>
```

where the schema mapping is as above.

The example below demonstrates using the output produced by these functions, The example shows an XSLT stylesheet that converts the output of `table_to_xml_and_xmlschema` to an HTML document containing a tabular rendition of the table data. In a similar manner, the results from these functions can be converted into other XML-based formats.

```
<?xml version="1.0"?>
<xsl:stylesheet version="1.0"
    xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
    xmlns:xsd="http://www.w3.org/2001/XMLSchema"
    xmlns="http://www.w3.org/1999/xhtml"
>

  <xsl:output method="xml"
      doctype-system="http://www.w3.org/TR/xhtml1/DTD/xhtml1-strict.dtd"
      doctype-public="-//W3C/DTD XHTML 1.0 Strict//EN"
      indent="yes"/>

  <xsl:template match="/*">
    <xsl:variable name="schema" select="//xsd:schema"/>
    <xsl:variable name="tabletypename"
                  select="$schema/xsd:element[@name=name(current())]/@type"/>
    <xsl:variable name="rowtypename"
                  select="$schema/xsd:complexType[@name=$tabletypename]/xsd:sequence/xsd:element[@name='row']/@type"/>

    <html>
      <head>
        <title><xsl:value-of select="name(current())"/></title>
      </head>
      <body>
        <table>
          <tr>
            <xsl:for-each select="$schema/xsd:complexType[@name=$rowtypename]/xsd:sequence/xsd:element/@name">
              <th><xsl:value-of select="."/></th>
            </xsl:for-each>
          </tr>

          <xsl:for-each select="row">
            <tr>
              <xsl:for-each select="*">
                <td><xsl:value-of select="."/></td>
              </xsl:for-each>
            </tr>
          </xsl:for-each>
        </table>
      </body>
    </html>
  </xsl:template>

</xsl:stylesheet>
```

XML Function Reference

The functions described in this section operate on values of type `xml`. The section XML Predicatesalso contains information about the `xml` functions and function-like expressions.

Function:

`xmlcomment`

Synopsis:

```
xmlcomment(<text>)
```

The function `xmlcomment` creates an XML value containing an XML comment with the specified text as content. The text cannot contain "--" or end with a "-" so that the resulting construct is a valid XML comment. If the argument is null, the result is null.

Example:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
SELECT xmlcomment('hello');

  xmlcomment
--------------
 <!--hello-->
```

Function:

`xmlconcat`

Synopsis:

```
xmlconcat(xml[, …])
```

The function `xmlconcat` concatenates a list of individual XML values to create a single value containing an XML content fragment. Null values are omitted; the result is only null if there are no nonnull arguments.

Example:

```
SELECT xmlconcat('<abc/>', '<bar>foo</bar>');

      xmlconcat
----------------------
 <abc/><bar>foo</bar>
```

XML declarations, if present, are combined as follows:

- If all argument values have the same XML version declaration, that version is used in the result, else no version is used.
- If all argument values have the standalone declaration value "yes", then that value is used in the result.
- If all argument values have a standalone declaration value and at least one is "no", then that is used in the result. Otherwise, the result will have no standalone declaration.
- If the result is determined to require a standalone declaration but no version declaration, a version declaration with version 1.0 will be used because XML requires an XML declaration to contain a version declaration.

Encoding declarations are ignored and removed in all cases.

Example:

```
SELECT xmlconcat('<?xml version="1.1"?><foo/>', '<?xml version="1.1" standalone="no"?><bar/>');

             xmlconcat
-----------------------------------
 <?xml version="1.1"?><foo/><bar/>
```

Function:

`xmlelement`

Synopsis:

```
xmlelement(name name [, xmlattributes(value [AS attname] [, ... ])] [, content, ...])
```

The `xmlelement` expression produces an XML element with the given name, attributes, and content.

Examples:

```
SELECT xmlelement(name foo);

 xmlelement
------------
 <foo/>

SELECT xmlelement(name foo, xmlattributes('xyz' as bar));

    xmlelement
------------------
 <foo bar="xyz"/>

SELECT xmlelement(name foo, xmlattributes(current_date as bar), 'cont', 'ent');

             xmlelement
---------------------------------------
 <foo bar="2017-01-26">content</foo>
```

Element and attribute names that are not valid XML names are escaped by replacing the offending characters by the sequence `_xHHHH_`, where HHHH is the character's Unicode codepoint in hexadecimal notation. For example:

```
SELECT xmlelement(name "foo$bar", xmlattributes('xyz' as "a&b"));

            xmlelement
-----------------------------------
 <foo_x0024_bar a_x0026_b="xyz"/>
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

An explicit attribute name need not be specified if the attribute value is a column reference, in which case the column's name will be used as the attribute name by default. In other cases, the attribute must be given an explicit name. So this example is valid:

```
CREATE TABLE test (a xml, b xml);
SELECT xmlelement(name test, xmlattributes(a, b)) FROM test;
```

But these are not:

```
SELECT xmlelement(name test, xmlattributes('constant'), a, b) FROM test;
SELECT xmlelement(name test, xmlattributes(func(a, b))) FROM test;
```

Element content, if specified, will be formatted according to its data type. If the content is itself of type `xml`, complex XML documents can be constructed. For example:

```
SELECT xmlelement(name foo, xmlattributes('xyz' as bar),
                            xmlelement(name abc),
                            xmlcomment('test'),
                            xmlelement(name xyz));

                 xmlelement
----------------------------------------------
 <foo bar="xyz"><abc/><!--test--><xyz/></foo>
```

Content of other types will be formatted into valid XML character data. This means in particular that the characters `<`, `>`, and `&` will be converted to entities. Binary data (data type `bytea`) will be represented in base64 or hex encoding, depending on the setting of the configuration parameter xmlbinary. The particular behavior for individual data types is expected to evolve in order to align the SQL and WarehousePG data types with the XML schema specification, at which point a more precise description will appear.

Function:

`xmlforest`

Synopsis:

```
xmlforest(<content> [AS <name>] [, ...])
```

The `xmlforest` expression produces an XML forest (sequence) of elements using the given names and content.

Examples:

```
SELECT xmlforest('abc' AS foo, 123 AS bar);

          xmlforest
------------------------------
 <foo>abc</foo><bar>123</bar>

SELECT xmlforest(table_name, column_name)
FROM information_schema.columns
WHERE table_schema = 'pg_catalog';

                                       xmlforest
----------------------------------------------------------------------------------------
 <table_name>pg_authid</table_name><column_name>rolname</column_name>
 <table_name>pg_authid</table_name><column_name>rolsuper</column_name>
```

As seen in the second example, the element name can be omitted if the content value is a column reference, in which case the column name is used by default. Otherwise, a name must be specified.

Element names that are not valid XML names are escaped as shown for `xmlelement` above. Similarly, content data is escaped to make valid XML content, unless it is already of type `xml`.

Note that XML forests are not valid XML documents if they consist of more than one element, so it might be useful to wrap `xmlforest` expressions in `xmlelement`.

Function:

`xmlpi`

Synopsis:

```
xmlpi(name <target> [, <content>])
```

The `xmlpi` expression creates an XML processing instruction. The content, if present, must not contain the character sequence `?>`.

Example:

```
SELECT xmlpi(name php, 'echo "hello world";');

            xmlpi
-----------------------------
 <?php echo "hello world";?>
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Function:

`xmlroot`

Synopsis:

```
xmlroot(<xml>, version <text> | no value [, standalone yes|no|no value])
```

The `xmlroot` expression alters the properties of the root node of an XML value. If a version is specified, it replaces the value in the root node's version declaration; if a standalone setting is specified, it replaces the value in the root node's standalone declaration.

```
SELECT xmlroot(xmlparse(document '<?xml version="1.1"?><content>abc</content>'),
               version '1.0', standalone yes);

                xmlroot
----------------------------------------
 <?xml version="1.0" standalone="yes"?>
 <content>abc</content>
```

Function:

`xmlagg`

```
xmlagg (<xml>)
```

The function `xmlagg` is, unlike the other functions described here, an aggregate function. It concatenates the input values to the aggregate function call, much like `xmlconcat` does, except that concatenation occurs across rows rather than across expressions in a single row. See Using Functions and Operators for additional information about aggregate functions.

Example:

```
CREATE TABLE test (y int, x xml);
INSERT INTO test VALUES (1, '<foo>abc</foo>');
INSERT INTO test VALUES (2, '<bar/>');
SELECT xmlagg(x) FROM test;
        xmlagg
----------------------
 <foo>abc</foo><bar/>
```

To determine the order of the concatenation, an `ORDER BY` clause may be added to the aggregate call. For example:

```
SELECT xmlagg(x ORDER BY y DESC) FROM test;
        xmlagg
----------------------
 <bar/><foo>abc</foo>
```

The following non-standard approach used to be recommended in previous versions, and may still be useful in specific cases:

```
SELECT xmlagg(x) FROM (SELECT * FROM test ORDER BY y DESC) AS tab;
        xmlagg
----------------------
 <bar/><foo>abc</foo>
```

XML Predicates

The expressions described in this section check properties of `xml` values.

Expression:

`IS DOCUMENT`

Synopsis:

```
<xml> IS DOCUMENT
```

The expression `IS DOCUMENT` returns true if the argument XML value is a proper XML document, false if it is not (that is, it is a content fragment), or null if the argument is null.

Expression:

`XMLEXISTS`

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Synopsis:

```
XMLEXISTS(<text> PASSING [BY REF] <xml> [BY REF])
```

The function `xmlexists` returns true if the XPath expression in the first argument returns any nodes, and false otherwise. (If either argument is null, the result is null.)

Example:

```
SELECT xmlexists('//town[<text>() = ''Toronto'']' PASSING BY REF '<towns><town>Toronto</town><town>Ottawa</town></towns>');

 xmlexists
------------
 t
(1 row)
```

The `BY REF` clauses have no effect in WarehousePG, but are allowed for SQL conformance and compatibility with other implementations. Per SQL standard, the first `BY REF` is required, the second is optional. Also note that the SQL standard specifies the `xmlexists` construct to take an XQuery expression as first argument, but WarehousePG currently only supports XPath, which is a subset of XQuery.

Expression:

`xml_is_well_formed`

Synopsis:

```
xml_is_well_formed(<text>)
xml_is_well_formed_document(<text>)
xml_is_well_formed_content(<text>)
```

These functions check whether a text string is well-formed XML, returning a Boolean result. `xml_is_well_formed_document` checks for a well-formed document, while `xml_is_well_formed_content` checks for well-formed content. `xml_is_well_formed` does the former if the `xmloption` configuration parameter is set to `DOCUMENT`, or the latter if it is set to `CONTENT`. This means that `xml_is_well_formed` is useful for seeing whether a simple cast to type `xml` will succeed, whereas the other two functions are useful for seeing whether the corresponding variants of `XMLPARSE` will succeed.

Examples:

```
SET xmloption TO DOCUMENT;
SELECT xml_is_well_formed('<>');
 xml_is_well_formed
--------------------
 f
(1 row)

SELECT xml_is_well_formed('<abc/>');
 xml_is_well_formed
--------------------
 t
(1 row)

SET xmloption TO CONTENT;
SELECT xml_is_well_formed('abc');
 xml_is_well_formed
--------------------
 t
(1 row)

SELECT xml_is_well_formed_document('<pg:foo xmlns:pg="http://postgresql.org/stuff">bar</pg:foo>');
 xml_is_well_formed_document
-----------------------------
 t
(1 row)

SELECT xml_is_well_formed_document('<pg:foo xmlns:pg="http://postgresql.org/stuff">bar</my:foo>');
 xml_is_well_formed_document
-----------------------------
 f
(1 row)
```

The last example shows that the checks include whether namespaces are correctly matched.

4.6.8 Using Full Text Search

WarehousePG provides data types, functions, operators, index types, and configurations for querying natural language documents.

- About Full Text Search
  This topic provides an overview of WarehousePG full text search, basic text search expressions, configuring, and customizing text search. WarehousePG full text search is compared with WarehousePG Text.
- Searching Text in Database Tables
  This topic shows how to use text search operators to search database tables and how to create indexes to speed up text searches.
- Controlling Text Search
  This topic shows how to create search and query vectors, how to rank search results, and how to highlight search terms in the results of text search queries.
- Additional Text Search Features
  WarehousePG has additional functions and operators you can use to manipulate search and query vectors, and to rewrite search queries.
- Text Search Parsers
  This topic describes the types of tokens the WarehousePG text search parser produces from raw text.
- Text Search Dictionaries
  Tokens produced by the WarehousePG full text search parser are passed through a chain of dictionaries to produce a normalized term or "lexeme". Different kinds of dictionaries are available to filter and transform tokens in different ways and for different languages.
- Text Search Configuration Example
  This topic shows how to create a customized text search configuration to process document and query text.
- Testing and Debugging Text Search
  This topic introduces the WarehousePG functions you can use to test and debug a search configuration or the individual parser and dictionaries specified in a configuration.
- GiST and GIN Indexes for Text Search
  This topic describes and compares the WarehousePG index types that are used for full text searching.
- psql Support
  The psql command-line utility provides a meta-command to display information about WarehousePG full text search configurations.
- Limitations
  This topic lists limitations and maximums for WarehousePG full text search objects.

Parent topic: Querying Data

4.6.8.1 About Full Text Search

This topic provides an overview of WarehousePG full text search, basic text search expressions, configuring, and customizing text search. WarehousePG full text search is compared with WarehousePG Text.

This section contains the following subtopics:

- What is a Document?
- Basic Text Matching
- Configurations

Full Text Searching (or just "text search") provides the capability to identify natural-language *documents* that satisfy a *query*, and optionally to rank them by relevance to the query. The most common type of search is to find all documents containing given *query terms* and return them in order of their *similarity* to the query.

WarehousePG provides a data type `tsvector` to store preprocessed documents, and a data type `tsquery` to store processed queries (Text Search Data Types). There are many functions and operators available for these data types (Text Search Functions and Operators), the most important of which is the match operator `@@`, which we introduce in Basic Text Matching. Full text searches can be accelerated using indexes (GiST and GIN Indexes for Text Search).

Notions of query and similarity are very flexible and depend on the specific application. The simplest search considers query as a set of words and similarity as the frequency of query words in the document.

WarehousePG supports the standard text matching operators `~`, `~*`, `LIKE`, and `ILIKE` for textual data types, but these operators lack many essential properties required for searching documents:

- There is no linguistic support, even for English. Regular expressions are not sufficient because they cannot easily handle derived words, e.g., `satisfies` and `satisfy`. You might miss documents that contain `satisfies`, although you probably would like to find them when searching for `satisfy`. It is possible to use OR to search for multiple derived forms, but this is tedious and error-prone (some words can have several thousand derivatives).
- They provide no ordering (ranking) of search results, which makes them ineffective when thousands of matching documents are found.
- They tend to be slow because there is no index support, so they must process all documents for every search.

Full text indexing allows documents to be preprocessed and an index saved for later rapid searching. Preprocessing includes:

- **Parsing documents into tokens.** It is useful to identify various classes of tokens, e.g., numbers, words, complex words, email addresses, so that they can be processed differently. In principle token classes depend on the specific application, but for most purposes it is adequate to use a predefined set of classes. WarehousePG uses a *parser* to perform this step. A standard parser is provided, and custom parsers can be created for specific needs.
- **Converting tokens into lexemes.** A lexeme is a string, just like a token, but it has been *normalized* so that different forms of the same word are made alike. For example, normalization almost always includes folding upper-case letters to lower-case, and often involves removal of suffixes (such as s or es in English). This allows searches to find variant forms of the same word, without tediously entering all the possible variants. Also, this step typically eliminates *stop words*, which are words that are so common that they are useless for searching. (In short, then, tokens are raw fragments of the document text, while lexemes are words that are believed useful for indexing and searching.) WarehousePG uses *dictionaries* to perform this step. Various standard dictionaries are provided, and custom ones can be created for specific needs.
- **Storing preprocessed documents optimized for searching.** For example, each document can be represented as a sorted array of normalized lexemes. Along with the lexemes it is often desirable to store positional information to use for *proximity ranking*, so that a document that contains a more "dense" region of query words is assigned a higher rank than one with scattered query words.

Dictionaries allow fine-grained control over how tokens are normalized. With appropriate dictionaries, you can:

- Define stop words that should not be indexed.
- Map synonyms to a single word using Ispell.
- Map phrases to a single word using a thesaurus.
- Map different variations of a word to a canonical form using an Ispell dictionary.
- Map different variations of a word to a canonical form using Snowball stemmer rules.

What is a Document?

A *document* is the unit of searching in a full text search system; for example, a magazine article or email message. The text search engine must be able to parse documents and store associations of lexemes (key words) with their parent document. Later, these associations are used to search for documents that contain query words.

For searches within WarehousePG, a document is normally a textual field within a row of a database table, or possibly a combination (concatenation) of such fields, perhaps stored in several tables or obtained dynamically. In other words, a document can be constructed from different parts for indexing and it might not be stored anywhere as a whole. For example:

```
SELECT title || ' ' ||  author || ' ' ||  abstract || ' ' || body AS document
FROM messages
WHERE mid = 12;

SELECT m.title || ' ' || m.author || ' ' || m.abstract || ' ' || d.body AS document
FROM messages m, docs d
WHERE m.mid = d.did AND m.mid = 12;
```

> **Note** In these example queries, `coalesce` should be used to prevent a single `NULL` attribute from causing a `NULL` result for the whole document.

Another possibility is to store the documents as simple text files in the file system. In this case, the database can be used to store the full text index and to run searches, and some unique identifier can be used to retrieve the document from the file system. However, retrieving files from outside the database requires superuser permissions or special function support, so this is usually less convenient than keeping all the data inside WarehousePG. Also, keeping everything inside the database allows easy access to document metadata to assist in indexing and display.

For text search purposes, each document must be reduced to the preprocessed `tsvector` format. Searching and ranking are performed entirely on the tsvector representation of a document — the original text need only be retrieved when the document has been selected for display to a user. We therefore often speak of the `tsvector` as being the document, but of course it is only a compact representation of the full document.

Basic Text Matching

Full text searching in WarehousePG is based on the match operator `@@`, which returns `true` if a `tsvector` (document) matches a `tsquery` (query). It does not matter which data type is written first:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
SELECT 'a fat cat sat on a mat and ate a fat rat'::tsvector @@ 'cat & rat'::tsquery;
 ?column?
----------
 t

SELECT 'fat & cow'::tsquery @@ 'a fat cat sat on a mat and ate a fat rat'::tsvector;
 ?column?
----------
 f
```

As the above example suggests, a `tsquery` is not just raw text, any more than a `tsvector` is. A `tsquery` contains search terms, which must be already-normalized lexemes, and may combine multiple terms using AND, OR, NOT, and FOLLOWED BY operators. (For details see Text Search Data Types) There are functions `to_tsquery`, `plainto_tsquery`, and `phraseto_query` that are helpful in converting user-written text into a proper `tsquery`, for example by normalizing words appearing in the text. Similarly, `to_tsvector` is used to parse and normalize a document string. So in practice a text search match would look more like this:

```
SELECT to_tsvector('fat cats ate fat rats') @@ to_tsquery('fat & rat');
 ?column?
----------
 t
```

Observe that this match would not succeed if written as

```
SELECT 'fat cats ate fat rats'::tsvector @@ to_tsquery('fat & rat');
 ?column?
----------
 f
```

since here no normalization of the word `rats` will occur. The elements of a `tsvector` are lexemes, which are assumed already normalized, so `rats` does not match `rat`.

The `@@` operator also supports `text` input, allowing explicit conversion of a text string to `tsvector` or `tsquery` to be skipped in simple cases. The variants available are:

```
tsvector @@ tsquery
tsquery  @@ tsvector
text @@ tsquery
text @@ text
```

The first two of these we saw already. The form `text @@ tsquery` is equivalent to `to_tsvector(x) @@ y`. The form `text @@ text` is equivalent to `to_tsvector(x) @@ plainto_tsquery(y)`.

Within a `tsquery`, the `&` (AND) operator specifies that both its arguments must appear in the document to have a match. Similarly, the `|` (OR) operator specifies that at least one of its arguments must appear, while the `!` (NOT) operator specifies that its argument must *not* appear in order to have a match. For example, the query `fat & ! rat` matches documents that contain `fat` but not `rat`.

Searching for phrases is possible with the help of the `<->` (FOLLOWED BY) `tsquery` operator, which matches only if its arguments have matches that are adjacent and in the given order. For example:

```
SELECT to_tsvector('fatal error') @@ to_tsquery('fatal <-> error');
 ?column?
----------
 t

SELECT to_tsvector('error is not fatal') @@ to_tsquery('fatal <-> error');
 ?column?
----------
 f
```

There is a more general version of the FOLLOWED BY operator having the form `<N>`, where *N* is an integer standing for the difference between the positions of the matching lexemes. `<1>` is the same as `<->`, while `<2>` allows exactly one other lexeme to appear between the matches, and so on. The `phraseto_tsquery` function makes use of this operator to construct a `tsquery` that can match a multi-word phrase when some of the words are stop words. For example:

```
SELECT phraseto_tsquery('cats ate rats');
       phraseto_tsquery
-------------------------------
 'cat' <-> 'ate' <-> 'rat'

SELECT phraseto_tsquery('the cats ate the rats');
       phraseto_tsquery
-------------------------------
 'cat' <-> 'ate' <2> 'rat'
```

A special case that's sometimes useful is that `<0>` can be used to require that two patterns match the same word.

Parentheses can be used to control nesting of the tsquery operators. Without parentheses, `|` binds least tightly, then `&`, then `<->`, and `!` most tightly.

It's worth noticing that the AND/OR/NOT operators mean something subtly different when they are within the arguments of a FOLLOWED BY operator than when they are not, because within FOLLOWED BY the exact position of the match is significant. For example, normally `!x` matches only documents that do not contain `x` anywhere. But `!x <-> y` matches `y` if it is not immediately after an `x`; an occurrence of `x` elsewhere in the document does not prevent a match. Another example is that `x & y` normally only requires that `x` and `y` both appear somewhere in the document, but `(x & y) <-> z` requires `x` and `y` to match at the same place, immediately before a `z`. Thus this query behaves differently from `x <-> z & y <-> z`, which will match a document containing two separate sequences `x z` and `y z`. (This specific query is useless as written, since `x` and `y` could not match at the same place; but with more complex situations such as prefix-match patterns, a query of this form could be useful.)

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Configurations

The above are all simple text search examples. As mentioned before, full text search functionality includes the ability to do many more things: skip indexing certain words (stop words), process synonyms, and use sophisticated parsing, e.g., parse based on more than just white space. This functionality is controlled by *text search configurations*. WarehousePG comes with predefined configurations for many languages, and you can easily create your own configurations. (psql's `\dF` command shows all available configurations.)

During installation an appropriate configuration is selected and default_text_search_config is set accordingly in `postgresql.conf`. If you are using the same text search configuration for the entire cluster you can use the value in `postgresql.conf`. To use different configurations throughout the cluster but the same configuration within any one database, use `ALTER DATABASE ... SET`. Otherwise, you can set `default_text_search_config` in each session.

Each text search function that depends on a configuration has an optional `regconfig` argument, so that the configuration to use can be specified explicitly. `default_text_search_config` is used only when this argument is omitted.

To make it easier to build custom text search configurations, a configuration is built up from simpler database objects. WarehousePG's text search facility provides four types of configuration-related database objects:

- *Text search parsers* break documents into tokens and classify each token (for example, as words or numbers).
- *Text search dictionaries* convert tokens to normalized form and reject stop words.
- *Text search templates* provide the functions underlying dictionaries. (A dictionary simply specifies a template and a set of parameters for the template.)
- *Text search configurations* select a parser and a set of dictionaries to use to normalize the tokens produced by the parser.

Text search parsers and templates are built from low-level C functions; therefore it requires C programming ability to develop new ones, and superuser privileges to install one into a database. (There are examples of add-on parsers and templates in the `contrib/` area of the WarehousePG distribution.) Since dictionaries and configurations just parameterize and connect together some underlying parsers and templates, no special privilege is needed to create a new dictionary or configuration. Examples of creating custom dictionaries and configurations appear later in this chapter.

Parent topic: Using Full Text Search

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.6.8.2 Searching Text in Database Tables

This topic shows how to use text search operators to search database tables and how to create indexes to speed up text searches.

The examples in the previous section illustrated full text matching using simple constant strings. This section shows how to search table data, optionally using indexes.

This section contains the following subtopics:

- Searching a Table
- Creating Indexes

Searching a Table

It is possible to do a full text search without an index. A simple query to print the `title` of each row that contains the word `friend` in its `body` field is:

```
SELECT title
FROM pgweb
WHERE to_tsvector('english', body) @@ to_tsquery('english', 'friend');
```

This will also find related words such as `friends` and `friendly`, since all these are reduced to the same normalized lexeme.

The query above specifies that the `english` configuration is to be used to parse and normalize the strings. Alternatively we could omit the configuration parameters:

```
SELECT title
FROM pgweb
WHERE to_tsvector(body) @@ to_tsquery('friend');
```

This query will use the configuration set by default_text_search_config.

A more complex example is to select the ten most recent documents that contain `create` and `table` in the `title` or `body`:

```
SELECT title
FROM pgweb
WHERE to_tsvector(title || ' ' || body) @@ to_tsquery('create & table')
ORDER BY last_mod_date DESC
LIMIT 10;
```

For clarity we omitted the `coalesce` function calls which would be needed to find rows that contain `NULL` in one of the two fields.

Although these queries will work without an index, most applications will find this approach too slow, except perhaps for occasional ad-hoc searches. Practical use of text searching usually requires creating an index.

Creating Indexes

We can create a GIN index (GiST and GIN Indexes for Text Search) to speed up text searches:

```
CREATE INDEX pgweb_idx ON pgweb USING GIN (to_tsvector('english', body));
```

Notice that the two-argument version of `to_tsvector` is used. Only text search functions that specify a configuration name can be used in expression indexes. This is because the index contents must be unaffected by default_text_search_config. If they were affected, the index contents might be inconsistent because different entries could contain `tsvector`s that were created with different text search configurations, and there would be no way to guess which was which. It would be impossible to dump and restore such an index correctly.

Because the two-argument version of `to_tsvector` was used in the index above, only a query reference that uses the two-argument version of `to_tsvector` with the same configuration name will use that index. That is, `WHERE to_tsvector('english', body) @@ 'a & b'` can use the index, but `WHERE to_tsvector(body) @@ 'a & b'` cannot. This ensures that an index will be used only with the same configuration used to create the index entries.

It is possible to set up more complex expression indexes wherein the configuration name is specified by another column, e.g.:

```
CREATE INDEX pgweb_idx ON pgweb USING GIN (to_tsvector(config_name, body));
```

where `config_name` is a column in the `pgweb` table. This allows mixed configurations in the same index while recording which configuration was used for each index entry. This would be useful, for example, if the document collection contained documents in different languages. Again, queries that are meant to use the index must be phrased to match, e.g., `WHERE to_tsvector(config_name, body) @@ 'a & b'`.

Indexes can even concatenate columns:

```
CREATE INDEX pgweb_idx ON pgweb USING GIN (to_tsvector('english', title || ' ' || body));
```

Another approach is to create a separate `tsvector` column to hold the output of `to_tsvector`. To keep this column automatically up to date with its source data, use a stored generated column. This example is a concatenation of title and body, using `coalesce` to ensure that one field will still be indexed when the other is NULL:

```
ALTER TABLE pgweb
    ADD COLUMN textsearchable_index_col tsvector
        GENERATED ALWAYS AS (to_tsvector('english', coalesce(title, '') || ' ' || coalesce(body, ''))) STORED;
```

Then we create a GIN index to speed up the search:

```
CREATE INDEX textsearch_idx ON pgweb USING GIN (textsearchable_index_col);
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Now we are ready to perform a fast full text search:

```
SELECT title FROM pgweb WHERE textsearchable_index_col @@ to_tsquery('create & table')
ORDER BY last_mod_date DESC LIMIT 10;
```

One advantage of the separate-column approach over an expression index is that it is not necessary to explicitly specify the text search configuration in queries in order to make use of the index. As shown in the example above, the query can depend on `default_text_search_config`. Another advantage is that searches will be faster, since it will not be necessary to redo the `to_tsvector` calls to verify index matches. (This is more important when using a GiST index than a GIN index; see GiST and GIN Indexes for Text Search.) The expression-index approach is simpler to set up, however, and it requires less disk space since the `tsvector` representation is not stored explicitly.

Parent topic: Using Full Text Search

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.6.8.3 Controlling Text Search

This topic shows how to create search and query vectors, how to rank search results, and how to highlight search terms in the results of text search queries.

To implement full text searching there must be a function to create a `tsvector` from a document and a `tsquery` from a user query. Also, we need to return results in a useful order, so we need a function that compares documents with respect to their relevance to the query. It's also important to be able to display the results nicely. WarehousePG provides support for all of these functions.

This topic contains the following subtopics:

- Parsing Documents
- Parsing Queries
- Ranking Search Results
- Highlighting Results

Parsing Documents

WarehousePG provides the function `to_tsvector` for converting a document to the `tsvector` data type.

```
to_tsvector([<config> regconfig, ] <document> text) returns tsvector
```

`to_tsvector` parses a textual document into tokens, reduces the tokens to lexemes, and returns a `tsvector` which lists the lexemes together with their positions in the document. The document is processed according to the specified or default text search configuration. Here is a simple example:

```
SELECT to_tsvector('english', 'a fat  cat sat on a mat - it ate a fat rats');
                  to_tsvector
-----------------------------------------------------
 'ate':9 'cat':3 'fat':2,11 'mat':7 'rat':12 'sat':4
```

In the example above we see that the resulting tsvector does not contain the words `a`, `on`, or `it`, the word `rats` became `rat`, and the punctuation sign `-` was ignored.

The `to_tsvector` function internally calls a parser which breaks the document text into tokens and assigns a type to each token. For each token, a list of dictionaries (Text Search Dictionaries) is consulted, where the list can vary depending on the token type. The first dictionary that *recognizes* the token emits one or more normalized *lexemes* to represent the token. For example, `rats` became `rat` because one of the dictionaries recognized that the word `rats` is a plural form of `rat`. Some words are recognized as *stop words*, which causes them to be ignored since they occur too frequently to be useful in searching. In our example these are `a`, `on`, and `it`. If no dictionary in the list recognizes the token then it is also ignored. In this example that happened to the punctuation sign `-` because there are in fact no dictionaries assigned for its token type (`Space symbols`), meaning space tokens will never be indexed. The choices of parser, dictionaries and which types of tokens to index are determined by the selected text search configuration (Text Search Configuration Example). It is possible to have many different configurations in the same database, and predefined configurations are available for various languages. In our example we used the default configuration `english` for the English language.

The function `setweight` can be used to label the entries of a `tsvector` with a given *weight*, where a weight is one of the letters `A`, `B`, `C`, or `D`. This is typically used to mark entries coming from different parts of a document, such as `title` versus `body`. Later, this information can be used for ranking of search results.

Because `to_tsvector(NULL)` will return `NULL`, it is recommended to use `coalesce` whenever a field might be null. Here is the recommended method for creating a tsvector from a structured document:

```
UPDATE tt SET ti = setweight(to_tsvector(coalesce(title,'')), 'A')
  || setweight(to_tsvector(coalesce(keyword,'')), 'B')
  || setweight(to_tsvector(coalesce(abstract,'')), 'C')
  || setweight(to_tsvector(coalesce(body,'')), 'D');
```

Here we have used `setweight` to label the source of each lexeme in the finished `tsvector`, and then merged the labeled `tsvector` values using the `tsvector` concatenation operator `||`. (Additional Text Search Features gives details about these operations.)

Parsing Queries

WarehousePG provides the functions `to_tsquery`, `plainto_tsquery`, `phraseto_tsquery`, and `websearch_to_tsquery` for converting a query to the `tsquery` data type. `to_tsquery` offers access to more features than `plainto_tsquery`, but is less forgiving about its input. `websearch_to_tsquery` is a simplified version of `to_tsquery` with an alternative syntax, similar to the one used by web search engines.

```
to_tsquery([<config> regconfig, ] <querytext> text) returns tsquery
```

`to_tsquery` creates a `tsquery` value from *querytext*, which must consist of single tokens separated by the Boolean operators `&` (AND), `|` (OR), `!` (NOT), and <-> (FOLLOWED BY), possibly grouped using parentheses. In other words, the input to `to_tsquery` must already follow the general rules for tsquery input, as described in Text Search Data Types. The difference is that while basic `tsquery` input takes the tokens at face value, `to_tsquery` normalizes each token to a lexeme using the specified or default configuration, and discards any tokens that are stop words according to the configuration. For example:

```
SELECT to_tsquery('english', 'The & Fat & Rats');
  to_tsquery
---------------
 'fat' & 'rat'
```

As in basic `tsquery` input, weight(s) can be attached to each lexeme to restrict it to match only `tsvector` lexemes of those weight(s). For example:

```
SELECT to_tsquery('english', 'Fat | Rats:AB');
    to_tsquery
------------------
 'fat' | 'rat':AB
```

Also, `*` can be attached to a lexeme to specify prefix matching:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
SELECT to_tsquery('supern:*A & star:A*B');
        to_tsquery
--------------------------
 'supern':*A & 'star':*AB
```

Such a lexeme will match any word in a `tsvector` that begins with the given string.

`to_tsquery` can also accept single-quoted phrases. This is primarily useful when the configuration includes a thesaurus dictionary that may trigger on such phrases. In the example below, a thesaurus contains the rule `supernovae stars : sn`:

```
SELECT to_tsquery('''supernovae stars'' & !crab');
  to_tsquery
---------------
 'sn' & !'crab'
```

Without quotes, `to_tsquery` will generate a syntax error for tokens that are not separated by an AND, OR, or FOLLOWED BY operator.

```
plainto_tsquery([ <config> regconfig, ] <querytext> ext) returns tsquery
```

`plainto_tsquery` transforms unformatted text `*querytext*` to `tsquery`. The text is parsed and normalized much as for `to_tsvector`, then the `&` (AND) Boolean operator is inserted between surviving words.

Example:

```
SELECT plainto_tsquery('english', 'The Fat Rats');
 plainto_tsquery
-----------------
 'fat' & 'rat'
```

Note that `plainto_tsquery` cannot recognize Boolean operators, weight labels, or prefix-match labels in its input:

```
SELECT plainto_tsquery('english', 'The Fat & Rats:C');
   plainto_tsquery
----------------------
 'fat' & 'rat' & 'c'
```

Here, all the input punctuation was discarded as being space symbols.

```
phraseto_tsquery([ <config> regconfig, ] <querytext> text) returns tsquery
```

`phraseto_tsquery` behaves much like `plainto_tsquery`, except that it inserts the `<->` (FOLLOWED BY) operator between surviving words instead of the `&` (AND) operator. Also, stop words are not simply discarded, but are accounted for by inserting `<N>` operators rather than `<->` operators. This function is useful when searching for exact lexeme sequences, since the FOLLOWED BY operators check lexeme order not just the presence of all the lexemes.

Example:

```
SELECT phraseto_tsquery('english', 'The Fat Rats');
 phraseto_tsquery
------------------
 'fat' <-> 'rat'
```

Like `plainto_tsquery`, the `phraseto_tsquery` function will not recognize `tsquery` operators, weight labels, or prefix-match labels in its input:

```
SELECT phraseto_tsquery('english', 'The Fat & Rats:C');
      phraseto_tsquery
-----------------------------
 'fat' <-> 'rat' <-> 'c'
```

```
websearch_to_tsquery([ <config> regconfig, ] <querytext> text) returns tsquery
```

`websearch_to_tsquery` creates a `tsquery` value from querytext using an alternative syntax in which simple unformatted text is a valid query. Unlike `plainto_tsquery` and `phraseto_tsquery`, it also recognizes certain operators. Moreover, this function should never raise syntax errors, which makes it possible to use raw user-supplied input for search. The following syntax is supported:

- `unquoted text`: text not inside quote marks will be converted to terms separated by `&` operators, as if processed by `plainto_tsquery`.
- `"quoted text"`: text inside quote marks will be converted to terms separated by `<->` operators, as if processed by `phraseto_tsquery`.
- `OR`: logical or will be converted to the `|` operator.
- `-`: the logical not operator, converted to the `!` operator.

Examples:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
SELECT websearch_to_tsquery('english', 'The fat rats');
 websearch_to_tsquery
----------------------
 'fat' & 'rat'
(1 row)

SELECT websearch_to_tsquery('english', '"supernovae stars" -crab');
       websearch_to_tsquery
---------------------------------
 'supernova' <-> 'star' & !'crab'
(1 row)

SELECT websearch_to_tsquery('english', '"sad cat" or "fat rat"');
       websearch_to_tsquery
-----------------------------------
 'sad' <-> 'cat' | 'fat' <-> 'rat'
(1 row)

SELECT websearch_to_tsquery('english', 'signal -"segmentation fault"');
         websearch_to_tsquery
---------------------------------------
 'signal' & !( 'segment' <-> 'fault' )
(1 row)

SELECT websearch_to_tsquery('english', '""" )( dummy \\ query <->');
 websearch_to_tsquery
----------------------
 'dummi' & 'queri'
(1 row)
```

Ranking Search Results

Ranking attempts to measure how relevant documents are to a particular query, so that when there are many matches the most relevant ones can be shown first. WarehousePG provides two predefined ranking functions, which take into account lexical, proximity, and structural information; that is, they consider how often the query terms appear in the document, how close together the terms are in the document, and how important is the part of the document where they occur. However, the concept of relevancy is vague and very application-specific. Different applications might require additional information for ranking, e.g., document modification time. The built-in ranking functions are only examples. You can write your own ranking functions and/or combine their results with additional factors to fit your specific needs.

The two ranking functions currently available are:

`ts_rank([ <weights> float4[], ] <vector> tsvector, <query> tsquery [, <normalization> integer ]) returns float4` Ranks vectors based on the frequency of their matching lexemes.

`ts_rank_cd([ <weights> float4[], ] <vector> tsvector, <query> tsquery [, <normalization> integer ]) returns float4` This function computes the *cover density* ranking for the given document vector and query, as described in Clarke, Cormack, and Tudhope's "Relevance Ranking for One to Three Term Queries" in the journal "Information Processing and Management", 1999. Cover density is similar to `ts_rank` ranking except that the proximity of matching lexemes to each other is taken into consideration.

This function requires lexeme positional information to perform its calculation. Therefore, it ignores any "stripped" lexemes in the `tsvector`. If there are no unstripped lexemes in the input, the result will be zero. (See Manipulating Documents for more information about the `strip` function and positional information in `tsvector`s.)

For both these functions, the optional `<weights>` argument offers the ability to weigh word instances more or less heavily depending on how they are labeled. The weight arrays specify how heavily to weigh each category of word, in the order:

```
{D-weight, C-weight, B-weight, A-weight}
```

If no `<weights>` are provided, then these defaults are used:

```
{0.1, 0.2, 0.4, 1.0}
```

Typically weights are used to mark words from special areas of the document, like the title or an initial abstract, so they can be treated with more or less importance than words in the document body.

Since a longer document has a greater chance of containing a query term it is reasonable to take into account document size, e.g., a hundred-word document with five instances of a search word is probably more relevant than a thousand-word document with five instances. Both ranking functions take an integer `<normalization>` option that specifies whether and how a document's length should impact its rank. The integer option controls several behaviors, so it is a bit mask: you can specify one or more behaviors using `|` (for example, `2|4`).

- 0 (the default) ignores the document length
- 1 divides the rank by 1 + the logarithm of the document length
- 2 divides the rank by the document length
- 4 divides the rank by the mean harmonic distance between extents (this is implemented only by `ts_rank_cd`)
- 8 divides the rank by the number of unique words in document
- 16 divides the rank by 1 + the logarithm of the number of unique words in document
- 32 divides the rank by itself + 1

If more than one flag bit is specified, the transformations are applied in the order listed.

It is important to note that the ranking functions do not use any global information, so it is impossible to produce a fair normalization to 1% or 100% as sometimes desired. Normalization option `32 (rank/(rank+1))` can be applied to scale all ranks into the range zero to one, but of course this is just a cosmetic change; it will not affect the ordering of the search results.

Here is an example that selects only the ten highest-ranked matches:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
SELECT title, ts_rank_cd(textsearch, query) AS rank
FROM apod, to_tsquery('neutrino|(dark & matter)') query
WHERE query @@ textsearch
ORDER BY rank DESC
LIMIT 10;
                     title                     |   rank
-----------------------------------------------+----------
 Neutrinos in the Sun                          |      3.1
 The Sudbury Neutrino Detector                 |      2.4
 A MACHO View of Galactic Dark Matter          |  2.01317
 Hot Gas and Dark Matter                       |  1.91171
 The Virgo Cluster: Hot Plasma and Dark Matter |  1.90953
 Rafting for Solar Neutrinos                   |      1.9
 NGC 4650A: Strange Galaxy and Dark Matter     |  1.85774
 Hot Gas and Dark Matter                       |   1.6123
 Ice Fishing for Cosmic Neutrinos              |      1.6
 Weak Lensing Distorts the Universe            | 0.818218
```

This is the same example using normalized ranking:

```
SELECT title, ts_rank_cd(textsearch, query, 32 /* rank/(rank+1) */ ) AS rank
FROM apod, to_tsquery('neutrino|(dark & matter)') query
WHERE  query @@ textsearch
ORDER BY rank DESC
LIMIT 10;
                     title                     |        rank
-----------------------------------------------+-------------------
 Neutrinos in the Sun                          | 0.756097569485493
 The Sudbury Neutrino Detector                 | 0.705882361190954
 A MACHO View of Galactic Dark Matter          | 0.668123210574724
 Hot Gas and Dark Matter                       |  0.65655958650282
 The Virgo Cluster: Hot Plasma and Dark Matter | 0.656301290640973
 Rafting for Solar Neutrinos                   | 0.655172410958162
 NGC 4650A: Strange Galaxy and Dark Matter     | 0.650072921219637
 Hot Gas and Dark Matter                       | 0.617195790024749
 Ice Fishing for Cosmic Neutrinos              | 0.615384618911517
 Weak Lensing Distorts the Universe            | 0.450010798361481
```

Ranking can be expensive since it requires consulting the tsvector of each matching document, which can be I/O bound and therefore slow. Unfortunately, it is almost impossible to avoid since practical queries often result in large numbers of matches.

Highlighting Results

To present search results it is ideal to show a part of each document and how it is related to the query. Usually, search engines show fragments of the document with marked search terms. WarehousePG provides a function `ts_headline` that implements this functionality.

```
ts_headline([<config> regconfig, ] <document> text, <query> tsquery [, <options> text ]) returns text
```

`ts_headline` accepts a document along with a query, and returns an excerpt from the document in which terms from the query are highlighted. The configuration to be used to parse the document can be specified by `*config*`; if `*config*` is omitted, the `default_text_search_config` configuration is used.

If an `*options*` string is specified it must consist of a comma-separated list of one or more `*option=value*` pairs. The available options are:

- `MaxWords`, `MinWords` (integers): these numbers determine the longest and shortest headlines to output. The default values are 35 and 15.
- `ShortWord` (integer): words of this length or less will be dropped at the start and end of a headline, unless they are query terms. The default value of three eliminates common English articles.
- `HighlightAll` (boolean): the whole document will be used as the headline, ignoring the preceding three parameters. The default is `false`.
- `MaxFragments` (integer): maximum number of text fragments to display. The default value of zero selects a non-fragment-based headline generation method. A value greater than zero selects fragment-based headline generation (see below).
- `StartSel`, `StopSel` (strings): the strings with which to delimit query words appearing in the document, to distinguish them from other excerpted words. The default values are `<b>` " and " `</b>` ", which can be suitable for HTML output.
- `FragmentDelimiter` (string): When more than one fragment is displayed, the fragments will be separated by this string. The default is " `...` ".

These option names are recognized case-insensitively. You must double-quote string values if they contain spaces or commas.

In non-fragment-based headline generation, `ts_headline` locates matches for the given `<query>` and chooses a single one to display, preferring matches that have more query words within the allowed headline length. In fragment-based headline generation, `ts_headline` locates the query matches and splits each match into “fragments” of no more than `MaxWords` words each, preferring fragments with more query words, and when possible “stretching” fragments to include surrounding words. The fragment-based mode is thus more useful when the query matches span large sections of the document, or when it’s desirable to display multiple matches. In either mode, if no query matches can be identified, then a single fragment of the first `MinWords` words in the document will be displayed.

For example:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
SELECT ts_headline('english',
  'The most common type of search
is to find all documents containing given query terms
and return them in order of their similarity to the
query.',
  to_tsquery('english', 'query & similarity'));
                        ts_headline
------------------------------------------------------------
 containing given <b>query</b> terms                       +
 and return them in order of their <b>similarity</b> to the+
 <b>query</b>.

SELECT ts_headline('english',
  'Search terms may occur
many times in a document,
requiring ranking of the search matches to decide which
occurrences to display in the result.',
  to_tsquery('english', 'search & term'),
  'MaxFragments=10, MaxWords=7, MinWords=3, StartSel=<<, StopSel=>>');
                        ts_headline
------------------------------------------------------------
 <<Search>> <<terms>> may occur                            +
 many times ... ranking of the <<search>> matches to decide
```

`ts_headline` uses the original document, not a `tsvector` summary, so it can be slow and should be used with care.

4.6.8.4 Additional Text Search Features

WarehousePG has additional functions and operators you can use to manipulate search and query vectors, and to rewrite search queries.

This section contains the following subtopics:

- Manipulating Documents
- Manipulating Queries
- Rewriting Queries
- Gathering Document Statistics

Manipulating Documents

Parsing Documents showed how raw textual documents can be converted into `tsvector` values. WarehousePG also provides functions and operators that can be used to manipulate documents that are already in `tsvector` form.

`tsvector || tsvector` The `tsvector` concatenation operator returns a vector which combines the lexemes and positional information of the two vectors given as arguments. Positions and weight labels are retained during the concatenation. Positions appearing in the right-hand vector are offset by the largest position mentioned in the left-hand vector, so that the result is nearly equivalent to the result of performing `to_tsvector` on the concatenation of the two original document strings. (The equivalence is not exact, because any stop-words removed from the end of the left-hand argument will not affect the result, whereas they would have affected the positions of the lexemes in the right-hand argument if textual concatenation were used.)

One advantage of using concatenation in the vector form, rather than concatenating text before applying `to_tsvector`, is that you can use different configurations to parse different sections of the document. Also, because the `setweight` function marks all lexemes of the given vector the same way, it is necessary to parse the text and do `setweight` before concatenating if you want to label different parts of the document with different weights.

`setweight(<vector> tsvector, <weight> "char") returns tsvector` `setweight` returns a copy of the input vector in which every position has been labeled with the given `<weight>`, either `A`, `B`, `C`, or `D`. (`D` is the default for new vectors and as such is not displayed on output.) These labels are retained when vectors are concatenated, allowing words from different parts of a document to be weighted differently by ranking functions.

Note that weight labels apply to **positions**, not **lexemes**. If the input vector has been stripped of positions then `setweight` does nothing.

`length(<vector> tsvector) returns integer` Returns the number of lexemes stored in the vector.

`strip(vector tsvector) returns tsvector` Returns a vector that lists the same lexemes as the given vector, but lacks any position or weight information. The result is usually much smaller than an unstripped vector, but it is also less useful. Relevance ranking does not work as well on stripped vectors as unstripped ones. Also, the `<->` (FOLLOWED BY) `tsquery` operator will never match stripped input, since it cannot determine the distance between lexeme occurrences.

A full list of tsvector-related functions is available in Text Search Functions and Operators in the PostgreSQL documentation.

Manipulating Queries

Parsing Queries showed how raw textual queries can be converted into `tsquery` values. WarehousePG also provides functions and operators that can be used to manipulate queries that are already in `tsquery` form.

`tsquery && tsquery` Returns the AND-combination of the two given queries.

`tsquery || tsquery` Returns the OR-combination of the two given queries.

`!! tsquery` Returns the negation (NOT) of the given query.

`tsquery <-> tsquery` Returns a query that searches for a match to the first given query immediately followed by a match to the second given query, using the `<->` (FOLLOWED BY) `tsquery` operator. For example:

```
SELECT to_tsquery('fat') <-> to_tsquery('cat | rat');
          ?column?
----------------------------
 'fat' <-> ( 'cat' | 'rat' )
```

`tsquery_phrase(<query1> tsquery, <query2> tsquery [, <distance> integer ]) returns tsquery` Returns a query that searches for a match to the first given query followed by a match to the second given query at a distance of exactly `<distance>` lexemes, using the `<N>` `tsquery` operator. For example:

```
SELECT tsquery_phrase(to_tsquery('fat'), to_tsquery('cat'), 10);
  tsquery_phrase
------------------
 'fat' <10> 'cat'
```

`numnode(<query> tsquery) returns integer` Returns the number of nodes (lexemes plus operators) in a tsquery. This function is useful to determine if the **query** is meaningful (returns > 0), or contains only stop words (returns 0). Examples:

```
SELECT numnode(plainto_tsquery('the any'));
NOTICE:  query contains only stopword(s) or doesn't contain lexeme(s), ignored
 numnode
---------
       0

SELECT numnode('foo & bar'::tsquery);
 numnode
---------
       3
```

`querytree(<query> tsquery) returns text` Returns the portion of a tsquery that can be used for searching an index. This function is useful for detecting unindexable queries, for example those containing only stop words or only negated terms. For example:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
SELECT querytree(to_tsquery('!defined'));
 querytree
-----------
```

Rewriting Queries

The `ts_rewrite` family of functions search a given `tsquery` for occurrences of a target subquery, and replace each occurrence with a substitute subquery. In essence this operation is a `tsquery`-specific version of substring replacement. A target and substitute combination can be thought of as a *query rewrite rule*. A collection of such rewrite rules can be a powerful search aid. For example, you can expand the search using synonyms (e.g. `new york`, `big apple`, `nyc`, `gotham`) or narrow the search to direct the user to some hot topic. There is some overlap in functionality between this feature and thesaurus dictionaries (Thesaurus Dictionary). However, you can modify a set of rewrite rules on-the-fly without reindexing, whereas updating a thesaurus requires reindexing to be effective.

`ts_rewrite(<query> tsquery, <target> tsquery, <substitute> tsquery) returns tsquery` This form of `ts_rewrite` simply applies a single rewrite rule: `<target>` is replaced by `<substitute>` wherever it appears in `<query>`. For example:

```
SELECT ts_rewrite('a & b'::tsquery, 'a'::tsquery, 'c'::tsquery);
 ts_rewrite
------------
 'b' & 'c'
```

`ts_rewrite(<query> tsquery, <select> text) returns tsquery` This form of `ts_rewrite` accepts a starting `<query>` and a SQL `<select>` command, which is given as a text string. The `<select>` must yield two columns of `tsquery` type. For each row of the `<select>` result, occurrences of the first column value (the target) are replaced by the second column value (the substitute) within the current `<query>` value. For example:

```
CREATE TABLE aliases (id int, t tsquery, s tsquery);
INSERT INTO aliases VALUES(1, 'a', 'c');

SELECT ts_rewrite('a & b'::tsquery, 'SELECT t,s FROM aliases');
 ts_rewrite
------------
 'b' & 'c'
```

Note that when multiple rewrite rules are applied in this way, the order of application can be important; so in practice you will want the source query to `ORDER BY` some ordering key.

Let's consider a real-life astronomical example. We'll expand query `supernovae` using table-driven rewriting rules:

```
CREATE TABLE aliases (id int, t tsquery primary key, s tsquery);
INSERT INTO aliases VALUES(1, to_tsquery('supernovae'), to_tsquery('supernovae|sn'));

SELECT ts_rewrite(to_tsquery('supernovae & crab'), 'SELECT t, s FROM aliases');
           ts_rewrite
---------------------------------
 'crab' & ( 'supernova' | 'sn' )
```

We can change the rewriting rules just by updating the table:

```
UPDATE aliases
SET s = to_tsquery('supernovae|sn & !nebulae')
WHERE t = to_tsquery('supernovae');

SELECT ts_rewrite(to_tsquery('supernovae & crab'), 'SELECT t, s FROM aliases');
                 ts_rewrite
---------------------------------------------
 'crab' & ( 'supernova' | 'sn' & !'nebula' )
```

Rewriting can be slow when there are many rewriting rules, since it checks every rule for a possible match. To filter out obvious non-candidate rules we can use the containment operators for the `tsquery` type. In the example below, we select only those rules which might match the original query:

```
SELECT ts_rewrite('a & b'::tsquery,
                  'SELECT t,s FROM aliases WHERE ''a & b''::tsquery @> t');
 ts_rewrite
------------
 'b' & 'c'
```

Gathering Document Statistics

The function `ts_stat` is useful for checking your configuration and for finding stop-word candidates.

```
ts_stat(<sqlquery> text, [ <weights> text, ]
        OUT <word> text, OUT <ndoc> integer,
        OUT <nentry> integer) returns setof record
```

`<sqlquery>` is a text value containing an SQL query which must return a single `tsvector` column. `ts_stat` runs the query and returns statistics about each distinct lexeme (word) contained in the `tsvector` data. The columns returned are

- `<word> text` — the value of a lexeme
- `<ndoc> integer` — number of documents (`tsvector`s) the word occurred in
- `<nentry> integer` — total number of occurrences of the word

If weights is supplied, only occurrences having one of those weights are counted.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

For example, to find the ten most frequent words in a document collection:

```
SELECT * FROM ts_stat('SELECT vector FROM apod')
ORDER BY nentry DESC, ndoc DESC, word
LIMIT 10;
```

The same, but counting only word occurrences with weight `A` or `B`:

```
SELECT * FROM ts_stat('SELECT vector FROM apod', 'ab')
ORDER BY nentry DESC, ndoc DESC, word
LIMIT 10;
```

4.6.8.5 Text Search Parsers

This topic describes the types of tokens the WarehousePG text search parser produces from raw text.

Text search parsers are responsible for splitting raw document text into *tokens* and identifying each token's type, where the set of possible types is defined by the parser itself. Note that a parser does not modify the text at all — it simply identifies plausible word boundaries. Because of this limited scope, there is less need for application-specific custom parsers than there is for custom dictionaries. At present WarehousePG provides just one built-in parser, which has been found to be useful for a wide range of applications.

The built-in parser is named `pg_catalog.default`. It recognizes 23 token types, shown in the following table.

Alias	Description	Example
asciiword	Word, all ASCII letters	elephant
word	Word, all letters	mañana
numword	Word, letters and digits	beta1
asciihword	Hyphenated word, all ASCII	up-to-date
hword	Hyphenated word, all letters	lógico-matemática
numhword	Hyphenated word, letters and digits	postgresql-beta1
hword_asciipart	Hyphenated word part, all ASCII	postgresql in the context postgresql-beta1
hword_part	Hyphenated word part, all letters	lógico or matemática in the context lógico-matemática
hword_numpart	Hyphenated word part, letters and digits	beta1 in the context postgresql-beta1
email	Email address	foo@example.com
protocol	Protocol head	http\://
url	URL	example.com/stuff/index.html
host	Host	example.com
url_path	URL path	/stuff/index.html, in the context of a URL
file	File or path name	/usr/local/foo.txt, if not within a URL
sfloat	Scientific notation	-1.234e56
float	Decimal notation	-1.234
int	Signed integer	-1234
uint	Unsigned integer	1234
version	Version number	8.3.0
tag	XML tag	\<a href="dictionaries.html">
entity	XML entity	\&
blank	Space symbols	(any whitespace or punctuation not otherwise recognized)

> **Note** The parser's notion of a "letter" is determined by the database's locale setting, specifically `lc_ctype`. Words containing only the basic ASCII letters are reported as a separate token type, since it is sometimes useful to distinguish them. In most European languages, token types `word` and `asciiword` should be treated alike.

`email` does not support all valid email characters as defined by RFC 5322. Specifically, the only non-alphanumeric characters supported for email user names are period, dash, and underscore.

It is possible for the parser to produce overlapping tokens from the same piece of text. As an example, a hyphenated word will be reported both as the entire word and as each component:

```
SELECT alias, description, token FROM ts_debug('foo-bar-beta1');
      alias      |              description                |     token
-----------------+-----------------------------------------+---------------
 numword         | Hyphenated word, letters and digits     | foo-bar-beta1
 hword_asciipart | Hyphenated word part, all ASCII         | foo
 blank           | Space symbols                           | -
 hword_asciipart | Hyphenated word part, all ASCII         | bar
 blank           | Space symbols                           | -
 hword_numpart   | Hyphenated word part, letters and digits | beta1
```

This behavior is desirable since it allows searches to work for both the whole compound word and for components. Here is another instructive example:

```
SELECT alias, description, token FROM ts_debug('http://example.com/stuff/index.html');
  alias   |  description  |            token
----------+---------------+------------------------------
 protocol | Protocol head | http://
 url      | URL           | example.com/stuff/index.html
 host     | Host          | example.com
 url_path | URL path      | /stuff/index.html
```

4.6.8.6 Text Search Dictionaries

Tokens produced by the WarehousePG full text search parser are passed through a chain of dictionaries to produce a normalized term or "lexeme". Different kinds of dictionaries are available to filter and transform tokens in different ways and for different languages.

This section contains the following subtopics:

- About Text Search Dictionaries
- Stop Words
- Simple Dictionary
- Synonym Dictionary
- Thesaurus Dictionary
- Ispell Dictionary
- SnowBall Dictionary

About Text Search Dictionaries

Dictionaries are used to eliminate words that should not be considered in a search (*stop words*), and to *normalize* words so that different derived forms of the same word will match. A successfully normalized word is called a*lexeme*. Aside from improving search quality, normalization and removal of stop words reduces the size of the `tsvector` representation of a document, thereby improving performance. Normalization does not always have linguistic meaning and usually depends on application semantics.

Some examples of normalization:

- Linguistic - Ispell dictionaries try to reduce input words to a normalized form; stemmer dictionaries remove word endings
- URL locations can be canonicalized to make equivalent URLs match:
  - `http://www.pgsql.ru/db/mw/index.html`
  - `http://www.pgsql.ru/db/mw/`
  - `http://www.pgsql.ru/db/../db/mw/index.html`
- Color names can be replaced by their hexadecimal values, e.g., `red`, `green`, `blue`, `magenta` -> `FF0000`, `00FF00`, `0000FF`, `FF00FF`
- If indexing numbers, we can remove some fractional digits to reduce the range of possible numbers, so for example 3.14159265359, 3.1415926, 3.14 will be the same after normalization if only two digits are kept after the decimal point.

A dictionary is a program that accepts a token as input and returns:

- an array of lexemes if the input token is known to the dictionary (notice that one token can produce more than one lexeme)
- a single lexeme with the `TSL_FILTER` flag set, to replace the original token with a new token to be passed to subsequent dictionaries (a dictionary that does this is called a*filtering dictionary*)
- an empty array if the dictionary knows the token, but it is a stop word
- `NULL` if the dictionary does not recognize the input token

WarehousePG provides predefined dictionaries for many languages. There are also several predefined templates that can be used to create new dictionaries with custom parameters. Each predefined dictionary template is described below. If no existing template is suitable, it is possible to create new ones; see the `contrib/` area of the WarehousePG distribution for examples.

A text search configuration binds a parser together with a set of dictionaries to process the parser's output tokens. For each token type that the parser can return, a separate list of dictionaries is specified by the configuration. When a token of that type is found by the parser, each dictionary in the list is consulted in turn, until some dictionary recognizes it as a known word. If it is identified as a stop word, or if no dictionary recognizes the token, it will be discarded and not indexed or searched for. Normally, the first dictionary that returns a `non-NULL` output determines the result, and any remaining dictionaries are not consulted; but a filtering dictionary can replace the given word with a modified word, which is then passed to subsequent dictionaries.

The general rule for configuring a list of dictionaries is to place first the most narrow, most specific dictionary, then the more general dictionaries, finishing with a very general dictionary, like a Snowball stemmer or `simple`, which recognizes everything. For example, for an astronomy-specific search (`astro_en` configuration) one could bind token type `asciiword` (ASCII word) to a synonym dictionary of astronomical terms, a general English dictionary and a Snowball English stemmer:

```
ALTER TEXT SEARCH CONFIGURATION astro_en
    ADD MAPPING FOR asciiword WITH astrosyn, english_ispell, english_stem;
```

A filtering dictionary can be placed anywhere in the list, except at the end where it'd be useless. Filtering dictionaries are useful to partially normalize words to simplify the task of later dictionaries. For example, a filtering dictionary could be used to remove accents from accented letters, as is done by the unaccent module.

Stop Words

Stop words are words that are very common, appear in almost every document, and have no discrimination value. Therefore, they can be ignored in the context of full text searching. For example, every English text contains words like `a` and `the`, so it is useless to store them in an index. However, stop words do affect the positions in `tsvector`, which in turn affect ranking:

```
SELECT to_tsvector('english', 'in the list of stop words');
        to_tsvector
----------------------------
 'list':3 'stop':5 'word':6
```

The missing positions 1,2,4 are because of stop words. Ranks calculated for documents with and without stop words are quite different:

```
SELECT ts_rank_cd (to_tsvector('english', 'in the list of stop words'), to_tsquery('list & stop'));
 ts_rank_cd
------------
       0.05

SELECT ts_rank_cd (to_tsvector('english', 'list stop words'), to_tsquery('list & stop'));
 ts_rank_cd
------------
        0.1
```

It is up to the specific dictionary how it treats stop words. For example, `ispell` dictionaries first normalize words and then look at the list of stop words, while `Snowball` stemmers first check the list of stop words. The reason for the different behavior is an attempt to decrease noise.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Simple Dictionary

The simple dictionary template operates by converting the input token to lower case and checking it against a file of stop words. If it is found in the file then an empty array is returned, causing the token to be discarded. If not, the lower-cased form of the word is returned as the normalized lexeme. Alternatively, the dictionary can be configured to report non-stop-words as unrecognized, allowing them to be passed on to the next dictionary in the list.

Here is an example of a dictionary definition using the simple template:

```
CREATE TEXT SEARCH DICTIONARY public.simple_dict (
    TEMPLATE = pg_catalog.simple,
    STOPWORDS = english
);
```

Here, `english` is the base name of a file of stop words. The file's full name will be `$SHAREDIR/tsearch_data/english.stop`, where `$SHAREDIR` means the WarehousePG installation's shared-data directory, often `/usr/edb/whpg7/share/postgresql` (use `pg_config --sharedir` to determine it if you're not sure). The file format is simply a list of words, one per line. Blank lines and trailing spaces are ignored, and upper case is folded to lower case, but no other processing is done on the file contents.

Now we can test our dictionary:

```
SELECT ts_lexize('public.simple_dict', 'YeS');
 ts_lexize
-----------
 {yes}

SELECT ts_lexize('public.simple_dict', 'The');
 ts_lexize
-----------
 {}
```

We can also choose to return `NULL`, instead of the lower-cased word, if it is not found in the stop words file. This behavior is selected by setting the dictionary's `Accept` parameter to false. Continuing the example:

```
ALTER TEXT SEARCH DICTIONARY public.simple_dict ( Accept = false );

SELECT ts_lexize('public.simple_dict', 'YeS');
 ts_lexize
-----------
 {yes}

SELECT ts_lexize('public.simple_dict', 'The');
 ts_lexize
-----------
 {}
```

With the default setting of `Accept = true`, it is only useful to place a simple dictionary at the end of a list of dictionaries, since it will never pass on any token to a following dictionary. Conversely, `Accept = false` is only useful when there is at least one following dictionary.

CAUTION:

Most types of dictionaries rely on configuration files, such as files of stop words. These files *must* be stored in UTF-8 encoding. They will be translated to the actual database encoding, if that is different, when they are read into the server.

CAUTION:

Normally, a database session will read a dictionary configuration file only once, when it is first used within the session. If you modify a configuration file and want to force existing sessions to pick up the new contents, issue an `ALTER TEXT SEARCH DICTIONARY` command on the dictionary. This can be a "dummy" update that doesn't actually change any parameter values.

Synonym Dictionary

This dictionary template is used to create dictionaries that replace a word with a synonym. Phrases are not supported—use the thesaurus template (Thesaurus Dictionary) for that. A synonym dictionary can be used to overcome linguistic problems, for example, to prevent an English stemmer dictionary from reducing the word "Paris" to "pari". It is enough to have a `Paris paris` line in the synonym dictionary and put it before the `english_stem` dictionary. For example:

```
SELECT * FROM ts_debug('english', 'Paris');
   alias   |   description   | token |  dictionaries  |  dictionary  | lexemes
-----------+-----------------+-------+----------------+--------------+---------
 asciiword | Word, all ASCII | Paris | {english_stem} | english_stem | {pari}

CREATE TEXT SEARCH DICTIONARY my_synonym (
    TEMPLATE = synonym,
    SYNONYMS = my_synonyms
);

ALTER TEXT SEARCH CONFIGURATION english
    ALTER MAPPING FOR asciiword
    WITH my_synonym, english_stem;

SELECT * FROM ts_debug('english', 'Paris');
   alias   |   description   | token |       dictionaries        | dictionary | lexemes
-----------+-----------------+-------+---------------------------+------------+---------
 asciiword | Word, all ASCII | Paris | {my_synonym,english_stem} | my_synonym | {paris}
```

The only parameter required by the synonym template is `SYNONYMS`, which is the base name of its configuration file — `my_synonyms` in the above example. The file's full name will be `$SHAREDIR/tsearch_data/my_synonyms.syn` (where `$SHAREDIR` means the WarehousePG installation's shared-data directory). The file format is just one line per word to be substituted, with the word followed by its synonym, separated by white space. Blank lines and trailing spaces are ignored.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

The synonym template also has an optional parameter `CaseSensitive`, which defaults to `false`. When `CaseSensitive` is `false`, words in the synonym file are folded to lower case, as are input tokens. When it is `true`, words and tokens are not folded to lower case, but are compared as-is.

An asterisk (*) can be placed at the end of a synonym in the configuration file. This indicates that the synonym is a prefix. The asterisk is ignored when the entry is used in `to_tsvector()`, but when it is used in `to_tsquery()`, the result will be a query item with the prefix match marker (see Parsing Queries). For example, suppose we have these entries in `$SHAREDIR/tsearch_data/synonym_sample.syn`:

```
postgres pgsql postgresql pgsql postgre pgsql
gogle googl
indices index*
```

Then we will get these results:

```
mydb=# CREATE TEXT SEARCH DICTIONARY syn (template=synonym, synonyms='synonym_sample');
mydb=# SELECT ts_lexize('syn', 'indices');
 ts_lexize
-----------
 {index}
(1 row)

mydb=# CREATE TEXT SEARCH CONFIGURATION tst (copy=simple);
mydb=# ALTER TEXT SEARCH CONFIGURATION tst ALTER MAPPING FOR asciiword WITH syn;
mydb=# SELECT to_tsvector('tst', 'indices');
 to_tsvector
-------------
 'index':1
(1 row)

mydb=# SELECT to_tsquery('tst', 'indices');
 to_tsquery
------------
 'index':*
(1 row)

mydb=# SELECT 'indexes are very useful'::tsvector;
            tsvector
---------------------------------
 'are' 'indexes' 'useful' 'very'
(1 row)

mydb=# SELECT 'indexes are very useful'::tsvector @@ to_tsquery('tst', 'indices');
 ?column?
----------
 t
(1 row)
```

Thesaurus Dictionary

A thesaurus dictionary (sometimes abbreviated as TZ) is a collection of words that includes information about the relationships of words and phrases, i.e., broader terms (BT), narrower terms (NT), preferred terms, non-preferred terms, related terms, etc.

Basically a thesaurus dictionary replaces all non-preferred terms by one preferred term and, optionally, preserves the original terms for indexing as well. WarehousePG's current implementation of the thesaurus dictionary is an extension of the synonym dictionary with added *phrase* support. A thesaurus dictionary requires a configuration file of the following format:

```
# this is a comment
sample word(s) : indexed word(s)
more sample word(s) : more indexed word(s)
...
```

where the colon (`:`) symbol acts as a delimiter between a phrase and its replacement.

A thesaurus dictionary uses a *subdictionary* (which is specified in the dictionary's configuration) to normalize the input text before checking for phrase matches. It is only possible to select one subdictionary. An error is reported if the subdictionary fails to recognize a word. In that case, you should remove the use of the word or teach the subdictionary about it. You can place an asterisk (`*`) at the beginning of an indexed word to skip applying the subdictionary to it, but all sample words **must** be known to the subdictionary.

The thesaurus dictionary chooses the longest match if there are multiple phrases matching the input, and ties are broken by using the last definition.

Specific stop words recognized by the subdictionary cannot be specified; instead use `?` to mark the location where any stop word can appear. For example, assuming that `a` and `the` are stop words according to the subdictionary:

```
? one ? two : swsw
```

matches `a one the two` and `the one a two`; both would be replaced by `swsw`.

Since a thesaurus dictionary has the capability to recognize phrases it must remember its state and interact with the parser. A thesaurus dictionary uses these assignments to check if it should handle the next word or stop accumulation. The thesaurus dictionary must be configured carefully. For example, if the thesaurus dictionary is assigned to handle only the `asciiword` token, then a thesaurus dictionary definition like `one 7` will not work since token type `uint` is not assigned to the thesaurus dictionary.

CAUTION:

Thesauruses are used during indexing so any change in the thesaurus dictionary's parameters requires reindexing. For most other dictionary types, small changes such as adding or removing stopwords does not force reindexing.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Thesaurus Configuration

To define a new thesaurus dictionary, use the `thesaurus` template. For example:

```
CREATE TEXT SEARCH DICTIONARY thesaurus_simple (
    TEMPLATE = thesaurus,
    DictFile = mythesaurus,
    Dictionary = pg_catalog.english_stem
);
```

Here:

- `thesaurus_simple` is the new dictionary's name
- `mythesaurus` is the base name of the thesaurus configuration file. (Its full name will be `$SHAREDIR/tsearch_data/mythesaurus.ths`, where `$SHAREDIR` means the installation shared-data directory.)
- `pg_catalog.english_stem` is the subdictionary (here, a Snowball English stemmer) to use for thesaurus normalization. Notice that the subdictionary will have its own configuration (for example, stop words), which is not shown here.

Now it is possible to bind the thesaurus dictionary `thesaurus_simple` to the desired token types in a configuration, for example:

```
ALTER TEXT SEARCH CONFIGURATION russian
    ALTER MAPPING FOR asciiword, asciihword, hword_asciipart
    WITH thesaurus_simple;
```

Thesaurus Example

Consider a simple astronomical thesaurus `thesaurus_astro`, which contains some astronomical word combinations:

```
supernovae stars : sn
crab nebulae : crab
```

Below we create a dictionary and bind some token types to an astronomical thesaurus and English stemmer:

```
CREATE TEXT SEARCH DICTIONARY thesaurus_astro (
    TEMPLATE = thesaurus,
    DictFile = thesaurus_astro,
    Dictionary = english_stem
);

ALTER TEXT SEARCH CONFIGURATION russian
    ALTER MAPPING FOR asciiword, asciihword, hword_asciipart
    WITH thesaurus_astro, english_stem;
```

Now we can see how it works. `ts_lexize` is not very useful for testing a thesaurus, because it treats its input as a single token. Instead we can use `plainto_tsquery` and `to_tsvector`, which will break their input strings into multiple tokens:

```
SELECT plainto_tsquery('supernova star');
 plainto_tsquery
-----------------
 'supernova' & 'star'

SELECT to_tsvector('supernova star');
 to_tsvector
-------------
 'star':2 'supernova':1
```

In principle, one can use `to_tsquery` if you quote the argument:

```
SELECT to_tsquery('''supernova star''');
 to_tsquery
------------
 'supernova' & 'star'
```

Notice that `supernova star` matches `supernovae stars` in `thesaurus_astro` because we specified the `english_stem` stemmer in the `thesaurus` definition. The stemmer removed the `e` and `s`.

To index the original phrase as well as the substitute, just include it in the right-hand part of the definition:

```
supernovae stars : sn supernovae stars

SELECT plainto_tsquery('supernova star');
       plainto_tsquery
-----------------------------
 'supernova' & 'star'
```

Ispell Dictionary

The Ispell dictionary template supports *morphological dictionaries*, which can normalize many different linguistic forms of a word into the same lexeme. For example, an English Ispell dictionary can match all declensions and conjugations of the search term `bank`, e.g., `banking`, `banked`, `banks`, `banks'`, and `bank's`.

The standard WarehousePG distribution does not include any Ispell configuration files. Dictionaries for a large number of languages are available from Ispell. Also, some more modern dictionary file formats are supported — MySpell (OO < 2.0.1) and Hunspell (OO >= 2.0.2). A large list of dictionaries is available on the OpenOffice Wiki.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

To create an Ispell dictionary perform these steps:

1. Download dictionary configuration files. OpenOffice extension files have the `.oxt` extension. It is necessary to extract `.aff` and `.dic` files, change extensions to `.affix` and `.dict`. For some dictionary files it is also needed to convert characters to the UTF-8 encoding with commands (for example, for a Norwegian language dictionary):

   ```
   iconv -f ISO_8859-1 -t UTF-8 -o nn_no.affix nn_NO.aff
   iconv -f ISO_8859-1 -t UTF-8 -o nn_no.dict nn_NO.dic
   ```

2. Copy files to the `$SHAREDIR/tsearch_data` directory.

3. Load files into PostgreSQL with the following command:

   ```
   CREATE TEXT SEARCH DICTIONARY english_hunspell (
   TEMPLATE = ispell,
   DictFile = en_us,
   AffFile = en_us,
   Stopwords = english);
   ```

Here, `DictFile`, `AffFile`, and `StopWords` specify the base names of the dictionary, affixes, and stop-words files. The stop-words file has the same format explained above for the `simple` dictionary type. The format of the other files is not specified here but is available from the above-mentioned web sites.

Ispell dictionaries usually recognize a limited set of words, so they should be followed by another broader dictionary; for example, a Snowball dictionary, which recognizes everything.

The `.affix` file of Ispell has the following structure:

```
prefixes
flag *A:
    .           >   RE      # As in enter > reenter
suffixes
flag T:
    E           >   ST      # As in late > latest
    [^AEIOU]Y   >   -Y,IEST # As in dirty > dirtiest
    [AEIOU]Y    >   EST     # As in gray > grayest
    [^EY]       >   EST     # As in small > smallest
```

And the `.dict` file has the following structure:

```
lapse/ADGRS
lard/DGRS
large/PRTY
lark/MRS
```

Format of the `.dict` file is:

```
basic_form/affix_class_name
```

In the `.affix` file every affix flag is described in the following format:

```
condition > [-stripping_letters,] adding_affix
```

Here, condition has a format similar to the format of regular expressions. It can use groupings `[...]` and `[^...]`. For example, `[AEIOU]Y` means that the last letter of the word is "y" and the penultimate letter is "a", "e", "i", "o" or "u". `[^EY]` means that the last letter is neither "e" nor "y".

Ispell dictionaries support splitting compound words; a useful feature. Notice that the affix file should specify a special flag using the `compoundwords controlled` statement that marks dictionary words that can participate in compound formation:

```
compoundwords  controlled z
```

Here are some examples for the Norwegian language:

```
SELECT ts_lexize('norwegian_ispell', 'overbuljongterningpakkmesterassistent');
   {over,buljong,terning,pakk,mester,assistent}
SELECT ts_lexize('norwegian_ispell', 'sjokoladefabrikk');
   {sjokoladefabrikk,sjokolade,fabrikk}
```

MySpell format is a subset of Hunspell. The `.affix` file of Hunspell has the following structure:

```
PFX A Y 1
PFX A   0     re         .
SFX T N 4
SFX T   0     st         e
SFX T   y     iest       [^aeiou]y
SFX T   0     est        [aeiou]y
SFX T   0     est        [^ey]
```

The first line of an affix class is the header. Fields of an affix rules are listed after the header:

- parameter name (PFX or SFX)
- flag (name of the affix class)

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

- stripping characters from beginning (at prefix) or end (at suffix) of the word
- adding affix
- condition that has a format similar to the format of regular expressions.

The `.dict` file looks like the `.dict` file of Ispell:

```
larder/M
lardy/RT
large/RSPMYT
largehearted
```

> **Note** MySpell does not support compound words. Hunspell has sophisticated support for compound words. At present, WarehousePG implements only the basic compound word operations of Hunspell.

SnowBall Dictionary

The Snowball dictionary template is based on a project by Martin Porter, inventor of the popular Porter's stemming algorithm for the English language. Snowball now provides stemming algorithms for many languages (see the Snowball site for more information). Each algorithm understands how to reduce common variant forms of words to a base, or stem, spelling within its language. A Snowball dictionary requires a language parameter to identify which stemmer to use, and optionally can specify a stopword file name that gives a list of words to eliminate. (WarehousePG's standard stopword lists are also provided by the Snowball project.) For example, there is a built-in definition equivalent to

```
CREATE TEXT SEARCH DICTIONARY english_stem (
    TEMPLATE = snowball,
    Language = english,
    StopWords = english
);
```

The stopword file format is the same as already explained.

A Snowball dictionary recognizes everything, whether or not it is able to simplify the word, so it should be placed at the end of the dictionary list. It is useless to have it before any other dictionary because a token will never pass through it to the next dictionary.

Parent topic: Using Full Text Search

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.6.8.7 Text Search Configuration Example

This topic shows how to create a customized text search configuration to process document and query text.

A text search configuration specifies all options necessary to transform a document into a `tsvector`: the parser to use to break text into tokens, and the dictionaries to use to transform each token into a lexeme. Every call of `to_tsvector` or `to_tsquery` needs a text search configuration to perform its processing. The configuration parameter default_text_search_config specifies the name of the default configuration, which is the one used by text search functions if an explicit configuration parameter is omitted. It can be set in `postgresql.conf` using the `gpconfig` command-line utility, or set for an individual session using the `SET` command.

Several predefined text search configurations are available, and you can create custom configurations easily. To facilitate management of text search objects, a set of SQL commands is available, and there are several psql commands that display information about text search objects (psql Support).

As an example we will create a configuration `pg`, starting by duplicating the built-in `english` configuration:

```
CREATE TEXT SEARCH CONFIGURATION public.pg ( COPY = pg_catalog.english );
```

We will use a PostgreSQL-specific synonym list and store it in `$SHAREDIR/tsearch_data/pg_dict.syn`. The file contents look like:

```
postgres    pg
pgsql       pg
postgresql  pg
```

We define the synonym dictionary like this:

```
CREATE TEXT SEARCH DICTIONARY pg_dict (
    TEMPLATE = synonym,
    SYNONYMS = pg_dict
);
```

Next we register the Ispell dictionary `english_ispell`, which has its own configuration files:

```
CREATE TEXT SEARCH DICTIONARY english_ispell (
    TEMPLATE = ispell,
    DictFile = english,
    AffFile = english,
    StopWords = english
);
```

Now we can set up the mappings for words in configuration `pg`:

```
ALTER TEXT SEARCH CONFIGURATION pg
    ALTER MAPPING FOR asciiword, asciihword, hword_asciipart,
                      word, hword, hword_part
    WITH pg_dict, english_ispell, english_stem;
```

We choose not to index or search some token types that the built-in configuration does handle:

```
ALTER TEXT SEARCH CONFIGURATION pg
    DROP MAPPING FOR email, url, url_path, sfloat, float;
```

Now we can test our configuration:

```
SELECT * FROM ts_debug('public.pg', '
PostgreSQL, the highly scalable, SQL compliant, open source object-relational
database management system, is now undergoing beta testing of the next
version of our software.
');
```

The next step is to set the session to use the new configuration, which was created in the `public` schema:

```
=> \dF
   List of text search configurations
 Schema  | Name | Description
---------+------+-------------
 public  | pg   |

SET default_text_search_config = 'public.pg';
SET

SHOW default_text_search_config;
 default_text_search_config
----------------------------
 public.pg
```

4.6.8.8 Testing and Debugging Text Search

This topic introduces the WarehousePG functions you can use to test and debug a search configuration or the individual parser and dictionaries specified in a configuration.

The behavior of a custom text search configuration can easily become confusing. The functions described in this section are useful for testing text search objects. You can test a complete configuration, or test parsers and dictionaries separately.

This section contains the following subtopics:

- Configuration Testing
- Parser Testing
- Dictionary Testing

Configuration Testing

The function `ts_debug` allows easy testing of a text search configuration.

```
ts_debug([<config> regconfig, ] <document> text,
         OUT <alias> text,
         OUT <description> text,
         OUT <token> text,
         OUT <dictionaries> regdictionary[],
         OUT <dictionary> regdictionary,
         OUT <lexemes> text[])
         returns setof record
```

`ts_debug` displays information about every token of `*document*` as produced by the parser and processed by the configured dictionaries. It uses the configuration specified by `*config*`, or `default_text_search_config` if that argument is omitted.

`ts_debug` returns one row for each token identified in the text by the parser. The columns returned are

- `*alias* text` — short name of the token type
- `*description* text` — description of the token type
- `*token* text` — text of the token
- `*dictionaries* regdictionary[]` — the dictionaries selected by the configuration for this token type
- `*dictionary* regdictionary` — the dictionary that recognized the token, or `NULL` if none did
- `*lexemes* text[]` — the lexeme(s) produced by the dictionary that recognized the token, or `NULL` if none did; an empty array (`{}`) means it was recognized as a stop word

Here is a simple example:

```
SELECT * FROM ts_debug('english', 'a fat  cat sat on a mat - it ate a fat rats');
   alias   |   description   | token |  dictionaries  |  dictionary  | lexemes
-----------+-----------------+-------+----------------+--------------+---------
 asciiword | Word, all ASCII | a     | {english_stem} | english_stem | {}
 blank     | Space symbols   |       | {}             |              |
 asciiword | Word, all ASCII | fat   | {english_stem} | english_stem | {fat}
 blank     | Space symbols   |       | {}             |              |
 asciiword | Word, all ASCII | cat   | {english_stem} | english_stem | {cat}
 blank     | Space symbols   |       | {}             |              |
 asciiword | Word, all ASCII | sat   | {english_stem} | english_stem | {sat}
 blank     | Space symbols   |       | {}             |              |
 asciiword | Word, all ASCII | on    | {english_stem} | english_stem | {}
 blank     | Space symbols   |       | {}             |              |
 asciiword | Word, all ASCII | a     | {english_stem} | english_stem | {}
 blank     | Space symbols   |       | {}             |              |
 asciiword | Word, all ASCII | mat   | {english_stem} | english_stem | {mat}
 blank     | Space symbols   |       | {}             |              |
 blank     | Space symbols   | -     | {}             |              |
 asciiword | Word, all ASCII | it    | {english_stem} | english_stem | {}
 blank     | Space symbols   |       | {}             |              |
 asciiword | Word, all ASCII | ate   | {english_stem} | english_stem | {ate}
 blank     | Space symbols   |       | {}             |              |
 asciiword | Word, all ASCII | a     | {english_stem} | english_stem | {}
 blank     | Space symbols   |       | {}             |              |
 asciiword | Word, all ASCII | fat   | {english_stem} | english_stem | {fat}
 blank     | Space symbols   |       | {}             |              |
 asciiword | Word, all ASCII | rats  | {english_stem} | english_stem | {rat}
```

For a more extensive demonstration, we first create a `public.english` configuration and Ispell dictionary for the English language:

```
CREATE TEXT SEARCH CONFIGURATION public.english ( COPY = pg_catalog.english );

CREATE TEXT SEARCH DICTIONARY english_ispell (
    TEMPLATE = ispell,
    DictFile = english,
    AffFile = english,
    StopWords = english
);

ALTER TEXT SEARCH CONFIGURATION public.english
   ALTER MAPPING FOR asciiword WITH english_ispell, english_stem;
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
SELECT * FROM ts_debug('public.english', 'The Brightest supernovaes');
   alias   |   description   |    token    |         dictionaries          |   dictionary   |   lexemes
-----------+-----------------+-------------+-------------------------------+----------------+-------------
 asciiword | Word, all ASCII | The         | {english_ispell,english_stem} | english_ispell | {}
 blank     | Space symbols   |             | {}                            |                |
 asciiword | Word, all ASCII | Brightest   | {english_ispell,english_stem} | english_ispell | {bright}
 blank     | Space symbols   |             | {}                            |                |
 asciiword | Word, all ASCII | supernovaes | {english_ispell,english_stem} | english_stem   | {supernova}
```

In this example, the word `Brightest` was recognized by the parser as an `ASCII` word (alias `asciiword`). For this token type the dictionary list is `english_ispell` and `english_stem`. The word was recognized by `english_ispell`, which reduced it to the noun `bright`. The word `supernovaes` is unknown to the `english_ispell` dictionary so it was passed to the next dictionary, and, fortunately, was recognized (in fact, `english_stem` is a Snowball dictionary which recognizes everything; that is why it was placed at the end of the dictionary list).

The word `The` was recognized by the `english_ispell` dictionary as a stop word (Stop Words) and will not be indexed. The spaces are discarded too, since the configuration provides no dictionaries at all for them.

You can reduce the width of the output by explicitly specifying which columns you want to see:

```
SELECT alias, token, dictionary, lexemes FROM ts_debug('public.english', 'The Brightest supernovaes');
  alias    |    token    |   dictionary   |    lexemes
-----------+-------------+----------------+-------------
 asciiword | The         | english_ispell | {}
 blank     |             |                |
 asciiword | Brightest   | english_ispell | {bright}
 blank     |             |                |
 asciiword | supernovaes | english_stem   | {supernova}
```

Parser Testing

The following functions allow direct testing of a text search parser.

```
ts_parse(<parser_name> text, <document> text,
         OUT <tokid> integer, OUT <token> text) returns setof record
ts_parse(<parser_oid> oid, <document> text,
         OUT <tokid> integer, OUT <token> text) returns setof record
```

`ts_parse` parses the given document and returns a series of records, one for each token produced by parsing. Each record includes a `tokid` showing the assigned token type and a `token`, which is the text of the token. For example:

```
SELECT * FROM ts_parse('default', '123 - a number');
 tokid | token
-------+--------
    22 | 123
    12 |
    12 | -
     1 | a
    12 |
     1 | number
```

```
ts_token_type(<parser_name> text, OUT <tokid> integer,
              OUT <alias> text, OUT <description> text) returns setof record
ts_token_type(<parser_oid> oid, OUT <tokid> integer,
              OUT <alias> text, OUT <description> text) returns setof record
```

`ts_token_type` returns a table which describes each type of token the specified parser can recognize. For each token type, the table gives the integer `tokid` that the parser uses to label a token of that type, the `alias` that names the token type in configuration commands, and a short `description`. For example:

```
SELECT * FROM ts_token_type('default');
 tokid |      alias      |               description
-------+-----------------+------------------------------------------
     1 | asciiword       | Word, all ASCII
     2 | word            | Word, all letters
     3 | numword         | Word, letters and digits
     4 | email           | Email address
     5 | url             | URL
     6 | host            | Host
     7 | sfloat          | Scientific notation
     8 | version         | Version number
     9 | hword_numpart   | Hyphenated word part, letters and digits
    10 | hword_part      | Hyphenated word part, all letters
    11 | hword_asciipart | Hyphenated word part, all ASCII
    12 | blank           | Space symbols
    13 | tag             | XML tag
    14 | protocol        | Protocol head
    15 | numhword        | Hyphenated word, letters and digits
    16 | asciihword      | Hyphenated word, all ASCII
    17 | hword           | Hyphenated word, all letters
    18 | url_path        | URL path
    19 | file            | File or path name
    20 | float           | Decimal notation
    21 | int             | Signed integer
    22 | uint            | Unsigned integer
    23 | entity          | XML entity
```

Dictionary Testing

The `ts_lexize` function facilitates dictionary testing.

```
ts_lexize(*dictreg* dictionary, *token* text) returns text[]
```

`ts_lexize` returns an array of lexemes if the input `*token*` is known to the dictionary, or an empty array if the token is known to the dictionary but it is a stop word, or `NULL` if it is an unknown word.

Examples:

```
SELECT ts_lexize('english_stem', 'stars');
 ts_lexize
-----------
 {star}

SELECT ts_lexize('english_stem', 'a');
 ts_lexize
-----------
 {}
```

> **Note** The `ts_lexize` function expects a single token, not text. Here is a case where this can be confusing:

```
SELECT ts_lexize('thesaurus_astro','supernovae stars') is null;
 ?column?
----------
 t
```

The thesaurus dictionary `thesaurus_astro` does know the phrase `supernovae stars`, but `ts_lexize` fails since it does not parse the input text but treats it as a single token. Use `plainto_tsquery` or `to_tsvector` to test thesaurus dictionaries, for example:

```
SELECT plainto_tsquery('supernovae stars');
 plainto_tsquery
-----------------
 'sn'
```

4.6.8.9 Preferred Index Types for Text Search

There are two kinds of indexes that can be used to speed up full text searches: GIN and GiST. Indexes are not mandatory for full text searching, but in cases where a column is searched on a regular basis, an index is usually desirable.

To create such an index, do one of:

`CREATE INDEX <name> ON <table> USING gin(<column>);` Creates a GIN (Generalized Inverted Index)-based index. The `<column>` must be of `tsvector` type.

`CREATE INDEX <name> ON <table> USING gist(<column>);` Creates a GiST (Generalized Search Tree)-based index. The `<column>` can be of `tsvector` or `tsquery` type.

GIN indexes are the preferred text search index type. As inverted indexes, they contain an index entry for each word (lexeme), with a compressed list of matching locations. Multi-word searches can find the first match, then use the index to remove rows that are lacking additional words. GIN indexes store only the words (lexemes) of `tsvector` values, and not their weight labels. Thus a table row recheck is needed when using a query that involves weights.

A GiST index is lossy, meaning that the index might produce false matches, and it is necessary to check the actual table row to eliminate such false matches. (PostgreSQL does this automatically when needed.) GiST indexes are lossy because each document is represented in the index by a fixed-length signature. The signature is generated by hashing each word into a single bit in an n-bit string, with all these bits OR-ed together to produce an n-bit document signature. When two words hash to the same bit position there will be a false match. If all words in the query have matches (real or false) then the table row must be retrieved to see if the match is correct.

A GiST index can be covering, i.e., use the `INCLUDE` clause. Included columns can have data types without any GiST operator class. Included attributes will be stored uncompressed.

Lossiness causes performance degradation due to unnecessary fetches of table records that turn out to be false matches. Since random access to table records is slow, this limits the usefulness of GiST indexes. The likelihood of false matches depends on several factors, in particular the number of unique words, so using dictionaries to reduce this number is recommended.

Note that GIN index build time can often be improved by increasing maintenance_work_mem, while GiST index build time is not sensitive to that parameter.

Partitioning of big collections and the proper use of GiST and GIN indexes allows the implementation of very fast searches with online update. Partitioning can be done at the database level using table inheritance, or by distributing documents over servers and collecting search results using dblink. The latter is possible because ranking functions use only local information.

4.6.8.10 psql Support

The psql command-line utility provides a meta-command to display information about WarehousePG full text search configurations.

Information about text search configuration objects can be obtained in psql using a set of commands:

```
\dF{d,p,t}[+] [PATTERN]
```

An optional `+` produces more details.

The optional parameter `PATTERN` can be the name of a text search object, optionally schema-qualified. If `PATTERN` is omitted then information about all visible objects will be displayed. `PATTERN` can be a regular expression and can provide **separate** patterns for the schema and object names. The following examples illustrate this:

```
=> \dF *fulltext*
       List of text search configurations
 Schema |  Name        | Description
--------+--------------+-------------
 public | fulltext_cfg |
```

```
=> \dF *.fulltext*
       List of text search configurations
 Schema   |  Name        | Description
----------+--------------------------
 fulltext | fulltext_cfg |
 public   | fulltext_cfg |
```

The available commands are:

`\dF[+] [PATTERN]` List text search configurations (add `+` for more detail).

```
=> \dF russian
            List of text search configurations
   Schema   |  Name   |            Description
------------+---------+-----------------------------------
 pg_catalog | russian | configuration for russian language

=> \dF+ russian
Text search configuration "pg_catalog.russian"
Parser: "pg_catalog.default"
      Token      | Dictionaries
-----------------+--------------
 asciihword      | english_stem
 asciiword       | english_stem
 email           | simple
 file            | simple
 float           | simple
 host            | simple

4.6.8.11 Limitations

This topic lists limitations and maximums for WarehousePG full text search objects.

The current limitations of WarehousePG's text search features are:

- The `tsvector` and `tsquery` types are not supported in the distribution key for a WarehousePG table
- The length of each lexeme must be less than 2K bytes
- The length of a `tsvector` (lexemes + positions) must be less than 1 megabyte
- The match distance in a `<N>` (FOLLOWED BY) `tsquery` operator cannot be more than 16,384
- The number of lexemes must be less than 264
- Position values in `tsvector` must be greater than 0 and no more than 16,383
- No more than 256 positions per lexeme
- The number of nodes (lexemes + operators) in a tsquery must be less than 32,768

For comparison, the PostgreSQL 8.1 documentation contained 10,441 unique words, a total of 335,420 words, and the most frequent word "postgresql" was mentioned 6,127 times in 655 documents.

Another example — the PostgreSQL mailing list archives contained 910,989 unique words with 57,491,343 lexemes in 461,020 messages.

4.6.9 Query Performance

WarehousePG dynamically eliminates irrelevant partitions in a table and optimally allocates memory for different operators in a query.These enhancements scan less data for a query, accelerate query processing, and support more concurrency.

- Dynamic Partition Elimination

  In WarehousePG, values available only when a query runs are used to dynamically prune partitions, which improves query processing speed. Enable or deactivate dynamic partition elimination by setting the server configuration parameter `gp_dynamic_partition_pruning` to `ON` or `OFF`; it is `ON` by default.

- Memory Optimizations

  WarehousePG allocates memory optimally for different operators in a query and frees and re-allocates memory during the stages of processing a query.

> **Note** WarehousePG uses GPORCA, the WarehousePG next generation query optimizer, by default. GPORCA extends the planning and optimization capabilities of the Postgres optimizer. For information about the features and limitations of GPORCA, see Overview of GPORCA.

Parent topic: SQL: Querying Data

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.6.10 Managing Spill Files Generated by Queries

WarehousePG creates spill files, also known as workfiles, on disk if it does not have sufficient memory to run an SQL query in memory.

The maximum number of spill files for a given query is governed by the gp_workfile_limit_files_per_query server configuration parameter setting. The default value of 100,000 spill files is sufficient for the majority of queries.

If a query creates more than the configured number of spill files, WarehousePG returns this error:

```
ERROR: number of workfiles per query limit exceeded
```

WarehousePG may generate a large number of spill files when:

- Data skew is present in the queried data. To check for data skew, see Checking for Data Distribution Skew.
- The amount of memory allocated for the query is too low. You control the maximum amount of memory that can be used by a query with the WarehousePG server configuration parametersmax_statement_mem and statement_mem, or through resource group or resource queue configuration.

You might be able to run the query successfully by changing the query, changing the data distribution, or changing the system memory configuration. The `gp_toolkit` *gp_workfile_** views display spill file usage information. You can use this information to troubleshoot and tune queries. The *gp_workfile_** views are described in Checking Query Disk Spill Space Usage.

Additional documentation resources:

- Memory Consumption Parameters identifies the memory-related spill file server configuration parameters.
- Using Resource Groups describes memory and spill considerations when resource group-based resource management is active.
- Using Resource Queues describes memory and spill considerations when resource queue-based resource management is active.

Parent topic: SQL: Querying Data

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.6.11 Query Profiling

Examine the query plans of poorly performing queries to identify possible performance tuning opportunities.

WarehousePG devises a *query plan* for each query. Choosing the right query plan to match the query and data structure is necessary for good performance. A query plan defines how WarehousePG will run the query in the parallel execution environment.

The query optimizer uses data statistics maintained by the database to choose a query plan with the lowest possible cost. Cost is measured in disk I/O, shown as units of disk page fetches. The goal is to minimize the total execution cost for the plan.

View the plan for a given query with the `EXPLAIN` command. `EXPLAIN` shows the query optimizer's estimated cost for the query plan. For example:

```
EXPLAIN SELECT * FROM names WHERE id=22;
```

`EXPLAIN ANALYZE` runs the statement in addition to displaying its plan. This is useful for determining how close the optimizer's estimates are to reality. For example:

```
EXPLAIN ANALYZE SELECT * FROM names WHERE id=22;
```

> **Note** In WarehousePG, the default GPORCA optimizer co-exists with the Postgres-based planner. The EXPLAIN output generated by GPORCA is different than the output generated by the Postgres-based planner.

By default, WarehousePG uses GPORCA to generate an execution plan for a query when possible.

When the `EXPLAIN ANALYZE` command uses GPORCA, the `EXPLAIN` plan shows only the number of partitions that are being eliminated. The scanned partitions are not shown. To show name of the scanned partitions in the segment logs set the server configuration parameter `gp_log_dynamic_partition_pruning` to `on`. This example `SET` command enables the parameter.

```
SET gp_log_dynamic_partition_pruning = on;
```

For information about GPORCA, see SQL: Querying Data.

Parent topic: SQL: Querying Data

Reading EXPLAIN Output

A query plan is a tree of nodes. Each node in the plan represents a single operation, such as a table scan, join, aggregation, or sort.

Read plans from the bottom to the top: each node feeds rows into the node directly above it. The bottom nodes of a plan are usually table scan operations: sequential, index, or bitmap index scans. If the query requires joins, aggregations, sorts, or other operations on the rows, there are additional nodes above the scan nodes to perform these operations. The topmost plan nodes are usually WarehousePG motion nodes: redistribute, explicit redistribute, broadcast, or gather motions. These operations move rows between segment instances during query processing.

The output of `EXPLAIN` has one line for each node in the plan tree and shows the basic node type and the following execution cost estimates for that plan node:

- **cost** —Measured in units of disk page fetches. 1.0 equals one sequential disk page read. The first estimate is the start-up cost of getting the first row and the second is the total cost of cost of getting all rows. The total cost assumes all rows will be retrieved, which is not always true; for example, if the query uses `LIMIT`, not all rows are retrieved.

  > **Note** The cost values generated by GPORCA and the Postgres-based planner are not directly comparable. The two optimizers use different cost models, as well as different algorithms, to determine the cost of an execution plan. Nothing can or should be inferred by comparing cost values between the two optimizers.

  In addition, the cost generated for any given optimizer is valid only for comparing plan alternatives for a given single query and set of statistics. Different queries can generate plans with different costs, even when keeping the optimizer a constant.

  To summarize, the cost is essentially an internal number used by a given optimizer, and nothing should be inferred by examining only the cost value displayed in the `EXPLAIN` plans.

- **rows** —The total number of rows output by this plan node. This number is usually less than the number of rows processed or scanned by the plan node, reflecting the estimated selectivity of any `WHERE` clause conditions. Ideally, the estimate for the topmost node approximates the number of rows that the query actually returns, updates, or deletes.

- **width** —The total bytes of all the rows that this plan node outputs.

Note the following:

- The cost of a node includes the cost of its child nodes. The topmost plan node has the estimated total execution cost for the plan. This is the number the optimizer intends to minimize.
- The cost reflects only the aspects of plan execution that the query optimizer takes into consideration. For example, the cost does not reflect time spent transmitting result rows to the client.

EXPLAIN Example

The following example describes how to read an `EXPLAIN` query plan for a query:

```
EXPLAIN SELECT * FROM names WHERE name = 'Joelle';
                      QUERY PLAN
-------------------------------------------------------------
Gather Motion 2:1 (slice1) (cost=0.00..20.88 rows=1 width=13)

   -> Seq Scan on 'names' (cost=0.00..20.88 rows=1 width=13)
         Filter: name::text ~~ 'Joelle'::text
```

Read the plan from the bottom to the top. To start, the query optimizer sequentially scans the *names* table. Notice the `WHERE` clause is applied as a *filter* condition. This means the scan operation checks the condition for each row it scans and outputs only the rows that satisfy the condition.

The results of the scan operation are passed to a *gather motion* operation. In WarehousePG, a gather motion is when segments send rows to the coordinator. In this example, we have two segment instances that send to one coordinator instance. This operation is working on `slice1` of the parallel query execution plan. A query plan is divided into *slices* so the segments can work on portions of the query plan in parallel.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

The estimated startup cost for this plan is `00.00` (no cost) and a total cost of `20.88` disk page fetches. The optimizer estimates this query will return one row.

Reading EXPLAIN ANALYZE Output

`EXPLAIN ANALYZE` plans and runs the statement. The `EXPLAIN ANALYZE` plan shows the actual execution cost along with the optimizer's estimates. This allows you to see if the optimizer's estimates are close to reality. `EXPLAIN ANALYZE` also shows the following:

- The total runtime (in milliseconds) in which the query ran.
- The memory used by each slice of the query plan, as well as the memory reserved for the whole query statement.
- The number of *workers* (segments) involved in a plan node operation. Only segments that return rows are counted.
- The maximum number of rows returned by the segment that produced the most rows for the operation. If multiple segments produce an equal number of rows, `EXPLAIN ANALYZE` shows the segment with the longest *<time> to end*.
- The segment id of the segment that produced the most rows for an operation.
- For relevant operations, the amount of memory (`work_mem`) used by the operation. If the `work_mem` was insufficient to perform the operation in memory, the plan shows the amount of data spilled to disk for the lowest-performing segment. For example:

  ```
  Work_mem used: 64K bytes avg, 64K bytes max (seg0).
  Work_mem wanted: 90K bytes avg, 90K byes max (seg0) to lessen
  workfile I/O affecting 2 workers.
  ```

- The time (in milliseconds) in which the segment that produced the most rows retrieved the first row, and the time taken for that segment to retrieve all rows. The result may omit*<time> to first row* if it is the same as the *<time> to end*.

EXPLAIN ANALYZE Examples

This example describes how to read an `EXPLAIN ANALYZE` query plan using the same query. The `bold` parts of the plan show actual timing and rows returned for each plan node, as well as memory and time statistics for the whole query.

```
EXPLAIN ANALYZE SELECT * FROM names WHERE name = 'Joelle';
                     QUERY PLAN
-------------------------------------------------------------
Gather Motion 2:1 (slice1; segments: 2) (cost=0.00..20.88 rows=1 width=13)
    Rows out: 1 rows at destination with 0.305 ms to first row, 0.537 ms to end, start offset by 0.289 ms.
        -> Seq Scan on names (cost=0.00..20.88 rows=1 width=13)
             Rows out: Avg 1 rows x 2 workers. Max 1 rows (seg0) with 0.255 ms to first row, 0.486 ms to end, start offset by 0.968 ms.
                 Filter: name = 'Joelle'::text
 Slice statistics:

      (slice0) Executor memory: 135K bytes.

    (slice1) Executor memory: 151K bytes avg x 2 workers, 151K bytes max (seg0).

Statement statistics:
 Memory used: 128000K bytes
 Total runtime: 22.548 ms
```

Read the plan from the bottom to the top. The total elapsed time to run this query was *22.548* milliseconds.

The *sequential scan* operation had only one segment (*seg0*) that returned rows, and it returned just *1 row*. It took *0.255* milliseconds to find the first row and *0.486* to scan all rows. This result is close to the optimizer's estimate: the query optimizer estimated it would return one row for this query. The *gather motion* (segments sending data to the coordinator) received 1 row . The total elapsed time for this operation was *0.537* milliseconds.

Determining the Query Optimizer

You can view EXPLAIN output to determine if GPORCA is enabled for the query plan and whether GPORCA or the Postgres-based planner generated the explain plan. The information appears at the end of the EXPLAIN output. The `Settings` line displays the setting of the server configuration parameter `OPTIMIZER`. The `Optimizer:` line displays whether GPORCA or the Postgres-based planner generated the explain plan.

For these two example query plans, GPORCA is enabled, the server configuration parameter `OPTIMIZER` is `on`. For the first plan, GPORCA generated the EXPLAIN plan. For the second plan, WarehousePG fell back to the Postgres-based planner to generate the query plan.

```
                     QUERY PLAN
------------------------------------------------------------------------------
 Aggregate  (cost=0.00..296.14 rows=1 width=8)
   ->  Gather Motion 2:1  (slice1; segments: 2)  (cost=0.00..295.10 rows=1 width=8)
         ->  Aggregate  (cost=0.00..294.10 rows=1 width=8)
               ->  Seq Scan on part  (cost=0.00..97.69 rows=100040 width=1)
 Settings:  optimizer=on
 Optimizer: GPORCA
(5 rows)
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
explain select count(*) from part;

                      QUERY PLAN
-----------------------------------------------------------------------------------------
 Aggregate  (cost=3519.05..3519.06 rows=1 width=8)
   ->  Gather Motion 2:1  (slice1; segments: 2)  (cost=3518.99..3519.03 rows=1 width=8)
         ->  Aggregate  (cost=3518.99..3519.00 rows=1 width=8)
               ->  Seq Scan on part  (cost=0.00..3018.79 rows=100040 width=1)
 Settings:  optimizer=on
 Optimizer: Postgres-based planner
(5 rows)
```

For this query, the server configuration parameter `OPTIMIZER` is `off`.

```
explain select count(*) from part;

                      QUERY PLAN
-----------------------------------------------------------------------------------------
 Aggregate  (cost=3519.05..3519.06 rows=1 width=8)
   ->  Gather Motion 2:1  (slice1; segments: 2)  (cost=3518.99..3519.03 rows=1 width=8)
         ->  Aggregate  (cost=3518.99..3519.00 rows=1 width=8)
               ->  Seq Scan on part  (cost=0.00..3018.79 rows=100040 width=1)
 Settings: optimizer=off
 Optimizer: Postgres-based planner
(5 rows)
```

Examining Query Plans to Solve Problems

If a query performs poorly, examine its query plan and ask the following questions:

- **Do operations in the plan take an exceptionally long time?** Look for an operation consumes the majority of query processing time. For example, if an index scan takes longer than expected, the index could be out-of-date and need to be reindexed. Or, adjust `enable_<operator>` parameters to see if you can force the Postgres-based planner to choose a different plan by deactivating a particular query plan operator for that query.
- **Does the query planning time exceed query execution time?** When the query involves many table joins, the Postgres-based planner uses a dynamic algorithm to plan the query that is in part based on the number of table joins. You can reduce the amount of time that the Postgres-based planner spends planning the query by setting the `join_collapse_limit` and `from_collapse_limit` server configuration parameters to a smaller value, such as `8`. Note that while smaller values reduce planning time, they may also yield inferior query plans.
- **Are the optimizer's estimates close to reality?** Run `EXPLAIN ANALYZE` and see if the number of rows the optimizer estimates is close to the number of rows the query operation actually returns. If there is a large discrepancy, collect more statistics on the relevant columns.

  See the *WarehousePG Reference Guide* for more information on the `EXPLAIN ANALYZE` and `ANALYZE` commands.
- **Are selective predicates applied early in the plan?** Apply the most selective filters early in the plan so fewer rows move up the plan tree. If the query plan does not correctly estimate query predicate selectivity, collect more statistics on the relevant columns. See the `ANALYZE` command in the *WarehousePG Reference Guide* for more information collecting statistics.You can also try reordering the `WHERE` clause of your SQL statement.
- **Does the optimizer choose the best join order?** When you have a query that joins multiple tables, make sure that the optimizer chooses the most selective join order. Joins that eliminate the largest number of rows should be done earlier in the plan so fewer rows move up the plan tree.

  If the plan is not choosing the optimal join order, set `join_collapse_limit=1` and use explicit `JOIN` syntax in your SQL statement to force the Postgres-based planner to the specified join order. You can also collect more statistics on the relevant join columns.

  See the `ANALYZE` command in the *WarehousePG Reference Guide* for more information collecting statistics.
- **Does the optimizer selectively scan partitioned tables?** If you use table partitioning, is the optimizer selectively scanning only the child tables required to satisfy the query predicates? Scans of the parent tables should return 0 rows since the parent tables do not contain any data. See Verifying the Partition Strategy for an example of a query plan that shows a selective partition scan.
- **Does the optimizer choose hash aggregate and hash join operations where applicable?** Hash operations are typically much faster than other types of joins or aggregations. Row comparison and sorting is done in memory rather than reading/writing from disk. To enable the query optimizer to choose hash operations, there must be sufficient memory available to hold the estimated number of rows. Try increasing work memory to improve performance for a query. If possible, run an `EXPLAIN ANALYZE` for the query to show which plan operations spilled to disk, how much work memory they used, and how much memory was required to avoid spilling to disk. For example:

  `Work_mem used: 23430K bytes avg, 23430K bytes max (seg0). Work_mem wanted: 33649K bytes avg, 33649K bytes max (seg0) to lessen workfile I/O affecting 2 workers.`

  The "bytes wanted" message from `EXPLAIN ANALYZE` is based on the amount of data written to work files and is not exact. The minimum `work_mem` needed can differ from the suggested value.

4.6.12 Just-in-Time Compilation (JIT)

This topic provides an explanation of what Just-in-Time compilation is and how to configure it in WarehousePG.

Parent topic: SQL: Querying Data

What is JIT compilation?

Just-in-Time (JIT) compilation is the process of turning some form of interpreted program evaluation into a native program, and doing so at run time. For example, instead of using general-purpose code that can evaluate arbitrary SQL expressiones to evaluate a particular SQL predicate like `WHERE a.col=3`, it is possible to generate a function that is specific to that expression and can be natively executed by the CPU, resulting in faster execution.

WarehousePG uses LLVM for JIT compilation and it is enabled with all RPM distributions of WarehousePG. If you build WarehousePG from source, you must include the `--with-llvm` build option to include JIT compilation support.

It is possible to use JIT with both GPORCA and Postgres-based planner. Since GPORCA and Postgres-based planner use different algorithms and the values for the calculated costs are different, you must tune the JIT thresholds according to your usage. See When to JIT? for more information.

JIT accelerated operations

Currently WarehousePG's JIT implementation supports for accelerating expression evaluation and tuple deforming.

Expression evaluation is used to evaluate `WHERE` clauses, target lists, aggregates and projections. It can be accelerated by generating code specific to each case.

Tuple deforming is the process of transforming an on-disk tuple into its in-memory representation. It can be accelerated by creating a function specific to the table layout and the number of columns to be extracted.

In-line compilation (inlining)

WarehousePG is very extensible and allows new data types, functions, operators and other database objects to be defined. In fact, the built-in objects are implemented using nearly the same mechanisms. This extensibility implies some overhead, for example due to function calls. To reduce that overhead, JIT can use in-line compilation to fit the bodies of small functions into the expressions using them. That allows a significant percentage of the overhead to be optimized away.

Optimization

LLVM has support for optimizing generated code. Some of the optimizations are cheap enough to be performed whenever JIT is used, while others are only beneficial for longer-running queries. See the LLVM Documentation for more details about optimizations.

When to JIT?

JIT compilation is beneficial primarily for long-running CPU-bound queries. Frequently these are analytical queries. For short queries the added overhead of performing JIT compilation will often be higher than the time it can save.

> **Note** In order to use JIT, you must first install the LLVM libraries in your system by running the command `yum install llvm-libs`.

The internal workflow of JIT can be divided into three different stages:

1. Planner Stage

   This stage takes place in the WarehousePG coordinator. The planner generates the plan tree of a query and its estimated cost. By default, WarehousePG uses GPORCA to generate a query plan. Otherwise it uses Postgres-based planner as a fallback method.

   The planner decides to trigger JIT compilation if:

   - The server configuration parameter jit is `true`.
   - The estimated cost of the query is higher than the value of the configuration parameter optimizer_jit_above_cost (or jit_above_cost for Postgres-based planner).

   If the parameter jit_expressions is enabled, the planner suggests to the executor to compile the expressions in JIT space. Additionally, the planner must make other decisions; if the estimated cost is more than the setting of optimizer_jit_inline_above_cost (or jit_inline_above_cost for Postgres-based planner), the planner compiles short functions and operators used in the query using in-line compilation. If the estimated cost is more than the setting of optimizer_jit_optimize_above_cost (or jit_optimize_above_cost for Postgres-based planner), it applies expensive optimizations to improve the generated code. If the configuration parameterjit_tuple_deforming is enabled, it generates a custom function to deform the target table. Each of these options increases the JIT compilation overhead, but can reduce query execution time considerably.

   Verify the values of these configuration parameters for both GPORCA and Postgres-based planner, as the meaning of cost is different. When using GPORCA, WarehousePG may sometimes fall back to Postgres-based planner for some operations. Note that setting the JIT cost parameters to '0' forces all queries to be JIT-compiled and, as a result, slows down queries. Setting them to a negative value will disable the feature the parameter provides.

   When the plan is ready, the planner provides the plan trees and JIT flags to the executor.

2. Executor Initialization Stage

   This stage takes place in the WarehousePG segments. WarehousePG creates the expression evaluation steps. If JIT is used, it re-writes the steps as functions in the JIT space. The decisions made at plan time determine whether or not JIT compilation is adviced to be triggered in execution stage, along with the JIT strategy to apply if it is triggered. However, it is at execution time when WarehousePG makes the decision of using JIT if the configuration parameter `jit` is enabled and the JIT libraries are loaded successfully. The executor may ignore the cached decisions if `jit` or `jit_expression` has been changed to `false` between planner and execution stages or if it encounters an error.

   Additionally, the executor checks the following developer configuration parameters:

   - jit_provider : Specifies the name of the JIT provider library to be used.
   - jit_dump_bitcode: Writes the generated LLVM IR out to the file system, inside data_directory.
   - jit_profiling_support: If LLVM has the required functionality, emits the data needed to allow `perf` command to profile functions generated by JIT.
   - jit_debugging_support: If LLVM has the required functionality, registers generated functions with GDB.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

3. Executor Run Stage

   This stage also occurs in the WarehousePG segments which execute the steps provided by the initialization stage. The functions in JIT space are combined as a whole before the first call.

The JIT workflow can also handle executor fault tolerance: if JIT fails to load on the segments, the execution mode fails back to non-JIT.

Examples

In the examples below, the configuration parameter `optimizer_jit_above_cost` / `jit_above_cost` was modified so it would trigger JIT compilation. Note that the use of JIT might add more overhead than the potential savings. JIT was used, but inlining and expensive optimization were not. If `optimizer_jit_inline_above_cost` / `jit_inline_above_cost` or `optimizer_jit_optimize_above_cost` / `jit_optimize_above_cost` were also lowered, they could be triggered.

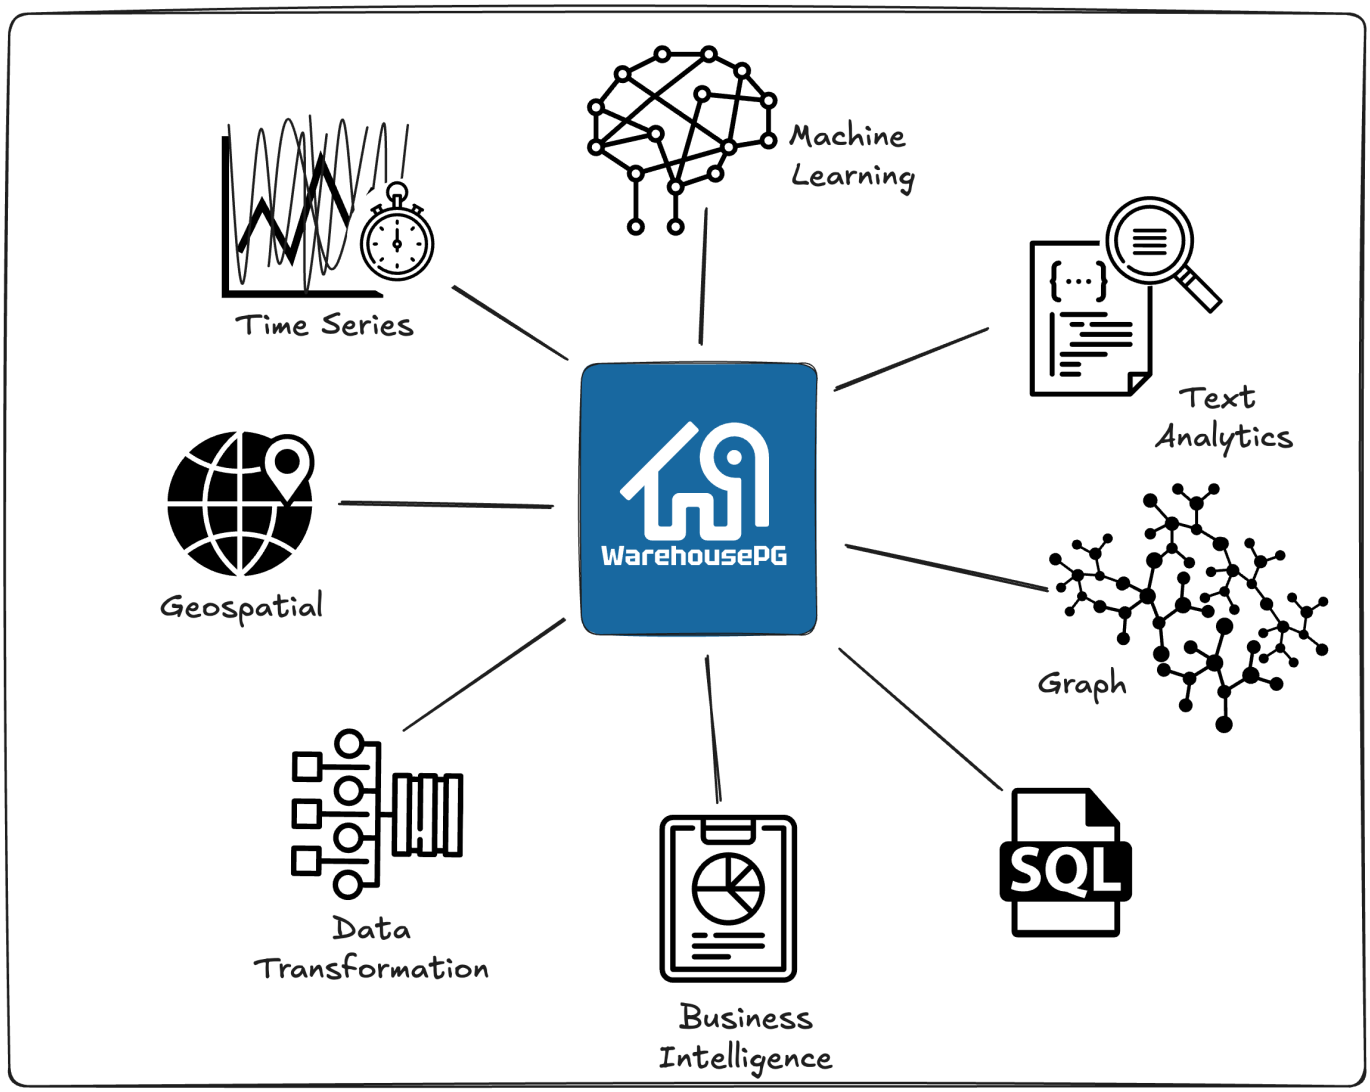
You may enable the configuration parameter gp_explain_jit to display summarized JIT information from all query executions when running the `EXPLAIN` command. You must turn it off when running regression tests.

Note that the output from `EXPLAIN` provides information on JIT such as the slice average timing spent in JIT, what segment the maximum vector comes from, or how many JIT functions are created and total time spent in JIT tasks. This information can be helpful when tuning JIT or debugging a timing problem. Run `EXPLAIN (ANALYZE, VERBOSE)` to view this information.

With GPORCA:

```
EXPLAIN (ANALYZE) SELECT * FROM jit_explain_output LIMIT 10;
QUERY PLAN
Limit  (cost=0.00..431.00 rows=1 width=4) (actual time=1.103..1.107 rows=10 loops=1)
  ->  Gather Motion 3:1  (slice1; segments: 3)  (cost=0.00..431.00 rows=1 width=4) (actual time=0.013..0.014 rows=10 loops=1)
        ->  Seq Scan on jit_explain_output  (cost=0.00..431.00 rows=1 width=4) (actual time=0.025..0.030 rows=38 loops=1)
Optimizer: GPORCA
Planning Time: 5.824 ms
  (slice0)    Executor memory: 37K bytes.
  (slice1)    Executor memory: 36K bytes avg x 3 workers, 36K bytes max (seg0).
Memory used:  128000kB
JIT:
  Options: Inlining false, Optimization false, Expressions true, Deforming true.
  (slice0): Functions: 2.00. Timing: 1.137 ms total.
Execution Time: 1.597 ms
(12 rows)
```

With Postgres-based planner:



```
EXPLAIN (ANALYZE) SELECT * FROM jit_explain_output LIMIT 10;
QUERY PLAN
Limit  (cost=35.50..35.67 rows=10 width=4) (actual time=13.199..13.310 rows=10 loops=1)
  ->  Gather Motion 3:1  (slice1; segments: 3)  (cost=35.50..36.01 rows=30 width=4) (actual time=11.848..11.890 rows=10 loops=1)
        ->  Limit  (cost=35.50..35.61 rows=10 width=4) (actual time=0.861..0.971 rows=10 loops=1)
              ->  Seq Scan on jit_explain_output  (cost=0.00..355.00 rows=32100 width=4) (actual time=0.029..0.070 rows=10 loops=1)
Optimizer: Postgres-based planner
Planning Time: 0.158 ms
  (slice0)    Executor memory: 37K bytes.
  (slice1)    Executor memory: 36K bytes avg x 3 workers, 36K bytes max (seg0).
Memory used:  128000kB
JIT:
  Options: Inlining false, Optimization false, Expressions true, Deforming true.
  (slice0): Functions: 2.00. Timing: 1.381 ms total.
  (slice1): Functions: 1.00 avg x 3 workers, 1.00 max (seg0). Timing: 0.830 ms avg x 3 workers, 0.854 ms max (seg1).
Execution Time: 24.023 ms
(14 rows)
```

4.7 Overview of WarehousePG integrated analytics

WarehousePG offers a unique combination of a powerful, massively parallel processing (MPP) database and advanced data analytics. This combination creates an ideal framework for data scientists, data architects and business decision makers to explore artificial intelligence (AI), machine learning, deep learning, text analytics, and geospatial analytics.

The WarehousePG Integrated Analytics Ecosystem

The following WarehousePG analytics extensions are explored in different documentation sections, with installation and usage instructions:

Machine Learning and Deep Learning

The Apache MADlib extension allows WarehousePG users to run different machine learning and deep learning functions, including feature engineering, model training, evaluation and scoring.

Geospatial Analytics

PostGIS is a spatial database extension for PostgreSQL that allows GIS (Geographic Information Systems) objects to be stored in the database. The WarehousePG PostGIS extension includes support for GiST-based R-Tree spatial indexes and functions for analysis and processing of GIS objects.

Text Analytics

Text Analytics and Search enables processing of mass quantities of raw text data (such as social media feeds or e-mail databases) into mission-critical information that guides project and business decisions.

Programming Language Extensions

WarehousePG supports a variety of procedural languages that you can use for programming database analytics. Refer to the linked documentation for installation and usage instructions.

- PL/Java
- PL/Perl
- PL/pgSQL
- PL/Python
- PL/R

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Advanced Analytics and WarehousePG

The importance of advanced analytics in its various forms is growing rapidly in enterprise computing. Key enterprise data typically resides in relational and document form and it is inefficient to copy data between systems to perform analytical operations. WarehousePG is able to run both traditional and advanced analytics workloads in-database. This integrated capability greatly reduces the cost and the silos created by procuring and maintaining multiple tools and libraries.

WarehousePG advanced analytics can be used to address a wide variety of problems in many verticals including automotive, finance, manufacturing, energy, government, education, telecommunications, on-line and traditional retail.

The WarehousePG analytics capabilities allow you to:

- Analyze a multitude of data types – structured, text, geospatial, and graph – in a single environment, which can scale to petabytes and run algorithms designed for parallelism.
- Leverage existing SQL knowledge: WarehousePG can run dozens of statistical, machine learning, and graph methods, via SQL.
- Train more models in less time by taking advantage of the parallelism in the MPP architecture and in-database analytics.
- Access the data where it lives, therefore integrate data and analytics in one place. WarehousePG is infrastructure-agnostic and runs on bare metal, private cloud, and public cloud deployments.
- Use a multitude of data extensions. WarehousePG supports extensions for HDFS, Hive, and HBase as well as reading/writing data from/to cloud storage, including Amazon S3 objects. Review the capabilities of the WarehousePG Platform Extension Framework (PXF), which provides *connectors* that enable you to access data stored in sources external to your WarehousePG deployment.
- Use familiar and leading BI and advanced analytics software that are ODBC/JDBC compatible, or have native integrations, including SAS, IBM Cognos, SAP Analytics Solutions, Qlik, Tableau, Apache Zeppelin, and Jupyter.
- Run deep learning algorithms using popular frameworks like Keras and TensorFlow in an MPP relational database, with GPU (Graphical Processing Unit) acceleration.
- Use containers capable of isolating executors from the host OS. WarehousePG PL/Container implements a trusted language execution engine which permits customized data science workloads or environments created for different end user workloads.
- Use procedural languages to customize your analytics. WarehousePG supports development in R, Python, Java, and other standard languages allowing you to distribute execution across the entire cluster to take advantage of the scale and parallelism.

4.7.1 Machine Learning and Deep Learning using MADlib

Apache MADlib is an open-source library for scalable in-database analytics. The WarehousePG MADlib extension provides the ability to run machine learning and deep learning workloads in a WarehousePG.

You can install it as an extension in a WarehousePG cluster you can run data-parallel implementations of mathematical, statistical, graph, machine learning, and deep learning methods on structured and unstructured data. For WarehousePG and MADlib version compatibility, refer to MADlib FAQ.

MADlib's suite of SQL-based algorithms run at scale within a single WarehousePG engine without needing to transfer data between the database and other tools.

MADlib is part of the database fabric with no changes to the WarehousePG architecture. This makes it easy for database administrators to deploy and manage since it is not a separate daemon or separate software running outside the database.

Machine Learning

Apache MADlib consists of methods to support the full spectrum of data science activities. This includes data transformation and feature engineering, using methods in descriptive and inferential statistics, pivoting, sessionization and encoding categorical variables. There is also a comprehensive library of graph, supervised learning and unsupervised learning methods.

In the area of model selection, MADlib supports cross validation and the most common prediction metrics for evaluating the quality of predictions of a model. Please refer to theMADlib user guide for more information on these methods.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Deep Learning

WarehousePG supports using Keras and TensorFlow for deep learning. You can review the supported libraries and configuration instructions on the Apache MADlib pages as well as user documentation for Keras API using the Tensorflow backend.

MADlib supports Keras with a TensorFlow backend, with or without Graphics Processing Units (GPUs). GPUs can significantly accelerate the training of deep neural networks so they are typically used for enterprise level workloads. For further GPU information, visit the MADlib wiki, https://cwiki.apache.org/confluence/display/MADLIB/Deep+Learning.

PivotalR

MADlib can be used with PivotalR, an R client package that enables users to interact with data resident in the WarehousePG. PivotalR can be considered as a wrapper around MADlib that translates R code into SQL to run on MPP databases and is designed for users familiar with R but with data sets that are too large for R.

The R language is an open-source language that is used for statistical computing. PivotalR is an R package that enables users to interact with data resident in WarehousePG using the R client. Using PivotalR requires that MADlib is installed on the WarehousePG.

PivotalR allows R users to leverage the scalability and performance of in-database analytics without leaving the R command line. The computational work is run in-database, while the end user benefits from the familiar R interface. Compared with respective native R functions, there is an increase in scalability and a decrease in running time. Furthermore, data movement, which can take hours for very large data sets, is eliminated with PivotalR.

Key features of the PivotalR package:

- Explore and manipulate data in the database with R syntax. SQL translation is performed by PivotalR.
- Use the familiar R syntax for predictive analytics algorithms, for example linear and logistic regression. PivotalR accesses the MADlib in-database analytics function calls.
- Comprehensive documentation package with examples in standard R format accessible from an R client.
- The PivotalR package also supports access to the MADlib functionality.

For information about PivotalR, including supported MADlib functionality, see https://cwiki.apache.org/confluence/display/MADLIB/PivotalR.

The R package for PivotalR can be found at https://cran.r-project.org/web/packages/PivotalR/index.html.

Prerequisites

MADlib requires the `m4` macro processor version 1.4.13 or later. Ensure that you have access to, or superuser permissions to install, this package on each WarehousePG host.

MADlib 2.1.0 requires Python 3, which should already be installed as a dependency when you install the WarehousePG software on each WarehousePG host.

Installing MADlib

To install MADlib on WarehousePG, you first install a compatible WarehousePG MADlib package and then install the MADlib function libraries on all databases that will use MADlib.

If you have GPUs installed on some or across all hosts in the cluster, then the segments residing on those hosts can benefit from GPU acceleration. GPUs and deep learning libraries such as Keras, TensorFlow, cudNN, and CUDA are managed separately from MADlib. For more information see the MADlib wiki instructions for deep learning and the MADlib user documentation for deep learning .

Installing the WarehousePG MADlib Package

Before you install the MADlib package, make sure that your WarehousePG is running, you have sourced `greenplum_path.sh` , and that the `$COORDINATOR_DATA_DIRECTORY` and `$GPHOME` variables are set.

1. Download the MADlib extension package.
2. Copy the MADlib package to the WarehousePG coordinator host.
3. Unpack the MADlib distribution package. For example:

   ```
   $ tar xzvf madlib-2.1.0-gp7-rhel8-x86_64.tar.gz
   ```

4. Install the software package

Adding MADlib Functions to a Database

After installing the MADlib package, run the `madpack` command to add MADlib functions to WarehousePG. `madpack` is in `$GPHOME/madlib/bin` .

```
$ madpack [-s <schema_name>] -p greenplum -c <user>@<host>:<port>/<database> install
```

For example, this command creates MADlib functions in the WarehousePG `testdb` running on server `cdw` on port `5432` . The `madpack` command logs in as the user `gpadmin` and prompts for password. The target schema is `madlib` .

```
$ madpack -s madlib -p greenplum -c gpadmin@cdw:5432/testdb install
```

After installing the functions, The WarehousePG `gpadmin` superuser role should grant all privileges on the target schema (in the example `madlib`) to users who will be accessing MADlib functions. Users without access to the functions will get the error `ERROR: permission denied for schema MADlib` .

The madpack `install-check` option runs test using Madlib modules to check the MADlib installation:

```
$ madpack -s madlib -p greenplum -c gpadmin@cdw:5432/testdb install-check
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

> **Note** The command `madpack -h` displays information for the utility.

Uninstalling MADlib

When you remove MADlib support from a database, routines that you created in the database that use MADlib functionality will no longer work.

Examples

Following are examples using the WarehousePG MADlib extension:

- Linear Regression
- Association Rules
- Naive Bayes Classification

See the MADlib documentation for additional examples.

Linear Regression

This example runs a linear regression on the table `regr_example`. The dependent variable data are in the `y` column and the independent variable data are in the `x1` and `x2` columns.

The following statements create the `regr_example` table and load some sample data:

```
DROP TABLE IF EXISTS regr_example;
CREATE TABLE regr_example (
   id int,
   y int,
   x1 int,
   x2 int
);
INSERT INTO regr_example VALUES
   (1,  5, 2, 3),
   (2, 10, 7, 2),
   (3,  6, 4, 1),
   (4,  8, 3, 4);
```

The MADlib `linregr_train()` function produces a regression model from an input table containing training data. The following `SELECT` statement runs a simple multivariate regression on the `regr_example` table and saves the model in the `reg_example_model` table.

```
SELECT madlib.linregr_train (
   'regr_example',         -- source table
   'regr_example_model',   -- output model table
   'y',                    -- dependent variable
   'ARRAY[1, x1, x2]'      -- independent variables
);
```

The `madlib.linregr_train()` function can have additional arguments to set grouping columns and to calculate the heteroskedasticity of the model.

> **Note** The intercept is computed by setting one of the independent variables to a constant `1`, as shown in the preceding example.

Running this query against the `regr_example` table creates the `regr_example_model` table with one row of data:

```
SELECT * FROM regr_example_model;
-[ RECORD 1 ]------------+------------------------
coef                     | {0.111111111111127,1.14814814814815,1.01851851851852}
r2                       | 0.968612680477111
std_err                  | {1.49587911309236,0.207043331249903,0.346449758034495}
t_stats                  | {0.0742781352708591,5.54544858420156,2.93987366103776}
p_values                 | {0.952799748147436,0.113579771006374,0.208730790695278}
condition_no             | 22.650203241881
num_rows_processed       | 4
num_missing_rows_skipped | 0
variance_covariance      | {{2.23765432098598,-0.257201646090342,-0.437242798353582},
                           {-0.257201646090342,0.042866941015057,0.0342935528120456},
                           {-0.437242798353582,0.0342935528120457,0.120027434842l6}}
```

The model saved in the `regr_example_model` table can be used with the MADlib linear regression prediction function, `madlib.linregr_predict()`, to view the residuals:

```
SELECT regr_example.*,
       madlib.linregr_predict ( ARRAY[1, x1, x2], m.coef ) as predict,
       y - madlib.linregr_predict ( ARRAY[1, x1, x2], m.coef ) as residual
FROM regr_example, regr_example_model m;
 id | y  | x1 | x2 |     predict      |      residual
----+----+----+----+------------------+--------------------
  1 |  5 |  2 |  3 | 5.46296296296297 | -0.462962962962971
  3 |  6 |  4 |  1 | 5.72222222222224 |  0.277777777777762
  2 | 10 |  7 |  2 | 10.1851851851852 | -0.185185185185201
  4 |  8 |  3 |  4 | 7.62962962962964 |  0.370370370370364
(4 rows)
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Association Rules

This example demonstrates the association rules data mining technique on a transactional data set. Association rule mining is a technique for discovering relationships between variables in a large data set. This example considers items in a store that are commonly purchased together. In addition to market basket analysis, association rules are also used in bioinformatics, web analytics, and other fields.

The example analyzes purchase information for seven transactions that are stored in a table with the MADlib function `MADlib.assoc_rules`. The function assumes that the data is stored in two columns with a single item and transaction ID per row. Transactions with multiple items consist of multiple rows with one row per item.

These commands create the table.

```
DROP TABLE IF EXISTS test_data;
CREATE TABLE test_data (
   trans_id INT,
   product text
);
```

This `INSERT` command adds the data to the table.

```
INSERT INTO test_data VALUES
   (1, 'beer'),
   (1, 'diapers'),
   (1, 'chips'),
   (2, 'beer'),
   (2, 'diapers'),
   (3, 'beer'),
   (3, 'diapers'),
   (4, 'beer'),
   (4, 'chips'),
   (5, 'beer'),
   (6, 'beer'),
   (6, 'diapers'),
   (6, 'chips'),
   (7, 'beer'),
   (7, 'diapers');
```

The MADlib function `madlib.assoc_rules()` analyzes the data and determines association rules with the following characteristics.

- A support value of at least .40. Support is the ratio of transactions that contain X to all transactions.
- A confidence value of at least .75. Confidence is the ratio of transactions that contain X to transactions that contain Y. One could view this metric as the conditional probability of X given Y.

This `SELECT` command determines association rules, creates the table `assoc_rules`, and adds the statistics to the table.

```
SELECT * FROM madlib.assoc_rules (
   .40,          -- support
   .75,          -- confidence
   'trans_id',   -- transaction column
   'product',    -- product purchased column
   'test_data',  -- table name
   'public',     -- schema name
   false);       -- display processing details
```

This is the output of the `SELECT` command. There are two rules that fit the characteristics.

```
 output_schema | output_table | total_rules | total_time
---------------+--------------+-------------+-----------------
public         | assoc_rules  |           2 | 00:00:01.153283
(1 row)
```

To view the association rules, you can run this `SELECT` command.

```
SELECT pre, post, support FROM assoc_rules
   ORDER BY support DESC;
```

This is the output. The `pre` and `post` columns are the itemsets of left and right hand sides of the association rule respectively.

```
    pre    |  post  |      support
-----------+--------+-------------------
 {diapers} | {beer} | 0.714285714285714
 {chips}   | {beer} | 0.428571428571429
(2 rows)
```

Based on the data, beer and diapers are often purchased together. To increase sales, you might consider placing beer and diapers closer together on the shelves.

Naive Bayes Classification

Naive Bayes analysis predicts the likelihood of an outcome of a class variable, or category, based on one or more independent variables, or attributes. The class variable is a non-numeric categorial variable, a variable that can have one of a limited number of values or categories. The class variable is represented with integers, each integer representing a category. For example, if the category can be one of "true", "false", or "unknown," the values can be represented with the integers 1, 2, or 3.

The attributes can be of numeric types and non-numeric, categorical, types. The training function has two signatures – one for the case where all attributes are numeric and another for mixed numeric and categorical types. Additional arguments for the latter identify the attributes that should be handled as numeric values. The attributes are submitted to the training function in an array.

The MADlib Naive Bayes training functions produce a features probabilities table and a class priors table, which can be used with the prediction function to provide the probability of a class for the set of attributes.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Naive Bayes Example 1 - Simple All-numeric Attributes

In the first example, the `class` variable is either 1 or 2 and there are three integer attributes.

1. The following commands create the input table and load sample data.

```
DROP TABLE IF EXISTS class_example CASCADE;
CREATE TABLE class_example (
   id int, class int, attributes int[]);
INSERT INTO class_example VALUES
   (1, 1, '{1, 2, 3}'),
   (2, 1, '{1, 4, 3}'),
   (3, 2, '{0, 2, 2}'),
   (4, 1, '{1, 2, 1}'),
   (5, 2, '{1, 2, 2}'),
   (6, 2, '{0, 1, 3}');
```

   Actual data in production scenarios is more extensive than this example data and yields better results. Accuracy of classification improves significantly with larger training data sets.

2. Train the model with the `create_nb_prepared_data_tables()` function.

```
SELECT * FROM madlib.create_nb_prepared_data_tables (
   'class_example',         -- name of the training table
   'class',                 -- name of the class (dependent) column
   'attributes',            -- name of the attributes column
   3,                       -- the number of attributes
   'example_feature_probs', -- name for the feature probabilities output table
   'example_priors'         -- name for the class priors output table
    );
```

3. Create a table with data to classify using the model.

```
DROP TABLE IF EXISTS class_example_topredict;
CREATE TABLE class_example_topredict (
   id int, attributes int[]);
INSERT INTO class_example_topredict VALUES
   (1, '{1, 3, 2}'),
   (2, '{4, 2, 2}'),
   (3, '{2, 1, 1}');
```

4. Create a classification view using the feature probabilities, class priors, and `class_example_topredict` tables.

```
SELECT madlib.create_nb_probs_view (
   'example_feature_probs',    -- feature probabilities output table
   'example_priors',           -- class priors output table
   'class_example_topredict',  -- table with data to classify
   'id',                       -- name of the key column
   'attributes',               -- name of the attributes column
    3,                         -- number of attributes
    'example_classified'       -- name of the view to create
    );
```

5. Display the classification results.

```
SELECT * FROM example_classified;
 key | class | nb_prob
-----+-------+---------
   1 |     1 |     0.4
   1 |     2 |     0.6
   3 |     1 |     0.5
   3 |     2 |     0.5
   2 |     1 |    0.25
   2 |     2 |    0.75
(6 rows)
```

Naive Bayes Example 2 – Weather and Outdoor Sports

This example calculates the probability that the user will play an outdoor sport, such as golf or tennis, based on weather conditions.

The table `weather_example` contains the example values.

The identification column for the table is `day`, an integer type.

The `play` column holds the dependent variable and has two classifications:

- 0 - No
- 1 - Yes

There are four attributes: outlook, temperature, humidity, and wind. These are categorical variables. The MADlib `create_nb_classify_view()` function expects the attributes to be provided as an array of `INTEGER`, `NUMERIC`, or `FLOAT8` values, so the attributes for this example are encoded with integers as follows:

- *outlook* may be sunny (1), overcast (2), or rain (3).
- *temperature* may be hot (1), mild (2), or cool (3).
- *humidity* may be high (1) or normal (2).
- *wind* may be strong (1) or weak (2).

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

The following table shows the training data, before encoding the variables.

```
  day | play | outlook  | temperature | humidity | wind
-----+------+----------+-------------+----------+--------
 2   | No   | Sunny    | Hot         | High     | Strong
 4   | Yes  | Rain     | Mild        | High     | Weak
 6   | No   | Rain     | Cool        | Normal   | Strong
 8   | No   | Sunny    | Mild        | High     | Weak
10   | Yes  | Rain     | Mild        | Normal   | Weak
12   | Yes  | Overcast | Mild        | High     | Strong
14   | No   | Rain     | Mild        | High     | Strong
 1   | No   | Sunny    | Hot         | High     | Weak
 3   | Yes  | Overcast | Hot         | High     | Weak
 5   | Yes  | Rain     | Cool        | Normal   | Weak
 7   | Yes  | Overcast | Cool        | Normal   | Strong
 9   | Yes  | Sunny    | Cool        | Normal   | Weak
11   | Yes  | Sunny    | Mild        | Normal   | Strong
13   | Yes  | Overcast | Hot         | Normal   | Weak
(14 rows)
```

1. Create the training table.

```
DROP TABLE IF EXISTS weather_example;
CREATE TABLE weather_example (
   day int,
   play int,
   attrs int[]
);
INSERT INTO weather_example VALUES
   ( 2, 0, '{1,1,1,1}'), -- sunny, hot, high, strong
   ( 4, 1, '{3,2,1,2}'), -- rain, mild, high, weak
   ( 6, 0, '{3,3,2,1}'), -- rain, cool, normal, strong
   ( 8, 0, '{1,2,1,2}'), -- sunny, mild, high, weak
   (10, 1, '{3,2,2,2}'), -- rain, mild, normal, weak
   (12, 1, '{2,2,1,1}'), -- etc.
   (14, 0, '{3,2,1,1}'),
   ( 1, 0, '{1,1,1,2}'),
   ( 3, 1, '{2,1,1,2}'),
   ( 5, 1, '{3,3,2,2}'),
   ( 7, 1, '{2,3,2,1}'),
   ( 9, 1, '{1,3,2,2}'),
   (11, 1, '{1,2,2,1}'),
   (13, 1, '{2,1,2,2}');
```

2. Create the model from the training table.

```
SELECT madlib.create_nb_prepared_data_tables (
   'weather_example',  -- training source table
   'play',             -- dependent class column
   'attrs',            -- attributes column
   4,                  -- number of attributes
   'weather_probs',    -- feature probabilities output table
   'weather_priors'    -- class priors
   );
```

3. View the feature probabilities:

```
SELECT * FROM weather_probs;
 class | attr | value | cnt | attr_cnt
-------+------+-------+-----+----------
     1 |    3 |     2 |   6 |        2
     1 |    1 |     2 |   4 |        3
     0 |    1 |     1 |   3 |        3
     0 |    1 |     3 |   2 |        3
     0 |    3 |     1 |   4 |        2
     1 |    4 |     1 |   3 |        2
     1 |    2 |     3 |   3 |        3
     1 |    2 |     1 |   2 |        3
     0 |    2 |     2 |   2 |        3
     0 |    4 |     2 |   2 |        2
     0 |    3 |     2 |   1 |        2
     0 |    1 |     2 |   0 |        3
     1 |    1 |     1 |   2 |        3
     1 |    1 |     3 |   3 |        3
     1 |    3 |     1 |   3 |        2
     0 |    4 |     1 |   3 |        2
     0 |    2 |     3 |   1 |        3
     0 |    2 |     1 |   2 |        3
     1 |    2 |     2 |   4 |        3
     1 |    4 |     2 |   6 |        2
(20 rows)
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4. To classify a group of records with a model, first load the data into a table. In this example, the table `t1` has four rows to classify.

```
DROP TABLE IF EXISTS t1;
CREATE TABLE t1 (
   id integer,
   attributes integer[]);
insert into t1 values
   (1, '{1, 2, 1, 1}'),
   (2, '{3, 3, 2, 1}'),
   (3, '{2, 1, 2, 2}'),
   (4, '{3, 1, 1, 2}');
```

5. Use the MADlib `create_nb_classify_view()` function to classify the rows in the table.

```
SELECT madlib.create_nb_classify_view (
   'weather_probs',      -- feature probabilities table
   'weather_priors',     -- classPriorsName
   't1',                 -- table containing values to classify
   'id',                 -- key column
   'attributes',         -- attributes column
   4,                    -- number of attributes
   't1_out'              -- output table name
);
```

The result is four rows, one for each record in the `t1` table.

```
SELECT * FROM t1_out ORDER BY key;
 key | nb_classification
-----+-------------------
 1 | {0}
 2 | {1}
 3 | {1}
 4 | {0}
 (4 rows)
```

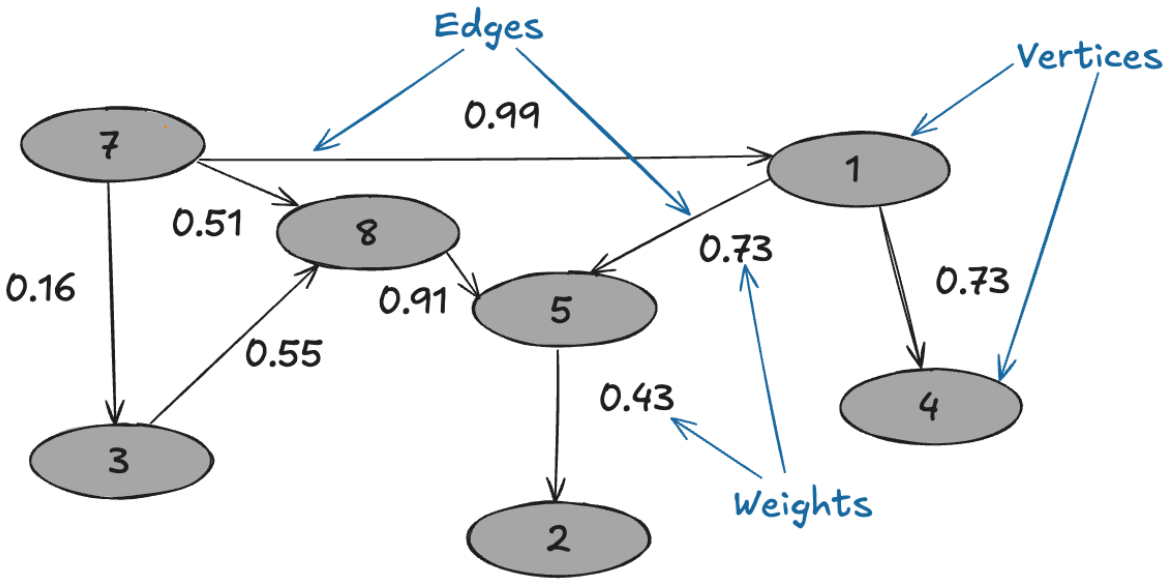
4.7.2 Graph Analytics

Many modern business problems involve connections and relationships between entities, and are not solely based on discrete data. Graphs are powerful at representing complex interconnections, and graph data modeling is very effective and flexible when the number and depth of relationships increase exponentially.



The use cases for graph analytics are diverse: social networks, transportation routes, autonomous vehicles, cyber security, criminal networks, fraud detection, health research, epidemiology, and so forth.

This chapter contains the following information:

- What is a Graph?
- Graph Analytics on WarehousePG
- Using Graph
- Graph Modules
- References

What is a Graph?

Graphs represent the interconnections between objects (vertices) and their relationships (edges). Example objects could be people, locations, cities, computers, or components on a circuit board. Example connections could be roads, circuits, cables, or interpersonal relationships. Edges can have directions and weights, for example the distance between towns.

Graphs can be small and easily traversed - as with a small group of friends - or extremely large and complex, similar to contacts in a modern-day social network.

Graph Analytics on WarehousePG

Efficient processing of very large graphs can be challenging. WarehousePG offers a suitable environment for this work for these key reasons:

1. Using MADlib graph functions in WarehousePG brings the graph computation close to where the data lives. Otherwise, large data sets need to be moved to a specialized graph database, requiring additional time and resources.
2. Specialized graph databases frequently use purpose-built languages. With WarehousePG, you can invoke graph functions using the familiar SQL interface. For example, for thePageRank graph algorithm:

```
SELECT madlib.pagerank('vertex',     -- Vertex table
              'id',                  -- Vertex id column
              'edge',                -- Edge table
              'src=src, dest=dest', -- Comma delimited string of edge arguments
              'pagerank_out',        -- Output table of PageRank
               0.5);                 -- Damping factor
SELECT * FROM pagerank_out ORDER BY pagerank DESC;
```

3. A lot of data science problems are solved using a combination of models, with graphs being just one. Regression, clustering, and other methods available in WarehousePG, make for a powerful combination.
4. WarehousePG offers great benefits of scale, taking advantage of years of query execution and optimization research focused on large data sets.

Using Graph

Installing Graph Modules

To use the MADlib graph modules, install the version of MADlib corresponding to your WarehousePG version.

Graph modules on MADlib support many algorithms.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Creating a Graph in WarehousePG

To represent a graph in WarehousePG, create tables that represent the vertices, edges, and their properties.

Using SQL, create the relevant tables in the database you want to use. This example uses `testdb`:

```
gpadmin@cdw ~]$ psql
dev=# \c testdb
```

Create a table for vertices, called `vertex`, and a table for edges and their weights, called `edge`:

```
testdb=# DROP TABLE IF EXISTS vertex, edge;
testdb=# CREATE TABLE vertex(id INTEGER);
testdb=# CREATE TABLE edge(
         src INTEGER,
         dest INTEGER,
         weight FLOAT8
         );
```

Insert values related to your specific use case. For example :

```
testdb#=> INSERT INTO vertex VALUES
(0),
(1),
(2),
(3),
(4),
(5),
(6),
(7);

testdb#=> INSERT INTO edge VALUES
(0, 1, 1.0),
(0, 2, 1.0),
(0, 4, 10.0),
(1, 2, 2.0),
(1, 3, 10.0),
(2, 3, 1.0),
(2, 5, 1.0),
(2, 6, 3.0),
(3, 0, 1.0),
(4, 0, -2.0),
(5, 6, 1.0),
(6, 7, 1.0);
```

Now select the Graph Module that suits your analysis.

Graph Modules

This section lists the graph functions supported in MADlib. They include: All Pairs Shortest Path (APSP), Breadth-First Search, Hyperlink-Induced Topic Search (HITS), PageRank and Personalized PageRank, Single Source Shortest Path (SSSP), Weakly Connected Components, and Measures. Explore each algorithm using the example `edge` and `vertex` tables already created.

All Pairs Shortest Path (APSP)

The all pairs shortest paths (APSP) algorithm finds the length (summed weights) of the shortest paths between all pairs of vertices, such that the sum of the weights of the path edges is minimized.

The function is:

```
graph_apsp( vertex_table,
vertex_id,
edge_table,
edge_args,
out_table,
grouping_cols
)
```

For details on the parameters, with examples, see the All Pairs Shortest Path in the Apache MADlib documentation.

Breadth-First Search

Given a graph and a source vertex, the breadth-first search (BFS) algorithm finds all nodes reachable from the source vertex by searching / traversing the graph in a breadth-first manner.

The function is:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
graph_bfs( vertex_table,
          vertex_id,
          edge_table,
          edge_args,
          source_vertex,
          out_table,
          max_distance,
          directed,
          grouping_cols
          )
```

For details on the parameters, with examples, see the Breadth-First Search in the Apache MADlib documentation.

Hyperlink-Induced Topic Search (HITS)

The all pairs shortest paths (APSP) algorithm finds the length (summed weights) of the shortest paths between all pairs of vertices, such that the sum of the weights of the path edges is minimized.

The function is:

```
graph_apsp( vertex_table,
           vertex_id,
           edge_table,
           edge_args,
           out_table,
           grouping_cols
           )
```

For details on the parameters, with examples, see the Hyperlink-Induced Topic Search in the Apache MADlib documentation.

PageRank and Personalized PageRank

Given a graph, the PageRank algorithm outputs a probability distribution representing a person's likelihood to arrive at any particular vertex while randomly traversing the graph.

MADlib graph also includes a personalized PageRank, where a notion of importance provides personalization to a query. For example, importance scores can be biased according to a specified set of graph vertices that are of interest or special in some way.

The function is:

```
pagerank( vertex_table,
          vertex_id,
          edge_table,
          edge_args,
          out_table,
          damping_factor,
          max_iter,
          threshold,
          grouping_cols,
          personalization_vertices
          )
```

For details on the parameters, with examples, see the PageRank in the Apache MADlib documentation.

Single Source Shortest Path (SSSP)

Given a graph and a source vertex, the single source shortest path (SSSP) algorithm finds a path from the source vertex to every other vertex in the graph, such that the sum of the weights of the path edges is minimized.

The function is:

```
graph_sssp ( vertex_table,
vertex_id,
edge_table,
edge_args,
source_vertex,
out_table,
grouping_cols
)
```

For details on the parameters, with examples, see the Single Source Shortest Path in the Apache MADlib documentation.

Weakly Connected Components

Given a directed graph, a weakly connected component (WCC) is a subgraph of the original graph where all vertices are connected to each other by some path, ignoring the direction of edges.

The function is:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
weakly_connected_components(
vertex_table,
vertex_id,
edge_table,
edge_args,
out_table,
grouping_cols
)
```

For details on the parameters, with examples, see the Weakly Connected Components in the Apache MADlib documentation.

Measures

These algorithms relate to metrics computed on a graph and include: Average Path Length, Closeness Centrality , Graph Diameter, and In-Out Degree.

Average Path Length

This function computes the shortest path average between pairs of vertices. Average path length is based on "reachable target vertices", so it averages the path lengths in each connected component and ignores infinite-length paths between unconnected vertices. If the user requires the average path length of a particular component, the weakly connected components function may be used to isolate the relevant vertices.

The function is:

```
graph_avg_path_length( apsp_table,
                       output_table
                       )
```

This function uses a previously run APSP (All Pairs Shortest Path) output. For details on the parameters, with examples, see theAverage Path Length in the Apache MADlib documentation.

Closeness Centrality

The closeness centrality algorithm helps quantify how much information passes through a given vertex. The function returns various closeness centrality measures and the k-degree for a given subset of vertices.

The function is:

```
graph_closeness( apsp_table,
output_table,
vertex_filter_expr
)
```

This function uses a previously run APSP (All Pairs Shortest Path) output. For details on the parameters, with examples, see theCloseness in the Apache MADlib documentation.

Graph Diameter

Graph diameter is defined as the longest of all shortest paths in a graph. The function is:

```
graph_diameter( apsp_table,
output_table
)
```

This function uses a previously run APSP (All Pairs Shortest Path) output. For details on the parameters, with examples, see theGraph Diameter in the Apache MADlib documentation.

In-Out Degree

This function computes the degree of each node. The node degree is the number of edges adjacent to that node. The node in-degree is the number of edges pointing in to the node and node out-degree is the number of edges pointing out of the node.

The function is:

```
graph_vertex_degrees( vertex_table,
vertex_id,
edge_table,
edge_args,
out_table,
grouping_cols
)
```

For details on the parameters, with examples, see the In-out Degree page in the Apache MADlib documentation.

4.7.3 Geospatial Analytics

PostGIS is a spatial database extension for PostgreSQL that allows you to store GIS (Geographic Information Systems) objects in the database. The WarehousePG PostGIS extension supports some PostGIS optional extensions such as GiST-based R-Tree spatial indexes, and functions for analysis and processing of GIS objects. It also includes support for the PostGIS `raster` data type. With the PostGIS Raster objects, the PostGIS `geometry` data type offers a single set of overlay SQL functions (such as `ST_Intersects`) operating seamlessly on vector and raster geospatial data. PostGIS Raster uses the GDAL (Geospatial Data Abstraction Library) translator library for raster geospatial data formats that presents a single raster abstract data model to a calling application.

For information about WarehousePG PostGIS extension support, see PostGIS Extension Support and Limitations.

For information about PostGIS, see https://postgis.net/

For information about GDAL, see https://gdal.org/.

WarehousePG PostGIS Extension

WarehousePG supports the PostGIS extension with these component versions:

- PostGIS 3.3.2
- Proj 8.2.1
- Geos 3.10.2
- GDAL 3.6.3
- Json 0.12
- Expat 2.5.0

For information about the supported WarehousePG extension packages and software versions, see Extensions.

There are significant changes in PostGIS 3.3.2 compared with earlier versions. For a list of new and enhanced functions in PostGIS 3.3, see the PostGIS documentation PostGIS Functions new or enhanced in 3.3 and Release 3.3.2.

This table lists the PostGIS extensions support by WarehousePG PostGIS.

Table 1. WarehousePG PostGIS Extensions

PostGIS Extension	WarehousePG PostGIS Notes
`postgis` PostGIS and PostGIS Raster support	Supported. Both PostGIS and PostGIS Raster are enabled when the WarehousePG `postgis` extension is enabled.
`postgis_tiger_geocoder` The US TIGER geocoder	Supported. Installed with WarehousePG PostGIS. Requires the `postgis` and `fuzzystrmatch` extensions. The US TIGER geocoder converts addresses (like a street address) to geographic coordinates.
`address_standardizer` Rule-based address standardizer	Supported. Installed but not enabled with WarehousePG PostGIS. Can be used with TIGER geocoder. A single line address parser that takes an input address and normalizes it based on a set of rules stored in a table and helper `lex` and `gaz` tables.
`address_standardizer_data_us` Sample rules tables for US address data	Supported. Installed but not enabled with WarehousePG PostGIS. Can be used with the address standardizer. The extension contains `gaz`, `lex`, and `rules` tables for US address data. If you are using other types of tables, see PostGIS Extension Limitations.
`fuzzystrmatch` Fuzzy string matching	Supported. This extension is bundled but not enabled with WarehousePG Database. Required for the PostGIS TIGER geocoder.

> **Note** The PostGIS topology extension `postgis_topology` and the PostGIS 3D and geoprocessing extension `postgis_sfcgal` are not supported by WarehousePG PostGIS and are not included in the WarehousePG PostGIS extension package.

For information about the PostGIS extensions, see the PostGIS documentation.

For information about WarehousePG PostGIS feature support, see PostGIS Extension Support and Limitations.

Enabling and Removing PostGIS Support

This section describes how to enable and remove PostGIS and the supported PostGIS extensions, and how to configure PostGIS Raster.

Enabling PostGIS Support

To enable PostGIS support, install the WarehousePG PostGIS extension package into the WarehousePG cluster, and then use the `CREATE EXTENSION` command to enable PostGIS support for an individual database.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Installing the WarehousePG PostGIS Extension Package

After installing the package, source the `greenplum_path.sh` file and restart WarehousePG. This command restarts WarehousePG.

```
gpstop -ra
```

Installing the WarehousePG PostGIS extension package updates the WarehousePG cluster, including installing the supported PostGIS extensions to the system and updating `greenplum_path.sh` file with these lines for PostGIS Raster support.

```
export GDAL_DATA=$GPHOME/share/gdal
export POSTGIS_ENABLE_OUTDB_RASTERS=0
export POSTGIS_GDAL_ENABLED_DRIVERS=DISABLE_ALL
```

Using the CREATE EXTENSION Command

These steps enable the PostGIS extension and the extensions that are used with PostGIS.

1. To enable PostGIS and PostGIS Raster in a database, run this command after logging into the database.

   ```
   CREATE EXTENSION postgis ;
   ```

   To enable PostGIS and PostGIS Raster in a specific schema, create the schema, set the `search_path` to the PostGIS schema, and then enable the `postgis` extension with the `WITH SCHEMA` clause.

   ```
   SHOW search_path ; -- display the current search_path
   CREATE SCHEMA <schema_name> ;
   SET search_path TO <schema_name> ;
   CREATE EXTENSION postgis WITH SCHEMA <schema_name> ;
   ```

   After enabling the extension, reset the `search_path` and include the PostGIS schema in the `search_path` if needed.

2. If needed, enable the PostGIS TIGER geocoder after enabling the `postgis` extension.

   To enable the PostGIS TIGER geocoder, you must enable the `fuzzystrmatch` extension before enabling `postgis_tiger_geocoder`. These two commands enable the extensions.

   ```
   CREATE EXTENSION fuzzystrmatch ;
   CREATE EXTENSION postgis_tiger_geocoder ;
   ```

3. If needed, enable the rules-based address standardizer and add rules tables for the standardizer. These commands enable the extensions.

   ```
   CREATE EXTENSION address_standardizer ;
   CREATE EXTENSION address_standardizer_data_us ;
   ```

Enabling GDAL Raster Drivers

PostGIS uses GDAL raster drivers when processing raster data with commands such as `ST_AsJPEG()`. As the default, PostGIS deactivates all raster drivers. You enable raster drivers by setting the value of the `POSTGIS_GDAL_ENABLED_DRIVERS` environment variable in the `greenplum_path.sh` file on all WarehousePG hosts.

Alternatively, you can do it at the session level by setting `postgis.gdal_enabled_drivers`. For a WarehousePG session, this example `SET` command enables three GDAL raster drivers.

```
SET postgis.gdal_enabled_drivers TO 'GTiff PNG JPEG';
```

This `SET` command sets the enabled drivers to the default for a session.

```
SET postgis.gdal_enabled_drivers = default;
```

To see the list of supported GDAL raster drivers for a WarehousePG cluster, run the `raster2pgsql` utility with the `-G` option on the WarehousePG coordinator.

```
raster2pgsql -G
```

The command lists the driver long format name. The *GDAL Raster* table at https://gdal.org/drivers/raster/index.html lists the long format names and the corresponding codes that you specify as the value of the environment variable. For example, the code for the long name Portable Network Graphics is `PNG`. This example `export` line enables four GDAL raster drivers.

```
export POSTGIS_GDAL_ENABLED_DRIVERS="GTiff PNG JPEG GIF"
```

The `gpstop -r` command restarts the WarehousePG cluster to use the updated settings in the `greenplum_path.sh` file.

After you have updated the `greenplum_path.sh` file on all hosts, and have restarted the WarehousePG cluster, you can display the enabled raster drivers with the `ST_GDALDrivers()` function. This `SELECT` command lists the enabled raster drivers.

```
SELECT short_name, long_name FROM ST_GDALDrivers();
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Enabling Out-of-Database Rasters

After installing PostGIS, the default setting `POSTGIS_ENABLE_OUTDB_RASTERS=0` in the `greenplum_path.sh` file deactivates support for out-of-database rasters. To enable this feature, you can set the value to true (a non-zero value) on all hosts and restart the WarehousePG cluster.

You can also activate or deactivate this feature for a WarehousePG session. For example, this `SET` command enables the feature for the current session.

```
SET postgis.enable_outdb_rasters = true;
```

> **Note** When the feature is enabled, the server configuration parameter `postgis.gdal_enabled_drivers` determines the accessible raster formats.

Removing PostGIS Support

You use the `DROP EXTENSION` command to remove support for the PostGIS extension and the extensions that are used with PostGIS.

Removing PostGIS support from a database does not remove these PostGIS Raster environment variables from the `greenplum_path.sh` file: `GDAL_DATA`, `POSTGIS_ENABLE_OUTDB_RASTERS`, `POSTGIS_GDAL_ENABLED_DRIVERS`. The environment variables are removed when you uninstall the PostGIS extension package.

> **Caution** Removing PostGIS support from a database drops PostGIS database objects from the database without warning. Users accessing PostGIS objects might interfere with the dropping of PostGIS objects. SeeNotes.

Using the DROP EXTENSION Command

Depending on the extensions you enabled for PostGIS, drop support for the extensions in the database.

1. If you enabled the address standardizer and sample rules tables, these commands drop support for those extensions from the current database.

   ```
   DROP EXTENSION IF EXISTS address_standardizer_data_us;
   DROP EXTENSION IF EXISTS address_standardizer;
   ```

2. If you enabled the TIGER geocoder and the `fuzzystrmatch` extension to use the TIGER geocoder, these commands drop support for those extensions.

   ```
   DROP EXTENSION IF EXISTS postgis_tiger_geocoder;
   DROP EXTENSION IF EXISTS fuzzystrmatch;
   ```

3. Drop support for PostGIS and PostGIS Raster. This command drops support for those extensions.

   ```
   DROP EXTENSION IF EXISTS postgis;
   ```

   If you enabled support for PostGIS and specified a specific schema with the `CREATE EXTENSION` command, you can update the `search_path` and drop the PostGIS schema if required.

Notes

Removing PostGIS support from a database drops PostGIS objects from the database. Dropping the PostGIS objects cascades to objects that reference the PostGIS objects. Before removing PostGIS support, ensure that no users are accessing the database. Users accessing PostGIS objects might interfere with dropping PostGIS objects.

For example, this `CREATE TABLE` command creates a table with column `b` that is defined with the PostGIS `geometry` data type.

```
CREATE TABLE test(a int, b geometry) DISTRIBUTED RANDOMLY;
```

This is the table definition in a database with PostGIS enabled.

```
\d test
 Table "public.test"
 Column |   Type   | Modifiers
--------+----------+-----------
 a      | integer  |
 b      | geometry |
Distributed randomly
```

This is the table definition in a database after PostGIS support has been removed.

```
\d test
  Table "public.test"
 Column |  Type   | Modifiers
--------+---------+-----------
 a      | integer |
Distributed randomly
```

Usage

The following example SQL statements create non-OpenGIS tables and geometries.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
CREATE TABLE geom_test ( gid int4, geom geometry,
  name varchar(25) );

INSERT INTO geom_test ( gid, geom, name )
  VALUES ( 1, 'POLYGON((0 0 0,0 5 0,5 5 0,5 0 0,0 0 0))', '3D Square');
INSERT INTO geom_test ( gid, geom, name )
  VALUES ( 2, 'LINESTRING(1 1 1,5 5 5,7 7 5)', '3D Line' );
INSERT INTO geom_test ( gid, geom, name )
  VALUES ( 3, 'MULTIPOINT(3 4,8 9)', '2D Aggregate Point' );

SELECT * from geom_test WHERE geom &&
  Box3D(ST_GeomFromEWKT('LINESTRING(2 2 0, 3 3 0)'));
```

The following example SQL statements create a table and add a geometry column to the table with a SRID integer value that references an entry in the `SPATIAL_REF_SYS` table. The `INSERT` statements add two geopoints to the table.

```
CREATE TABLE geotest (id INT4, name VARCHAR(32) );
SELECT AddGeometryColumn('geotest','geopoint', 4326,'POINT',2);

INSERT INTO geotest (id, name, geopoint)
  VALUES (1, 'Olympia', ST_GeometryFromText('POINT(-122.90 46.97)', 4326));
INSERT INTO geotest (id, name, geopoint)
  VALUES (2, 'Renton', ST_GeometryFromText('POINT(-122.22 47.50)', 4326));

SELECT name,ST_AsText(geopoint) FROM geotest;
```

Spatial Indexes

PostgreSQL provides support for GiST spatial indexing. The GiST scheme offers indexing even on large objects. It uses a system of lossy indexing in which smaller objects act as proxies for larger ones in the index. In the PostGIS indexing system, all objects use their bounding boxes as proxies in the index.

Building a Spatial Index

You can build a GiST index as follows:

```
CREATE INDEX indexname
  ON tablename
  USING GIST ( geometryfield );
```

PostGIS Extension Support and Limitations

This section describes WarehousePG PostGIS extension feature support and limitations. In general, the WarehousePG PostGIS extension does not support the following features:

- The PostGIS topology extension `postgis_topology`
- The PostGIS 3D and geoprocessing extension `postgis_sfcgal`
- A small number of user defined functions and aggregates
- PostGIS long transactions

For the PostGIS extensions supported by WarehousePG PostGIS, see WarehousePG PostGIS Extension.

Supported PostGIS Data Types

WarehousePG PostGIS extension supports these PostGIS data types:

- box2d
- box3d
- geometry
- geography

For a list of PostGIS data types, operators, and functions, see thePostGIS reference documentation.

Supported PostGIS Raster Data Types

WarehousePG PostGIS supports these PostGIS Raster data types.

- geomval
- addbandarg
- rastbandarg
- raster
- reclassarg
- summarystats
- unionarg

For information about PostGIS Raster data Management, queries, and applications, see thePostGIS documentation.

For a list of PostGIS Raster data types, operators, and functions, see thePostGIS Raster reference documentation.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Supported PostGIS Index

WarehousePG PostGIS extension supports the GiST (Generalized Search Tree) index.

PostGIS Extension Limitations

This section lists the WarehousePG PostGIS extension limitations for user-defined functions (UDFs), data types, and aggregates.

- Data types and functions related to PostGIS topology functionality, such as TopoGeometry, are not supported by WarehousePG.
- These PostGIS aggregates are not supported by WarehousePG:
    - ST_Collect
    - ST_MakeLine

  On a WarehousePG with multiple segments, the aggregate might return different answers if it is called several times repeatedly.
- WarehousePG does not support PostGIS long transactions.

  PostGIS relies on triggers and the PostGIS table `public.authorization_table` for long transaction support. When PostGIS attempts to acquire locks for long transactions, WarehousePG reports errors citing that the function cannot access the relation, `authorization_table`.
- The `_postgis_index_extent` function is not supported on WarehousePG 7 due to its dependence on spatial index operations.
- The `<->` operator (`geometry <-> geometry`) returns the centroid/centroid distance for WarehousePG 7.
- The TIGER geocoder extension is supported. However, upgrading the TIGER geocoder extension is not supported.
- The `standardize_address()` function uses `lex`, `gaz` or `rules` tables as parameters. If you are using tables apart from `us_lex`, `us_gaz` or `us_rules`, you should create them with the distribution policy `DISTRIBUTED REPLICATED` to work for WarehousePG.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.7.4 Geospatial Indexing with H3 and H3-PG

H3 is a geospatial indexing system using a hexagonal grid that can be (approximately) subdivided into finer and finer hexagonal grids. It includes functions for converting from latitude and longitude coordinates to the containing H3 cell, finding the center of H3 cells, finding the boundary geometry of H3 cells, finding neighbors of H3 cells, and more.

H3-PG is a PostgreSQL extension that adds bindings for H3 functions and compatibility with PostGIS defined types.

For information about H3, see https://h3geo.org/

WarehousePG H3-PG Extension

The WarehousePG H3-PG extension package is installed with WarehousePG.

WarehousePG supports the H3 extension with these component versions:

- H3 4.1.3
- PostGIS 3.3.2

For information about the supported WarehousePG extension packages and software versions, see Extensions.

For information about WarehousePG PostGIS feature support, see WarehousePG PostGIS.

Enabling H3 Support

To enable H3 support first enable plpython3u support with the `CREATE LANGUAGE plpython3u` command on your target database. If your database already has this language enabled you can skip this step. Next, use the `CREATE EXTENSION h3_postgis CASCADE` command on your target database. This command will install the following extensions: `postgis`, `postgis_raster`, `h3`, and `h3_postgis`.

Removing H3 Support

You use the `DROP EXTENSION` command to remove support for the H3 extension and the extensions that are used with H3.

> **Caution** Removing H3 support from a database drops H3 database objects from the database without warning. Users accessing H3 objects might interfere with the dropping of H3 objects. Please refer to the following note from PostGIS documentation for a detailed explanation: Notes.

Using the DROP EXTENSION Command

Depending on the extensions you enabled for PostGIS, drop support for the extensions in the database.

1. Use the following commands to drop the H3-PG SQL bindings and H3 library.

```
DROP EXTENSION IF EXISTS h3_postgis;
DROP EXTENSION IF EXISTS h3;
```

2. If you want to drop support for PostGIS and PostGIS raster as well, use the following commands.

```
DROP EXTENSION IF EXISTS postgis_raster;
DROP EXTENSION IF EXISTS postgis;
```

Usage

Create a table with a geometry column. The `INSERT` statements add 10 geopoints to the table.

```
DROP TABLE IF EXISTS test_buildings;
CREATE TABLE test_buildings (gid INTEGER, type VARCHAR(32), center GEOGRAPHY) DISTRIBUTED BY (gid);

INSERT INTO test_buildings (gid, type, center)
VALUES (1, '', 'POINT(-78.88054167312363 43.03597938296738)');
INSERT INTO test_buildings (gid, type, center)
VALUES (2, '', 'POINT(-78.25103469999999 42.987796800000005)');
INSERT INTO test_buildings (gid, type, center)
VALUES (3, '', 'POINT(-77.278319 43.056357)');
INSERT INTO test_buildings (gid, type, center)
VALUES (4, '', 'POINT(-76.53755992503561 42.486039090444734)');
INSERT INTO test_buildings (gid, type, center)
VALUES (5, '', 'POINT(-77.35210400000001 42.745183)');
INSERT INTO test_buildings (gid, type, center)
VALUES (6, '', 'POINT(-76.4586205 42.20662450000001)');
INSERT INTO test_buildings (gid, type, center)
VALUES (7, '', 'POINT(-73.99734793983018 41.99385572155095)');
INSERT INTO test_buildings (gid, type, center)
VALUES (8, 'house', 'POINT(-72.97949770000001 40.83532615000001)');
INSERT INTO test_buildings (gid, type, center)
VALUES (9, 'house', 'POINT(-72.95980417527308 40.8958175447567)');
INSERT INTO test_buildings (gid, type, center)
VALUES (10, 'house', 'POINT(-72.46734516736213 41.046857297778395)');
```

Find H3 indexes at resolution 7 and redistribute the data.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
SELECT h3_redistribute_table('test_buildings', 'h3_test_buildings', 'gid', 'center', 7, 'type');
```

Create a different table with existing H3 indexes.

```
DROP TABLE IF EXISTS h3_test_incidents;
CREATE TABLE h3_test_incidents (gid INTEGER, h3_res7 h3index) DISTRIBUTED BY (gid);

INSERT INTO h3_test_incidents (gid, h3_res7)
VALUES (1,'872a1070bffffff');
INSERT INTO h3_test_incidents (gid, h3_res7)
VALUES (2,'872a10764ffffff');
INSERT INTO h3_test_incidents (gid, h3_res7)
VALUES (3,'872a1072dffffff');
INSERT INTO h3_test_incidents (gid, h3_res7)
VALUES (4,'872a10743ffffff');
INSERT INTO h3_test_incidents (gid, h3_res7)
VALUES (5,'872a100d9ffffff');
INSERT INTO h3_test_incidents (gid, h3_res7)
VALUES (6,'872a1070bffffff');
INSERT INTO h3_test_incidents (gid, h3_res7)
VALUES (7,'872a10764ffffff');
INSERT INTO h3_test_incidents (gid, h3_res7)
VALUES (8,'872a10740ffffff');
INSERT INTO h3_test_incidents (gid, h3_res7)
VALUES (9,'872a10741ffffff');
INSERT INTO h3_test_incidents (gid, h3_res7)
VALUES (10,'872a10763ffffff');
```

Find every incident that happened within 50 hexes for each building.

```
DROP TABLE IF EXISTS h3_out_table;
SELECT h3_dwithin_batch('h3_test_buildings', 'h3_test_incidents', 'h3_out_table', 'gid', 'gid', '__h3_res7', 'h3_res7', 50);
SELECT * FROM h3_out_table ORDER BY 1,2;
```

Find the hex distance and approximate real world distance between every building of type 'house' and every incident.

```
DROP TABLE IF EXISTS h3_out_table;
CREATE VIEW h3_test_buildings_view AS SELECT * FROM h3_test_buildings WHERE type = 'house';
SELECT h3_distance_batch('h3_test_buildings_view', 'h3_test_incidents', 'h3_out_table', 'gid', 'gid', '__h3_res7', 'h3_res7');
SELECT * FROM h3_out_table ORDER BY 1,2;
```

4.7.5 Procedural Languages

WarehousePG supports a pluggable procedural language architecture by virtue of its PostgreSQL heritage. This allows user-defined functions to be written in languages other than SQL and C. It may be more convenient to develop analytics functions in a familiar procedural language compared to using only SQL constructs. For example, suppose you have existing Python code that you want to use on data in WarehousePG, you can wrap this code in a PL/Python function and call it from SQL.

The available WarehousePG procedural languages are typically packaged as extensions. You register a language in a database using the CREATE EXTENSION command. You remove a language from a database with DROP EXTENSION.

The WarehousePG distribution supports the following procedural languages; refer to the linked language documentation for installation and usage instructions:

- PL/Java
- PL/Perl
- PL/pgSQL
- PL/Python
- PL/R

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.7.5.1 PL/Java Language

This section contains an overview of the WarehousePG PL/Java language.

- About PL/Java
- About WarehousePG PL/Java
- Installing Java
- Installing PL/Java
- Enabling PL/Java and Installing JAR Files
- Uninstalling PL/Java
- Writing PL/Java functions
- Using JDBC
- Exception Handling
- Savepoints
- Logging
- Security
- Some PL/Java Issues and Solutions
- Example
- References

About PL/Java

With the WarehousePG PL/Java extension, you can write Java methods using your favorite Java IDE and install the JAR files that contain those methods into WarehousePG.

WarehousePG PL/Java package is based on the open source PL/Java 1.5.0. WarehousePG PL/Java provides the following features.

- Ability to run PL/Java functions with Java 8, Java 11 and Java 17.
- Ability to specify Java runtime.
- Standardized utilities (modeled after the SQL 2003 proposal) to install and maintain Java code in the database.
- Standardized mappings of parameters and result. Complex types as well as sets are supported.
- An embedded, high performance, JDBC driver utilizing the internal WarehousePG SPI routines.
- Metadata support for the JDBC driver. Both `DatabaseMetaData` and `ResultSetMetaData` are included.
- The ability to return a ResultSet from a query as an alternative to building a ResultSet row by row.
- Full support for savepoints and exception handling.
- The ability to use IN, INOUT, and OUT parameters.
- Two separate WarehousePG languages:
    - pljava, TRUSTED PL/Java language
    - pljavau, UNTRUSTED PL/Java language

- Transaction and Savepoint listeners enabling code execution when a transaction or savepoint is committed or rolled back.
- Integration with GNU GCJ on selected platforms.

A function in SQL will appoint a static method in a Java class. In order for the function to run, the appointed class must available on the class path specified by the WarehousePG server configuration parameter `pljava_classpath`. The PL/Java extension adds a set of functions that helps installing and maintaining the java classes. Classes are stored in normal Java archives, JAR files. A JAR file can optionally contain a deployment descriptor that in turn contains SQL commands to be run when the JAR is deployed or undeployed. The functions are modeled after the standards proposed for SQL 2003.

PL/Java implements a standardized way of passing parameters and return values. Complex types and sets are passed using the standard JDBC ResultSet class.

A JDBC driver is included in PL/Java. This driver calls WarehousePG internal SPI routines. The driver is essential since it is common for functions to make calls back to the database to fetch data. When PL/Java functions fetch data, they must use the same transactional boundaries that are used by the main function that entered PL/Java execution context.

PL/Java is optimized for performance. The Java virtual machine runs within the same process as the backend to minimize call overhead. PL/Java is designed with the objective to enable the power of Java to the database itself so that database intensive business logic can run as close to the actual data as possible.

The standard Java Native Interface (JNI) is used when bridging calls between the backend and the Java VM.

About WarehousePG PL/Java

There are a few key differences between the implementation of PL/Java in standard PostgreSQL and WarehousePG.

Functions

The following functions are not supported in WarehousePG. The classpath is handled differently in a distributed WarehousePG environment than in the PostgreSQL environment.

- `sqlj.install_jar`
- `sqlj.replace_jar`
- `sqlj.remove_jar`
- `sqlj.get_classpath`
- `sqlj.set_classpath`

WarehousePG uses the `pljava_classpath` server configuration parameter in place of the `sqlj.set_classpath` function.

Server Configuration Parameters

The following server configuration parameters are used by PL/Java in WarehousePG. These parameters replace the `pljava.*` parameters that are used in the standard PostgreSQL PL/Java implementation:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

- `pljava_classpath`

  A colon (`:`) separated list of the jar files containing the Java classes used in any PL/Java functions. The jar files must be installed in the same locations on all WarehousePG hosts. With the trusted PL/Java language handler, jar file paths must be relative to the `$GPHOME/lib/postgresql/java/` directory. With the untrusted language handler (javaU language tag), paths may be relative to `$GPHOME/lib/postgresql/java/` or absolute.

  The server configuration parameter `pljava_classpath_insecure` controls whether the server configuration parameter `pljava_classpath` can be set by a user without WarehousePG superuser privileges. When `pljava_classpath_insecure` is enabled, WarehousePG developers who are working on PL/Java functions do not have to be database superusers to change `pljava_classpath` .

  > **Caution** Enabling `pljava_classpath_insecure` exposes a security risk by giving non-administrator database users the ability to run unauthorized Java methods.

- `pljava_statement_cache_size`

  Sets the size in KB of the Most Recently Used (MRU) cache for prepared statements.

- `pljava_release_lingering_savepoints`

  If `TRUE` , lingering savepoints will be released on function exit. If `FALSE` , they will be rolled back.

- `pljava_vmoptions`

  Defines the start up options for the WarehousePG Java VM.

See the *WarehousePG Reference Guide* for information about the WarehousePG server configuration parameters.

Installing Java

PL/Java requires a Java runtime environment on each WarehousePG host. Ensure that the same Java environment is at the same location on all hosts: coordinators and segments. The command `java -version` displays the Java version.

The commands that you use to install Java depend on the host system operating system and Java version. To install OpenJDK 8, OpenJDK 11 or OpenJDK 17 (Java 8 JDK, Java 11 JDK, Java 17 JDK) on RHEL/Oracle/Rocky Linux:

```
$ sudo yum install java-<version>-openjdk-devel
```

For OpenJDK 8 the version is `1.8.0` , for OpenJDK 11 the version is `11` , for OpenJDK 17 the version is `17` .

After installing OpenJDK on a RHEL system, run this `update-alternatives` command to change the default Java. Enter the number that represents the OpenJDK version to use as the default.

```
$ sudo update-alternatives --config java
```

> **Note** When configuring host systems, you can use the gpssh utility to run bash shell commands on multiple remote hosts.

Installing PL/Java

For WarehousePG, the PL/Java extension is available as a package.

To install and use PL/Java:

1. Specify the Java version used by PL/Java. Set the environment variables `JAVA_HOME` and `LD_LIBRARY_PATH` in the `greenplum_path.sh` .
2. Install the WarehousePG PL/Java extension.
3. Enable the language for each database where you intend to use PL/Java.
4. Install user-created JAR files containing Java methods into the same directory on all WarehousePG hosts.
5. Add the name of the JAR file to the WarehousePG server configuration parameter `pljava_classpath` . The parameter lists the installed JAR files. For information about the parameter, see the*WarehousePG Reference Guide*.

Installing the WarehousePG PL/Java Extension

Before you install the PL/Java extension, make sure that your WarehousePG is running, you have sourced `greenplum_path.sh` , and that the `$COORDINATOR_DATA_DIRECTORY` and `$GPHOME` variables are set.

1. Download the PL/Java extension package then copy it to the coordinator host.

2. Install the software extension package

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

3. Ensure that the environment variables `JAVA_HOME` and `LD_LIBRARY_PATH` are set properly in `$GPHOME/greenplum_path.sh` on all WarehousePG hosts.

    - Set the `JAVA_HOME` variable to the directory where your Java Runtime is installed. For example, for Oracle JRE this directory would be `/usr/java/latest`. For OpenJDK, the directory is `/usr/lib/jvm`. This example changes the environment variable to use `/usr/lib/jvm`.

      ```
      export JAVA_HOME=/usr/lib/jvm
      ```

    - Set the `LD_LIBRARY_PATH` to include the directory with the Java server runtime libraries. PL/Java depends on `libjvm.so` and the shared object should be in your `LD_LIBRARY_PATH`. By default, `libjvm.so` is available in `$JAVA_HOME/lib/server` with JDK 11 and JDK 17, or in `$JAVA_HOME/jre/lib/amd64/server` with JDK 8. This example adds the JDK 11 directory to the environment variable.

      ```
      export LD_LIBRARY_PATH=$GPHOME/lib:$GPHOME/ext/python/lib:$JAVA_HOME/lib/server:$LD_LIBRARY_PATH
      ```

    This example gpsync command copies the file to all hosts specified in the file `gphosts_file`.

    ```
    $ gpsync -f gphosts_file $GPHOME/greenplum_path.sh
    =:$GPHOME/greenplum_path.sh
    ```

4. Reload `greenplum_path.sh`.

    ```
    $ source $GPHOME/greenplum_path.sh
    ```

5. Restart WarehousePG.

    ```
    $ gpstop -r
    ```

Enabling PL/Java and Installing JAR Files

Perform the following steps as the WarehousePG administrator `gpadmin`.

1. Enable PL/Java in a database by running the `CREATE EXTENSION` command to register the language. For example, this command enables PL/Java in the `testdb` database:

    ```
    $ psql -d testdb -c 'CREATE EXTENSION pljava;'
    ```

    > **Note** The PL/Java `install.sql` script, used in previous releases to register the language, is deprecated.

2. Copy your Java archives (JAR files) to the same directory on all WarehousePG hosts. This example uses the WarehousePG `gpsync` utility to copy the file `myclasses.jar` to the directory `$GPHOME/lib/postgresql/java/`:

    ```
    $ gpsync -f gphosts_file myclasses.jar
    =:/usr/edb/whpg7/lib/postgresql/java/
    ```

    The file `gphosts_file` contains a list of the WarehousePG hosts.

3. Set the `pljava_classpath` server configuration parameter in the coordinator `postgresql.conf` file. For this example, the parameter value is a colon (:) separated list of the JAR files. For example:

    ```
    $ gpconfig -c pljava_classpath -v 'examples.jar:myclasses.jar'
    ```

    The file `examples.jar` is installed when you install the PL/Java extension package

    > **Note** If you install JAR files in a directory other than `$GPHOME/lib/postgresql/java/`, you must specify the absolute path to the JAR file. Each JAR file must be in the same location on all WarehousePG hosts. For more information about specifying the location of JAR files, see the information about the `pljava_classpath` server configuration parameter in the *WarehousePG Reference Guide*.

4. Reload the `postgresql.conf` file.

    ```
    $ gpstop -u
    ```

5. (optional) WarehousePG provides an `examples.sql` file containing sample PL/Java functions that you can use for testing. Run the commands in this file to create the test functions (which use the Java classes in `examples.jar`).

    ```
    $ psql -f $GPHOME/share/postgresql/pljava/examples.sql
    ```

Uninstalling PL/Java

- Remove PL/Java Support for a Database

Remove PL/Java Support for a Database

Use the `DROP EXTENSION` command to remove support for PL/Java from a database. For example, this command deactivates the PL/Java language in the `testdb` database:

```
$ psql -d testdb -c 'DROP EXTENSION pljava;'
```

The default command fails if any existing objects (such as functions) depend on the language. Specify the `CASCADE` option to also drop all dependent objects, including functions that you created with PL/Java.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

> **Note** The PL/Java `uninstall.sql` script, used in previous releases to remove the language registration, is deprecated.

Writing PL/Java functions

Information about writing functions with PL/Java.

- SQL Declaration
- Type Mapping
- NULL Handling
- Complex Types
- Returning Complex Types
- Returning Complex Types
- Functions That Return Sets
- Returning a SETOF <scalar type>
- Returning a SETOF <complex type>

SQL Declaration

A Java function is declared with the name of a class and a static method on that class. The class will be resolved using the classpath that has been defined for the schema where the function is declared. If no classpath has been defined for that schema, the public schema is used. If no classpath is found there either, the class is resolved using the system classloader.

The following function can be declared to access the static method `getProperty` on `java.lang.System` class:

```
CREATE FUNCTION getsysprop(VARCHAR)
  RETURNS VARCHAR
  AS 'java.lang.System.getProperty'
  LANGUAGE java;
```

Run the following command to return the Java `user.home` property:

```
SELECT getsysprop('user.home');
```

Type Mapping

Scalar types are mapped in a straight forward way. This table lists the current mappings.

PostgreSQL	Java
bool	boolean
char	byte
int2	short
int4	int
int8	long
varchar	java.lang.String
text	java.lang.String
bytea	byte[ ]
date	java.sql.Date
time	java.sql.Time (stored value treated as local time)
timetz	java.sql.Time
timestamp	java.sql.Timestamp (stored value treated as local time)
timestamptz	java.sql.Timestamp
complex	java.sql.ResultSet
setof complex	java.sql.ResultSet

All other types are mapped to java.lang.String and will utilize the standard `textin` / `textout` routines registered for respective type.

NULL Handling

The scalar types that map to Java primitives can not be passed as `NULL` values. To pass `NULL` values, those types can have an alternative mapping. You enable this mapping by explicitly denoting it in the method reference.

```
CREATE FUNCTION trueIfEvenOrNull(integer)
  RETURNS bool
  AS 'foo.fee.Fum.trueIfEvenOrNull(java.lang.Integer)'
  LANGUAGE java;
```

The Java code would be similar to this:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
package foo.fee;
public class Fum
{
  static boolean trueIfEvenOrNull(Integer value)
  {
    return (value == null)
      ? true
      : (value.intValue() % 2) == 0;
  }
}
```

The following two statements both yield true:

```
SELECT trueIfEvenOrNull(NULL);
SELECT trueIfEvenOrNull(4);
```

In order to return `NULL` values from a Java method, you use the object type that corresponds to the primitive (for example, you return `java.lang.Integer` instead of `int`). The PL/Java resolve mechanism finds the method regardless. Since Java cannot have different return types for methods with the same name, this does not introduce any ambiguity.

Complex Types

A complex type will always be passed as a read-only `java.sql.ResultSet` with exactly one row. The ResultSet is positioned on its row so a call to `next()` should not be made. The values of the complex type are retrieved using the standard getter methods of the ResultSet.

Example:

```
CREATE TYPE complexTest
  AS(base integer, incbase integer, ctime timestamptz);
CREATE FUNCTION useComplexTest(complexTest)
  RETURNS VARCHAR
  AS 'foo.fee.Fum.useComplexTest'
  IMMUTABLE LANGUAGE java;
```

In the Java class `Fum`, we add the following static method:

```
public static String useComplexTest(ResultSet complexTest)
throws SQLException
{
  int base = complexTest.getInt(1);
  int incbase = complexTest.getInt(2);
  Timestamp ctime = complexTest.getTimestamp(3);
  return "Base = \"" + base +
    "\", incbase = \"" + incbase +
    "\", ctime = \"" + ctime + "\"";
}
```

Returning Complex Types

Java does not stipulate any way to create a ResultSet. Hence, returning a ResultSet is not an option. The SQL-2003 draft suggests that a complex return value should be handled as an IN/OUT parameter. PL/Java implements a ResultSet that way. If you declare a function that returns a complex type, you will need to use a Java method with boolean return type with a last parameter of type `java.sql.ResultSet`. The parameter will be initialized to an empty updateable ResultSet that contains exactly one row.

Assume that the `complexTest` type in previous section has been created.

```
CREATE FUNCTION createComplexTest(int, int)
  RETURNS complexTest
  AS 'foo.fee.Fum.createComplexTest'
  IMMUTABLE LANGUAGE java;
```

The PL/Java method resolve will now find the following method in the `Fum` class:

```
public static boolean complexReturn(int base, int increment,
  ResultSet receiver)
throws SQLException
{
  receiver.updateInt(1, base);
  receiver.updateInt(2, base + increment);
  receiver.updateTimestamp(3, new
    Timestamp(System.currentTimeMillis()));
  return true;
}
```

The return value denotes if the receiver should be considered as a valid tuple (true) or NULL (false).

Functions That Return Sets

When returning result sets, you should not build a result set before returning it, because building a large result set would consume a large amount of resources. It is better to produce one row at a time. Incidentally, that is what the WarehousePG backend expects a function with SETOF return to do. You can return a SETOF a scalar type such as an `int`, `float` or `varchar`, or you can return a SETOF a complex type.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Returning a SETOF <scalar type>

In order to return a set of a scalar type, you need create a Java method that returns something that implements the `java.util.Iterator` interface. Here is an example of a method that returns a SETOF `varchar`:

```
CREATE FUNCTION javatest.getSystemProperties()
  RETURNS SETOF varchar
  AS 'foo.fee.Bar.getNames'
  IMMUTABLE LANGUAGE java;
```

This simple Java method returns an iterator:

```
package foo.fee;
import java.util.Iterator;

public class Bar
{
    public static Iterator getNames()
    {
        ArrayList names = new ArrayList();
        names.add("Lisa");
        names.add("Bob");
        names.add("Bill");
        names.add("Sally");
        return names.iterator();
    }
}
```

Returning a SETOF <complex type>

A method returning a SETOF <complex type> must use either the interface `org.postgresql.pljava.ResultSetProvider` or `org.postgresql.pljava.ResultSetHandle`. The reason for having two interfaces is that they cater for optimal handling of two distinct use cases. The former is for cases when you want to dynamically create each row that is to be returned from the SETOF function. The latter makes sense in cases where you want to return the result of a query after it runs.

Using the ResultSetProvider Interface

This interface has two methods. The boolean `assignRowValues(java.sql.ResultSet tupleBuilder, int rowNumber)` and the `void close()` method. The WarehousePG query evaluator will call the `assignRowValues` repeatedly until it returns false or until the evaluator decides that it does not need any more rows. Then it calls close.

You can use this interface the following way:

```
CREATE FUNCTION javatest.listComplexTests(int, int)
  RETURNS SETOF complexTest
  AS 'foo.fee.Fum.listComplexTest'
  IMMUTABLE LANGUAGE java;
```

The function maps to a static java method that returns an instance that implements the `ResultSetProvider` interface.

```
public class Fum implements ResultSetProvider
{
  private final int m_base;
  private final int m_increment;
  public Fum(int base, int increment)
  {
    m_base = base;
    m_increment = increment;
  }
  public boolean assignRowValues(ResultSet receiver, int
currentRow)
  throws SQLException
  {
    // Stop when we reach 12 rows.
    //
    if(currentRow >= 12)
      return false;
    receiver.updateInt(1, m_base);
    receiver.updateInt(2, m_base + m_increment * currentRow);
    receiver.updateTimestamp(3, new
Timestamp(System.currentTimeMillis()));
    return true;
  }
  public void close()
  {
   // Nothing needed in this example
  }
  public static ResultSetProvider listComplexTests(int base,
int increment)
  throws SQLException
  {
    return new Fum(base, increment);
  }
}
```

The `listComplextTests` method is called once. It may return `NULL` if no results are available or an instance of the `ResultSetProvider`. Here the Java class `Fum` implements this interface so it returns an instance of itself. The method `assignRowValues` will then be called repeatedly until it returns false. At that time, close will be called.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Using the ResultSetHandle Interface

This interface is similar to the `ResultSetProvider` interface in that it has a `close()` method that will be called at the end. But instead of having the evaluator call a method that builds one row at a time, this method has a method that returns a ResultSet. The query evaluator will iterate over this set and deliver the RestulSet contents, one tuple at a time, to the caller until a call to `next()` returns false or the evaluator decides that no more rows are needed.

Here is an example that runs a query using a statement that it obtained using the default connection. The SQL suitable for the deployment descriptor looks like this:

```
CREATE FUNCTION javatest.listSupers()
  RETURNS SETOF pg_user
  AS 'org.postgresql.pljava.example.Users.listSupers'
  LANGUAGE java;
CREATE FUNCTION javatest.listNonSupers()
  RETURNS SETOF pg_user
  AS 'org.postgresql.pljava.example.Users.listNonSupers'
  LANGUAGE java;
```

And in the Java package `org.postgresql.pljava.example` a class `Users` is added:

```
public class Users implements ResultSetHandle
{
  private final String m_filter;
  private Statement m_statement;
  public Users(String filter)
  {
    m_filter = filter;
  }
  public ResultSet getResultSet()
  throws SQLException
  {
    m_statement =
      DriverManager.getConnection("jdbc:default:connection").cr
eateStatement();
    return m_statement.executeQuery("SELECT * FROM pg_user
       WHERE " + m_filter);
  }

  public void close()
  throws SQLException
  {
    m_statement.close();
  }

  public static ResultSetHandle listSupers()
  {
    return new Users("usesuper = true");
  }

  public static ResultSetHandle listNonSupers()
  {
    return new Users("usesuper = false");
  }
}
```

Using JDBC

PL/Java contains a JDBC driver that maps to the PostgreSQL SPI functions. A connection that maps to the current transaction can be obtained using the following statement:

```
Connection conn =
  DriverManager.getConnection("jdbc:default:connection");
```

After obtaining a connection, you can prepare and run statements similar to other JDBC connections. These are limitations for the PL/Java JDBC driver:

- The transaction cannot be managed in any way. Thus, you cannot use methods on the connection such as:
  - `commit()`
  - `rollback()`
  - `setAutoCommit()`
  - `setTransactionIsolation()`
- Savepoints are available with some restrictions. A savepoint cannot outlive the function in which it was set and it must be rolled back or released by that same function.
- A ResultSet returned from `executeQuery()` are always `FETCH_FORWARD` and `CONCUR_READ_ONLY`.
- Metadata is only available in PL/Java 1.1 or higher.
- `CallableStatement` (for stored procedures) is not implemented.
- The types `Clob` or `Blob` are not completely implemented, they need more work. The types `byte[]` and `String` can be used for `bytea` and `text` respectively.

Exception Handling

You can catch and handle an exception in the WarehousePG backend just like any other exception. The backend ErrorData structure is exposed as a property in a class called `org.postgresql.pljava.ServerException` (derived from `java.sql.SQLException`) and the Java try/catch mechanism is synchronized with the backend mechanism.

> **Important** You will not be able to continue running backend functions until your function has returned and the error has been propagated when the backend has generated an exception unless you have used a savepoint. When a savepoint is rolled back, the exceptional condition is reset and you can continue your execution.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Savepoints

WarehousePG savepoints are exposed using the java.sql.Connection interface. Two restrictions apply.

- A savepoint must be rolled back or released in the function where it was set.
- A savepoint must not outlive the function where it was set.

Logging

PL/Java uses the standard Java Logger. Hence, you can write things like:

```
Logger.getAnonymousLogger().info( "Time is " + new
Date(System.currentTimeMillis()));
```

At present, the logger uses a handler that maps the current state of the WarehousePG configuration setting `log_min_messages` to a valid Logger level and that outputs all messages using the WarehousePG backend function `elog()`.

> **Note** The `log_min_messages` setting is read from the database the first time a PL/Java function in a session is run. On the Java side, the setting does not change after the first PL/Java function execution in a specific session until the WarehousePG session that is working with PL/Java is restarted.

The following mapping apply between the Logger levels and the WarehousePG backend levels.

java.util.logging.Level	WarehousePG Level
SEVERE ERROR	ERROR
WARNING	WARNING
CONFIG	LOG
INFO	INFO
FINE	DEBUG1
FINER	DEBUG2
FINEST	DEBUG3

Security

- Installation
- Trusted Language

Installation

Only a database superuser can install PL/Java. The PL/Java utility functions are installed using SECURITY DEFINER so that they run with the access permissions that were granted to the creator of the functions.

Trusted Language

PL/Java is a *trusted* language. The trusted PL/Java language has no access to the file system as stipulated by PostgreSQL definition of a trusted language. Any database user can create and access functions in a trusted language.

PL/Java also installs a language handler for the language `javau`. This version is *not trusted* and only a superuser can create new functions that use it. Any user can call the functions.

To install both the trusted and untrusted languages, register the extension by running the `'CREATE EXTENSION pljava'` command when Enabling PL/Java and Installing JAR Files.

To install only the trusted language, register the extension by running the `'CREATE EXTENSION pljavat'` command when Enabling PL/Java and Installing JAR Files.

Some PL/Java Issues and Solutions

When writing the PL/Java, mapping the JVM into the same process-space as the WarehousePG backend code, some concerns have been raised regarding multiple threads, exception handling, and memory management. Here are brief descriptions explaining how these issues where resolved.

- Multi-threading
- Exception Handling
- Java Garbage Collector Versus palloc() and Stack Allocation

Multi-threading

Java is inherently multi-threaded. The WarehousePG backend is not. There is nothing stopping a developer from utilizing multiple Threads class in the Java code. Finalizers that call out to the backend might have been spawned from a background Garbage Collection thread. Several third party Java-packages that are likely to be used make use of multiple threads. How can this model coexist with the WarehousePG backend in the same process?

Solution

The solution is simple. PL/Java defines a special object called the `Backend.THREADLOCK`. When PL/Java is initialized, the backend immediately grabs this objects monitor (i.e. it will synchronize on this object). When the backend calls a Java function, the monitor is released and then immediately regained when the call returns. All calls from Java out to backend code are synchronized on the same lock. This ensures that only one thread at a time can call the backend from Java, and only at a time when the backend is awaiting the return of a Java function call.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Exception Handling

Java makes frequent use of try/catch/finally blocks. WarehousePG sometimes use an exception mechanism that calls `longjmp` to transfer control to a known state. Such a jump would normally effectively bypass the JVM.

Solution

The backend now allows errors to be caught using the macros `PG_TRY/PG_CATCH` / `PG_END_TRY` and in the catch block, the error can be examined using the ErrorData structure. PL/Java implements a `java.sql.SQLException` subclass called `org.postgresql.pljava.ServerException`. The ErrorData can be retrieved and examined from that exception. A catch handler is allowed to issue a rollback to a savepoint. After a successful rollback, execution can continue.

Java Garbage Collector Versus palloc() and Stack Allocation

Primitive types are always be passed by value. This includes the `String` type (this is a must since Java uses double byte characters). Complex types are often wrapped in Java objects and passed by reference. For example, a Java object can contain a pointer to a palloc'ed or stack allocated memory and use native JNI calls to extract and manipulate data. Such data will become stale once a call has ended. Further attempts to access such data will at best give very unpredictable results but more likely cause a memory fault and a crash.

Solution

The PL/Java contains code that ensures that stale pointers are cleared when the MemoryContext or stack where they were allocated goes out of scope. The Java wrapper objects might live on but any attempt to use them will result in a stale native handle exception.

Example

The following simple Java example creates a JAR file that contains a single method and runs the method.

> **Note** The example requires Java SDK to compile the Java file.

The following method returns a substring.

```
{
public static String substring(String text, int beginIndex,
  int endIndex)
    {
    return text.substring(beginIndex, endIndex);
    }
}
```

Enter the java code in a text file `example.class`.

Contents of the file `manifest.txt`:

```
Manifest-Version: 1.0
Main-Class: Example
Specification-Title: "Example"
Specification-Version: "1.0"
Created-By: 1.6.0_35-b10-428-11M3811
Build-Date: 01/20/2013 10:09 AM
```

Compile the java code:

```
javac *.java
```

Create a JAR archive named analytics.jar that contains the class file and the manifest file MANIFEST file in the JAR.

```
jar cfm analytics.jar manifest.txt *.class
```

Upload the jar file to the WarehousePG coordinator host.

Run the `gpsync` utility to copy the jar file to the WarehousePG Java directory. Use the `-f` option to specify the file that contains a list of the coordinator and segment hosts.

```
gpsync -f gphosts_file analytics.jar
=:/usr/edb/whpg7/lib/postgresql/java/
```

Use the `gpconfig` utility to set the WarehousePG `pljava_classpath` server configuration parameter. The parameter lists the installed jar files.

```
gpconfig -c pljava_classpath -v 'analytics.jar'
```

Run the `gpstop` utility with the `-u` option to reload the configuration files.

```
gpstop -u
```

From the `psql` command line, run the following command to show the installed jar files.

```
show pljava_classpath
```

The following SQL commands create a table and define a Java function to test the method in the jar file:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
create table temp (a varchar) distributed randomly;
insert into temp values ('my string');
--Example function
create or replace function java_substring(varchar, int, int)
returns varchar as 'Example.substring' language java;
--Example execution
select java_substring(a, 1, 5) from temp;
```

You can place the contents in a file, `mysample.sql` and run the command from a `psql` command line:

```
> \i mysample.sql
```

The output is similar to this:

```
java_substring
----------------
 y st
(1 row)
```

4.7.5.2 PL/Perl Language

This chapter includes the following information:

- About WarehousePG PL/Perl
- WarehousePG PL/Perl Limitations
- Trusted/Untrusted Language
- Developing Functions with PL/Perl
- About Developing PL/Perl Procedures

About WarehousePG PL/Perl

With the WarehousePG PL/Perl extension, you can write user-defined functions and procedures in Perl that take advantage of its advanced string manipulation operators and functions. PL/Perl provides both trusted and untrusted variants of the language.

PL/Perl is embedded in your WarehousePG distribution. WarehousePG PL/Perl requires Perl to be installed on the system of each database host.

Refer to the PostgreSQL PL/Perl documentation for additional information.

WarehousePG PL/Perl Limitations

Limitations of the WarehousePG PL/Perl language include:

- WarehousePG does not support PL/Perl triggers.
- PL/Perl functions cannot call each other directly.
- SPI is not yet fully implemented.
- If you fetch very large data sets using `spi_exec_query()`, you should be aware that these will all go into memory. You can avoid this problem by using `spi_query()/spi_fetchrow()`. A similar problem occurs if a set-returning function passes a large set of rows back to WarehousePG via a `return` statement. Use `return_next` for each row returned to avoid this problem.
- When a session ends normally, not due to a fatal error, PL/Perl runs any `END` blocks that you have defined. No other actions are currently performed. (File handles are not automatically flushed and objects are not automatically destroyed.)

Trusted/Untrusted Language

PL/Perl includes trusted and untrusted language variants.

The PL/Perl trusted language is named `plperl`. The trusted PL/Perl language restricts file system operations, as well as `require`, `use`, and other statements that could potentially interact with the operating system or database server process. With these restrictions in place, any WarehousePG user can create and run functions in the trusted `plperl` language.

The PL/Perl untrusted language is named `plperlu`. You cannot restrict the operation of functions you create with the `plperlu` untrusted language. Only database superusers have privileges to create untrusted PL/Perl user-defined functions. And only database superusers and other database users that are explicitly granted the permissions can run untrusted PL/Perl user-defined functions.

PL/Perl has limitations with respect to communication between interpreters and the number of interpreters running in a single process. Refer to the PostgreSQL Trusted and Untrusted PL/Perl documentation for additional information.

Enabling and Removing PL/Perl Support

You must register the PL/Perl language with a database before you can create and run a PL/Perl user-defined function within that database. To remove PL/Perl support, you must explicitly remove the extension from each database in which it was registered. You must be a database superuser or owner to register or remove trusted languages in WarehousePGs.

> **Note** Only database superusers may register or remove support for the *untrusted* PL/Perl language `plperlu`.

Before you enable or remove PL/Perl support in a database, ensure that:

- Your WarehousePG is running.
- You have sourced `greenplum_path.sh`.
- You have set the `$COORDINATOR_DATA_DIRECTORY` and `$GPHOME` environment variables.

Enabling PL/Perl Support

For each database in which you want to enable PL/Perl, register the language using the SQLCREATE EXTENSION command. For example, run the following command as the `gpadmin` user to register the trusted PL/Perl language for the database named `testdb`:

```
$ psql -d testdb -c 'CREATE EXTENSION plperl;'
```

Removing PL/Perl Support

To remove support for PL/Perl from a database, run the SQL DROP EXTENSION command. For example, run the following command as the `gpadmin` user to remove support for the trusted PL/Perl language from the database named `testdb`:

```
$ psql -d testdb -c 'DROP EXTENSION plperl;'
```

The default command fails if any existing objects (such as functions) depend on the language. Specify the `CASCADE` option to also drop all dependent objects, including functions that you created with PL/Perl.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Developing Functions with PL/Perl

You define a PL/Perl function using the standard SQL CREATE FUNCTION syntax. The body of a PL/Perl user-defined function is ordinary Perl code. The PL/Perl interpreter wraps this code inside a Perl subroutine.

You can also create an anonymous code block with PL/Perl. An anonymous code block, called with the SQL DO command, receives no arguments, and whatever value it might return is discarded. Otherwise, a PL/Perl anonymous code block behaves just like a function. Only database superusers create an anonymous code block with the untrusted `plperlu` language.

The syntax of the `CREATE FUNCTION` command requires that you write the PL/Perl function body as a string constant. While it is more convenient to use dollar-quoting, you can choose to use escape string syntax `E''`) provided that you double any single quote marks and backslashes used in the body of the function.

PL/Perl arguments and results are handled as they are in Perl. Arguments you pass in to a PL/Perl function are accessed via the `@_` array. You return a result value with the `return` statement, or as the last expression evaluated in the function. A PL/Perl function cannot directly return a non-scalar type because you call it in a scalar context. You can return non-scalar types such as arrays, records, and sets in a PL/Perl function by returning a reference.

PL/Perl treats null argument values as "undefined". Adding the `STRICT` keyword to the `LANGUAGE` subclause instructs WarehousePG to immediately return null when any of the input arguments are null. When created as `STRICT`, the function itself need not perform null checks.

The following PL/Perl function utilizes the `STRICT` keyword to return the greater of two integers, or null if any of the inputs are null:

```
CREATE FUNCTION perl_max (integer, integer) RETURNS integer AS $$
    if ($_[0] > $_[1]) { return $_[0]; }
    return $_[1];
$$ LANGUAGE plperl STRICT;

SELECT perl_max( 1, 3 );
 perl_max
----------
        3
(1 row)

SELECT perl_max( 1, null );
 perl_max
----------

(1 row)
```

PL/Perl considers anything in a function argument that is not a reference to be a string, the standard WarehousePG external text representation. The argument values supplied to a PL/Perl function are simply the input arguments converted to text form (just as if they had been displayed by a `SELECT` statement). In cases where the function argument is not an ordinary numeric or text type, you must convert the WarehousePG type to a form that is more usable by Perl. Conversely, the `return` and `return_next` statements accept any string that is an acceptable input format for the function's declared return type.

Refer to the PostgreSQL PL/Perl Functions and Arguments documentation for additional information, including composite type and result set manipulation.

Built-in PL/Perl Functions

PL/Perl includes built-in functions to access the database, including those to prepare and perform queries and manipulate query results. The language also includes utility functions for error logging and string manipulation.

The following example creates a simple table with an integer and a text column. It creates a PL/Perl user-defined function that takes an input string argument and invokes the `spi_exec_query()` built-in function to select all columns and rows of the table. The function returns all rows in the query results where the `v` column includes the function input string.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
CREATE TABLE test (
    i int,
    v varchar
);
INSERT INTO test (i, v) VALUES (1, 'first line');
INSERT INTO test (i, v) VALUES (2, 'line2');
INSERT INTO test (i, v) VALUES (3, '3rd line');
INSERT INTO test (i, v) VALUES (4, 'different');

CREATE OR REPLACE FUNCTION return_match(varchar) RETURNS SETOF test AS $$
    # store the input argument
    $ss = $_[0];

    # run the query
    my $rv = spi_exec_query('select i, v from test;');

    # retrieve the query status
    my $status = $rv->{status};

    # retrieve the number of rows returned in the query
    my $nrows = $rv->{processed};

    # loop through all rows, comparing column v value with input argument
    foreach my $rn (0 .. $nrows - 1) {
        my $row = $rv->{rows}[$rn];
        my $textstr = $row->{v};
        if( index($textstr, $ss) != -1 ) {
            # match!  return the row.
            return_next($row);
        }
    }
    return undef;
$$ LANGUAGE plperl EXECUTE ON COORDINATOR ;

SELECT return_match( 'iff' );
 return_match
---------------
 (4,different)
(1 row)
```

Refer to the PostgreSQL PL/Perl Built-in Functions documentation for a detailed discussion of available functions.

Global Values in PL/Perl

You can use the global hash map `%_SHARED` to share data, including code references, between PL/Perl function calls for the lifetime of the current session.

The following example uses `%_SHARED` to share data between the user-defined `set_var()` and `get_var()` PL/Perl functions:

```
CREATE OR REPLACE FUNCTION set_var(name text, val text) RETURNS text AS $$
    if ($_SHARED{$_[0]} = $_[1]) {
        return 'ok';
    } else {
        return "cannot set shared variable $_[0] to $_[1]";
    }
$$ LANGUAGE plperl;

CREATE OR REPLACE FUNCTION get_var(name text) RETURNS text AS $$
    return $_SHARED{$_[0]};
$$ LANGUAGE plperl;

SELECT set_var('key1', 'value1');
 set_var
---------
 ok
(1 row)

SELECT get_var('key1');
 get_var
---------
 value1
(1 row)
```

For security reasons, PL/Perl creates a separate Perl interpreter for each role. This prevents accidental or malicious interference by one user with the behavior of another user's PL/Perl functions. Each such interpreter retains its own value of the `%_SHARED` variable and other global state. Two PL/Perl functions share the same value of `%_SHARED` if and only if they are run by the same SQL role.

There are situations where you must take explicit steps to ensure that PL/Perl functions can share data in `%_SHARED`. For example, if an application runs under multiple SQL roles (via `SECURITY DEFINER` functions, use of `SET ROLE`, etc.) in a single session, make sure that functions that need to communicate are owned by the same user, and mark these functions as `SECURITY DEFINER`.

Notes

Additional considerations when developing PL/Perl functions:

- PL/Perl internally utilizes the UTF-8 encoding. It converts any arguments provided in other encodings to UTF-8, and converts return values from UTF-8 back to the original encoding.
- Nesting named PL/Perl subroutines retains the same dangers as in Perl.
- Only the untrusted PL/Perl language variant supports module import. Use `plperlu` with care.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

- Any module that you use in a `plperlu` function must be available from the same location on all WarehousePG hosts.

About Developing PL/Perl Procedures

A PL/Perl procedure is similar to a PL/Perl function. Refer to User-Defined Procedures for more information on procedures in WarehousePG and how they differ from functions.

In a PL/Perl procedure, any return value from the Perl code is ignored.

Output arguments of PL/Perl procedures can be returned as a hash reference:

```
CREATE PROCEDURE perl_triple(INOUT a integer, INOUT b integer) AS
$$
    my ($a, $b) =
@_;
    return {a => $a * 3, b => $b *
3};
$$ LANGUAGE
plperl;

CALL perl_triple(5, 10);
```

`spi_commit()` and `spi_rollback()` can be called only from the top level in a procedure. (Note that it is not possible to run the SQL commands `COMMIT` or `ROLLBACK` via `spi_exec_query()` or similar. Commit and rollback must be done using these functions.) After a transaction is ended, a new transaction is automatically started, so there is no separate function for that.

Here is an example:

```
CREATE PROCEDURE
transaction_test1()
LANGUAGE
plperl
AS $$
foreach my $i (0..9)
{
    spi_exec_query("INSERT INTO tbl1 (a) VALUES
($i)");
    if ($i % 2 == 0)
{
        spi_commit();
    } else
{
        spi_rollback();

}
}
$$;

CALL transaction_test1();
```

4.7.5.3 PL/Python Language

This section contains an overview of the WarehousePG PL/Python Language.

- About WarehousePG PL/Python
- Enabling and Removing PL/Python support
- Developing Functions with PL/Python
- About Developing PL/Python Procedures
- Installing Python Modules
- Examples
- References

About WarehousePG PL/Python

PL/Python is a loadable procedural language. With the WarehousePG PL/Python extensions, you can write WarehousePG user-defined functions and procedures in Python that take advantage of Python features and modules to quickly build robust database applications.

You can run PL/Python code blocks as anonymous code blocks. See the DO command in the *WarehousePG Reference Guide*.

The WarehousePG PL/Python extension is installed by default with WarehousePG. `plpython3u` supports developing functions using Python 3.11. The WarehousePG installation process installs a Python 3.11 environment to your system as one of its dependencies.

WarehousePG PL/Python Limitations

- WarehousePG does not support PL/Python triggers.
- PL/Python is available only as a WarehousePG untrusted language.
- Updatable cursors (`UPDATE...WHERE CURRENT OF` and `DELETE...WHERE CURRENT OF`) are not supported.

Enabling and Removing PL/Python support

The PL/Python language is installed with WarehousePG. To create and run a PL/Python user-defined function (UDF) in a database, you must register the PL/Python language with the database.

Enabling PL/Python Support

For each database that requires its use, register the PL/Python language with the SQL command `CREATE EXTENSION`. Because PL/Python is an untrusted language, only superusers can register PL/Python with a database.

Run this command as the `gpadmin` user to register PL/Python with Python 3.11 support:

```
$ psql -d testdb -c 'CREATE EXTENSION plpython3u;'
```

PL/Python is registered as an untrusted language.

Removing PL/Python Support

Run this command as the `gpadmin` user to remove support for PL/Python for Python 3.11:

```
$ psql -d testdb -c 'DROP EXTENSION plpython3u;'
```

The default command fails if any existing objects (such as functions) depend on the language. Specify the `CASCADE` option to also drop all dependent objects, including functions that you created with PL/Python.

Developing Functions with PL/Python

The body of a PL/Python user-defined function is a Python script. When the function is called, its arguments are passed as elements of the array `args[]`. Named arguments are also passed as ordinary variables to the Python script. The result is returned from the PL/Python function with `return` statement, or `yield` statement in case of a result-set statement. If you do not provide a return value, Python returns the default `None`. PL/Python translates Python's `None` into the SQL null value.

Data Type Mapping

The WarehousePG to Python data type mapping follows.

WarehousePG Primitive Type	Python Data Type
boolean[1]	bool
bytea	bytes
smallint, bigint, oid	int
real, double	float
numeric	decimal
other primitive types	string
SQL null value	None

[1] When the UDF return type is `boolean`, the WarehousePG evaluates the return value for truth according to Python rules. That is, `0` and empty string are `false`, but notably `'f'` is `true`.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Example:

```
CREATE OR REPLACE FUNCTION pybool_func(a int) RETURNS boolean AS $$
    if (a > 0):
        return True
    else:
        return False
$$ LANGUAGE plpython3u;

SELECT pybool_func(-1);

 pybool_func
-------------
 f
(1 row)
```

Arrays and Lists

You pass SQL array values into PL/Python functions with a Python list. Similarly, PL/Python functions return SQL array values as a Python list. In the typical PL/Python usage pattern, you will specify an array with `[]`.

The following example creates a PL/Python function that returns an array of integers:

```
CREATE FUNCTION return_py_int_array()
  RETURNS int[]
AS $$
  return [1, 11, 21, 31]
$$ LANGUAGE plpython3u;

SELECT return_py_int_array();
 return_py_int_array
---------------------
 {1,11,21,31}
(1 row)
```

PL/Python treats multi-dimensional arrays as lists of lists. You pass a multi-dimensional array to a PL/Python function using nested Python lists. When a PL/Python function returns a multi-dimensional array, the inner lists at each level must all be of the same size.

The following example creates a PL/Python function that takes a multi-dimensional array of integers as input. The function displays the type of the provided argument, and returns the multi-dimensional array:

```
CREATE FUNCTION return_multidim_py_array(x int4[])
  RETURNS int4[]
AS $$
  plpy.info(x, type(x))
  return x
$$ LANGUAGE plpython3u;

SELECT * FROM return_multidim_py_array(ARRAY[[1,2,3], [4,5,6]]);
INFO:  ([[1, 2, 3], [4, 5, 6]], <class 'list'>)
CONTEXT:  PL/Python function "return_multidim_py_type"
 return_multidim_py_array
--------------------------
 {{1,2,3},{4,5,6}}
(1 row)
```

PL/Python also accepts other Python sequences, such as tuples, as function arguments for backwards compatibility with WarehousePG versions where multi-dimensional arrays were not supported. In such cases, the Python sequences are always treated as one-dimensional arrays because they are ambiguous with composite types.

Composite Types

You pass composite-type arguments to a PL/Python function using Python mappings. The element names of the mapping are the attribute names of the composite types. If an attribute has the null value, its mapping value is `None`.

You can return a composite type result as a sequence type (tuple or list). You must specify a composite type as a tuple, rather than a list, when it is used in a multi-dimensional array. You cannot return an array of composite types as a list because it would be ambiguous to determine whether the list represents a composite type or another array dimension. In the typical usage pattern, you will specify composite type tuples with `()`.

In the following example, you create a composite type and a PL/Python function that returns an array of the composite type:

```
CREATE TYPE type_record AS (
  first text,
  second int4
);

CREATE FUNCTION composite_type_as_list()
  RETURNS type_record[]
AS $$
  return [[('first', 1), ('second', 1)], [('first', 2), ('second', 2)], [('first', 3), ('second', 3)]];
$$ LANGUAGE plpython3u;

SELECT * FROM composite_type_as_list();
                              composite_type_as_list
-------------------------------------------------------------------------------
 {{"(first,1)","(second,1)"},{"(first,2)","(second,2)"},{"(first,3)","(second,3)"}}
(1 row)
```

Refer to the PostgreSQL Arrays, Lists documentation for additional information on PL/Python handling of arrays and composite types.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Set-Returning Functions

A Python function can return a set of scalar or composite types from any sequence type (for example: tuple, list, set).

In the following example, you create a composite type and a Python function that returns a `SETOF` of the composite type:

```
CREATE TYPE greeting AS (
  how text,
  who text
);

CREATE FUNCTION greet (how text)
  RETURNS SETOF greeting
AS $$
  # return tuple containing lists as composite types
  # all other combinations work also
  return ( {"how": how, "who": "World"}, {"how": how, "who": "WarehousePG"} )
$$ LANGUAGE plpython3u;

select greet('hello');
       greet
-------------------
 (hello,World)
 (hello,WarehousePG)
(2 rows)
```

Running and Preparing SQL Queries

The PL/Python `plpy` module provides two Python functions to run an SQL query and prepare an execution plan for a query, `plpy.execute` and `plpy.prepare`. Preparing the execution plan for a query is useful if you run the query from multiple Python functions.

PL/Python also supports the `plpy.subtransaction()` function to help manage `plpy.execute` calls in an explicit subtransaction. See Explicit Subtransactions in the PostgreSQL documentation for additional information about `plpy.subtransaction()`.

plpy.execute

Calling `plpy.execute` with a query string and an optional limit argument causes the query to be run and the result to be returned in a Python result object. The result object emulates a list or dictionary object. The rows returned in the result object can be accessed by row number and column name. The result set row numbering starts with 0 (zero). The result object can be modified. The result object has these additional methods:

- `nrows` that returns the number of rows returned by the query.
- `status` which is the `SPI_execute()` return value.

For example, this Python statement in a PL/Python user-defined function runs a query.

```
rv = plpy.execute("SELECT * FROM my_table", 5)
```

The `plpy.execute` function returns up to 5 rows from `my_table`. The result set is stored in the `rv` object. If `my_table` has a column `my_column`, it would be accessed as:

```
my_col_data = rv[i]["my_column"]
```

Since the function returns a maximum of 5 rows, the index `i` can be an integer between 0 and 4.

plpy.prepare

The function `plpy.prepare` prepares the execution plan for a query. It is called with a query string and a list of parameter types, if you have parameter references in the query. For example, this statement can be in a PL/Python user-defined function:

```
plan = plpy.prepare("SELECT last_name FROM my_users WHERE
  first_name = $1", [ "text" ])
```

The string `text` is the data type of the variable that is passed for the variable $1. After preparing a statement, you use the function `plpy.execute` to run it:

```
rv = plpy.execute(plan, [ "Fred" ], 5)
```

The third argument is the limit for the number of rows returned and is optional.

When you prepare an execution plan using the PL/Python module the plan is automatically saved. See the Postgres Server Programming Interface (SPI) documentation for information about the execution plans https://www.postgresql.org/docs/12/spi.html.

To make effective use of saved plans across function calls you use one of the Python persistent storage dictionaries `SD` or `GD`.

The global dictionary `SD` is available to store data between function calls. This variable is private static data. The global dictionary `GD` is public data, available to all Python functions within a session. Use GD with care.

Each function gets its own execution environment in the Python interpreter, so that global data and function arguments from `myfunc` are not available to `myfunc2`. The exception is the data in the `GD` dictionary, as mentioned previously.

This example uses the `SD` dictionary:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
CREATE FUNCTION usesavedplan() RETURNS trigger AS $$
  if SD.has_key("plan"):
    plan = SD["plan"]
  else:
    plan = plpy.prepare("SELECT 1")
    SD["plan"] = plan

    # rest of function

$$ LANGUAGE plpython3u;
```

Handling Python Errors and Messages

The Python module `plpy` implements these functions to manage errors and messages:

- `plpy.debug`
- `plpy.log`
- `plpy.info`
- `plpy.notice`
- `plpy.warning`
- `plpy.error`
- `plpy.fatal`
- `plpy.debug`

The message functions `plpy.error` and `plpy.fatal` raise a Python exception which, if uncaught, propagates out to the calling query, causing the current transaction or subtransaction to be cancelled. The functions `raise plpy.ERROR(msg)` and `raise plpy.FATAL(msg)` are equivalent to calling `plpy.error` and `plpy.fatal`, respectively. The other message functions only generate messages of different priority levels.

Whether messages of a particular priority are reported to the client, written to the server log, or both is controlled by the WarehousePG server configuration parameters `log_min_messages` and `client_min_messages`. For information about the parameters see the *WarehousePG Reference Guide*.

Using the dictionary GD To Improve PL/Python Performance

In terms of performance, importing a Python module is an expensive operation and can affect performance. If you are importing the same module frequently, you can use Python global variables to load the module on the first invocation and not require importing the module on subsequent calls. The following PL/Python function uses the GD persistent storage dictionary to avoid importing a module if it has already been imported and is in the GD.

```
CREATE FUNCTION pytest() returns text as $$
  if 'mymodule' not in GD:
    import mymodule
    GD['mymodule'] = mymodule
  return GD['mymodule'].sumd([1,2,3])
$$ LANGUAGE plpython3u;
```

About PL/Python Procedures

A PL/Python procedure is similar to a PL/Python function. Refer to User-Defined Procedures for more information on procedures in WarehousePG and how they differ from functions.

In a PL/Python procedure, the result from the Python code must be `None` (typically achieved by ending the procedure without a `return` statement or by using a `return` statement without argument); otherwise, an error will be raised.

You can pass back output parameters of a PL/Python procedure in the same way that you do for a function. For example:

```
CREATE PROCEDURE python_triple(INOUT a integer, INOUT b integer) AS
$$
return (a * 3, b *
3)
$$ LANGUAGE
plpython3u;

CALL python_triple(5,
10);
```

About Transaction Management in Procedures

In a procedure called from the top level or an anonymous code block (`DO` command) called from the top level it is possible to control transactions. To commit the current transaction, call `plpy.commit()`. To roll back the current transaction, call `plpy.rollback()`. (Note that it is not possible to run the SQL commands `COMMIT` or `ROLLBACK` via `plpy.execute()` or similar. You must commit or rollback using these functions.) After a transaction is ended, a new transaction is automatically started, so there is no separate function for that.

Here is an example:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
CREATE PROCEDURE
transaction_test1()
LANGUAGE plpython3u
AS $$
for i in range(0,
10):
    plpy.execute("INSERT INTO test1 (a) VALUES (%d)" %
i)
    if i % 2 ==
0:
        plpy.commit()
    else:
        plpy.rollback()
$$;

CALL transaction_test1();
```

A transaction cannot be ended when an explicit subtransaction is active.

Installing Python Modules

When you install a Python module for development with PL/Python, the WarehousePG Python environment must have the module added to it across all segment hosts and mirror hosts in the cluster. When expanding WarehousePG, you must add the Python modules to the new segment hosts.

WarehousePG provides a collection of data science-related Python modules that you can use to easily develop PL/Python functions in WarehousePG. See Python Data Science Module Packages for installation instructions and descriptions of the provided modules.

To develop with modules that are not part of the Python Data Science Module packages, you can use WarehousePG utilities such as `gpssh` and `gpsync` to run commands or copy files to all hosts in the WarehousePG cluster. These sections describe how to use those utilities to install and use additional Python modules:

- Verifying the Python Environment
- Installing Python pip
- Installing Python Packages for Python 3.11
- Building and Installing Python Modules Locally
- Testing Installed Python Modules

Verifying the Python Environment

The plpython3u is built with Python 3.11. To check the Python environment, you can use the `which` command:

```
which python3.11
```

When running shell commands on remote hosts with `gpssh`, specify the `-s` option to source the `greenplum_path.sh` file before running commands on the remote hosts. For example, this command should display the Python installed with WarehousePG on each host specified in the `gpdb_hosts` file.

```
gpssh -s -f gpdb_hosts which python3.11
```

To display the list of currently installed Python modules, run this command.

```
python3.11 -c "help('modules')"
```

You can optionally run `gpssh` in interactive mode to display Python modules on remote hosts. This example starts `gpssh` in interactive mode and lists the Python modules on the WarehousePG host `sdw1`.

```
$ gpssh -s -h sdw1
=> python3.11 -c "help('modules')"
. . .
=> exit
$
```

Installing Python pip

The Python utility `pip` installs Python packages that contain Python modules and other resource files from versioned archive files.

For Python 3.11, use:

```
python3.11 -m ensurepip --default-pip
```

The command runs the `ensurepip` module to bootstrap (install and configure) the `pip` utility from the local Python installation.

You can run this command to ensure the `pip`, `setuptools` and `wheel` projects are current. Current Python projects ensure that you can install Python packages from source distributions or pre-built distributions (wheels).

```
python3.11 -m pip install --upgrade pip setuptools wheel
```

You can use `gpssh` to run the commands on the WarehousePG hosts. This example runs `gpssh` in interactive mode to install `pip` on the hosts listed in the file `gpdb_hosts`.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
$ gpssh -s -f gpdb_hosts
=> python3.11 -m ensurepip --default-pip
[centos6-cdw1] Ignoring indexes: https://pypi.python.org/simple
[centos6-cdw1] Collecting setuptools
[centos6-cdw1] Collecting pip
[centos6-cdw1] Installing collected packages: setuptools, pip
[centos6-cdw1] Successfully installed pip-8.1.1 setuptools-20.10.1
[centos6-sdw1] Ignoring indexes: https://pypi.python.org/simple
[centos6-sdw1] Collecting setuptools
[centos6-sdw1] Collecting pip
[centos6-sdw1] Installing collected packages: setuptools, pip
[centos6-sdw1] Successfully installed pip-8.1.1 setuptools-20.10.1
=> exit
$
```

The `=>` is the inactive prompt for `gpssh`. The utility displays the output from each host. The `exit` command exits from `gpssh` interactive mode.

This `gpssh` command runs a single command on all hosts listed in the file `gpdb_hosts`.

```
gpssh -s -f gpdb_hosts python -m pip install --upgrade pip setuptools wheel
```

The utility displays the output from each host.

For more information about installing Python packages, see https://packaging.python.org/tutorials/installing-packages/.

```
python3.11 -m pip install --user numpy scipy
```

The `--user` option attempts to avoid conflicts when installing Python packages.

You can use `gpssh` to run the command on the WarehousePG hosts.

For information about these and other Python packages, see References.

Installing Python Packages to a Non-Standard Location

You can optionally install Python 3.11 modules to a non-standard location by using the `--prefix` option with `pip`. For example:

```
gpssh -s -f gpdb_hosts
=> unset PYTHONHOME
=> unset PYTHONPATH
=> $GPHOME/ext/python3.11 -m pip install --prefix=/home/gpadmin/my_python numpy scipy
```

If you use this option, keep in mind that the `PYTHONPATH` environment variable setting is cleared before initializing or executing functions using `plpython3u`. If you want to use modules installed to a custom location, you must configure the paths to those modules using the WarehousePG configuration parameter `plpython3.python_path` instead of `PYTHONPATH`. For example:

```
$ psql -d testdb
testdb=# SET plpython3.python_path='/home/gpadmin/my_python';
```

WarehousePG uses the value of `plpython3.python_path` to set `PYTHONPATH` in the environment used to create or call `plpython3u` functions.

Ensure that you configure `plpython3.python_path` *before* you create or call `plpython3` functions in a session. If you set or change the parameter after `plpython3u` is initialized you receive the error:

```
ERROR: SET PYTHONPATH failed, the GUC value can only be changed before initializing the python interpreter.
```

To set a default value for the configuration parameter, use `gpconfig` instead:

```
gpconfig -c plpython3.python_path \
    -v "'/home/gpadmin/my_python'" \
    --skipvalidation
gpstop -u
```

Building and Installing Python Modules Locally

If you are building a Python module, you must ensure that the build creates the correct executable. For example on a Linux system, the build should create a 64-bit executable.

Before building a Python module to be installed, ensure that the appropriate software to build the module is installed and properly configured. The build environment is required only on the host where you build the module.

You can use the WarehousePG utilities `gpssh` and `gpsync` to run commands on WarehousePG hosts and to copy files to the hosts.

Testing Installed Python Modules

You can create a simple PL/Python user-defined function (UDF) to validate that Python a module is available in the WarehousePG. This example tests the NumPy module.

This PL/Python UDF imports the NumPy module. The function returns `SUCCESS` if the module is imported, and `FAILURE` if an import error occurs.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
CREATE OR REPLACE FUNCTION plpy_test()
returns text
as $$
  try:
      import numpy
      return 'SUCCESS'
  except ImportError:
      return 'FAILURE'
$$ language plpython3u;
```

This `SELECT` command runs the UDF on the all segments by using `gp_dist_random('gp_id')`;

```
SELECT gp_segment_id, plpy_test() from gp_dist_random('gp_id');
```

The `SELECT` command returns `SUCCESS` if the UDF imported the Python module on the WarehousePG segment instance. If the `SELECT` command returns `FAILURE`, you can find the segment host of the segment instance host. The WarehousePG cluster table `gp_segment_configuration` contains information about mirroring and segment configuration. This command returns the host name for a segment ID.

```
SELECT hostname, content AS seg_ID FROM gp_segment_configuration
  WHERE content = <seg_id> ;
```

If `FAILURE` is returned, these are some possible causes:

- A problem accessing required libraries. For the NumPy example, a WarehousePG might have a problem accessing the OpenBLAS libraries or the Python libraries on a segment host.

  Make sure you get no errors when running command on the segment host as the `gpadmin` user. This `gpssh` command tests importing the numpy module on the segment host `cdw1`.

  ```
  gpssh -s -h cdw1 python3.11 -c "import numpy"
  ```

- The `plpython3.python_path` has not been set to the correct location.

Examples

This PL/Python function example uses Python 3.11 and returns the value of pi using the `numpy` module:

```
CREATE OR REPLACE FUNCTION testpi()
  RETURNS float
AS $$
  import numpy
  return numpy.pi
$$ LANGUAGE plpython3u;
```

Use `SELECT` to call the function:

```
SELECT testpi();
       testpi
------------------
 3.14159265358979
(1 row)
```

This PL/Python UDF returns the maximum of two integers:

```
CREATE FUNCTION pymax (a integer, b integer)
RETURNS integer
AS $$
  if (a is None) or (b is None):
    return None
  if a > b:
    return a
  return b
$$ LANGUAGE plpython3u;
```

You can use the `STRICT` property to perform the null handling instead of using the two conditional statements.

```
CREATE FUNCTION pymax (a integer, b integer)
RETURNS integer AS $$
return max(a,b)
$$ LANGUAGE plpython3u STRICT;
```

You can run the user-defined function `pymax` with `SELECT` command. This example runs the UDF and shows the output.

```
SELECT pymax(123, 43);
column1
---------
     123
(1 row)
```

This example that returns data from an SQL query that is run against a table. These two commands create a simple table and add data to the table.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
CREATE TABLE sales (id int, year int, qtr int, day int, region text)
  DISTRIBUTED BY (id) ;

INSERT INTO sales VALUES
 (1, 2014, 1,1, 'usa'),
 (2, 2002, 2,2, 'europe'),
 (3, 2014, 3,3, 'asia'),
 (4, 2014, 4,4, 'usa'),
 (5, 2014, 1,5, 'europe'),
 (6, 2014, 2,6, 'asia'),
 (7, 2002, 3,7, 'usa') ;
```

This PL/Python UDF runs a `SELECT` command that returns 5 rows from the table. The Python function returns the `REGION` value from the row specified by the input value. In the Python function, the row numbering starts from 0. Valid input for the function is an integer between 0 and 4.

```
CREATE OR REPLACE FUNCTION mypytest(a integer)
  RETURNS setof text
AS $$
  rv = plpy.execute("SELECT * FROM sales ORDER BY id", 5)
  region =[]
  region.append(rv[a]["region"])
  return region
$$ language plpython3u EXECUTE ON COORDINATOR;
```

Running this `SELECT` statement returns the `REGION` column value from the third row of the result set.

```
SELECT mypytest(2) ;
```

This command deletes the UDF from the database.

```
DROP FUNCTION mypytest(integer) ;
```

This example runs the PL/Python function in the previous example as an anonymous block with the `DO` command. In the example, the anonymous block retrieves the input value from a temporary table.

```
CREATE TEMP TABLE mytemp AS VALUES (2) DISTRIBUTED RANDOMLY;
DO $$
  temprow = plpy.execute("SELECT * FROM mytemp", 1)
  myval = temprow[0]["column1"]
  rv = plpy.execute("SELECT * FROM sales ORDER BY id", 5)
  region = rv[myval]["region"]
  plpy.notice("region is %s" % region)
$$ language plpython3u;
```

4.7.5.4 PL/R Language

This chapter contains the following information:

- About WarehousePG PL/R
- Installing R
- Installing PL/R
- Uninstalling PL/R
- Enabling PL/R Language Support
- Examples
- Downloading and Installing R Packages
- Displaying R Library Information
- Loading R Modules at Startup
- References

About WarehousePG PL/R

PL/R is a procedural language. With the WarehousePG PL/R extension you can write database functions in the R programming language and use R packages that contain R functions and data sets.

For information about supported PL/R versions, see the *WarehousePG Release Notes*.

Installing R

For RHEL/Oracle/Rocky, installing the PL/R package installs R in `$GPHOME/ext/R-<version>` and updates `$GPHOME/greenplum_path.sh` for WarehousePG to use R.

> **Note** You can use the gpssh utility to run bash shell commands on multiple remote hosts.

1. To install R, run these `apt` commands on all host systems.

   ```
   $ sudo apt update && sudo apt install r-base
   ```

   Installing `r-base` also installs dependent packages including `r-base-core`.

2. To configure WarehousePG to use R, add the `R_HOME` environment variable to `$GPHOME/greenplum_path.sh` on all hosts. This example command returns the R home directory.

   ```
   $ R RHOME
   /usr/lib/R
   ```

   Using the previous R home directory as an example, add this line to the file on all hosts.

   ```
   export R_HOME=/usr/lib/R
   ```

3. Source `$GPHOME/greenplum_path.sh` and restart WarehousePG. For example, run these commands on the WarehousePG coordinator host.

   ```
   $ source $GPHOME/greenplum_path.sh
   $ gpstop -r
   ```

Installing PL/R

The PL/R extension is available as a package.

Installing the Extension Package

Before you install the PL/R extension, make sure that your WarehousePG is running, you have sourced `greenplum_path.sh`, and that the `$COORDINATOR_DATA_DIRECTORY` and `$GPHOME` variables are set.

1. Download the PL/R extension package.
2. Copy the PL/R package to the WarehousePG coordinator host.
3. Install the software extension package
4. Source the file `$GPHOME/greenplum_path.sh`.
5. Restart WarehousePG.

   ```
   $ gpstop -r
   ```

Enabling PL/R Language Support

For each database that requires its use, register the PL/R language with the SQL command `CREATE EXTENSION`. Because PL/R is an untrusted language, only superusers can register PL/R with a database. For example, run this command as the `gpadmin` user to register the language with the database named `testdb`:

```
$ psql -d testdb -c 'CREATE EXTENSION plr;'
```

PL/R is registered as an untrusted language.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Uninstalling PL/R

- Remove PL/R Support for a Database
- Uninstall R (Ubuntu)

When you remove PL/R language support from a database, the PL/R routines that you created in the database will no longer work.

Remove PL/R Support for a Database

For a database that no longer requires the PL/R language, remove support for PL/R with the SQL command `DROP EXTENSION`. Because PL/R is an untrusted language, only superusers can remove support for the PL/R language from a database. For example, run this command as the `gpadmin` user to remove support for PL/R from the database named `testdb`:

```
$ psql -d testdb -c 'DROP EXTENSION plr;'
```

The default command fails if any existing objects (such as functions) depend on the language. Specify the `CASCADE` option to also drop all dependent objects, including functions that you created with PL/R.

Uninstall R (Ubuntu)

For Ubuntu systems, remove R from all WarehousePG host systems. These commands remove R from an Ubuntu system.

```
$ sudo apt remove r-base
$ sudo apt remove r-base-core
```

Removing `r-base` does not uninstall the R executable. Removing `r-base-core` uninstalls the R executable.

Examples

The following are simple PL/R examples.

Example 1: Using PL/R for single row operators

This function generates an array of numbers with a normal distribution using the R function `rnorm()`.

```
CREATE OR REPLACE FUNCTION r_norm(n integer, mean float8,
  std_dev float8) RETURNS float8[ ] AS
$$
  x<-rnorm(n,mean,std_dev)
  return(x)
$$
LANGUAGE 'plr';
```

The following `CREATE TABLE` command uses the `r_norm()` function to populate the table. The `r_norm()` function creates an array of 10 numbers.

```
CREATE TABLE test_norm_var
        AS SELECT id, r_norm(10,0,1) as x
        FROM (SELECT generate_series(1,30:: bigint) AS ID) foo
        DISTRIBUTED BY (id);
```

Example 2: Returning PL/R data.frames in Tabular Form

Assuming your PL/R function returns an R `data.frame` as its output, unless you want to use arrays of arrays, some work is required to see your `data.frame` from PL/R as a simple SQL table:

- Create a `TYPE` in a WarehousePG with the same dimensions as your R `data.frame:`

  ```
  CREATE TYPE t1 AS ...
  ```

- Use this `TYPE` when defining your PL/R function

  ```
  ... RETURNS SET OF t1 AS ...
  ```

Sample SQL for this is given in the next example.

Example 3: Hierarchical Regression using PL/R

The SQL below defines a `TYPE` and runs hierarchical regression using PL/R:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
--Create TYPE to store model results
DROP TYPE IF EXISTS wj_model_results CASCADE;
CREATE TYPE wj_model_results AS (
  cs text, coefext float, ci_95_lower float, ci_95_upper float,
  ci_90_lower float, ci_90_upper float, ci_80_lower float,
  ci_80_upper float);

--Create PL/R function to run model in R
DROP FUNCTION IF EXISTS wj_plr_RE(float [ ], text [ ]);
CREATE FUNCTION wj_plr_RE(response float [ ], cs text [ ])
RETURNS SETOF wj_model_results AS
$$
  library(arm)
  y<- log(response)
  cs<- cs
  d_temp<- data.frame(y,cs)
  m0 <- lmer (y ~ 1 + (1 | cs), data=d_temp)
  cs_unique<- sort(unique(cs))
  n_cs_unique<- length(cs_unique)
  temp_m0<- data.frame(matrix0,n_cs_unique, 7))
  for (i in 1:n_cs_unique){temp_m0[i,]<-
    c(exp(coef(m0)$cs[i,1] + c(0,-1.96,1.96,-1.65,1.65,
      -1.28,1.28)*se.ranef(m0)$cs[i]))}
  names(temp_m0)<- c("Coefest", "CI_95_Lower",
    "CI_95_Upper", "CI_90_Lower", "CI_90_Upper",
   "CI_80_Lower", "CI_80_Upper")
  temp_m0_v2<- data.frames(cs_unique, temp_m0)
  return(temp_m0_v2)
$$
LANGUAGE 'plr';

--Run modeling plr function and store model results in a
--table
DROP TABLE IF EXISTS wj_model_results_roi;
CREATE TABLE wj_model_results_roi AS SELECT *
  FROM wj_plr_RE('{1,1,1}', '{"a", "b", "c"}');
```

Downloading and Installing R Packages

R packages are modules that contain R functions and data sets. You can install R packages to extend R and PL/R functionality in WarehousePG.

WarehousePG provides a collection of data science-related R libraries that can be used with the WarehousePG PL/R language. For information about the libraries, seeR Data Science Library Package.

> **Note** If you expand WarehousePG and add segment hosts, you must install the R packages in the R installation of the new hosts.

1. For an R package, identify all dependent R packages and each package web URL. The information can be found by selecting the given package from the following navigation page:

   https://cran.r-project.org/web/packages/available_packages_by_name.html

   As an example, the page for the R package arm indicates that the package requires the following R libraries: Matrix, lattice, lme4, R2WinBUGS, coda, abind, foreign, and MASS.

   You can also try installing the package with `R CMD INSTALL` command to determine the dependent packages.

   For the R installation included with the WarehousePG PL/R extension, the required R packages are installed with the PL/R extension. However, the Matrix package requires a newer version.

2. From the command line, use the `wget` utility to download the `tar.gz` files for the arm package to the WarehousePG coordinator host:

   ```
   wget https://cran.r-project.org/src/contrib/Archive/arm/arm_1.5-03.tar.gz
   ```

   ```
   wget https://cran.r-project.org/src/contrib/Archive/Matrix/Matrix_0.9996875-1.tar.gz
   ```

3. Use the gpsync utility and the `hosts_all` file to copy the `tar.gz` files to the same directory on all nodes of the WarehousePG cluster. The `hosts_all` file contains a list of all the WarehousePG segment hosts. You might require root access to do this.

   ```
   gpsync -f hosts_all Matrix_0.9996875-1.tar.gz =:/home/gpadmin
   ```

   ```
   gpsync -f /hosts_all arm_1.5-03.tar.gz =:/home/gpadmin
   ```

4. Use the `gpssh` utility in interactive mode to log into each WarehousePG segment host (`gpssh -f all_hosts`). Install the packages from the command prompt using the `R CMD INSTALL` command. Note that this may require root access. For example, this R install command installs the packages for the arm package.

   ```
   $R_HOME/bin/R CMD INSTALL Matrix_0.9996875-1.tar.gz   arm_1.5-03.tar.gz
   ```

5. Ensure that the package is installed in the `$R_HOME/library` directory on all the segments (the `gpssh` can be used to install the package). For example, this `gpssh` command list the contents of the R library directory.

   ```
   gpssh -s -f all_hosts "ls $R_HOME/library"
   ```

   The `gpssh` option `-s` sources the `greenplum_path.sh` file before running commands on the remote hosts.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

6. Test if the R package can be loaded.

   This function performs a simple test to determine if an R package can be loaded:

   ```
   CREATE OR REPLACE FUNCTION R_test_require(fname text)
   RETURNS boolean AS
   $BODY$
       return(require(fname,character.only=T))
   $BODY$
   LANGUAGE 'plr';
   ```

   This SQL command checks if the R package arm can be loaded:

   ```
   SELECT R_test_require('arm');
   ```

Displaying R Library Information

You can use the R command line to display information about the installed libraries and functions on the WarehousePG host. You can also add and remove libraries from the R installation. To start the R command line on the host, log into the host as the `gadmin` user and run the script R from the directory `$GPHOME/ext/R-3.3.3/bin`.

This R function lists the available R packages from the R command line:

```
> library()
```

Display the documentation for a particular R package

```
> library(help="<package_name>")
> help(package="<package_name>")
```

Display the help file for an R function:

```
> help("<function_name>")
> ?<function_name>
```

To see what packages are installed, use the R command `installed.packages()`. This will return a matrix with a row for each package that has been installed. Below, we look at the first 5 rows of this matrix.

```
> installed.packages()
```

Any package that does not appear in the installed packages matrix must be installed and loaded before its functions can be used.

An R package can be installed with `install.packages()`:

```
> install.packages("<package_name>")
> install.packages("mypkg", dependencies = TRUE, type="source")
```

Load a package from the R command line.

```
> library(" <package_name> ")
```

An R package can be removed with `remove.packages`

```
> remove.packages("<package_name>")
```

You can use the R command `-e` option to run functions from the command line. For example, this command displays help on the R package MASS.

```
$ R -e 'help("MASS")'
```

Loading R Modules at Startup

PL/R can automatically load saved R code during interpreter initialization. To use this feature, you create the `plr_modules` database table and then insert the R modules you want to auto-load into the table. If the table exists, PL/R will load the code it contains into the interpreter.

In a WarehousePG cluster, table rows are usually distributed so that each row exists at only one segment instance. The R interpreter at each segment instance, however, needs to load all of the modules, so a normally distributed table will not work. You must create the `plr_modules` table as a *replicated table* in the default schema so that all rows in the table are present at every segment instance. For example:

```
CREATE TABLE public.plr_modules {
  modseq int4,
  modsrc text
) DISTRIBUTED REPLICATED;
```

See https://www.joeconway.com/plr/doc/plr-module-funcs.html for more information about using the PL/R auto-load feature.

4.7.5.5 PL/pgSQL Language

This section contains an overview of the WarehousePG PL/pgSQL language.

- About WarehousePG PL/pgSQL
- PL/pgSQL Plan Caching
- PL/pgSQL Examples
- About Developing PL/pgSQL Procedures
- References

About WarehousePG PL/pgSQL

WarehousePG PL/pgSQL is a loadable procedural language that is installed and registered by default with WarehousePG. You can create user-defined functions and procedures using SQL statements, functions, and operators.

With PL/pgSQL you can group a block of computation and a series of SQL queries inside the database server, thus having the power of a procedural language and the ease of use of SQL. Also, with PL/pgSQL you can use all the data types, operators and functions of WarehousePG SQL.

The PL/pgSQL language is a subset of Oracle PL/SQL. WarehousePG PL/pgSQL is based on Postgres PL/pgSQL. The Postgres PL/pgSQL documentation is at https://www.postgresql.org/docs/12/plpgsql.html

When using PL/pgSQL functions, function attributes affect how WarehousePG creates query plans. You can specify the attribute `IMMUTABLE`, `STABLE`, or `VOLATILE` as part of the `LANGUAGE` clause to classify the type of function. For information about the creating functions and function attributes, see the CREATE FUNCTION command in the *WarehousePG Reference Guide*.

You can run PL/SQL code blocks as anonymous code blocks. See the DO command in the *WarehousePG Reference Guide*.

WarehousePG SQL Limitations

When using WarehousePG PL/pgSQL, limitations include

- Triggers are not supported
- Cursors are forward moving only (not scrollable)
- Updatable cursors (`UPDATE...WHERE CURRENT OF` and `DELETE...WHERE CURRENT OF`) are not supported.
- Parallel retrieve cursors (`DECLARE...PARALLEL RETRIEVE`) are not supported.

For information about WarehousePG SQL conformance, see Summary of WarehousePG Features in the *WarehousePG Reference Guide*.

The PL/pgSQL Language

PL/pgSQL is a block-structured language. The complete text of a function definition must be a block. A block is defined as:

```
[ <label> ]
[ DECLARE
   declarations ]
BEGIN
   statements
END [ <label> ];
```

Each declaration and each statement within a block is terminated by a semicolon (;). A block that appears within another block must have a semicolon after `END`, as shown in the previous block. The `END` that concludes a function body does not require a semicolon.

A label is required only if you want to identify the block for use in an `EXIT` statement, or to qualify the names of variables declared in the block. If you provide a label after `END`, it must match the label at the block's beginning.

> **Important** Do not confuse the use of the `BEGIN` and `END` keywords for grouping statements in PL/pgSQL with the database commands for transaction control. The PL/pgSQL `BEGIN` and `END` keywords are only for grouping; they do not start or end a transaction. Functions are always run within a transaction established by an outer query — they cannot start or commit that transaction, since there would be no context for them to run in. However, a PL/pgSQL block that contains an `EXCEPTION` clause effectively forms a subtransaction that can be rolled back without affecting the outer transaction. For more about the `EXCEPTION` clause, see the PostgreSQL documentation on trapping errors at https://www.postgresql.org/docs/12/plpgsql-control-structures.html#PLPGSQL-ERROR-TRAPPING.

Keywords are case-insensitive. Identifiers are implicitly converted to lowercase unless double-quoted, just as they are in ordinary SQL commands.

Comments work the same way in PL/pgSQL code as in ordinary SQL:

- A double dash (--) starts a comment that extends to the end of the line.
- A /* starts a block comment that extends to the matching occurrence of */.

  Block comments nest.

Any statement in the statement section of a block can be a subblock. Subblocks can be used for logical grouping or to localize variables to a small group of statements.

Variables declared in a subblock mask any similarly-named variables of outer blocks for the duration of the subblock. You can access the outer variables if you qualify their names with their block's label. For example this function declares a variable named `quantity` several times:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
CREATE FUNCTION testfunc() RETURNS integer AS $$
<< outerblock >>
DECLARE
   quantity integer := 30;
BEGIN
   RAISE NOTICE 'Quantity here is %', quantity;  -- Prints 30
   quantity := 50;
   --
   -- Create a subblock
   --
   DECLARE
      quantity integer := 80;
   BEGIN
      RAISE NOTICE 'Quantity here is %', quantity;  -- Prints 80
      RAISE NOTICE 'Outer quantity here is %', outerblock.quantity;  -- Prints 50
   END;
   RAISE NOTICE 'Quantity here is %', quantity;  -- Prints 50
   RETURN quantity;
END;
$$ LANGUAGE plpgsql;
```

Running SQL Commands

You can run SQL commands with PL/pgSQL statements such as `EXECUTE`, `PERFORM`, and `SELECT ... INTO`. For information about the PL/pgSQL statements, see https://www.postgresql.org/docs/12/plpgsql-statements.html.

> **Note** The PL/pgSQL statement `SELECT INTO` is not supported in the `EXECUTE` statement.

PL/pgSQL Plan Caching

A PL/pgSQL function's volatility classification has implications on how WarehousePG caches plans that reference the function. Refer to Function Volatility and Plan Caching in the *WarehousePG Administrator Guide* for information on plan caching considerations for WarehousePG function volatility categories.

When a PL/pgSQL function runs for the first time in a database session, the PL/pgSQL interpreter parses the function's SQL expressions and commands. The interpreter creates a prepared execution plan as each expression and SQL command is first run in the function. The PL/pgSQL interpreter reuses the execution plan for a specific expression and SQL command for the life of the database connection. While this reuse substantially reduces the total amount of time required to parse and generate plans, errors in a specific expression or command cannot be detected until run time when that part of the function is run.

WarehousePG will automatically re-plan a saved query plan if there is any schema change to any relation used in the query, or if any user-defined function used in the query is redefined. This makes the re-use of a prepared plan transparent in most cases.

The SQL commands that you use in a PL/pgSQL function must refer to the same tables and columns on every execution. You cannot use a parameter as the name of a table or a column in an SQL command.

PL/pgSQL caches a separate query plan for each combination of actual argument types in which you invoke a polymorphic function to ensure that data type differences do not cause unexpected failures.

Refer to the PostgreSQL Plan Caching documentation for a detailed discussion of plan caching considerations in the PL/pgSQL language.

PL/pgSQL Examples

The following are examples of PL/pgSQL user-defined functions.

Example: Aliases for Function Parameters

Parameters passed to functions are named with identifiers such as `$1`, `$2`. Optionally, aliases can be declared for `$n` parameter names for increased readability. Either the alias or the numeric identifier can then be used to refer to the parameter value.

There are two ways to create an alias. The preferred way is to give a name to the parameter in the `CREATE FUNCTION` command, for example:

```
CREATE FUNCTION sales_tax(subtotal real) RETURNS real AS $$
BEGIN
   RETURN subtotal * 0.06;
END;
$$ LANGUAGE plpgsql;
```

You can also explicitly declare an alias, using the declaration syntax:

```
name ALIAS FOR $n;
```

This example, creates the same function with the `DECLARE` syntax.

```
CREATE FUNCTION sales_tax(real) RETURNS real AS $$
DECLARE
    subtotal ALIAS FOR $1;
BEGIN
    RETURN subtotal * 0.06;
END;
$$ LANGUAGE plpgsql;
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Example: Using the Data Type of a Table Column

When declaring a variable, you can use the `%TYPE` construct to specify the data type of a variable or table column. This is the syntax for declaring a variable whose type is the data type of a table column:

```
name table.column_name%TYPE;
```

You can use the `%TYPE` construct to declare variables that will hold database values. For example, suppose you have a column named `user_id` in your `users` table. To declare a variable named `my_userid` with the same data type as the `users.user_id` column:

```
my_userid users.user_id%TYPE;
```

`%TYPE` is particularly valuable in polymorphic functions, since the data types needed for internal variables may change from one call to the next. Appropriate variables can be created by applying `%TYPE` to the function's arguments or result placeholders.

Example: Composite Type Based on a Table Row

A variable of a composite type is called a row variable. The following syntax declares a composite variable based on table row:

```
name table_name%ROWTYPE;
```

Such a row variable can hold a whole row of a `SELECT` or `FOR` query result, so long as that query's column set matches the declared type of the variable. The individual fields of the row value are accessed using the usual dot notation, for example `rowvar.column`.

Parameters to a function can be composite types (complete table rows). In that case, the corresponding identifier `$n` will be a row variable, and fields can be selected from it, for `example $1.user_id`.

Only the user-defined columns of a table row are accessible in a row-type variable, not the OID or other system columns. The fields of the row type inherit the table's field size or precision for data types such as `char(n)`.

The next example function uses a row variable composite type. Before creating the function, create the table that is used by the function with this command.

```
CREATE TABLE table1 (
  f1 text,
  f2 numeric,
  f3 integer
) distributed by (f1);
```

This `INSERT` command adds data to the table.

```
INSERT INTO table1 values
 ('test1', 14.1, 3),
 ('test2', 52.5, 2),
 ('test3', 32.22, 6),
 ('test4', 12.1, 4) ;
```

This function uses a column `%TYPE` variable and `%ROWTYPE` composite variable based on `table1`.

```
CREATE OR REPLACE FUNCTION t1_calc( name text) RETURNS integer
AS $$
DECLARE
    t1_row   table1%ROWTYPE;
    calc_int table1.f3%TYPE;
BEGIN
    SELECT * INTO t1_row FROM table1 WHERE table1.f1 = $1 ;
    calc_int = (t1_row.f2 * t1_row.f3)::integer ;
    RETURN calc_int ;
END;
$$ LANGUAGE plpgsql VOLATILE;
```

> **Note** The previous function is classified as a `VOLATILE` function because function values could change within a single table scan.

The following `SELECT` command uses the function.

```
select t1_calc( 'test1' );
```

> **Note** The example PL/pgSQL function uses `SELECT` with the `INTO` clause. It is different from the SQL command `SELECT INTO`. If you want to create a table from a `SELECT` result inside a PL/pgSQL function, use the SQL command `CREATE TABLE AS`.

Example: Using a Variable Number of Arguments

You can declare a PL/pgSQL function to accept variable numbers of arguments, as long as all of the optional arguments are of the same data type. You must mark the last argument of the function as `VARIADIC` and declare the argument using an array type. You can refer to a function that includes `VARIADIC` arguments as a variadic function.

For example, this variadic function returns the minimum value of a variable array of numerics:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
CREATE FUNCTION mleast (VARIADIC numeric[])
    RETURNS numeric AS $$
  DECLARE minval numeric;
  BEGIN
    SELECT min($1[i]) FROM generate_subscripts( $1, 1) g(i) INTO minval;
    RETURN minval;
END;
$$ LANGUAGE plpgsql;
CREATE FUNCTION

SELECT mleast(10, -1, 5, 4.4);
 mleast
--------
     -1
(1 row)
```

Effectively, all of the actual arguments at or beyond the `VARIADIC` position are gathered up into a one-dimensional array.

You can pass an already-constructed array into a variadic function. This is particularly useful when you want to pass arrays between variadic functions. Specify `VARIADIC` in the function call as follows:

```
SELECT mleast(VARIADIC ARRAY[10, -1, 5, 4.4]);
```

This prevents PL/pgSQL from expanding the function's variadic parameter into its element type.

Example: Using Default Argument Values

You can declare PL/pgSQL functions with default values for some or all input arguments. The default values are inserted whenever the function is called with fewer than the declared number of arguments. Because arguments can only be omitted from the end of the actual argument list, you must provide default values for all arguments after an argument defined with a default value.

For example:

```
CREATE FUNCTION use_default_args(a int, b int DEFAULT 2, c int DEFAULT 3)
    RETURNS int AS $$
DECLARE
    sum int;
BEGIN
    sum := $1 + $2 + $3;
    RETURN sum;
END;
$$ LANGUAGE plpgsql;

SELECT use_default_args(10, 20, 30);
 use_default_args
------------------
               60
(1 row)

SELECT use_default_args(10, 20);
 use_default_args
------------------
               33
(1 row)

SELECT use_default_args(10);
 use_default_args
------------------
               15
(1 row)
```

You can also use the `=` sign in place of the keyword `DEFAULT`.

Example: Using Polymorphic Data Types

PL/pgSQL supports the polymorphic *anyelement*, *anyarray*, *anyenum*, and *anynonarray* types. Using these types, you can create a single PL/pgSQL function that operates on multiple data types. Refer toWarehousePG Data Types for additional information on polymorphic type support in WarehousePG.

A special parameter named `$0` is created when the return type of a PL/pgSQL function is declared as a polymorphic type. The data type of `$0` identifies the return type of the function as deduced from the actual input types.

In this example, you create a polymorphic function that returns the sum of two values:

```
CREATE FUNCTION add_two_values(v1 anyelement,v2 anyelement)
    RETURNS anyelement AS $$
DECLARE
    sum ALIAS FOR $0;
BEGIN
    sum := v1 + v2;
    RETURN sum;
END;
$$ LANGUAGE plpgsql;
```

Run `add_two_values()` providing integer input values:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
SELECT add_two_values(1, 2);
 add_two_values
----------------
              3
(1 row)
```

The return type of `add_two_values()` is integer, the type of the input arguments. Now execute `add_two_values()` providing float input values:

```
SELECT add_two_values (1.1, 2.2);
 add_two_values
----------------
            3.3
(1 row)
```

The return type of `add_two_values()` in this case is float.

You can also specify `VARIADIC` arguments in polymorphic functions.

Example: Anonymous Block

This example runs the statements in the `t1_calc()` function from a previous example as an anonymous block using the `DO` command. In the example, the anonymous block retrieves the input value from a temporary table.

```
CREATE TEMP TABLE list AS VALUES ('test1') DISTRIBUTED RANDOMLY;

DO $$
DECLARE
    t1_row   table1%ROWTYPE;
    calc_int table1.f3%TYPE;
BEGIN
    SELECT * INTO t1_row FROM table1, list WHERE table1.f1 = list.column1 ;
    calc_int = (t1_row.f2 * t1_row.f3)::integer ;
    RAISE NOTICE 'calculated value is %', calc_int ;
END $$ LANGUAGE plpgsql ;
```

About Developing PL/pgSQL Procedures

A PL/pgSQL procedure is similar to a PL/pgSQL function. Refer to User-Defined Procedures for more information on procedures in WarehousePG and how they differ from functions.

A PL/pgSQL procedure does not have a return value, and as such can end without a `RETURN` statement. If you wish to use a `RETURN` statement to exit the code early, write just `RETURN` with no expression.

If the PL/pgSQL procedure has output parameters, the final values of the output parameter variables will be returned to the caller.

A PL/pgSQL function, procedure, or `DO` block can call a procedure using `CALL`. Output parameters are handled differently from the way that `CALL` works in plain SQL. Each `INOUT` parameter of the procedure must correspond to a variable in the `CALL` statement, and whatever the procedure returns is assigned back to that variable after it returns. For example:

```
CREATE PROCEDURE triple(INOUT x
int)
LANGUAGE plpgsql
AS $$
BEGIN
    x := x *
3;
END;
$$;

DO $$
DECLARE myvar int := 5;
BEGIN
  CALL
triple(myvar);
  RAISE NOTICE 'myvar = %', myvar;  -- prints
15
END;
$$;
```

About Transaction Management in Procedures

In procedures invoked by the `CALL` command as well as in anonymous code blocks (`DO` command), it is possible to end transactions using the commands `COMMIT` and `ROLLBACK`. A new transaction is started automatically after a transaction is ended using these commands, so there is no separate `START TRANSACTION` command. (Note that `BEGIN` and `END` have different meanings in PL/pgSQL.)

Here is a simple example:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
CREATE PROCEDURE
transaction_test1()
LANGUAGE plpgsql
AS $$
BEGIN
    FOR i IN 0..9
LOOP
        INSERT INTO test1 (a) VALUES
(i);
        IF i % 2 = 0
THEN
            COMMIT;
        ELSE
            ROLLBACK;
        END IF;
    END LOOP;
END;
$$;

CALL transaction_test1();
```

A new transaction starts out with default transaction characteristics such as transaction isolation level. In cases where transactions are committed in a loop, it might be desirable to start new transactions automatically with the same characteristics as the previous one. The commands COMMIT AND CHAIN and ROLLBACK AND CHAIN accomplish this.

Transaction control is only possible in `CALL` or `DO` invocations from the top level or nested `CALL` or `DO` invocations without any other intervening command. For example, if the call stack is `CALL proc1()` → `CALL proc2()` → `CALL proc3()`, then the second and third procedures can perform transaction control actions. But if the call stack is `CALL proc1()` → `SELECT func2()` → `CALL proc3()`, the last procedure cannot perform transaction control because of the `SELECT` in between.

4.8 Working with External Data

Both external and foreign tables provide access to data stored in data sources outside of WarehousePG as if the data were stored in regular database tables. You can read data from and write data to external and foreign tables.

> **Important** WarehousePG 7 internally converts external tables to foreign tables, and internally operates on and represents the table using the foreign table data structures and catalog. Refer toUnderstanding the External Table to Foreign Table Mapping for detailed information about this conversion, and its runtime implications.

Parent topic: WarehousePG Administrator Guide

About Foreign Tables

A foreign table is a WarehousePG table backed with data that resides outside of the database. Foreign tables are often used to load and unload database data. You can both read from and write to the same foreign table. You can use foreign tables in SQL commands just as you would a regular database table. For example, you can `SELECT`, `INSERT`, and `JOIN` foreign tables with other WarehousePG tables.

Refer to Accessing External Data with Foreign Tables for more information about accessing external data using foreign tables.

About External Tables

An external table is different kind of WarehousePG table backed with data that resides outside of the database. External tables are often used to load and unload database data. You create a readable external table to read data from the external data source and create a writable external table to write data to the external source. You can use external tables in SQL commands just as you would a regular database table. For example, you can `SELECT` (readable external table), `INSERT` (writable external table), and `JOIN` external tables with other WarehousePG tables.

Refer to Acessing External Data with External Tables for more information about using external tables to access external data.

About gpfdist External Tables

You can use the `gpfdist` file server utility and external tables to serve up external data to WarehousePG. When external data is served by `gpfdist`, all segments in the WarehousePG cluster can read or write external table data in parallel. Refer to Using the WarehousePG Parallel File Server (gpfdist) for more information.

About Web-Based External Tables

Web-based external tables provide access to data served by an HTTP server or an operating system process. See Creating and Using External Web Tables for more about web-based tables.

About Accessing External Data with pxf

Data managed by your organization may already reside in external sources such as Hadoop, object stores, and other SQL databases. The WarehousePG Platform Extension Framework (PXF) provides access to this external data via built-in connectors that map an external data source to a WarehousePG table definition. Refer to Accessing External Data with PXF for more information about using PXF.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.8.1 Accessing External Data with Foreign Tables

WarehousePG implements portions of the SQL/MED specification, allowing you to access data that resides outside of WarehousePG using regular SQL queries. Such data is referred to as *foreign* or external data.

You can access foreign data with help from a *foreign-data wrapper*. A foreign-data wrapper is a library that communicates with a remote data source. This library hides the source-specific connection and data access details.

The WarehousePG distribution includes the postgres_fdw foreign data wrapper. You can also download and install the EDB-provided module whpg_fdw.

If none of the existing PostgreSQL or WarehousePG foreign-data wrappers suit your needs, you can write your own as described in Writing a Foreign Data Wrapper.

To access foreign data, you create a *foreign server* object, which defines how to connect to a particular remote data source according to the set of options used by its supporting foreign-data wrapper. Then you create one or more *foreign tables*, which define the structure of the remote data. A foreign table can be used in queries just like a normal table, but a foreign table has no storage in the WarehousePG server. Whenever a foreign table is accessed, WarehousePG asks the foreign-data wrapper to fetch data from, or update data in (if supported by the wrapper), the remote source.

Accessing remote data may require authenticating to the remote data source. This information can be provided by a *user mapping*, which can provide additional data such as a user name and password based on the current WarehousePG role.

For additional information, refer to the CREATE FOREIGN DATA WRAPPER, CREATE SERVER, CREATE USER MAPPING, and CREATE FOREIGN TABLE SQL reference pages.

Using Foreign-Data Wrappers with WarehousePG

Most PostgreSQL foreign-data wrappers should work with WarehousePG. However, PostgreSQL foreign-data wrappers connect only through the WarehousePG coordinator by default and do not access the WarehousePG segment instances directly.

WarehousePG adds an `mpp_execute` option to FDW-related SQL commands. If the foreign-data wrapper supports it, you can specify `mpp_execute '<value>'` in the `OPTIONS` clause when you create the FDW, server, or foreign table to identify the WarehousePG host from which the foreign-data wrapper reads or writes data. Valid `<value>` s are:

- `coordinator` (the default) - Read or write data from the coordinator host.
- `any` - Read data from either the coordinator host or any one segment, depending on which path costs less.
- `all segments` - Read or write data from all segments. If a foreign-data wrapper supports this value, for correct results it should have a policy that matches segments to data.

(A PostgreSQL foreign-data wrapper may work with the various `mpp_execute` option settings, but the results are not guaranteed to be correct. For example, a segment may not be able to connect to the foriegn server, or segments may receive overlapping results resulting in duplicate rows.)

Parent topic: Working with External Data

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.8.1.1 Writing a Foreign Data Wrapper

This chapter outlines how to write a new foreign-data wrapper.

All operations on a foreign table are handled through its foreign-data wrapper (FDW), a library that consists of a set of functions that the core WarehousePG server calls. The foreign-data wrapper is responsible for fetching data from the remote data store and returning it to the WarehousePG executor. If updating foreign-data is supported, the wrapper must handle that, too.

The foreign-data wrappers included in the WarehousePG open source github repository are good references when trying to write your own. You may want to examine the source code for thefile_fdw and postgres_fdw modules in the `contrib/` directory. The CREATE FOREIGN DATA WRAPPER reference page also provides some useful details.

> **Note** The SQL standard specifies an interface for writing foreign-data wrappers. WarehousePG does not implement that API, however, because the effort to accommodate it into WarehousePG would be large, and the standard API hasn't yet gained wide adoption.

Parent topic: Accessing External Data with Foreign Tables

Requirements

When you develop with the WarehousePG foreign-data wrapper API:

- You must develop your code on a system with the same hardware and software architecture as that of your WarehousePG hosts.
- Your code must be written in a compiled language such as C, using the version-1 interface. For details on C language calling conventions and dynamic loading, refer toC Language Functions in the PostgreSQL documentation.
- Symbol names in your object files must not conflict with each other nor with symbols defined in the WarehousePG server. You must rename your functions or variables if you get error messages to this effect.
- Review the foreign table introduction described in Accessing External Data with Foreign Tables.

Known Issues and Limitations

The WarehousePG 7 foreign-data wrapper implementation has the following known issues and limitations:

- WarehousePG supports all values of the `mpp_execute` option value for foreign table scans only. WarehousePG supports parallel write operations only when `mpp_execute` is set to `'all segments'`; WarehousePG initiates write operations through the coordinator for all other `mpp_execute` settings. See WarehousePG Considerations.

Header Files

The WarehousePG header files that you may use when you develop a foreign-data wrapper are located in the `gpdb/src/include/` directory (when developing against the WarehousePG open source github repository), or installed in the `$GPHOME/include/postgresql/server/` directory (when developing against a WarehousePG installation):

- `foreign/fdwapi.h` - FDW API structures and callback function signatures
- `foreign/foreign.h` - foreign-data wrapper helper structs and functions
- `catalog/pg_foreign_table.h` - foreign table definition
- `catalog/pg_foreign_server.h` - foreign server definition

Your FDW code may also be dependent on header files and libraries required to access the remote data store.

Foreign Data Wrapper Functions

The developer of a foreign-data wrapper must implement an SQL-invokable *handler* function, and optionally an SQL-invokable *validator* function. Both functions must be written in a compiled language such as C, using the version-1 interface.

The *handler* function simply returns a struct of function pointers to callback functions that will be called by the WarehousePG planner, executor, and various maintenance commands. The *handler* function must be registered with WarehousePG as taking no arguments and returning the special pseudo-type `fdw_handler`. For example:

```
CREATE FUNCTION NEW_fdw_handler()
  RETURNS fdw_handler
  AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;
```

Most of the effort in writing a foreign-data wrapper is in implementing the callback functions. The FDW API callback functions, plain C functions that are not visible or callable at the SQL level, are described inForeign Data Wrapper Callback Functions.

The *validator* function is responsible for validating options provided in `CREATE` and `ALTER` commands for its foreign-data wrapper, as well as foreign servers, user mappings, and foreign tables using the wrapper. The*validator* function must be registered as taking two arguments, a text array containing the options to be validated, and an OID representing the type of object with which the options are associated. For example:

```
CREATE FUNCTION NEW_fdw_validator( text[], oid )
  RETURNS void
  AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;
```

The OID argument reflects the type of the system catalog that the object would be stored in, one of `ForeignDataWrapperRelationId`, `ForeignServerRelationId`, `UserMappingRelationId`, or `ForeignTableRelationId`. If no *validator* function is supplied by a foreign data wrapper, WarehousePG does not check option validity at object creation time or object alteration time.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Foreign Data Wrapper Callback Functions

The foreign-data wrapper API defines callback functions that WarehousePG invokes when scanning and updating foreign tables. The API also includes callbacks for performing explain and analyze operations on a foreign table.

The *handler* function of a foreign-data wrapper returns a `palloc`'d `FdwRoutine` struct containing pointers to callback functions described below. The `FdwRoutine` struct is located in the `foreign/fdwapi.h` header file, and is defined as follows:

```
/*
 * FdwRoutine is the struct returned by a foreign-data wrapper's handler
 * function.  It provides pointers to the callback functions needed by the
 * planner and executor.
 *
 * More function pointers are likely to be added in the future.  Therefore
 * it's recommended that the handler initialize the struct with
 * makeNode(FdwRoutine) so that all fields are set to NULL.  This will
 * ensure that no fields are accidentally left undefined.
 */
typedef struct FdwRoutine
{
    NodeTag     type;

    /* Functions for scanning foreign tables */
    GetForeignRelSize_function GetForeignRelSize;
    GetForeignPaths_function GetForeignPaths;
    GetForeignPlan_function GetForeignPlan;
    BeginForeignScan_function BeginForeignScan;
    IterateForeignScan_function IterateForeignScan;
    ReScanForeignScan_function ReScanForeignScan;
    EndForeignScan_function EndForeignScan;

    /*
     * Remaining functions are optional.  Set the pointer to NULL for any that
     * are not provided.
     */

    /* Functions for updating foreign tables */
    AddForeignUpdateTargets_function AddForeignUpdateTargets;
    PlanForeignModify_function PlanForeignModify;
    BeginForeignModify_function BeginForeignModify;
    ExecForeignInsert_function ExecForeignInsert;
    ExecForeignUpdate_function ExecForeignUpdate;
    ExecForeignDelete_function ExecForeignDelete;
    EndForeignModify_function EndForeignModify;
    IsForeignRelUpdatable_function IsForeignRelUpdatable;

    /* Support functions for EXPLAIN */
    ExplainForeignScan_function ExplainForeignScan;
    ExplainForeignModify_function ExplainForeignModify;

    /* Support functions for ANALYZE */
    AnalyzeForeignTable_function AnalyzeForeignTable;
} FdwRoutine;
```

You must implement the scan-related functions in your foreign-data wrapper; implementing the other callback functions is optional.

Scan-related callback functions include:

Callback Signature	Description
`void GetForeignRelSize (PlannerInfo *root, RelOptInfo *baserel, Oid foreigntableid)`	Obtain relation size estimates for a foreign table. Called at the beginning of planning for a query on a foreign table.
`void GetForeignPaths (PlannerInfo *root, RelOptInfo *baserel, Oid foreigntableid)`	Create possible access paths for a scan on a foreign table. Called during query planning. Note: A WarehousePG Database-compatible FDW must call `create_foreignscan_path()` in its `GetForeignPaths()` callback function.
`ForeignScan * GetForeignPlan (PlannerInfo *root, RelOptInfo *baserel, Oid foreigntableid, ForeignPath *best_path, List *tlist, List *scan_clauses)`	Create a `ForeignScan` plan node from the selected foreign access path. Called at the end of query planning.
`void BeginForeignScan (ForeignScanState *node, int eflags)`	Begin running a foreign scan. Called during executor startup.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Callback Signature	Description
`TupleTableSlot * IterateForeignScan (ForeignScanState *node)`	Fetch one row from the foreign source, returning it in a tuple table slot; return NULL if no more rows are available.
`void ReScanForeignScan (ForeignScanState *node)`	Restart the scan from the beginning.
`void EndForeignScan (ForeignScanState *node)`	End the scan and release resources.

If a foreign data wrapper supports writable foreign tables, it should provide the update-related callback functions that are required by the capabilities of the FDW. Update-related callback functions include:

Callback Signature	Description
`void AddForeignUpdateTargets (Query *parsetree, RangeTblEntry *target_rte, Relation target_relation)`	Add additional information in the foreign table that will be retrieved during an update or delete operation to identify the exact row on which to operate.
`List * PlanForeignModify (PlannerInfo *root, ModifyTable *plan, Index resultRelation, int subplan_index)`	Perform additional planning actions required for an insert, update, or delete operation on a foreign table, and return the information generated.
`void BeginForeignModify (ModifyTableState *mtstate, ResultRelInfo *rinfo, List *fdw_private, int subplan_index, int eflags)`	Begin executing a modify operation on a foreign table. Called during executor startup.
`TupleTableSlot * ExecForeignInsert (EState *estate, ResultRelInfo *rinfo, TupleTableSlot *slot, TupleTableSlot *planSlot)`	Insert a single tuple into the foreign table. Return a slot containing the data that was actually inserted, or NULL if no row was inserted.
`TupleTableSlot * ExecForeignUpdate (EState *estate, ResultRelInfo *rinfo, TupleTableSlot *slot, TupleTableSlot *planSlot)`	Update a single tuple in the foreign table. Return a slot containing the row as it was actually updated, or NULL if no row was updated.
`TupleTableSlot * ExecForeignDelete (EState *estate, ResultRelInfo *rinfo, TupleTableSlot *slot, TupleTableSlot *planSlot)`	Delete a single tuple from the foreign table. Return a slot containing the row that was deleted, or NULL if no row was deleted.
`void EndForeignModify (EState *estate, ResultRelInfo *rinfo)`	End the update and release resources.
`int IsForeignRelUpdatable (Relation rel)`	Report the update operations supported by the specified foreign table.

Refer to Foreign Data Wrapper Callback Routines in the PostgreSQL documentation for detailed information about the inputs and outputs of the FDW callback functions.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Foreign Data Wrapper Helper Functions

The FDW API exports several helper functions from the WarehousePG core server so that authors of foreign-data wrappers have easy access to attributes of FDW-related objects, such as options provided when the user creates or alters the foreign-data wrapper, server, or foreign table. To use these helper functions, you must include `foreign.h` header file in your source file:

```
#include "foreign/foreign.h"
```

The FDW API includes the helper functions listed in the table below. Refer to Foreign Data Wrapper Helper Functions in the PostgreSQL documentation for more information about these functions.

Helper Signature	Description
`ForeignDataWrapper * GetForeignDataWrapper(Oid fdwid);`	Returns the `ForeignDataWrapper` object for the foreign-data wrapper with the given OID.
`ForeignDataWrapper * GetForeignDataWrapperByName(const char *name, bool missing_ok);`	Returns the `ForeignDataWrapper` object for the foreign-data wrapper with the given name.
`ForeignServer * GetForeignServer(Oid serverid);`	Returns the `ForeignServer` object for the foreign server with the given OID.
`ForeignServer * GetForeignServerByName(const char *name, bool missing_ok);`	Returns the `ForeignServer` object for the foreign server with the given name.
`UserMapping * GetUserMapping(Oid userid, Oid serverid);`	Returns the `UserMapping` object for the user mapping of the given role on the given server.
`ForeignTable * GetForeignTable(Oid relid);`	Returns the `ForeignTable` object for the foreign table with the given OID.
`List * GetForeignColumnOptions(Oid relid, AttrNumber attnum);`	Returns the per-column FDW options for the column with the given foreign table OID and attribute number.

WarehousePG Considerations

A WarehousePG user can specify the `mpp_execute` option when they create or alter a foreign table, foreign server, or foreign data wrapper. A WarehousePG-compatible foreign-data wrapper examines the `mpp_execute` option value and uses it to determine where to request or send data - from the `coordinator` (the default), `any` (coordinator or any one segment), or `all segments` (parallel read/write).

WarehousePG supports all `mpp_execute` settings for a scan.

WarehousePG supports parallel write when `mpp_execute 'all segments"` is set. For all other `mpp_execute` settings, WarehousePG executes write/update operations initiated by a foreign data wrapper on the WarehousePG coordinator node.

> **Note** When `mpp_execute 'all segments'` is set, WarehousePG creates the foreign table with a random partition policy. This enables a foreign data wrapper to write to a foreign table from all segments.

The following scan code snippet probes the `mpp_execute` value associated with a foreign table:

```
ForeignTable *table = GetForeignTable(foreigntableid);
if (table->exec_location == FTEXECLOCATION_ALL_SEGMENTS)
{
    ...
}
else if (table->exec_location == FTEXECLOCATION_ANY)
{
    ...
}
else if (table->exec_location == FTEXECLOCATION_COORDINATOR)
{
    ...
}
```

If the foreign table was not created with an `mpp_execute` option setting, the `mpp_execute` setting of the foreign server, and then the foreign data wrapper, is probed and used. If none of the foreign-data-related objects has an `mpp_execute` setting, the default setting is `coordinator`.

If a foreign-data wrapper supports `mpp_execute 'all'`, it will implement a policy that matches WarehousePG segments to data. So as not to duplicate data retrieved from the remote, the FDW on each segment must be able to establish which portion of the data is their responsibility. An FDW may use the segment identifier and the number of segments to help make this determination. The following code snippet demonstrates how a foreign-data wrapper may retrieve the segment number and total number of segments:

```
int segmentNumber = GpIdentity.segindex;
int totalNumberOfSegments = getgpsegmentCount();
```

Building a Foreign Data Wrapper Extension with PGXS

You compile the foreign-data wrapper functions that you write with the FDW API into one or more shared libraries that the WarehousePG server loads on demand.

You can use the PostgreSQL build extension infrastructure (PGXS) to build the source code for your foreign-data wrapper against a WarehousePG installation. This framework automates common build rules for simple modules. If you have a more complicated use case, you will need to write your own build system.

To use the PGXS infrastructure to generate a shared library for your FDW, create a simple `Makefile` that sets PGXS-specific variables.

> **Note** Refer to Extension Building Infrastructure in the PostgreSQL documentation for information about the `Makefile` variables supported by PGXS.

For example, the following `Makefile` generates a shared library in the current working directory named `base_fdw.so` from two C source files, base_fdw_1.c and base_fdw_2.c:

```
MODULE_big = base_fdw
OBJS = base_fdw_1.o base_fdw_2.o

PG_CONFIG = pg_config
PGXS := $(shell $(PG_CONFIG) --pgxs)

PG_CPPFLAGS = -I$(shell $(PG_CONFIG) --includedir)
SHLIB_LINK = -L$(shell $(PG_CONFIG) --libdir)
include $(PGXS)
```

A description of the directives used in this `Makefile` follows:

- `MODULE_big` - identifes the base name of the shared library generated by the `Makefile`
- `PG_CPPFLAGS` - adds the WarehousePG installation `include/` directory to the compiler header file search path
- `SHLIB_LINK` adds the WarehousePG installation library directory (`$GPHOME/lib/`) to the linker search path
- The `PG_CONFIG` and `PGXS` variable settings and the `include` statement are required and typically reside in the last three lines of the `Makefile` .

To package the foreign-data wrapper as a WarehousePG extension, you create script (`newfdw--version.sql`) and control (`newfdw.control`) files that register the FDW *handler* and *validator* functions, create the foreign data wrapper, and identify the characteristics of the FDW shared library file.

> **Note** Packaging Related Objects into an Extension in the PostgreSQL documentation describes how to package an extension.

Example foreign-data wrapper extension script file named `base_fdw--1.0.sql` :

```
CREATE FUNCTION base_fdw_handler()
  RETURNS fdw_handler
  AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;

CREATE FUNCTION base_fdw_validator(text[], oid)
  RETURNS void
  AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;

CREATE FOREIGN DATA WRAPPER base_fdw
  HANDLER base_fdw_handler
  VALIDATOR base_fdw_validator;
```

Example FDW control file named `base_fdw.control` :

```
# base_fdw FDW extension
comment = 'base foreign-data wrapper implementation; does not do much'
default_version = '1.0'
module_pathname = '$libdir/base_fdw'
relocatable = true
```

When you add the following directives to the `Makefile` , you identify the FDW extension control file base name (`EXTENSION`) and SQL script (`DATA`):

```
EXTENSION = base_fdw
DATA = base_fdw--1.0.sql
```

Running `make install` with these directives in the `Makefile` copies the shared library and FDW SQL and control files into the specified or default locations in your WarehousePG installation (`$GPHOME`).

Deployment Considerations

You must package the FDW shared library and extension files in a form suitable for deployment in a WarehousePG cluster. When you construct and deploy the package, take into consideration the following:

- The FDW shared library must be installed to the same file system location on the coordinator host and on every segment host in the WarehousePG cluster. You specify this location in the `.control` file. This location is typically the `$GPHOME/lib/postgresql/` directory.
- The FDW `.sql` and `.control` files must be installed to the `$GPHOME/share/postgresql/extension/` directory on the coordinator host and on every segment host in the WarehousePG cluster.
- The `gpadmin` user must have permission to traverse the complete file system path to the FDW shared library file and extension files.

4.8.2 Accessing External Data with External Tables

examples originalFilePath: >- https://github.com/warehouse-pg/whpg-docs/blob/main/docs/docs/7x/admin_guide/external/external-tables/index.md editTarget: originalFilePath

External tables enable you to access external data as if it were a regular database table. They are often used to move data into and out of a WarehousePG, and can utilize WarehousePG parallelism by using the resources of all WarehousePG segments to load or unload data.

When you create an external table definition, you specify the structure and format of the data, the data access *protocol*, the location of the external data source, and other protocol-specific or format-specific options.

> **Important** WarehousePG 7 internally converts external tables to foreign tables, and internally operates on and represents the table using the foreign table data structures and catalog. Refer to Understanding the External Table to Foreign Table Mapping for detailed information about this conversion, and its runtime implications.

Parent topic: Working with External Data

About the External Table Data Access Protocols

An external table protocol identifies the data access method for an external data source. WarehousePG supports the following built-in (automatically-enabled) and opt-in (you enable) external table protocols:

Protocol Name	Description	Type
`file://`	Use to access external data files on segment hosts that the WarehousePG superuser (`gpadmin`) can access. Refer to file:// Protocol.	Built-in
`gpfdist://`	Use to serve external data files to all WarehousePG segments in parallel. See gpfdist:// Protocol.	Built-in
`gpfdists://`	The secure version of `gpfdist` . See gpfdists:// Protocol.	Built-in
`pxf://`	Use to access external object store systems (Azure, Google Cloud Storage, Minio, S3-compatible), Hadoop systems (HDFS, Hive, HBase), network file systems, and SQL databases with the WarehousePG Platform Extension Framework (PXF). See pxf:// Protocol.	Opt-in
`s3://`	Use to access files in an Amazon S3 bucket. See s3:// Protocol.	Opt-in

A third party can also create a custom protocol that connects WarehousePG to new external data sources. Refer to Creating a Custom Protocol for more information.

The opt-in/custom and built-in protocols differ in these ways:

- You must register opt-in and custom protocols. Built-in protocols are always available and cannot be unregistered.
- When you register an opt-in or custom protocol, WarehousePG adds a row to the `pg_extprotocol` catalog table to specify the handler functions that implement the protocol. The built-in protocols are not represented in this table.
- You must have installed the opt-in or custom protocol's shared libraries on all WarehousePG hosts. The built-in protocols have no additional libraries to install.
- You use `GRANT [SELECT | INSERT | ALL] ON PROTOCOL <name>` to grant users permissions on opt-in and custom protocols. To allow (or deny) users access to the built-in protocols, you use the `CREATE ROLE` or `ALTER ROLE` commands to add the `CREATEEXTTABLE` (or `NOCREATEEXTTABLE`) attribute to each user's role.

About External Table Operations

WarehousePG provides both readable (CREATE EXTERNAL TABLE) and writable (`CREATE WRITABLE EXTERNAL TABLE`) external tables.

Readable external tables are typically used for data loading, and allow only SELECT operations. They support:

- Basic extraction, transformation, and loading (ETL) tasks common in data warehousing
- Reading external table data in parallel from multiple WarehousePG segment instances, to optimize large load operations
- Filter pushdown. If a query contains a `WHERE` clause, it may be passed to the external data source. Refer to the gp_external_enable_filter_pushdown server configuration parameter discussion for more information. Note that this feature is currently supported only with the `pxf` protocol (see pxf:// Protocol).

Writable external tables are typically used for data unloading, and allow only INSERT operations. They support:

- Selecting data from database tables to insert into the writable external table
- Sending data to an application as a stream of data. For example, unload data from WarehousePG and send it to an application that connects to another database or ETL tool to load the data elsewhere.

About the External Table Types

External tables are typically file-based or web-based:

- Regular (file-based) external tables can access static flat files. Regular external tables are rescannable: the data is static while the query runs.
- Web (web-based) external tables access dynamic data sources, either on a web server with the `http://` protocol or by running OS commands or scripts. External web tables are not rescannable, the data can change while the query runs. Refer to Creating and Using External Web Tables for more information.

The `pxf://` protocol can also access other types of external data, such as SQL databases.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Creating an External Table

When you create an external table definition, you specify the structure and format of the data, the access protocol, the location of the external data source, and other protocol-specific or format-specific options.

Examples for Creating External Tables provides examples for different data types and different built-in protocols.

> **Important** After you create an external table, you must operate on the table using `ALTER EXTERNAL TABLE` and `DROP EXTERNAL TABLE` commands. WarehousePG does not recommend mixing and matching external table and foreign table syntaxes for table maintenance operations.

Other Considerations

WarehousePG backup and restore operations back up and restore only external and external web table *definitions*, not the data source data.

By default, if external table data contains an error, the command fails and no data loads into the target database table. See Handling Errors in External Table Data for more information.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.8.2.1 Understanding the External Table to Foreign Table Mapping

WarehousePG 7 uses the built-in `gp_exttable_fdw` foreign-data wrapper module to internally convert an external table that you define with the CREATE EXTERNAL TABLE command to a foreign table.

In the foreign data paradigm, a foreign-data wrapper (FDW) provides access to an external data source. A foreign server object associated with a specific FDW defines the connection details to a particular remote data source. A foreign table specifies the foreign server with which to access the remote data source. The foreign table also defines the structure of the remote data, just as you would define with an external table. Refer to Accessing External Data with Foreign Tables for more information about how to manage external data with FDWs.

WarehousePG internally maps the information that you provide in the `CREATE [WRITABLE] EXTERNAL TABLE` command to foreign data objects as follows:

Foreign Data Object	Name/Value	Comments
foreign-data wrapper	`gp_exttable_fdw`	WarehousePG maps all external tables that you create with the `CREATE [WRITABLE] EXTERNAL TABLE` command to the `gp_exttable_fdw` FDW. This FDW handles the external to foreign table conversion.
foreign server	`gp_exttable_server`	WarehousePG maps all external tables that you create with the `CREATE [WRITABLE] EXTERNAL TABLE` command to the `gp_exttable_server` server.
foreign table	`<external_table_name>`	WarehousePG maps an external table that you create with the `CREATE [WRITABLE] EXTERNAL TABLE` command to a foreign table of the same name.

When `gp_exttable_fdw` internally creates the foreign table, it maps the clauses and keywords that you provide in the `CREATE [WRITABLE] EXTERNAL TABLE` command to specific FDW options. In cases where no direct mapping exists, or where there is no equivalent external table clause, default FDW option values are provided.

The external table clause to foreign table option mapping follows:

CREATE EXTERNAL TABLE Clause	FDW Option(s) and Value(s)	Description	
CREATE EXTERNAL TABLE	`is_writable 'false'`	Readable external tables are not writable.	
CREATE WRITABLE EXTERNAL TABLE	`is_writable 'true'`	Writable external tables are writable and alterable.	
`LOCATION ('<location>' [, ...])`	`location_uris '<location>'`	The location of the external data. `gp_exttable_fdw` uses a pipe (`	`) character to separate locations when you provide more than one.
`FORMAT 'TEXT'`	`format 'text'`	The external data is text format.	
`FORMAT 'CSV'`	`format 'csv'`	The external data is comma-separated value format.	
`FORMAT 'CUSTOM'`	`format 'custom' formatter '<name>'`	The external data is of a custom format, and WarehousePG uses the specified formatter to parse the data.	
formatting options	`delimiter <value>` `escape <value>` `"null" <value>` `<option1> <value>` `...`	Format-dependent formatting options.	
`OPTIONS <key> '<value>' [, ...]`	`<key> <value>` `...`	The data access protocol-specific options.	
`ENCODING <encoding>`	`encoding '<encoding_str>'`	The table encoding (string).	
`LOG ERRORS`	`log_errors 'enable'`	Log errors to an error log. `gp_exttable_fdw` sets this FDW option to `log_errors 'disable'` when the `LOG ERRORS` clause is not provided.	
`LOG ERRORS PERSISTENTLY`	`log_errors 'persistently'`	Log errors to a persistent error log. `gp_exttable_fdw` sets this FDW option to `log_errors 'disable'` when the `LOG ERRORS` clause is not provided.	
`SEGMENT REJECT LIMIT <num_or_pct>`	`reject_limit '<num>' reject_limit_type '<type>'`	The number of errored rows (`<type>` is `rows`) or the errored row percentage (`<type>` is `percentage`) allowed.	
n/a	`execute_on 'ALL_SEGMENTS'`	Utilize the parallel processing inherent in WarehousePG.	

Implications

Because WarehousePG 7 converts an external table to a foreign table and uses foreign table structures and catalogs to internally represent external tables:

- External tables are included in the foreign table catalogs. Use the pg_foreign_table system catalog table and the `ftoptions` column to view external table definitions.
- Certain command output and error, detail, and notice messages about external tables refer to the table as a foreign table.
- External tables are included when you list or examine foreign tables (for example, the `\det psql` meta-command).

Example

Given the following external table definition:

```
CREATE EXTERNAL TABLE ext_expenses ( name text, date date, amount float4, category text, desc1 varchar )
  LOCATION ('gpfdist://etlhost-1:8081/*.txt', 'gpfdist://etlhost-2:8082/*.txt')
FORMAT 'TEXT' ( DELIMITER '|' NULL ' ' )
LOG ERRORS SEGMENT REJECT LIMIT 5;
```

`gp_exttable_fdw` creates a foreign table whose `psql` `\d+` output follows:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
\d+ ext_expenses
                                        Foreign table "public.ext_expenses"
  Column  |       Type        | Collation | Nullable | Default | FDW options | Storage  | Stats target | Description
----------+-------------------+-----------+----------+---------+-------------+----------+--------------+-------------
 name     | text              |           |          |         |             | extended |              |
 date     | date              |           |          |         |             | plain    |              |
 amount   | real              |           |          |         |             | plain    |              |
 category | text              |           |          |         |             | extended |              |
 desc1    | character varying |           |          |         |             | extended |              |
FDW options: (format 'text', delimiter '|', "null" ' ', escape E'\\', location_uris 'gpfdist://etlhost-1:8081/\*.txt|'gpfdist://etlhost-2:8082/\*.txt', execute_on
'ALL_SEGMENTS', reject_limit '5', reject_limit_type 'rows', log_errors 'enable', encoding 'UTF8', is_writable 'false')
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.8.2.2 About Changes to External Tables in WarehousePG 7

This topic describes the external table implementation and changes in WarehousePG 7, and is geared towards existing users of WarehousePG 6. WarehousePG 7 converts an external table that you define with the CREATE EXTERNAL TABLE command into a foreign table, and internally operates on and represents the table using the foreign table data structures and catalog.

(See also Understanding the External Table to Foreign Table Mapping for detailed information about the external table to foreign table conversion, and its runtime implications.)

Parent topic: Accessing External Data with External Tables

What's the Same?

If you used external tables in WarehousePG 6, the underlying functionality has not changed in WarehousePG 7. The following external table features and behaviors remain the same in WarehousePG 7:

- WarehousePG 7 fully supports the external table SQL command syntax of WarehousePG 6.
- WarehousePG 7 fully supports external table access to remote data sources via all existing protocols (`file`, `gpdist`, `pxf`, and `s3`).
- You must create separate tables to read from (`CREATE EXTERNAL TABLE`) and write to (`CREATE WRITABLE EXTERNAL TABLE`) the same external data location.
- The pg_exttable system catalog (now a view) provides the same information.

What Has Changed?

Note the following differences in the WarehousePG 7 external table implementation compared to WarehousePG 6:

- WarehousePG 7 uses foreign table data structures and catalogs to internally represent external tables. Use the pg_foreign_table system catalog table and the `ftoptions` column to view the table definition.
- A `pg_tables` query no longer returns external tables in the query results.
- The `pg_class.relkind` of an external table is now `f` (was previously `r`).
- The pg_exttable system catalog is now a view.
- In addition to `pg_exttable`, you can use the following query to list all of the foreign tables that were created using the `CREATE [WRITABLE] EXTERNAL TABLE` command:

```
SELECT * FROM pg_foreign_table ft
  JOIN pg_foreign_server fs ON ft.ftserver = fs.oid
  WHERE srvname = 'gp_exttable_server';
```

- Because an external table is internally represented as a foreign table:
  - Every external table is associated with the `gp_exttable_fdw` foreign-data wrapper.
  - Every external table is associated with the `gp_exttable_server` foreign server.
  - Certain command output and error, detail, and notice messages about external tables refer to the table as a foreign table.
  - External tables are included in the foreign table catalogs, for example pg_foreign_table.
  - External tables are included when you list or examine foreign tables (for example, the `\det` `psql` meta-command).
- External table-specific information displayed in `psql` `\dE+` output has changed; the relation `Type` of an external table is now `foreign table`. Example:

```
\dE
               List of relations
 Schema |     Name     |     Type      |  Owner
--------+--------------+---------------+---------
 public | ext_expenses | foreign table | gpadmin
```

- External table-specific information displayed in `psql` `\d+ <external_table_name>` output has changed; it now displays in foreign table format. For this example `CREATE EXTERNAL TABLE` call:

```
CREATE EXTERNAL TABLE ext_expenses ( name text, date date, amount float4, category text, desc1 varchar )
  LOCATION ('gpfdist://etlhost-1:8081/*.txt', 'gpfdist://etlhost-2:8082/*.txt')
FORMAT 'TEXT' ( DELIMITER '|' NULL ' ' )
LOG ERRORS SEGMENT REJECT LIMIT 5;
```

The example `\d+` output follows:

```
\d+ ext_expenses
                                    Foreign table "public.ext_expenses"
  Column  |       Type        | Collation | Nullable | Default | FDW options | Storage  | Stats target | Description
----------+-------------------+-----------+----------+---------+-------------+----------+--------------+-------------
 name     | text              |           |          |         |             | extended |              |
 date     | date              |           |          |         |             | plain    |              |
 amount   | real              |           |          |         |             | plain    |              |
 category | text              |           |          |         |             | extended |              |
 desc1    | character varying |           |          |         |             | extended |              |
FDW options: (format 'text', delimiter '|', "null" ' ', escape E'\\', location_uris 'gpfdist://etlhost-1:8081/\*.txt|'gpfdist://etlhost-2:8082/\*.txt',
execute_on 'ALL_SEGMENTS', reject_limit '5', reject_limit_type 'rows', log_errors 'enable', encoding 'UTF8', is_writable 'false')
```

- The `EXPLAIN` output for a query including an external table previously returned the text `External Scan`. `EXPLAIN` now returns `Foreign Scan` in this scenario.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Additional Considerations

Additional factors to consider:

- Even though an external table is internally represented as a foreign table, you cannot both read from and write to the same external table.
- You must change any scripts that you wrote that depend on external table DDL or `psql` `\dE` or `\d+` output.
- WarehousePG 7 dumps and restores the DDL of external tables using foreign table syntax.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.8.2.3 file:// Protocol

The `file://` protocol is used in a URI that specifies the location of an operating system file. External tables that you create that specify the `file://` protocol are read-only tables.

The URI includes the host name, port, and path to the file. Each file must reside on a segment host in a location accessible by the WarehousePG superuser (`gpadmin`). The host name used in the URI must match a segment host name registered in the `gp_segment_configuration` system catalog table.

The `LOCATION` clause can have multiple URIs, as shown in this example:

```
CREATE EXTERNAL TABLE ext_expenses (
   name text, date date, amount float4, category text, desc1 text )
LOCATION ('file://host1:5432/data/expense/*.csv',
          'file://host2:5432/data/expense/*.csv',
          'file://host3:5432/data/expense/*.csv')
FORMAT 'CSV' (HEADER);
```

The number of URIs you specify in the `LOCATION` clause is the number of segment instances that will work in parallel to access the external table. For each URI, WarehousePG assigns a primary segment on the specified host to the file. For maximum parallelism when loading data, divide the data into as many equally sized files as you have primary segments. This ensures that all segments participate in the load. The number of external files per segment host cannot exceed the number of primary segment instances on that host. For example, if your array has four primary segment instances per segment host, you can place four external files on each segment host. Tables based on the `file://` protocol can only be readable tables.

The system view `pg_max_external_files` shows how many external table files are permitted per external table. This view lists the available file slots per segment host when using the `file:// protocol` . The view is only applicable for the `file:// protocol` . For example:

```
SELECT * FROM pg_max_external_files;
```

Parent topic: Defining External Tables

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.8.2.4 gpfdist:// Protocol

The `gpfdist://` protocol is used in a URI to reference a running `gpfdist` instance.

The gpfdist utility serves external data files from a directory on a file host to all WarehousePG segments in parallel.

`gpfdist` is located in the `$GPHOME/bin` directory on your WarehousePG coordinator host and on each segment host.

Run `gpfdist` on the host where the external data files reside. For readable external tables, `gpfdist` uncompresses `gzip` (`.gz`) and `bzip2` (`.bz2`) files automatically. For writable external tables, data is compressed using `gzip` if the target file has a `.gz` extension. You can use the wildcard character (*) or other C-style pattern matching to denote multiple files to read. The files specified are assumed to be relative to the directory that you specified when you started the `gpfdist` instance.

> **Note** Compression is not supported for readable and writeable external tables when the `gpfdist` utility runs on Windows platforms.

All primary segments access the external file(s) in parallel, subject to the number of segments set in the `gp_external_max_segments` server configuration parameter. Use multiple `gpfdist` data sources in a `CREATE EXTERNAL TABLE` statement to scale the external table's scan performance.

`gpfdist` supports data transformations. You can write a transformation process to convert external data from or to a format that is not directly supported with WarehousePG external tables.

For more information about configuring `gpfdist`, see Using the WarehousePG Parallel File Server (gpfdist).

See the `gpfdist` reference documentation for more information about using `gpfdist` with external tables.

Parent topic: Defining External Tables

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.8.2.5 gpfdists:// Protocol

The `gpfdists://` protocol is a secure version of the `gpfdist:// protocol`.

To use it, you run the gpfdist utility with the `--ssl` option. When specified in a URI, the `gpfdists://` protocol enables encrypted communication and secure identification of the file server and the WarehousePG to protect against attacks such as eavesdropping and man-in-the-middle attacks.

`gpfdists` implements SSL security in a client/server scheme with the following attributes and limitations:

- Client certificates are required.
- Multilingual certificates are not supported.
- A Certificate Revocation List (CRL) is not supported.
- The `TLSv1` protocol is used with the `TLS_RSA_WITH_AES_128_CBC_SHA` encryption algorithm.
- SSL parameters cannot be changed.
- SSL renegotiation is supported.
- The SSL ignore host mismatch parameter is set to `false`.
- Private keys containing a passphrase are not supported for the `gpfdist` file server (`server.key`) and for the WarehousePG (`client.key`).
- Issuing certificates that are appropriate for the operating system in use is the user's responsibility. Generally, converting certificates as shown inhttps://www.sslshopper.com/ssl-converter.html is supported.

  > **Note** A server started with the `gpfdist --ssl` option can only communicate with the `gpfdists` protocol. A server that was started with `gpfdist` without the `--ssl` option can only communicate with the `gpfdist` protocol.

- The client certificate file, `client.crt`
- The client private key file, `client.key`

Use one of the following methods to invoke the `gpfdists` protocol.

- Run `gpfdist` with the `--ssl` option and then use the `gpfdists` protocol in the `LOCATION` clause of a `CREATE EXTERNAL TABLE` statement.
- Use a `gpload` YAML control file with the `SSL` option set to true. Running `gpload` starts the `gpfdist` server with the `--ssl` option, then uses the `gpfdists` protocol.

About the Required Certificate Files

The settings of the verify_gpfdists_cert server configuration parameter (default value `true`) and the gpfdist `--ssl_verify_peer <boolean>` option (default value `on`) control whether SSL certificate authentication is enabled when WarehousePG communicates with the `gpfdist` utility to either read data from or write data to an external data source. These settings also determine which of the following certificate files must reside in the `$PGDATA/gpfdists` directory on each WarehousePG segment:

- The client certificate file, `client.crt`
- The client private key file, `client.key`
- The trusted certificate authorities, `root.crt`

The certificate files required for each `verify_gpfdists_cert` and `--ssl_verify_peer` setting combination are identified in the table below:

verify_gpfdists_cert	--ssl_verify_peer	Required Certificate Files

on	on	`client.key`
		`client.crt`
		`root.crt`

on	off	`root.crt`
off	on	`client.key` `client.crt`
off	off	N/A

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.8.2.6 pxf:// Protocol

You can use the WarehousePG Platform Extension Framework (PXF) `pxf://` protocol to access data residing in object store systems (Azure, Google Cloud Storage, Minio, S3), external Hadoop systems (HDFS, Hive, HBase), and SQL databases.

The PXF `pxf` protocol is packaged as a WarehousePG extension. The `pxf` protocol supports reading from external data stores. You can also write text, binary, and parquet-format data with the `pxf` protocol.

When you use the `pxf` protocol to query an external data store, you specify the directory, file, or table that you want to access. PXF requests the data from the data store and delivers the relevant portions in parallel to each WarehousePG segment instance serving the query.

You must explicitly initialize and start PXF before you can use the `pxf` protocol to read or write external data. You must also enable PXF in each database in which you want to allow users to create external tables to access external data, and grant permissions on the `pxf` protocol to those WarehousePG users.

For detailed information about configuring and using PXF and the `pxf` protocol, refer to Accessing External Data with PXF.

Parent topic: Defining External Tables

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.8.2.7 s3:// Protocol

The `s3` protocol is used in a URL that specifies the location of an Amazon S3 bucket and a prefix to use for reading or writing files in the bucket.

Amazon Simple Storage Service (Amazon S3) provides secure, durable, highly-scalable object storage. For information about Amazon S3, see Amazon S3.

You can define read-only external tables that use existing data files in the S3 bucket for table data, or writable external tables that store the data from INSERT operations to files in the S3 bucket. WarehousePG uses the S3 URL and prefix specified in the protocol URL either to select one or more files for a read-only table, or to define the location and filename format to use when uploading S3 files for `INSERT` operations to writable tables.

The `s3` protocol also supports Dell Elastic Cloud Storage (ECS), an Amazon S3 compatible service.

> **Note** The `pxf` protocol can access data in S3 and other object store systems such as Azure, Google Cloud Storage, and Minio. The `pxf` protocol can also access data in external Hadoop systems (HDFS, Hive, HBase), and SQL databases. See pxf:// Protocol.

This topic contains the sections:

- Configuring the s3 Protocol
- Using s3 External Tables
- About the s3 Protocol LOCATION URL
- About Reading and Writing S3 Data Files
- s3 Protocol AWS Server-Side Encryption Support
- s3 Protocol Proxy Support
- About Providing the S3 Authentication Credentials
- About the s3 Protocol Configuration File
- About Specifying the Configuration File Location
- s3 Protocol Limitations
- Using the gpcheckcloud Utility

Configuring the s3 Protocol

You must configure the `s3` protocol before you can use it. Perform these steps in each database in which you want to use the protocol:

1. Create the read and write functions for the `s3` protocol library:

   ```
   CREATE OR REPLACE FUNCTION write_to_s3() RETURNS integer AS
      '$libdir/gps3ext.so', 's3_export' LANGUAGE C STABLE;
   ```

   ```
   CREATE OR REPLACE FUNCTION read_from_s3() RETURNS integer AS
      '$libdir/gps3ext.so', 's3_import' LANGUAGE C STABLE;
   ```

2. Declare the `s3` protocol and specify the read and write functions you created in the previous step:

   To allow only WarehousePG superusers to use the protocol, create it as follows:

   ```
   CREATE PROTOCOL s3 (writefunc = write_to_s3, readfunc = read_from_s3);
   ```

   If you want to permit non-superusers to use the `s3` protocol, create it as a `TRUSTED` protocol and `GRANT` access to those users. For example:

   ```
   CREATE TRUSTED PROTOCOL s3 (writefunc = write_to_s3, readfunc = read_from_s3);
   GRANT ALL ON PROTOCOL s3 TO user1, user2;
   ```

   > **Note** The protocol name `s3` must be the same as the protocol of the URL specified for the external table that you create to access an S3 resource.

   The corresponding function is called by every WarehousePG segment instance.

Using s3 External Tables

Follow these basic steps to use the `s3` protocol with WarehousePG external tables. Each step includes links to relevant topics from which you can obtain more information. See also s3 Protocol Limitations to better understand the capabilities and limitations of s3 external tables:

1. Configure the s3 Protocol.
2. Create the `s3` protocol configuration file:
   1. Create a template `s3` protocol configuration file using the `gpcheckcloud` utility:

      ```
      gpcheckcloud -t > ./mytest_s3.config
      ```

   2. (Optional) Edit the template file to specify the `accessid` and `secret` authentication credentials required to connect to the S3 location. See About Providing the S3 Authentication Credentials and About the s3 Protocol Configuration File for information about specifying these and other `s3` protocol configuration parameters.
3. WarehousePG can access an `s3` protocol configuration file when the file is located on each segment host or when the file is served up by an `http/https` server. Identify where you plan to locate the configuration file, and note the location and configuration option (if applicable). Refer to About Specifying the Configuration File Location for more information about the location options for the file.

   If you are relying on the AWS credential file to authenticate, this file must reside at `~/.aws/credentials` on each WarehousePG segment host.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4. Use the `gpcheckcloud` utility to validate connectivity to the S3 bucket. You must specify the S3 endpoint name and bucket that you want to check.

   For example, if the `s3` protocol configuration file resides in the default location, you would run the following command:

   ```
   gpcheckcloud -c "s3://<s3-endpoint>/<s3-bucket>"
   ```

   `gpcheckcloud` attempts to connect to the S3 endpoint and lists any files in the S3 bucket, if available. A successful connection ends with the message:

   ```
   Your configuration works well.
   ```

   You can optionally use `gpcheckcloud` to validate uploading to and downloading from the S3 bucket. Refer to Using the gpcheckcloud Utility for information about this utility and other usage examples.

5. Create an s3 external table by specifying an `s3` protocol URL in the `CREATE EXTERNAL TABLE` command, `LOCATION` clause.

   For read-only s3 tables, the URL defines the location and prefix used to select existing data files that comprise the s3 table. For example:

   ```
   CREATE READABLE EXTERNAL TABLE S3TBL (date text, time text, amt int)
      LOCATION('s3://s3-us-west-2.amazonaws.com/s3test.example.com/dataset1/normal/ config=/home/gpadmin/aws_s3/s3.conf')
      FORMAT 'csv';
   ```

   For writable s3 tables, the protocol URL defines the S3 location in which WarehousePG writes the data files that back the table for `INSERT` operations. You can also specify a prefix that WarehousePG will add to the files that it creates. For example:

   ```
   CREATE WRITABLE EXTERNAL TABLE S3WRIT (LIKE S3TBL)
      LOCATION('s3://s3-us-west-2.amazonaws.com/s3test.example.com/dataset1/normal/ config=/home/gpadmin/aws_s3/s3.conf')
      FORMAT 'csv';
   ```

   Refer to About the s3 Protocol LOCATION URL for more information about the `s3` protocol URL.

About the s3 Protocol LOCATION URL

When you use the `s3` protocol, you specify an S3 file location and optional configuration file location and region parameters in the `LOCATION` clause of the `CREATE EXTERNAL TABLE` command. The syntax follows:

```
's3://<S3_endpoint>[:<port>]/<bucket_name>/[<S3_prefix>] [region=<S3_region>] [config=<config_file_location> | config_server=<url>] [section=<section_name>]'
```

The `s3` protocol requires that you specify the S3 endpoint and S3 bucket name. Each WarehousePG segment host must have access to the S3 location. The optional S3_prefix value is used to select files for read-only S3 tables, or as a filename prefix to use when uploading files for s3 writable tables.

> **Note** The WarehousePG `s3` protocol URL must include the S3 endpoint hostname.

To specify an ECS endpoint (an Amazon S3 compatible service) in the `LOCATION` clause, you must set the `s3` protocol configuration file parameter `version` to `2`. The `version` parameter controls whether the `region` parameter is used in the `LOCATION` clause. You can also specify an Amazon S3 location when the `version` parameter is 2. For information about the `version` parameter, see About the s3 Protocol Configuration File.

> **Note** Although the S3_prefix is an optional part of the syntax, you should always include an S3 prefix for both writable and read-only s3 tables to separate datasets as part of theCREATE EXTERNAL TABLE syntax.

For writable s3 tables, the `s3` protocol URL specifies the endpoint and bucket name where WarehousePG uploads data files for the table. The S3 file prefix is used for each new file uploaded to the S3 location as a result of inserting data to the table. See About Reading and Writing S3 Data Files.

For read-only s3 tables, the S3 file prefix is optional. If you specify an S3_prefix, then the `s3` protocol selects all files that start with the specified prefix as data files for the external table. The `s3` protocol does not use the slash character (`/`) as a delimiter, so a slash character following a prefix is treated as part of the prefix itself.

For example, consider the following 5 files that each have the S3_endpoint named `s3-us-west-2.amazonaws.com` and the bucket_name `test1`:

```
s3://s3-us-west-2.amazonaws.com/test1/abc
s3://s3-us-west-2.amazonaws.com/test1/abc/
s3://s3-us-west-2.amazonaws.com/test1/abc/xx
s3://s3-us-west-2.amazonaws.com/test1/abcdef
s3://s3-us-west-2.amazonaws.com/test1/abcdefff
```

- If the S3 URL is provided as `s3://s3-us-west-2.amazonaws.com/test1/abc` , then the `abc` prefix selects all 5 files.
- If the S3 URL is provided as `s3://s3-us-west-2.amazonaws.com/test1/abc/` , then the `abc/` prefix selects the files `s3://s3-us-west-2.amazonaws.com/test1/abc/` and `s3://s3-us-west-2.amazonaws.com/test1/abc/xx` .
- If the S3 URL is provided as `s3://s3-us-west-2.amazonaws.com/test1/abcd` , then the `abcd` prefix selects the files `s3://s3-us-west-2.amazonaws.com/test1/abcdef` and `s3://s3-us-west-2.amazonaws.com/test1/abcdefff`

Wildcard characters are not supported in an S3_prefix; however, the S3 prefix functions as if a wildcard character immediately followed the prefix itself.

All of the files selected by the S3 URL (S3_endpoint/bucket_name/S3_prefix) are used as the source for the external table, so they must have the same format. Each file must also contain complete data rows. A data row cannot be split between files.

For information about the Amazon S3 endpoints see http://docs.aws.amazon.com/general/latest/gr/rande.html#s3_region. For information about S3 buckets and folders, see the Amazon S3 documentation https://aws.amazon.com/documentation/s3/. For information about the S3 file prefix, see the Amazon S3 documentationListing Keys Hierarchically Using a Prefix and Delimiter.

You use the `config` or `config_server` parameter to specify the location of the required `s3` protocol configuration file that contains AWS connection credentials and communication parameters as described in About Specifying the Configuration File Location.

Use the `section` parameter to specify the name of the configuration file section from which the `s3` protocol reads configuration parameters. The default `section` is named `default` . When you specify the section name in the configuration file, enclose it in brackets (for example, `[default]`).

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

About Reading and Writing S3 Data Files

You can use the `s3` protocol to read and write data files on Amazon S3.

Reading S3 Files

The S3 permissions on any file that you read must include `Open/Download` and `View` for the S3 user ID that accesses the files.

For read-only s3 tables, all of the files specified by the S3 file location (S3_endpoint/bucket_name/S3_prefix) are used as the source for the external table and must have the same format. Each file must also contain complete data rows. If the files contain an optional header row, the column names in the header row cannot contain a newline character (`\n`) or a carriage return (`\r`). Also, the column delimiter cannot be a newline character (`\n`) or a carriage return character (`\r`).

The `s3` protocol recognizes gzip and deflate compressed files and automatically decompresses the files. For gzip compression, the protocol recognizes the format of a gzip compressed file. For deflate compression, the protocol assumes a file with the `.deflate` suffix is a deflate compressed file.

Each WarehousePG segment can download one file at a time from the S3 location using several threads. To take advantage of the parallel processing performed by the WarehousePG segments, the files in the S3 location should be similar in size and the number of files should allow for multiple segments to download the data from the S3 location. For example, if the WarehousePG cluster consists of 16 segments and there was sufficient network bandwidth, creating 16 files in the S3 location allows each segment to download a file from the S3 location. In contrast, if the location contained only 1 or 2 files, only 1 or 2 segments download data.

Writing S3 Files

Writing a file to S3 requires that the S3 user ID have `Upload/Delete` permissions.

When you initiate an `INSERT` operation on a writable s3 table, each WarehousePG segment uploads a single file to the configured S3 bucket using the filename format `<prefix><segment_id><random>.<extension>[.gz]` where:

- `<prefix>` is the prefix specified in the S3 URL.
- `<segment_id>` is the WarehousePG segment ID.
- `<random>` is a random number that is used to ensure that the filename is unique.
- `<extension>` describes the file type (`.txt` or .csv, depending on the value you provide in the `FORMAT` clause of `CREATE WRITABLE EXTERNAL TABLE`). Files created by the `gpcheckcloud` utility always uses the extension .data.
- .gz is appended to the filename if compression is enabled for s3 writable tables (the default).

You can configure the buffer size and the number of threads that segments use for uploading files. See About the s3 Protocol Configuration File.

s3 Protocol AWS Server-Side Encryption Support

WarehousePG supports server-side encryption using Amazon S3-managed keys (SSE-S3) for AWS S3 files you access with readable and writable external tables created using the `s3` protocol. SSE-S3 encrypts your object data as it writes to disk, and transparently decrypts the data for you when you access it.

> **Note** The `s3` protocol supports SSE-S3 only for Amazon Web Services S3 files. SS3-SE is not supported when accessing files in S3 compatible services.

Your S3 account permissions govern your access to all S3 bucket objects, whether the data is encrypted or not. However, you must configure your client to use S3-managed keys for accessing encrypted data.

Refer to Protecting Data Using Server-Side Encryption in the AWS documentation for additional information about AWS Server-Side Encryption.

Configuring S3 Server-Side Encryption

`s3` protocol server-side encryption is deactivated by default. To take advantage of server-side encryption on AWS S3 objects you write using the WarehousePG `s3` protocol, you must set the `server_side_encryption` configuration parameter in your `s3` protocol configuration file to the value `sse-s3` :

```
server_side_encryption = sse-s3
```

When the configuration file you provide to a `CREATE WRITABLE EXTERNAL TABLE` call using the `s3` protocol includes the `server_side_encryption = sse-s3` setting, WarehousePG applies encryption headers for you on all `INSERT` operations on that external table. S3 then encrypts on write the object(s) identified by the URI you provided in the `LOCATION` clause.

S3 transparently decrypts data during read operations of encrypted files accessed via readable external tables you create using the `s3` protocol. No additional configuration is required.

For further encryption configuration granularity, you may consider creating Amazon Web Services S3 *Bucket Policy*(s), identifying the objects you want to encrypt and the write actions on those objects as described in the Protecting Data Using Server-Side Encryption with Amazon S3-Managed Encryption Keys (SSE-S3) AWS documentation.

s3 Protocol Proxy Support

You can specify a URL that is the proxy that S3 uses to connect to a data source. S3 supports these protocols: HTTP and HTTPS. You can specify a proxy with the `s3` protocol configuration parameter `proxy` or an environment variable. If the configuration parameter is set, the environment variables are ignored.

To specify proxy with an environment variable, you set the environment variable based on the protocol: `http_proxy` or `https_proxy` . You can specify a different URL for each protocol by setting the appropriate environment variable. S3 supports these environment variables.

- `all_proxy` specifies the proxy URL that is used if an environment variable for a specific protocol is not set.
- `no_proxy` specifies a comma-separated list of hosts names that do not use the proxy specified by an environment variable.

The environment variables must be set must and must be accessible to WarehousePG on all WarehousePG hosts.

For information about the configuration parameter `proxy` , see About the s3 Protocol Configuration File.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

About Providing the S3 Authentication Credentials

The `s3` protocol obtains the S3 authentication credentials as follows:

- You specify the S3 `accessid` and `secret` parameters and their values in a named `section` of an s3 protocol configuration file. The default section from which the `s3` protocol obtains this information is named `[default]`.
- If you do not specify the `accessid` and `secret`, or these parameter values are empty, the `s3` protocol attempts to obtain the S3 authentication credentials from the `aws_access_key_id` and `aws_secret_access_key` parameters specified in a named `section` of the user's AWS credential file. The default location of this file is `~/.aws/credentials`, and the default section is named `[default]`.

About the s3 Protocol Configuration File

An `s3` protocol configuration file contains Amazon Web Services (AWS) connection credentials and communication parameters.

The `s3` protocol configuration file is a text file that contains named sections and parameters. The default section is named `[default]`. An example configuration file follows:

```
[default]
secret = "secret"
accessid = "user access id"
threadnum = 3
chunksize = 67108864
```

You can use the WarehousePG `gpcheckcloud` utility to test the s3 protocol configuration file. See Using the gpcheckcloud Utility.

s3 Configuration File Parameters

`accessid` Optional. AWS S3 ID to access the S3 bucket. Refer to About Providing the S3 Authentication Credentials for more information about specifying authentication credentials.

`secret` Optional. AWS S3 passcode for the S3 ID to access the S3 bucket. Refer to About Providing the S3 Authentication Credentials for more information about specifying authentication credentials.

`autocompress` For writable s3 external tables, this parameter specifies whether to compress files (using gzip) before uploading to S3. Files are compressed by default if you do not specify this parameter.

`chunksize` The buffer size that each segment thread uses for reading from or writing to the S3 server. The default is 64 MB. The minimum is 8MB and the maximum is 128MB.

When inserting data to a writable s3 table, each WarehousePG segment writes the data into its buffer (using multiple threads up to the `threadnum` value) until it is full, after which it writes the buffer to a file in the S3 bucket. This process is then repeated as necessary on each segment until the insert operation completes.

Because Amazon S3 allows a maximum of 10,000 parts for multipart uploads, the minimum `chunksize` value of 8MB supports a maximum insert size of 80GB per WarehousePG segment. The maximum `chunksize` value of 128MB supports a maximum insert size 1.28TB per segment. For writable s3 tables, you must ensure that the `chunksize` setting can support the anticipated table size of your table. See Multipart Upload Overview in the S3 documentation for more information about uploads to S3.

`encryption` Use connections that are secured with Secure Sockets Layer (SSL). Default value is `true`. The values `true`, `t`, `on`, `yes`, and `y` (case insensitive) are treated as `true`. Any other value is treated as `false`.

If the port is not specified in the URL in the `LOCATION` clause of the `CREATE EXTERNAL TABLE` command, the configuration file `encryption` parameter affects the port used by the `s3` protocol (port 80 for HTTP or port 443 for HTTPS). If the port is specified, that port is used regardless of the encryption setting.

`gpcheckcloud_newline` When downloading files from an S3 location, the `gpcheckcloud` utility appends a new line character to last line of a file if the last line of a file does not have an EOL (end of line) character. The default character is `\n` (newline). The value can be `\n`, `\r` (carriage return), or `\n\r` (newline/carriage return).

Adding an EOL character prevents the last line of one file from being concatenated with the first line of next file.

`low_speed_limit` The upload/download speed lower limit, in bytes per second. The default speed is 10240 (10K). If the upload or download speed is slower than the limit for longer than the time specified by `low_speed_time`, then the connection is stopped and retried. After 3 retries, the `s3` protocol returns an error. A value of 0 specifies no lower limit.

`low_speed_time` When the connection speed is less than `low_speed_limit`, this parameter specified the amount of time, in seconds, to wait before cancelling an upload to or a download from the S3 bucket. The default is 60 seconds. A value of 0 specifies no time limit.

`proxy` Specify a URL that is the proxy that S3 uses to connect to a data source. S3 supports these protocols: HTTP and HTTPS. This is the format for the parameter.

```
proxy = <protocol>://[<user>:<password>@]<proxyhost>[:<port>]
```

If this parameter is not set or is an empty string (`proxy = ""`), S3 uses the proxy specified by the environment variable `http_proxy` or `https_proxy` (and the environment variables `all_proxy` and `no_proxy`). The environment variable that S3 uses depends on the protocol. For information about the environment variables, see s3 Protocol Proxy Support.

There can be at most one `proxy` parameter in the configuration file. The URL specified by the parameter is the proxy for all supported protocols.

`server_side_encryption` The S3 server-side encryption method that has been configured for the bucket. WarehousePG supports only server-side encryption with Amazon S3-managed keys, identified by the configuration parameter value `sse-s3`. Server-side encryption is deactivated (`none`) by default.

`threadnum` The maximum number of concurrent threads a segment can create when uploading data to or downloading data from the S3 bucket. The default is 4. The minimum is 1 and the maximum is 8.

`verifycert` Controls how the `s3` protocol handles authentication when establishing encrypted communication between a client and an S3 data source over HTTPS. The value is either `true` or `false`. The default value is `true`.

- `verifycert=false` - Ignores authentication errors and allows encrypted communication over HTTPS.
- `verifycert=true` - Requires valid authentication (a proper certificate) for encrypted communication over HTTPS.

Setting the value to `false` can be useful in testing and development environments to allow communication without changing certificates.

> **Caution** Setting the value to `false` exposes a security risk by ignoring invalid credentials when establishing communication between a client and a S3 data store.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

`version` Specifies the version of the information specified in the `LOCATION` clause of the `CREATE EXTERNAL TABLE` command. The value is either `1` or `2`. The default value is `1`.

If the value is `1`, the `LOCATION` clause supports an Amazon S3 URL, and does not contain the `region` parameter. If the value is `2`, the `LOCATION` clause supports S3 compatible services and must include the `region` parameter. The `region` parameter specifies the S3 data source region. For this S3 URL `s3://s3-us-west-2.amazonaws.com/s3test.example.com/dataset1/normal/`, the AWS S3 region is `us-west-2`.

If `version` is 1 or is not specified, this is an example of the `LOCATION` clause of the `CREATE EXTERNAL TABLE` command that specifies an Amazon S3 endpoint.

```
LOCATION ('s3://s3-us-west-2.amazonaws.com/s3test.example.com/dataset1/normal/ config=/home/gpadmin/aws_s3/s3.conf')
```

If `version` is 2, this is an example `LOCATION` clause with the `region` parameter for an AWS S3 compatible service.

```
LOCATION ('s3://test.company.com/s3test.company/test1/normal/ region=local-test config=/home/gpadmin/aws_s3/s3.conf')
```

If `version` is 2, the `LOCATION` clause can also specify an Amazon S3 endpoint. This example specifies an Amazon S3 endpoint that uses the `region` parameter.

```
LOCATION ('s3://s3-us-west-2.amazonaws.com/s3test.example.com/dataset1/normal/ region=us-west-2 config=/home/gpadmin/aws_s3/s3.conf')
```

> **Note** WarehousePG can require up to `threadnum * chunksize` memory on each segment host when uploading or downloading S3 files. Consider this `s3` protocol memory requirement when you configure overall WarehousePG memory.

About Specifying the Configuration File Location

The default location of the `s3` protocol configuration file is a file named `s3.conf` that resides in the data directory of each WarehousePG segment instance:

```
<gpseg_data_dir>/<gpseg_prefix><N>/s3/s3.conf
```

The gpseg_data_dir is the path to the WarehousePG segment data directory, the gpseg_prefix is the segment prefix, and N is the segment ID. The segment data directory, prefix, and ID are set when you initialize a WarehousePG cluster.

You may choose an alternate location for the `s3` protocol configuration file by specifying the optional `config` or `config_server` parameters in the `LOCATION` URL:

- You can simplify the configuration by using a single configuration file that resides in the same file system location on each segment host. In this scenario, you specify the `config` parameter in the `LOCATION` clause to identify the absolute path to the file. The following example specifies a location in the `gpadmin` home directory:

  ```
  LOCATION ('s3://s3-us-west-2.amazonaws.com/test/my_data config=/home/gpadmin/s3.conf')
  ```

  The `/home/gpadmin/s3.conf` file must reside on each segment host, and all segment instances on a host use the file.

- You also have the option to use an `http/https` server to serve up the configuration file. In this scenario, you specify an `http/https` server URL in the `config_server` parameter. You are responsible for configuring and starting the server, and each WarehousePG segment host must be able to access the server. The following example specifies an IP address and port for an `https` server:

  ```
  LOCATION ('s3://s3-us-west-2.amazonaws.com/test/my_data config_server=https://203.0.113.0:8553')
  ```

s3 Protocol Limitations

These are `s3` protocol limitations:

- Only the S3 path-style URL is supported.

  ```
  s3://<S3_endpoint>/<bucketname>/[<S3_prefix>]
  ```

- Only the S3 endpoint is supported. The protocol does not support virtual hosting of S3 buckets (binding a domain name to an S3 bucket).

- AWS signature version 4 signing process is supported.

  For information about the S3 endpoints supported by each signing process, see http://docs.aws.amazon.com/general/latest/gr/rande.html#s3_region.

- Only a single URL and optional configuration file location and region parameters is supported in the `LOCATION` clause of the `CREATE EXTERNAL TABLE` command.

- If the `NEWLINE` parameter is not specified in the `CREATE EXTERNAL TABLE` command, the newline character must be identical in all data files for specific prefix. If the newline character is different in some data files with the same prefix, read operations on the files might fail.

- For writable s3 external tables, only the `INSERT` operation is supported. `UPDATE`, `DELETE`, and `TRUNCATE` operations are not supported.

- Because Amazon S3 allows a maximum of 10,000 parts for multipart uploads, the maximum `chunksize` value of 128MB supports a maximum insert size of 1.28TB per WarehousePG segment for writable s3 tables. You must ensure that the `chunksize` setting can support the anticipated table size of your table. See Multipart Upload Overview in the S3 documentation for more information about uploads to S3.

- To take advantage of the parallel processing performed by the WarehousePG segment instances, the files in the S3 location for read-only s3 tables should be similar in size and the number of files should allow for multiple segments to download the data from the S3 location. For example, if the WarehousePG cluster consists of 16 segments and there was sufficient network bandwidth, creating 16 files in the S3 location allows each segment to download a file from the S3 location. In contrast, if the location contained only 1 or 2 files, only 1 or 2 segments download data.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Using the gpcheckcloud Utility

The WarehousePG utility `gpcheckcloud` helps users create an `s3` protocol configuration file and test a configuration file. You can specify options to test the ability to access an S3 bucket with a configuration file, and optionally upload data to or download data from files in the bucket.

If you run the utility without any options, it sends a template configuration file to `STDOUT`. You can capture the output and create an `s3` configuration file to connect to Amazon S3.

The utility is installed in the WarehousePG `$GPHOME/bin` directory.

Syntax

```
gpcheckcloud {-c | -d} "s3://<S3_endpoint>/<bucketname>/[<S3_prefix>] [config=<path_to_config_file>]"

gpcheckcloud -u <file_to_upload> "s3://<S3_endpoint>/<bucketname>/[<S3_prefix>] [config=<path_to_config_file>]"
gpcheckcloud -t

gpcheckcloud -h
```

Options

`-c` Connect to the specified S3 location with the configuration specified in the `s3` protocol URL and return information about the files in the S3 location.

If the connection fails, the utility displays information about failures such as invalid credentials, prefix, or server address (DNS error), or server not available.

`-d` Download data from the specified S3 location with the configuration specified in the `s3` protocol URL and send the output to `STDOUT`.

If files are gzip compressed or have a `.deflate` suffix to indicate deflate compression, the uncompressed data is sent to `STDOUT`.

`-u` Upload a file to the S3 bucket specified in the `s3` protocol URL using the specified configuration file if available. Use this option to test compression and `chunksize` and `autocompress` settings for your configuration.

`-t` Sends a template configuration file to `STDOUT`. You can capture the output and create an `s3` configuration file to connect to Amazon S3.

`-h` Display `gpcheckcloud` help.

Examples

This example runs the utility without options to create a template `s3` configuration file `mytest_s3.config` in the current directory.

```
gpcheckcloud -t > ./mytest_s3.config
```

This example attempts to upload a local file, test-data.csv to an S3 bucket location using the `s3` configuration file `s3.mytestconf`:

```
gpcheckcloud -u ./test-data.csv "s3://s3-us-west-2.amazonaws.com/test1/abc config=s3.mytestconf"
```

A successful upload results in one or more files placed in the S3 bucket using the filename format `abc<segment_id><random>.data[.gz]`. See About Reading and Writing S3 Data Files.

This example attempts to connect to an S3 bucket location with the `s3` protocol configuration file `s3.mytestconf`.

```
gpcheckcloud -c "s3://s3-us-west-2.amazonaws.com/test1/abc config=s3.mytestconf"
```

This example attempts to connect to an S3 bucket location using the default location for the `s3` protocol configuration file (`s3/s3.conf` in segment data directories):

```
gpcheckcloud -c "s3://s3-us-west-2.amazonaws.com/test1/abc"
```

Download all files from the S3 bucket location and send the output to `STDOUT`.

```
gpcheckcloud -d "s3://s3-us-west-2.amazonaws.com/test1/abc config=s3.mytestconf"
```

4.8.2.8 Creating a Custom Protocol

A custom protocol allows you to connect WarehousePG to a data source that cannot be accessed with the `file://`, `gpfdist://`, or `pxf://` protocols.

Creating a custom protocol requires that you implement a set of C functions with specified interfaces, declare the functions in WarehousePG, and then use the `CREATE TRUSTED PROTOCOL` command to enable the protocol in the database.

See Example Custom Data Access Protocol for an example.

Parent topic: Defining External Tables

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.8.2.9 Handling Errors in External Table Data

By default, if external table data contains an error, the command fails and no data loads into the target database table.

Define the external table with single row error handling to enable loading correctly formatted rows and to isolate data errors in external table data. See Handling Load Errors.

The `gpfdist` file server uses the `HTTP` protocol. External table queries that use `LIMIT` end the connection after retrieving the rows, causing an HTTP socket error. If you use `LIMIT` in queries of external tables that use the `gpfdist://` or `http:// protocols`, ignore these errors – data is returned to the database as expected.

Parent topic: Defining External Tables

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.8.2.10 Creating and Using External Web Tables

External web tables allow WarehousePG to treat dynamic data sources like regular database tables. Because web table data can change as a query runs, the data is not rescannable.

`CREATE EXTERNAL WEB TABLE` creates a web table definition. You can define command-based or URL-based external web tables. The definition forms are distinct: you cannot mix command-based and URL-based definitions.

Parent topic: Defining External Tables

Command-based External Web Tables

The output of a shell command or script defines command-based web table data. Specify the command in the `EXECUTE` clause of `CREATE EXTERNAL WEB TABLE`. The data is current as of the time the command runs. The `EXECUTE` clause runs the shell command or script on the specified coordinator, and/or segment host or hosts. The command or script must reside on the hosts corresponding to the host(s) defined in the `EXECUTE` clause.

By default, the command is run on segment hosts when active segments have output rows to process. For example, if each segment host runs four primary segment instances that have output rows to process, the command runs four times per segment host. You can optionally limit the number of segment instances that run the web table command. All segments included in the web table definition in the `ON` clause run the command in parallel.

The command that you specify in the external table definition is run from the database and cannot access environment variables from `.bashrc` or `.profile`. Set environment variables in the `EXECUTE` clause. For example:

```
=# CREATE EXTERNAL WEB TABLE output (output text)
    EXECUTE 'PATH=/home/gpadmin/programs; export PATH; myprogram.sh'
    FORMAT 'TEXT';
```

Scripts must be executable by the `gpadmin` user and reside in the same location on the coordinator or segment hosts.

The following command defines a web table that runs a script. The script runs on each segment host where a segment has output rows to process.

```
=# CREATE EXTERNAL WEB TABLE log_output
    (linenum int, message text)
    EXECUTE '/var/load_scripts/get_log_data.sh' ON HOST
    FORMAT 'TEXT' (DELIMITER '|');
```

URL-based External Web Tables

A URL-based web table accesses data from a web server using the HTTP protocol. Web table data is dynamic; the data is not rescannable.

Specify the `LOCATION` of files on a web server using `http://`. The web data file(s) must reside on a web server that WarehousePG segment hosts can access. The number of URLs specified corresponds to the number of segment instances that work in parallel to access the web table. For example, if you specify two external files to a WarehousePG cluster with eight primary segments, two of the eight segments access the web table in parallel at query runtime.

The following sample command defines a web table that gets data from several URLs.

```
=# CREATE EXTERNAL WEB TABLE ext_expenses (name text,
  date date, amount float4, category text, description text)
  LOCATION (

  'http://intranet.company.com/expenses/sales/file.csv',
  'http://intranet.company.com/expenses/exec/file.csv',
  'http://intranet.company.com/expenses/finance/file.csv',
  'http://intranet.company.com/expenses/ops/file.csv',
  'http://intranet.company.com/expenses/marketing/file.csv',
  'http://intranet.company.com/expenses/eng/file.csv'

   )
  FORMAT 'CSV' ( HEADER );
```

4.8.2.11 Examples for Creating External Tables

examples/index.md editTarget: originalFilePath

These examples show how to define external data with different protocols. Each `CREATE EXTERNAL TABLE` command can contain only one protocol.

> **Note** When using IPv6, always enclose the numeric IP addresses in square brackets.

Start gpfdist before you create external tables with the gpfdist protocol. The following code starts the gpfdist file server program in the background on port*8081* serving files from directory /var/data/staging. The logs are saved in /home/gpadmin/log.

```
gpfdist -p 8081 -d /var/data/staging -l /home/gpadmin/log &
```

4.8.2.11.1 Example 1—Single gpfdist instance on single-NIC machine

examples/example-1-single-gpfdist-instance-on-single-nic-machine.md editTarget: originalFilePath

---

Creates a readable external table, `ext_expenses`, using the `gpfdist` protocol. The files are formatted with a pipe (|) as the column delimiter.

```
=# CREATE EXTERNAL TABLE ext_expenses ( name text,
    date date, amount float4, category text, desc1 text )
    LOCATION ('gpfdist://etlhost-1:8081/*')
FORMAT 'TEXT' (DELIMITER '|');
```

Parent topic: Examples for Creating External Tables

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.8.2.11.2 Example 2—Multiple gpfdist instances

examples/example-2-multiple-gpfdist-instances.md editTarget: originalFilePath

---

Creates a readable external table, *ext_expenses,* using the gpfdist protocol from all files with the *txt* extension. The column delimiter is a pipe (|) and NULL (' ') is a space.

```
=# CREATE EXTERNAL TABLE ext_expenses ( name text,
   date date,  amount float4, category text, desc1 text )
   LOCATION ('gpfdist://etlhost-1:8081/*.txt',
             'gpfdist://etlhost-2:8081/*.txt')
   FORMAT 'TEXT' ( DELIMITER '|' NULL ' ') ;
```

Parent topic: Examples for Creating External Tables

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.8.2.11.3 Example 3—Multiple gpfdists instances

examples/example-3-multiple-gpfdists-instances.md editTarget: originalFilePath

---

Creates a readable external table, *ext_expenses*, from all files with the *txt* extension using the `gpfdists` protocol. The column delimiter is a pipe (|) and NULL (' ') is a space. For information about the location of security certificates, see gpfdists:// Protocol.

1. Run `gpfdist` with the `--ssl` option.

2. Run the following command.

```
=# CREATE EXTERNAL TABLE ext_expenses ( name text,
   date date,  amount float4, category text, desc1 text )
   LOCATION ('gpfdists://etlhost-1:8081/*.txt',
             'gpfdists://etlhost-2:8082/*.txt')
   FORMAT 'TEXT' ( DELIMITER '|' NULL ' ') ;
```

Parent topic: Examples for Creating External Tables

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.8.2.11.4 Example 4—Single gpfdist instance with error logging

examples/example-4-single-gpfdist-instance-with-error-logging.md editTarget: originalFilePath

---

Uses the gpfdist protocol to create a readable external table, `ext_expenses,` from all files with the *txt* extension. The column delimiter is a pipe (|) and NULL (' ') is a space.

Access to the external table is single row error isolation mode. Input data formatting errors are captured internally in WarehousePG with a description of the error. See Viewing Bad Rows in the Error Log for information about investigating error rows. You can view the errors, fix the issues, and then reload the rejected data. If the error count on a segment is greater than five (the `SEGMENT REJECT LIMIT` value), the entire external table operation fails and no rows are processed.

```
=# CREATE EXTERNAL TABLE ext_expenses ( name text,
   date date, amount float4, category text, desc1 text )
   LOCATION ('gpfdist://etlhost-1:8081/*.txt',
             'gpfdist://etlhost-2:8082/*.txt')
   FORMAT 'TEXT' ( DELIMITER '|' NULL ' ')
   LOG ERRORS SEGMENT REJECT LIMIT 5;
```

To create the readable ext_expenses table from CSV-formatted text files:

```
=# CREATE EXTERNAL TABLE ext_expenses ( name text,
   date date,  amount float4, category text, desc1 text )
   LOCATION ('gpfdist://etlhost-1:8081/*.txt',
             'gpfdist://etlhost-2:8082/*.txt')
   FORMAT 'CSV' ( DELIMITER ',' )
   LOG ERRORS SEGMENT REJECT LIMIT 5;
```

Parent topic: Examples for Creating External Tables

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.8.2.11.5 Example 5—TEXT Format on a Hadoop Distributed File Server

examples/example-5-text-format-on-a-hadoop-distributed-file-server.md editTarget: originalFilePath

---

Creates a readable external table, *ext_expenses*, using the `pxf` protocol. The column delimiter is a pipe (|).

```
=# CREATE EXTERNAL TABLE ext_expenses ( name text,
   date date,  amount float4, category text, desc1 text )
   LOCATION ('pxf://dir/data/filename.txt?PROFILE=hdfs:text')
   FORMAT 'TEXT' (DELIMITER '|');
```

Refer to Accessing External Data with PXF for information about using the WarehousePG Platform Extension Framework (PXF) to access data on a Hadoop Distributed File System.

Parent topic: Examples for Creating External Tables

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.8.2.11.6 Example 6—Multiple files in CSV format with header rows

examples/example-6-multiple-files-in-csv-format-with-header-rows.md editTarget: originalFilePath

---

Creates a readable external table, *ext_expenses*, using the `file` protocol. The files are `CSV` format and have a header row.

```
=# CREATE EXTERNAL TABLE ext_expenses ( name text,
   date date,  amount float4, category text, desc1 text )
   LOCATION ('file://filehost/data/international/*',
             'file://filehost/data/regional/*',
             'file://filehost/data/supplement/*.csv')
   FORMAT 'CSV' (HEADER);
```

Parent topic: Examples for Creating External Tables

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.8.2.11.7 Example 7—Readable External Web Table with Script

examples/example-7-readable-web-external-table-with-script.md editTarget: originalFilePath

---

Creates a readable external web table that runs a script once per segment host:

```
=# CREATE EXTERNAL WEB TABLE log_output (linenum int,
    message text)
   EXECUTE '/var/load_scripts/get_log_data.sh' ON HOST
   FORMAT 'TEXT' (DELIMITER '|');
```

Parent topic: Examples for Creating External Tables

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.8.2.11.8 Example 8—Writable External Table with gpfdist

examples/example-8-writable-external-table-with-gpfdist.md editTarget: originalFilePath

---

Creates a writable external table, *sales_out*, that uses gpfdist to write output data to the file *sales.out*. The column delimiter is a pipe (|) and NULL (' ') is a space. The file will be created in the directory specified when you started the gpfdist file server.

```
=# CREATE WRITABLE EXTERNAL TABLE sales_out (LIKE sales)
   LOCATION ('gpfdist://etl1:8081/sales.out')
   FORMAT 'TEXT' ( DELIMITER '|' NULL ' ')
   DISTRIBUTED BY (txn_id);
```

Parent topic: Examples for Creating External Tables

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.8.2.11.9 Example 9—Writable External Web Table with Script

examples/example-9-writable-external-web-table-with-script.md editTarget: originalFilePath

---

Creates a writable external web table, `campaign_out`, that pipes output data received by the segments to an executable script, `to_adreport_etl.sh`:

```
=# CREATE WRITABLE EXTERNAL WEB TABLE campaign_out
    (LIKE campaign)
    EXECUTE '/var/unload_scripts/to_adreport_etl.sh'
    FORMAT 'TEXT' (DELIMITER '|');
```

Parent topic: Examples for Creating External Tables

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.8.2.11.10 Example 10—Readable and Writable External Tables with XML Transformations

examples/example-10-readable-and-writable-external-tables-with-xml-transformations.md editTarget: originalFilePath

---

WarehousePG can read and write XML data to and from external tables with gpfdist. For information about setting up an XML transform, see Transforming External Data with gpfdist and gpload.

Parent topic: Examples for Creating External Tables

4.8.3 Accessing External Data with PXF

Data managed by your organization may already reside in external sources such as Hadoop, object stores, and other SQL databases. The WarehousePG Platform Extension Framework (PXF) provides access to this external data via built-in connectors that map an external data source to a WarehousePG table definition.

PXF is installed with Hadoop and Object Storage connectors. These connectors enable you to read and write external data stored in text, Avro, JSON, RCFile, Parquet, SequenceFile, and ORC formats. You can use the JDBC connector to access an external SQL database.

The WarehousePG Platform Extension Framework includes a C-language extension and a Java service. After you configure and initialize PXF, you start a single PXF JVM process on each WarehousePG segment host. This long- running process concurrently serves multiple query requests.

For detailed information about the architecture of and using PXF, refer to the WarehousePG Platform Extension Framework PXF documentation

Parent topic: Working with External Data

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.8.4 Using the WarehousePG Parallel File Server (gpfdist)

The gpfdist protocol is used in a `CREATE EXTERNAL TABLE` SQL command to access external data served by the WarehousePG `gpfdist` file server utility. When external data is served by gpfdist, all segments in the WarehousePG cluster can read or write external table data in parallel.

This topic describes the setup and management tasks for using gpfdist with external tables.

- About gpfdist and External Tables
- About gpfdist Setup and Performance
- Controlling Segment Parallelism
- Installing gpfdist
- Starting and Stopping gpfdist
- Troubleshooting gpfdist

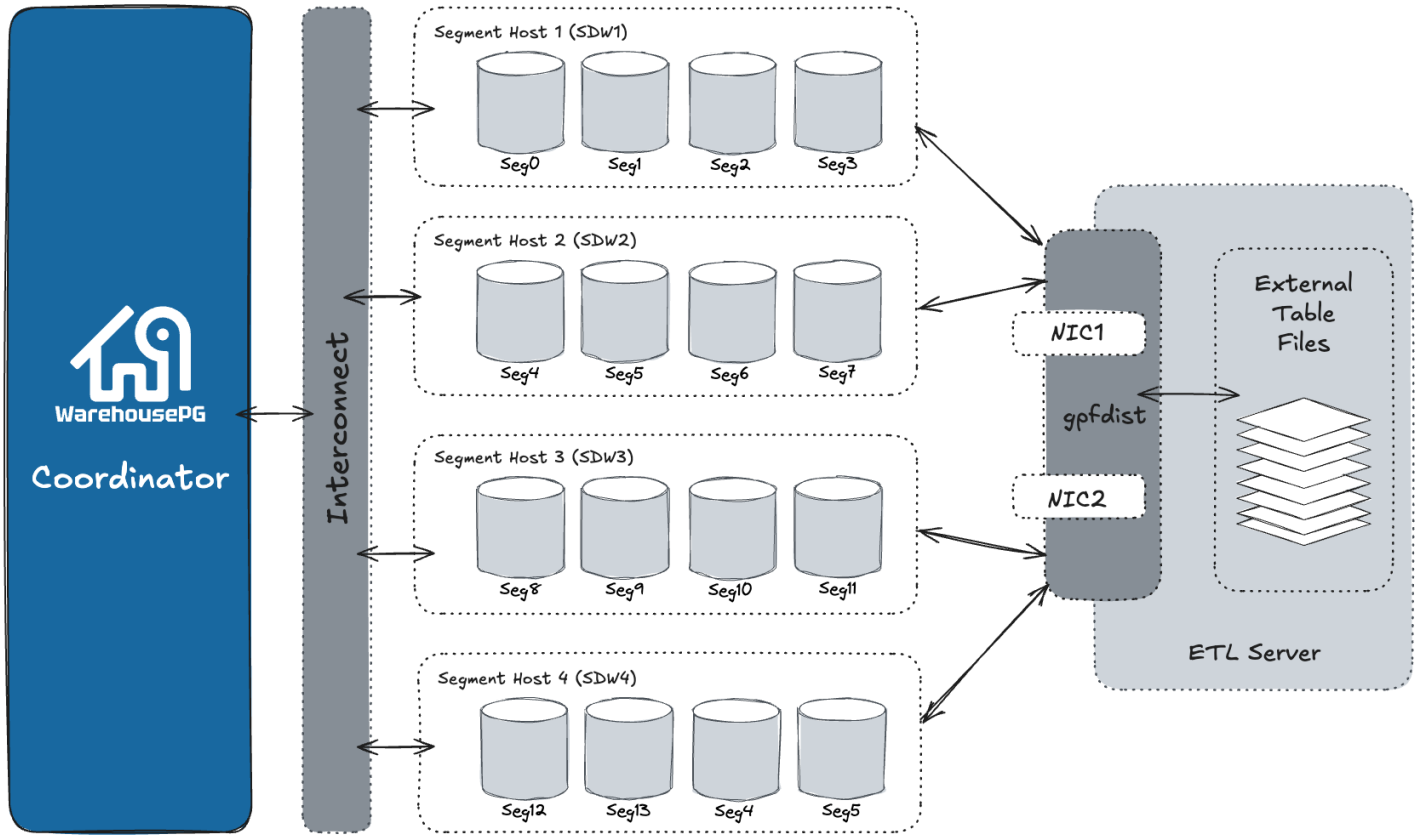
Parent topic: Working with External Data

About gpfdist and External Tables

The `gpfdist` file server utility is located in the `$GPHOME/bin` directory on your WarehousePG coordinator host and on each segment host. When you start a `gpfdist` instance you specify a listen port and the path to a directory containing files to read or where files are to be written. For example, this command runs `gpfdist` in the background, listening on port 8801, and serving files in the `/home/gpadmin/external_files` directory:

```
$ gpfdist -p 8801 -d /home/gpadmin/external_files &
```

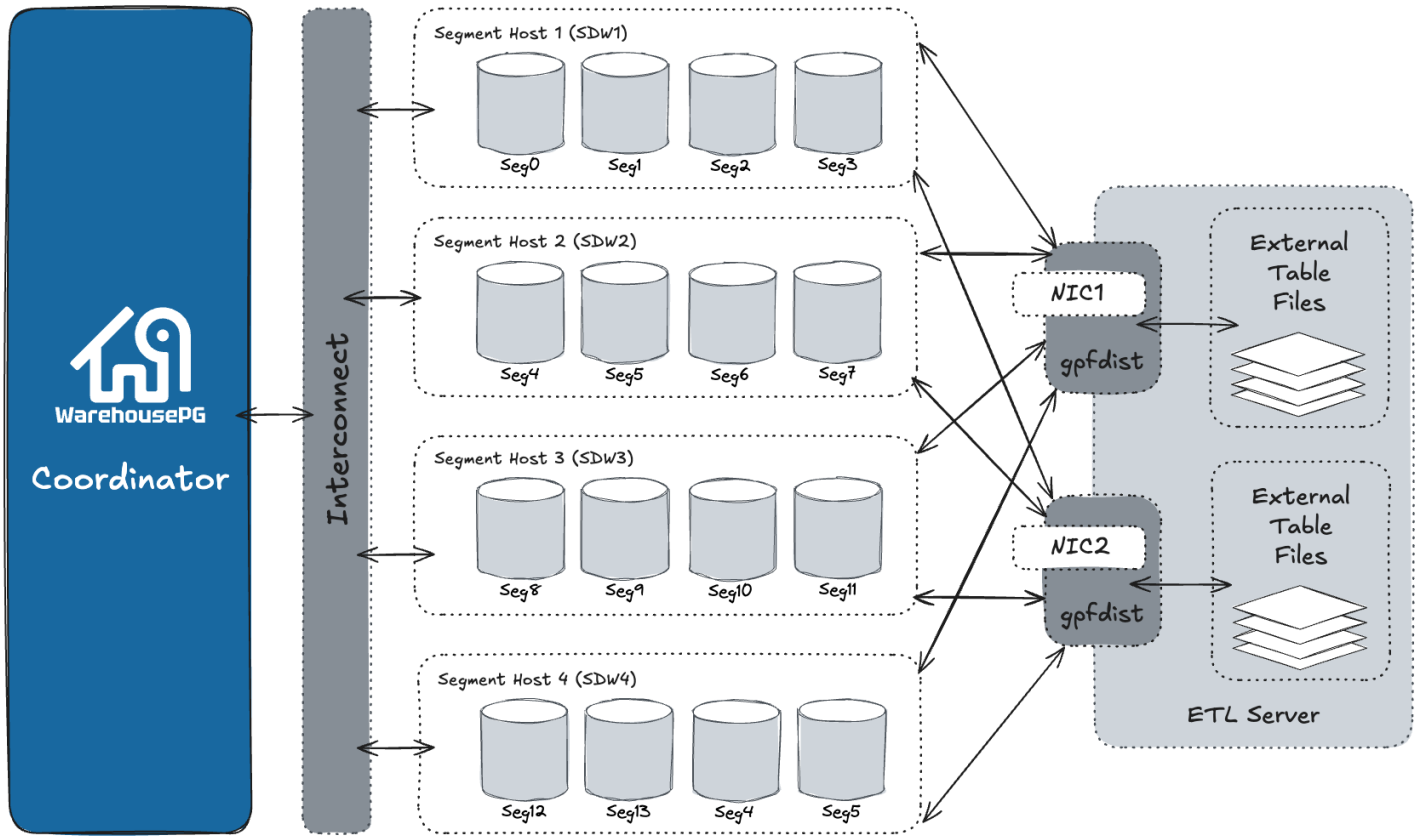
The `CREATE EXTERNAL TABLE` command `LOCATION` clause connects an external table definition to one or more `gpfdist` instances. If the external table is readable, the `gpfdist` server reads data records from files from in specified directory, packs them into a block, and sends the block in a response to a WarehousePG segment's request. The segments unpack rows they receive and distribute them according to the external table's distribution policy. If the external table is a writable table, segments send blocks of rows in a request to gpfdist and gpfdist writes them to the external file.



External data files can contain rows in CSV format or any delimited text format supported by the `FORMAT` clause of the `CREATE EXTERNAL TABLE` command. In addition, `gpfdist` can be configured with a YAML-formatted file to transform external data files between a supported text format and another format, for example XML or JSON. See <ref> for an example that shows how to use `gpfdist` to read external XML files into a WarehousePG readable external table.

For readable external tables, `gpfdist` uncompresses `gzip` (`.gz`) and `bzip2` (`.bz2`) files automatically. You can use the wildcard character (*) or other C-style pattern matching to denote multiple files to read. External files are assumed to be relative to the directory specified when you started the `gpfdist` instance.

About gpfdist Setup and Performance



You can run `gpfdist` instances on multiple hosts and you can run multiple `gpfdist` instances on each host. This allows you to deploy `gpfdist` servers strategically so that you can attain fast data load and unload rates by utilizing all of the available network bandwidth and WarehousePG's parallelism.

- Allow network traffic to use all ETL host network interfaces simultaneously. Run one instance of gpfdist for each interface on the ETL host, then declare the host name of each NIC in the `LOCATION` clause of your external table definition (see Examples for Creating External Tables).

- Divide external table data equally among multiple gpfdist instances on the ETL host. For example, on an ETL system with two NICs, run two gpfdist instances (one on each NIC) to optimize data load performance and divide the external table data files evenly between the two gpfdist servers.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Note Use pipes (|) to separate formatted text when you submit files to gpfdist. WarehousePG encloses comma-separated text strings in single or double quotes. gpfdist has to remove the quotes to parse the strings. Using pipes to separate formatted text avoids the extra step and improves performance.

Controlling Segment Parallelism

The `gp_external_max_segs` server configuration parameter controls the number of segment instances that can access a single gpfdist instance simultaneously. 64 is the default. You can set the number of segments such that some segments process external data files and some perform other database processing. Set this parameter in the `postgresql.conf` file of your coordinator instance.

Installing gpfdist

gpfdist is installed in `$GPHOME/bin` of your WarehousePG coordinator host installation. Run gpfdist on a machine other than the WarehousePG coordinator or standby coordinator, such as on a machine devoted to ETL processing. Running gpfdist on the coordinator or standby coordinator can have a performance impact on query execution. To install gpfdist on your ETL server, get it from the *WarehousePG Clients* package and follow its installation instructions.

Starting and Stopping gpfdist

You can start gpfdist in your current directory location or in any directory that you specify. The default port is `8080`.

From your current directory, type:

```
gpfdist &
```

From a different directory, specify the directory from which to serve files, and optionally, the HTTP port to run on.

To start gpfdist in the background and log output messages and errors to a log file:

```
$ gpfdist -d /var/load_files -p 8081 -l /home/`gpadmin`/log &
```

For multiple gpfdist instances on the same ETL host, use a different base directory and port for each instance. For example:

```
$ gpfdist -d /var/load_files1 -p 8081 -l /home/`gpadmin`/log1 &
$ gpfdist -d /var/load_files2 -p 8082 -l /home/`gpadmin`/log2 &
```

To stop gpfdist when it is running in the background:

First find its process id:

```
$ ps -ef | grep gpfdist
```

Then stop the process, for example (where 3456 is the process ID in this example):

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
$ kill 3456
```

Troubleshooting gpfdist

The segments access gpfdist at runtime. Ensure that the WarehousePG segment hosts have network access to gpfdist. gpfdist is a web server: test connectivity by running the following command from each host in the WarehousePG cluster (segments and coordinator):

```
$ wget http://<gpfdist_hostname>:<port>/<filename>
```

The `CREATE EXTERNAL TABLE` definition must have the correct host name, port, and file names for gpfdist. Specify file names and paths relative to the directory from which gpfdist serves files (the directory path specified when gpfdist started). See Examples for Creating External Tables.

If you start gpfdist on your system and IPv6 networking is deactivated, gpfdist displays this warning message when testing for an IPv6 port.

```
[WRN gpfdist.c:2050] Creating the socket failed
```

If the corresponding IPv4 port is available, gpfdist uses that port and the warning for IPv6 port can be ignored. To see information about the ports that gpfdist tests, use the `-V` option.

For information about IPv6 and IPv4 networking, see your operating system documentation.

When reading or writing data with the `gpfdist` or `gfdists` protocol, the `gpfdist` utility rejects HTTP requests that do not include `X-GP-PROTO` in the request header. If `X-GP-PROTO` is not detected in the header request `gpfdist` returns a 400 error in the status line of the HTTP response header: `400 invalid request (no gp-proto)`.

WarehousePG includes `X-GP-PROTO` in the HTTP request header to indicate that the request is from WarehousePG.

If the `gpfdist` utility hangs with no read or write activity occurring, you can generate a core dump the next time a hang occurs to help debug the issue. Set the environment variable `GPFDIST_WATCHDOG_TIMER` to the number of seconds of no activity to wait before `gpfdist` is forced to exit. When the environment variable is set and `gpfdist` hangs, the utility stops after the specified number of seconds, creates a core dump, and sends relevant information to the log file.

This example sets the environment variable on a Linux system so that `gpfdist` exits after 300 seconds (5 minutes) of no activity.

```
export GPFDIST_WATCHDOG_TIMER=300
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.9 Loading and Unloading Data

The topics in this section describe methods for loading and writing data into and out of a WarehousePG, and how to format data files.

WarehousePG supports high-performance parallel data loading and unloading, and for smaller amounts of data, single file, non-parallel data import and export.

WarehousePG can read from and write to several types of external data sources, including text files, Hadoop file systems, Amazon S3, and web servers.

- The `COPY` SQL command transfers data between an external text file on the coordinator host, or multiple text files on segment hosts, and a WarehousePG table.
- Readable external tables allow you to query data outside of the database directly and in parallel using SQL commands such as `SELECT` or `JOIN`, or sort external table data, and you can create views for external tables. External tables are often used to load external data into a regular database table using a command such as `CREATE TABLE table AS SELECT * FROM ext_table`.
- External web tables provide access to dynamic data. They can be backed with data from URLs accessed using the HTTP protocol or by the output of an OS script running on one or more segments.
- The `gpfdist` utility is the WarehousePG parallel file distribution program. It is an HTTP server that is used with external tables to allow WarehousePG segments to load external data in parallel, from multiple file systems. You can run multiple instances of `gpfdist` on different hosts and network interfaces and access them in parallel.
- The `gpload` utility automates the steps of a load task using `gpfdist` and a YAML-formatted control file.
- You can create readable and writable external tables with the WarehousePG Platform Extension Framework (PXF), and use these tables to load data into, or offload data from, WarehousePG. For information about using PXF, refer to Accessing External Data with PXF.

The method you choose to load data depends on the characteristics of the source data—its location, size, format, and any transformations required.

In the simplest case, the `COPY` SQL command loads data into a table from a text file that is accessible to the WarehousePG coordinator instance. This requires no setup and provides good performance for smaller amounts of data. With the `COPY` command, the data copied into or out of the database passes between a single file on the coordinator host and the database. This limits the total size of the dataset to the capacity of the file system where the external file resides and limits the data transfer to a single file write stream.

More efficient data loading options for large datasets take advantage of the WarehousePG MPP architecture, using the WarehousePG segments to load data in parallel. These methods allow data to load simultaneously from multiple file systems, through multiple NICs, on multiple hosts, achieving very high data transfer rates. External tables allow you to access external files from within the database as if they are regular database tables. When used with `gpfdist`, the WarehousePG parallel file distribution program, external tables provide full parallelism by using the resources of all WarehousePG segments to load or unload data.

WarehousePG leverages the parallel architecture of the Hadoop Distributed File System to access files on that system.

4.9.1 Loading Data Using an External Table

Use SQL commands such as `INSERT` and `SELECT` to query a readable external table, the same way that you query a regular database table. For example, to load travel expense data from an external table, `ext_expenses`, into a database table, `expenses_travel`:

```
=# INSERT INTO expenses_travel
    SELECT * from ext_expenses where category='travel';
```

To load all data into a new database table:

```
=# CREATE TABLE expenses AS SELECT * from ext_expenses;
```

Parent topic: Loading and Unloading Data

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.9.2 Loading and Writing Non-HDFS Custom Data

WarehousePG supports `TEXT` and `CSV` formats for importing and exporting data through external tables. You can load and save data in other formats by defining a custom format or custom protocol or by setting up a transformation with the `gpfdist` parallel file server.

- Using a Custom Format
- Using a Custom Protocol

Parent topic: Loading and Unloading Data

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.9.2.1 Using a Custom Format

You specify a custom data format in the `FORMAT` clause of `CREATE EXTERNAL TABLE`.

```
FORMAT 'CUSTOM' (formatter=format_function, key1=val1,...keyn=valn)
```

Where the `'CUSTOM'` keyword indicates that the data has a custom format and `formatter` specifies the function to use to format the data, followed by comma-separated parameters to the formatter function.

WarehousePG provides functions for formatting fixed-width data, but you must author the formatter functions for variable-width data. The steps are as follows.

1. Author and compile input and output functions as a shared library.
2. Specify the shared library function with `CREATE FUNCTION` in WarehousePG.
3. Use the `formatter` parameter of `CREATE EXTERNAL TABLE`'s `FORMAT` clause to call the function.

- **Importing and Exporting Fixed Width Data**
- **Examples: Read Fixed-Width Data**

Parent topic: Loading and Writing Non-HDFS Custom Data

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.9.2.1.1 Importing and Exporting Fixed Width Data

Each column/field in fixed-width text data contains a certain number of character positions. Use a WarehousePG custom format for fixed-width data by specifying the built-in formatter functions `fixedwith_in` (read) and `fixedwidth_out` (write).

The following example creates an external table that specifies the `file` protocol and references a directory. When the external table is `SELECT`ed, WarehousePG invokes the `fixedwidth_in` formatter function to format the data.

```
CREATE READABLE EXTERNAL TABLE students (
    name varchar(20), address varchar(30), age int)
LOCATION ('file://<host>/file/path/')
FORMAT 'CUSTOM' (formatter=fixedwidth_in, name='20', address='30', age='4');
```

The following options specify how to import fixed width data.

- Read all the data.

  To load all of the fields on a line of fixed-width data, you must load them in their physical order. You must specify `<field_name>=<field_lenth>` for each field; you cannot specify a starting and ending position. The field names that you specify in the `FORMAT` options must match the order in which you define the columns in the `CREATE EXTERNAL TABLE` command.

- Set options for blank and null characters.

  Trailing blanks are trimmed by default. To keep trailing blanks, use the `preserve_blanks=on` option. You can reset the trailing blanks option back to the default by specifying the `preserve_blanks=off` option.

  Use the `null='null_string_value'` option to specify a value for null characters.

- If you specify `preserve_blanks=on`, you must also define a value for null characters.

- If you specify `preserve_blanks=off`, null is not defined, and the field contains only blanks, WarehousePG writes a null to the table. If null is defined, WarehousePG writes an empty string to the table.

  Use the `line_delim='line_ending'` option to specify the line ending character. The following examples cover most cases. The `E` specifies an escape string constant.

  ```
  line_delim=E'\n'
  line_delim=E'\r'
  line_delim=E'\r\n'
  line_delim='abc'
  ```

Parent topic: Using a Custom Format

4.9.2.1.2 Examples of Reading Fixed-Width Data

The following examples show how to read fixed-width data.

Example 1 – Loading a table with all fields defined

```
CREATE READABLE EXTERNAL TABLE students (
name varchar(20), address varchar(30), age int)
LOCATION ('file://<host>/file/path/')
FORMAT 'CUSTOM' (formatter=fixedwidth_in,
         name=20, address=30, age=4);
```

Example 2 – Loading a table with PRESERVED_BLANKS on

```
CREATE READABLE EXTERNAL TABLE students (
name varchar(20), address varchar(30), age int)
LOCATION ('gpfdist://<host>:<portNum>/file/path/')
FORMAT 'CUSTOM' (formatter=fixedwidth_in,
         name=20, address=30, age=4,
        preserve_blanks='on',null='NULL');
```

Example 3 – Loading data with no line delimiter

```
CREATE READABLE EXTERNAL TABLE students (
name varchar(20), address varchar(30), age int)
LOCATION ('file://<host>/file/path/')
FORMAT 'CUSTOM' (formatter=fixedwidth_in,
         name='20', address='30', age='4', line_delim='?@')
```

Example 4 – Create a writable external table with a \r\n line delimiter

```
CREATE WRITABLE EXTERNAL TABLE students_out (
name varchar(20), address varchar(30), age int)
LOCATION ('gpfdist://<host>:<portNum>/file/path/students_out.txt')
FORMAT 'CUSTOM' (formatter=fixedwidth_out,
        name=20, address=30, age=4, line_delim=E'\r\n');
```

Parent topic: Using a Custom Format

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.9.2.2 Using a Custom Protocol

WarehousePG provides protocols such as gpfdist, `http`, and `file` for accessing data over a network, or you can author a custom protocol. You can use the standard data formats, `TEXT` and `CSV`, or a custom data format with custom protocols.

You can create a custom protocol whenever the available built-in protocols do not suffice for a particular need. For example, you could connect WarehousePG in parallel to another system directly, and stream data from one to the other without the need to materialize the data on disk or use an intermediate process such as gpfdist. You must be a superuser to create and register a custom protocol.

1. Author the send, receive, and (optionally) validator functions in C, with a predefined API. These functions are compiled and registered with the WarehousePG. For an example custom protocol, see Example Custom Data Access Protocol.

2. After writing and compiling the read and write functions into a shared object (.so), declare a database function that points to the .so file and function names.

   The following examples use the compiled import and export code.

   ```
   CREATE FUNCTION myread() RETURNS integer
   as '$libdir/gpextprotocol.so', 'myprot_import'
   LANGUAGE C STABLE;
   CREATE FUNCTION mywrite() RETURNS integer
   as '$libdir/gpextprotocol.so', 'myprot_export'
   LANGUAGE C STABLE;
   ```

   The format of the optional validator function is:

   ```
   CREATE OR REPLACE FUNCTION myvalidate() RETURNS void
   AS '$libdir/gpextprotocol.so', 'myprot_validate'
   LANGUAGE C STABLE;
   ```

3. Create a protocol that accesses these functions. `Validatorfunc` is optional.

   ```
   CREATE TRUSTED PROTOCOL myprot(
   writefunc='mywrite',
   readfunc='myread',
   validatorfunc='myvalidate');
   ```

4. Grant access to any other users, as necessary.

   ```
   GRANT ALL ON PROTOCOL myprot TO otheruser;
   ```

5. Use the protocol in readable or writable external tables.

   ```
   CREATE WRITABLE EXTERNAL TABLE ext_sales(LIKE sales)
   LOCATION ('myprot://<meta>/<meta>/…')
   FORMAT 'TEXT';
   CREATE READABLE EXTERNAL TABLE ext_sales(LIKE sales)
   LOCATION('myprot://<meta>/<meta>/…')
   FORMAT 'TEXT';
   ```

Declare custom protocols with the SQL command `CREATE TRUSTED PROTOCOL`, then use the `GRANT` command to grant access to your users. For example:

- Allow a user to create a readable external table with a trusted protocol

  ```
  GRANT SELECT ON PROTOCOL <protocol name> TO <user name>;
  ```

- Allow a user to create a writable external table with a trusted protocol

  ```
  GRANT INSERT ON PROTOCOL <protocol name> TO <user name>;
  ```

- Allow a user to create readable and writable external tables with a trusted protocol

  ```
  GRANT ALL ON PROTOCOL <protocol name> TO <user name>;
  ```

4.9.3 Handling Load Errors

Readable external tables are most commonly used to select data to load into regular database tables. You use the `CREATE TABLE AS SELECT` or `INSERT INTO` commands to query the external table data. By default, if the data contains an error, the entire command fails and the data is not loaded into the target database table.

The `SEGMENT REJECT LIMIT` clause allows you to isolate format errors in external table data and to continue loading correctly formatted rows. Use `SEGMENT REJECT LIMIT` to set an error threshold, specifying the reject limit `count` as number of `ROWS` (the default) or as a `PERCENT` of total rows (1-100).

The entire external table operation is cancelled, and no rows are processed, if the number of error rows reaches the `SEGMENT REJECT LIMIT`. The limit of error rows is per-segment, not per entire operation. The operation processes all good rows, and it discards and optionally logs formatting errors for erroneous rows, if the number of error rows does not reach the `SEGMENT REJECT LIMIT`.

The `LOG ERRORS` clause allows you to keep error rows for further examination. For information about the `LOG ERRORS` clause, see the `CREATE EXTERNAL TABLE` command in the *WarehousePG Reference Guide*.

When you set `SEGMENT REJECT LIMIT`, WarehousePG scans the external data in single row error isolation mode. Single row error isolation mode applies to external data rows with format errors such as extra or missing attributes, attributes of a wrong data type, or invalid client encoding sequences. WarehousePG does not check constraint errors, but you can filter constraint errors by limiting the `SELECT` from an external table at runtime. For example, to eliminate duplicate key errors:

```
=# INSERT INTO table_with_pkeys
    SELECT DISTINCT * FROM external_table;
```

> **Note** When loading data with the `COPY` command or an external table, the value of the server configuration parameter `gp_initial_bad_row_limit` limits the initial number of rows that are processed that are not formatted properly. The default is to stop processing if the first 1000 rows contain formatting errors. See the *WarehousePG Reference Guide* for information about the parameter.

- Define an External Table with Single Row Error Isolation
- Capture Row Formatting Errors and Declare a Reject Limit
- Viewing Bad Rows in the Error Log
- Moving Data between Tables

Parent topic: Loading and Unloading Data

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.9.3.1 Define an External Table with Single Row Error Isolation

The following example logs errors internally in WarehousePG and sets an error threshold of 10 errors.

```
=# CREATE EXTERNAL TABLE ext_expenses ( name text,
   date date,  amount float4, category text, desc1 text )
   LOCATION ('gpfdist://etlhost-1:8081/*',
             'gpfdist://etlhost-2:8082/*')
   FORMAT 'TEXT' (DELIMITER '|')
   LOG ERRORS SEGMENT REJECT LIMIT 10
     ROWS;
```

Use the built-in SQL function `gp_read_error_log('external_table')` to read the error log data. This example command displays the log errors for *ext_expenses*:

```
SELECT gp_read_error_log('ext_expenses');
```

For information about the format of the error log, see Viewing Bad Rows in the Error Log.

The built-in SQL function `gp_truncate_error_log('external_table')` deletes the error data. This example deletes the error log data created from the previous external table example :

```
SELECT gp_truncate_error_log('ext_expenses');
```

Parent topic: Handling Load Errors

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.9.3.2 Capture Row Formatting Errors and Declare a Reject Limit

The following SQL fragment captures formatting errors internally in WarehousePG and declares a reject limit of 10 rows.

```
LOG ERRORS SEGMENT REJECT LIMIT 10 ROWS
```

Use the built-in SQL function `gp_read_error_log()` to read the error log data. For information about viewing log errors, see Viewing Bad Rows in the Error Log.

Parent topic: Handling Load Errors

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.9.3.3 Viewing Bad Rows in the Error Log

If you use single row error isolation (see Define an External Table with Single Row Error Isolation or Running COPY in Single Row Error Isolation Mode), any rows with formatting errors are logged internally by WarehousePG.

WarehousePG captures the following error information in a table format:

column	type	description
cmdtime	timestamptz	Timestamp when the error occurred.
relname	text	The name of the external table or the target table of a `COPY` command.
filename	text	The name of the load file that contains the error.
linenum	int	If `COPY` was used, the line number in the load file where the error occurred. For external tables using file:// protocol or gpfdist:// protocol and CSV format, the file name and line number is logged.
bytenum	int	For external tables with the gpfdist:// protocol and data in TEXT format: the byte offset in the load file where the error occurred. gpfdist parses TEXT files in blocks, so logging a line number is not possible. CSV files are parsed a line at a time so line number tracking is possible for CSV files.
errmsg	text	The error message text.
rawdata	text	The raw data of the rejected row.
rawbytes	bytea	In cases where there is a database encoding error (the client encoding used cannot be converted to a server-side encoding), it is not possible to log the encoding error as *rawdata*. Instead the raw bytes are stored and you will see the octal code for any non seven bit ASCII characters.

You can use the WarehousePG built-in SQL function `gp_read_error_log()` to display formatting errors that are logged internally. For example, this command displays the error log information for the table *ext_expenses*:

```
SELECT gp_read_error_log('ext_expenses');
```

For information about managing formatting errors that are logged internally, see the command `COPY` or `CREATE EXTERNAL TABLE` in the *WarehousePG Reference Guide*.

Parent topic: Handling Load Errors

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.9.3.4 Moving Data between Tables

You can use `CREATE TABLE AS` or `INSERT...SELECT` to load external and external web table data into another (non-external) database table, and the data will be loaded in parallel according to the external or external web table definition.

If an external table file or external web table data source has an error, one of the following will happen, depending on the isolation mode used:

- **Tables without error isolation mode**: any operation that reads from that table fails. Loading from external and external web tables without error isolation mode is an all or nothing operation.
- **Tables with error isolation mode**: the entire file will be loaded, except for the problematic rows (subject to the configured REJECT_LIMIT)

Parent topic: Handling Load Errors

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.9.4 Loading Data with gpload

The WarehousePG `gpload` utility loads data using readable external tables and the WarehousePG parallel file server (gpfdist or `gpfdists`). It handles parallel file-based external table setup and allows users to configure their data format, external table definition, and gpfdist or `gpfdists` setup in a single configuration file.

> **Note** `gpfdist` and `gpload` are compatible only with the WarehousePG major version in which they are shipped. For example, a `gpfdist` utility that is installed with WarehousePG 6.x cannot be used with WarehousePG 7.x.

> **Note** `MERGE` and `UPDATE` operations are not supported if the target table column name is a reserved keyword, has capital letters, or includes any character that requires quotes (" ") to identify the column.

To use gpload

1. Ensure that your environment is set up to run `gpload`. Some dependent files from your WarehousePG installation are required, such as gpfdist and Python 3, as well as network access to the WarehousePG segment hosts. On Windows clients, `gpload` also requires that you install the following packages:

   ```
   pip install psycopg2 pyyaml
   ```

2. Create your load control file. This is a YAML-formatted file that specifies the WarehousePG connection information, gpfdist configuration information, external table options, and data format.

   See the *WarehousePG Reference Guide* for details.

   For example:

   ```
   ---
   VERSION: 1.0.0.1
   DATABASE: ops
   USER: gpadmin
   HOST: cdw-1
   PORT: 5432
   GPLOAD:
      INPUT:
       - SOURCE:
            LOCAL_HOSTNAME:
              - etl1-1
              - etl1-2
              - etl1-3
              - etl1-4
            PORT: 8081
            FILE:
              - /var/load/data/*
       - COLUMNS:
              - name: text
              - amount: float4
              - category: text
              - descr: text
              - date: date
       - FORMAT: text
       - DELIMITER: '|'
       - ERROR_LIMIT: 25
       - LOG_ERRORS: true
      OUTPUT:
       - TABLE: payables.expenses
       - MODE: INSERT
      PRELOAD:
       - REUSE_TABLES: true
   SQL:
      - BEFORE: "INSERT INTO audit VALUES('start', current_timestamp)"
      - AFTER: "INSERT INTO audit VALUES('end', current_timestamp)"
   ```

3. Run `gpload`, passing in the load control file. For example:

   ```
   gpload -f my_load.yml
   ```

Parent topic: Loading and Unloading Data

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.9.5 Transforming External Data with gpfdist and gpload

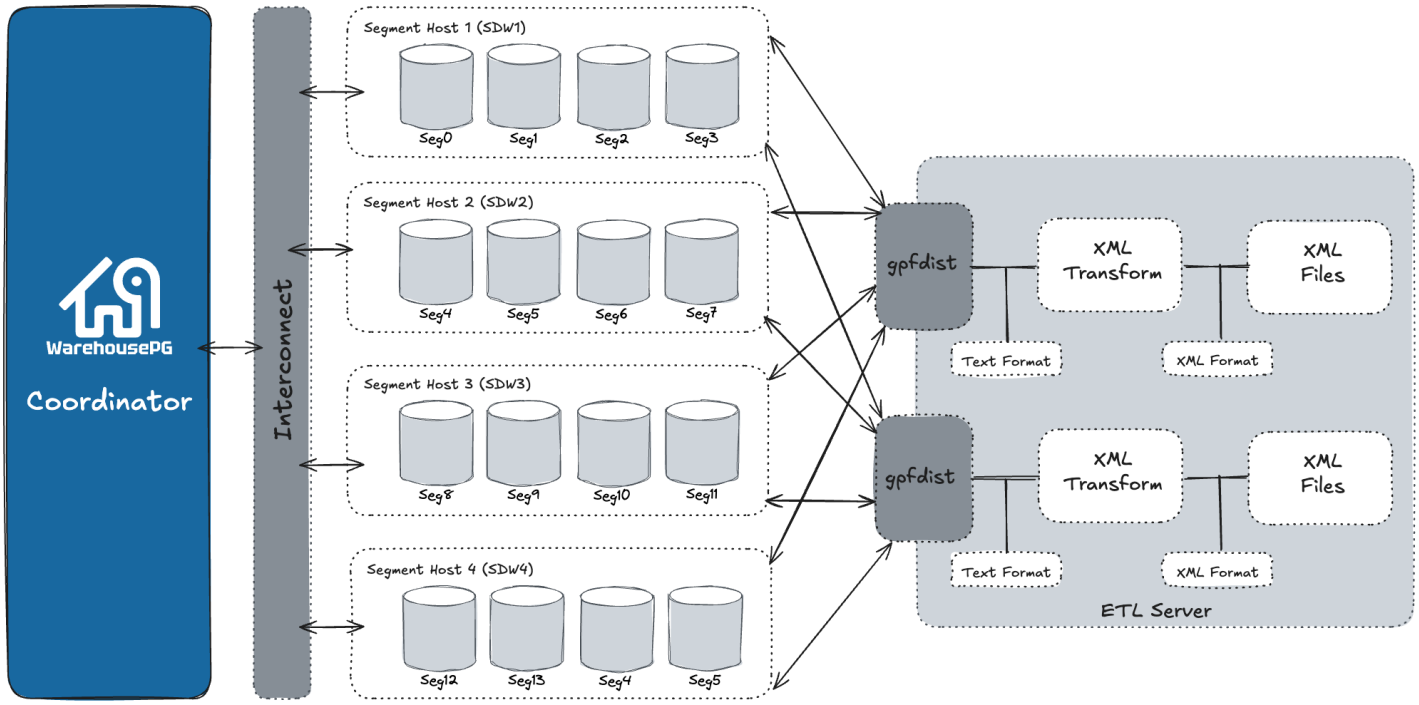
The `gpfdist` parallel file server allows you to set up transformations that enable WarehousePG external tables to read and write files in formats that are not supported with the `CREATE EXTERNAL TABLE` command's `FORMAT` clause. An *input* transformation reads a file in the foreign data format and outputs rows to `gpfdist` in the CSV or other text format specified in the external table's `FORMAT` clause. An *output* transformation receives rows from `gpfdist` in text format and converts them to the foreign data format.

> **Note** `gpfdist` and `gpload` are compatible only with the WarehousePG major version in which they are shipped. For example, a `gpfdist` utility that is installed with WarehousePG 6.x cannot be used with WarehousePG 7.x.

This topic describes the tasks to set up data transformations that work with `gpfdist` to read or write external data files with formats that WarehousePG does not support.

- About gpfdist Transformations
- Determine the Transformation Schema
- Write a Transformation
- Write the gpfdist Configuration File
- Transfer the Data
- Configuration File Format
- XML Transformation Examples

Parent topic: Loading and Unloading Data



About gpfdist Transformations

To set up a transformation for a data format, you provide an executable command that `gpfdist` can call with the name of the file containing data. For example, you could write a shell script that runs an XSLT transformation on an XML file to output rows with columns delimited with a vertical bar (`|`) character and rows delimited with linefeeds.

Transformations are configured in a YAML-formatted configuration file passed to `gpfdist` on the command line.

If you want to load the external data into a table in the WarehousePG, you can use the `gpload` utility to automate the tasks to create an external table, run `gpfdist` , and load the transformed data into the database table.

Accessing data in external XML files from within the database is a common example requiring transformation. The following diagram shows *gpfdist* performing a transformation on XML files on an ETL server.

Following are the high-level steps to set up a `gpfdist` transformation for external data files. The process is illustrated with an XML example.

1. Determine the transformation schema.
2. Write a transformation.
3. Write the gpfdist configuration file.
4. Transfer the data.

Determine the Transformation Schema

To prepare for the transformation project:

1. Determine the goal of the project, such as indexing data, analyzing data, combining data, and so on.
2. Examine the source files and note the file structure and element names.
3. Choose the elements to import and decide if any other limits are appropriate.

For example, the following XML file, *prices.xml*, is a simple XML file that contains price records. Each price record contains two fields: an item number and a price.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
<?xml version="1.0" encoding="ISO-8859-1" ?>
<prices>
  <pricerecord>
    <itemnumber>708421</itemnumber>
    <price>19.99</price>
  </pricerecord>
  <pricerecord>
    <itemnumber>708466</itemnumber>
    <price>59.25</price>
  </pricerecord>
  <pricerecord>
    <itemnumber>711121</itemnumber>
    <price>24.99</price>
  </pricerecord>
</prices>
```

The goal of this transformation is to import all the data into a WarehousePG readable external table with an integer `itemnumber` column and a decimal `price` column.

Write a Transformation

The transformation specifies what to extract from the data. You can use any authoring environment and language appropriate for your project. For XML transformations choose from technologies such as XSLT, Joost (STX), Java, Python, or Perl, based on the goals and scope of the project.

In the price example, the next step is to transform the XML data into a two-column delimited text format.

```
708421|19.99
708466|59.25
711121|24.99
```

The following STX transform, called *input_transform.stx*, performs the data transformation.

```
<?xml version="1.0"?>
<stx:transform version="1.0"
   xmlns:stx="http://stx.sourceforge.net/2002/ns"
   pass-through="none">
  <!-- declare variables -->
  <stx:variable name="itemnumber"/>
  <stx:variable name="price"/>
  <!-- match and output prices as columns delimited by | -->
  <stx:template match="/prices/pricerecord">
    <stx:process-children/>
    <stx:value-of select="$itemnumber"/>
<stx:text>|</stx:text>
    <stx:value-of select="$price"/>      <stx:text>
</stx:text>
  </stx:template>
  <stx:template match="itemnumber">
    <stx:assign name="itemnumber" select="."/>
  </stx:template>
  <stx:template match="price">
    <stx:assign name="price" select="."/>
  </stx:template>
</stx:transform>
```

This STX transform declares two temporary variables, `itemnumber` and `price`, and the following rules.

1. When an element that satisfies the XPath expression `/prices/pricerecord` is found, examine the child elements and generate output that contains the value of the `itemnumber` variable, a `|` character, the value of the price variable, and a newline.
2. When an `<itemnumber>` element is found, store the content of that element in the variable `itemnumber`.
3. When a <price> element is found, store the content of that element in the variable `price`.

Write the gpfdist Configuration File

The gpfdist configuration is specified as a YAML 1.1 document. It contains rules that gpfdist uses to select a transformation to apply when loading or extracting data.

This example gpfdist configuration contains the following items that are required for the *prices.xml* transformation scenario:

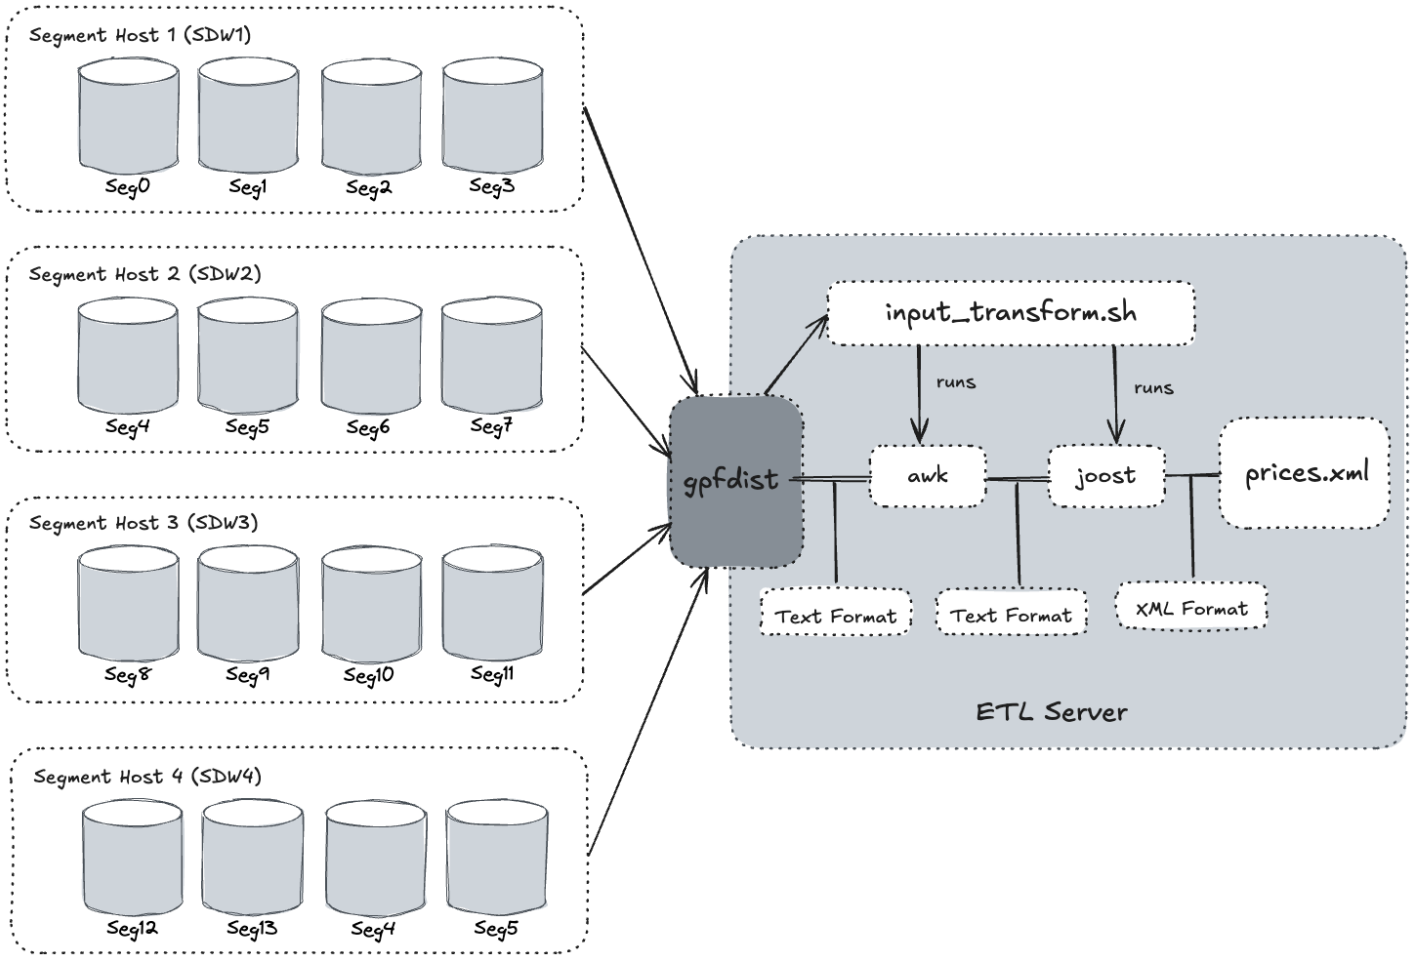
- the `config.yaml` file defining `TRANSFORMATIONS`
- the `input_transform.sh` wrapper script, referenced in the `config.yaml` file
- the `input_transform.stx` joost transformation, called from `input_transform.sh`

Aside from the ordinary YAML rules, such as starting the document with three dashes (`---`), a gpfdist configuration must conform to the following restrictions:

1. A `VERSION` setting must be present with the value `1.0.0.1`.
2. A `TRANSFORMATIONS` setting must be present and contain one or more mappings.
3. Each mapping in the `TRANSFORMATION` must contain:
    - a `TYPE` with the value 'input' or 'output'
    - a `COMMAND` indicating how the transformation is run.
4. Each mapping in the `TRANSFORMATION` can contain optional `CONTENT`, `SAFE`, and `STDERR` settings.

The following gpfdist configuration, called `config.yaml`, applies to the prices example. The initial indentation on each line is significant and reflects the hierarchical nature of the specification. The transformation name `prices_input` in the following example will be referenced later when creating the table in SQL.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.



```
---
VERSION: 1.0.0.1
TRANSFORMATIONS:
  prices_input:
    TYPE  input
    COMMAND:  /bin/bash input_transform.sh %filename%
```

The `COMMAND` setting uses a wrapper script called `input_transform.sh` with a `%filename%` placeholder. When gpfdist runs the `prices_input` transform, it invokes `input_transform.sh` with `/bin/bash` and replaces the `%filename%` placeholder with the path to the input file to transform. The wrapper script called `input_transform.sh` contains the logic to invoke the STX transformation and return the output.

If Joost is used, the Joost STX engine must be installed.

```
#!/bin/bash
# input_transform.sh - sample input transformation,
# demonstrating use of Java and Joost STX to convert XML into
# text to load into WarehousePG.
# java arguments:
#   -jar joost.jar         joost STX engine
#   -nodecl                  don't generate a <?xml?> declaration
#   $1                        filename to process
#   input_transform.stx    the STX transformation
#
# the AWK step eliminates a blank line joost emits at the end
java \
    -jar joost.jar \
    -nodecl \
    $1 \
    input_transform.stx \
 | awk 'NF>0'
```

The `input_transform.sh` file uses the Joost STX engine with the AWK interpreter. The following diagram shows the process flow as gpfdist runs the transformation.

Transfer the Data

Create the target database tables with SQL statements based on the appropriate schema.

There are no special requirements for WarehousePG tables that hold loaded data. In the prices example, the following command creates the `prices` table, where the data is to be loaded.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
CREATE TABLE prices (
  itemnumber integer,
  price       decimal
)
DISTRIBUTED BY (itemnumber);
```

Next, use one of the following approaches to transform the data with gpfdist.

- `gpload` supports only input transformations, but in many cases is easier to implement.
- `gpfdist` with `INSERT INTO SELECT FROM` supports both input and output transformations, but exposes details that `gpload` automates for you.

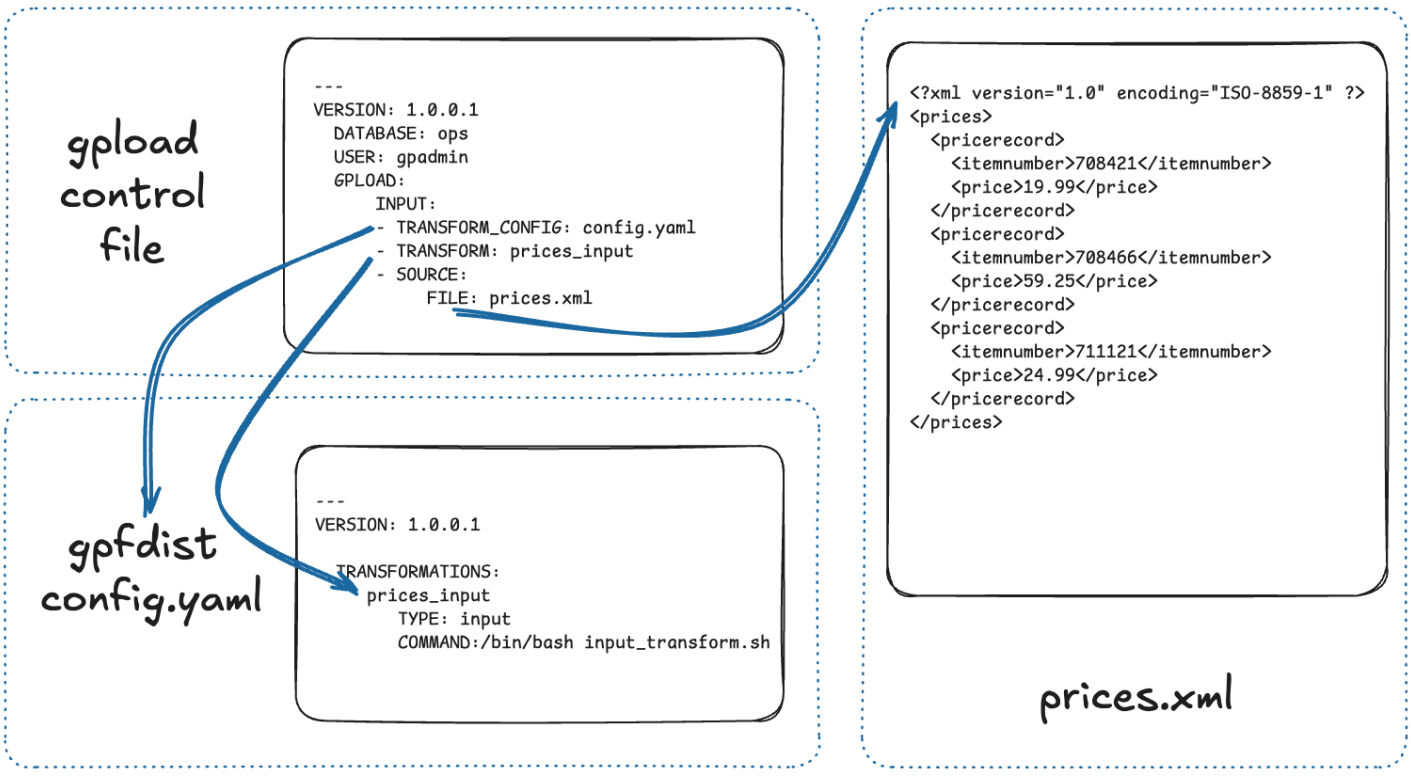
Transforming with gpload

The WarehousePG `gpload` utility orchestrates a data load operation using the `gpfdist` parallel file server and a YAML-formatted configuration file. `gpload` automates these tasks:

- Creates a readable external table in the database.
- Starts `gpfdist` instances with the configuration file that contains the transformation.
- Runs `INSERT INTO table\_name SELECT FROM external\_table` to load the data.
- Removes the external table definition.

Transforming data with `gpload` requires that the settings `TRANSFORM` and `TRANSFORM_CONFIG` appear in the `INPUT` section of the `gpload` control file.

For more information about the syntax and placement of these settings in the `gpload` control file, see the *WarehousePG Reference Guide*.



- `TRANSFORM_CONFIG` specifies the name of the gpfdist configuration file.
- The `TRANSFORM` setting indicates the name of the transformation that is described in the file named in `TRANSFORM_CONFIG`.

```
---
VERSION: 1.0.0.1
DATABASE: ops
USER: gpadmin
GPLOAD:
  INPUT:
    - TRANSFORM_CONFIG: config.yaml
    - TRANSFORM: prices_input
    - SOURCE:
        FILE: prices.xml
```

The transformation name must appear in two places: in the `TRANSFORM` setting of the gpfdist configuration file and in the `TRANSFORMATIONS` section of the file named in the `TRANSFORM_CONFIG` section.

In the `gpload` control file, the optional parameter `MAX_LINE_LENGTH` specifies the maximum length of a line in the XML transformation data that is passed to `gpload`.

The following diagram shows the relationships between the `gpload` control file, the gpfdist configuration file, and the XML data file.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Transforming with gpfdist and INSERT INTO SELECT FROM

With this load method, you perform each of the tasks that `gpload` automates. You start `gpfdist`, create an external table, load the data, and clean up by dropping the table and stopping `gpfdist`.

Specify the transformation in the `CREATE EXTERNAL TABLE` definition's `LOCATION` clause. For example, the transform is shown in bold in the following command. (Run gpfdist first, using the command `gpfdist -c config.yaml`).

```
CREATE READABLE EXTERNAL TABLE prices_readable (LIKE prices)
   LOCATION ('gpfdist://hostname:8080/prices.xml#transform=prices_input')
   FORMAT 'TEXT' (DELIMITER '|')
   LOG ERRORS SEGMENT REJECT LIMIT 10;
```

In the command above, change `hostname` to your hostname. `prices_input` comes from the `gpfdist` configuration file.

The following query then loads the data into the `prices` table.

```
INSERT INTO prices SELECT * FROM prices_readable;
```

Configuration File Format

The gpfdist configuration file uses the YAML 1.1 document format and implements a schema for defining the transformation parameters. The configuration file must be a valid YAML document.

The gpfdist program processes the document in order and uses indentation (spaces) to determine the document hierarchy and relationships of the sections to one another. The use of white space is significant. Do not use white space for formatting and do not use tabs.

The following is the basic structure of a configuration file.

```
---
VERSION1.0.0.1
TRANSFORMATIONS:
  transformation_name1:
    TYPE   input | output
    COMMANDcommand
    CONTENTdata | paths
    SAFE   posix-regex
    STDERR server | console
  transformation_name2:
    TYPE   input | output
    COMMANDcommand
...
```

VERSION Required. The version of the gpfdist configuration file schema. The current version is 1.0.0.1.

TRANSFORMATIONS Required. Begins the transformation specification section. A configuration file must have at least one transformation. When gpfdist receives a transformation request, it looks in this section for an entry with the matching transformation name.

TYPE Required. Specifies the direction of transformation. Values are `input` or `output`.

- `input`: gpfdist treats the standard output of the transformation process as a stream of records to load into WarehousePG.
- `output`: gpfdist treats the standard input of the transformation process as a stream of records from WarehousePG to transform and write to the appropriate output.

COMMAND Required. Specifies the command gpfdist will run to perform the transformation.

For input transformations, gpfdist invokes the command specified in the `CONTENT` setting. The command is expected to open the underlying file(s) as appropriate and produce one line of `TEXT` for each row to load into WarehousePG. The input transform determines whether the entire content should be converted to one row or to multiple rows.

For output transformations, gpfdist invokes this command as specified in the `CONTENT` setting. The output command is expected to open and write to the underlying file(s) as appropriate. The output transformation determines the final placement of the converted output.

CONTENT Optional. The values are `data` and `paths`. The default value is `data`.

- When `CONTENT` specifies `data`, the text `%filename%` in the `COMMAND` section is replaced by the path to the file to read or write.
- When `CONTENT` specifies `paths`, the text `%filename%` in the `COMMAND` section is replaced by the path to the temporary file that contains the list of files to read or write.

The following is an example of a `COMMAND` section showing the text `%filename%` that is replaced.

```
COMMAND: /bin/bash input_transform.sh %filename%
```

SAFE Optional. A `POSIX` regular expression that the paths must match to be passed to the transformation. Specify `SAFE` when there is a concern about injection or improper interpretation of paths passed to the command. The default is no restriction on paths.

STDERR Optional. The values are `server` and `console`.

This setting specifies how to handle standard error output from the transformation. The default, `server`, specifies that gpfdist will capture the standard error output from the transformation in a temporary file and send the first 8k of that file to WarehousePG as an error message. The error message will appear as an SQL error. `Console` specifies that gpfdist does not redirect or transmit the standard error output from the transformation.

XML Transformation Examples

The following examples demonstrate the complete process for different types of XML data and STX transformations. Files and detailed instructions associated with these examples are in the GitHub repo `https://github.com/warehouse-pg/warehouse-pg` in the gpMgmt/demo/gpfdist_transform directory. Read the README file in the *Before You Begin* section before you run the examples. The README file explains how to download the example data file used in the examples.

Command-based External Web Tables

The output of a shell command or script defines command-based web table data. Specify the command in the `EXECUTE` clause of `CREATE EXTERNAL WEB TABLE`. The data is current as of the time the command runs. The `EXECUTE` clause runs the shell command or script on the specified coordinator, and/or segment host or hosts. The command or script must reside on the hosts corresponding to the host(s) defined in the `EXECUTE` clause.

By default, the command is run on segment hosts when active segments have output rows to process. For example, if each segment host runs four primary segment instances that have output rows to process, the command runs four times per segment host. You can optionally limit the number of segment instances that run the web table command. All segments included in the web table definition in the `ON` clause run the command in parallel.

The command that you specify in the external table definition runs from the database and cannot access environment variables from `.bashrc` or `.profile`. Set environment variables in the `EXECUTE` clause. For example:

```
=# CREATE EXTERNAL WEB TABLE output (output text)
    EXECUTE 'PATH=/home/gpadmin/programs; export PATH; myprogram.sh'
    FORMAT 'TEXT';
```

Scripts must be executable by the `gpadmin` user and reside in the same location on the coordinator or segment hosts.

The following command defines a web table that runs a script. The script runs on each segment host where a segment has output rows to process.

```
=# CREATE EXTERNAL WEB TABLE log_output
    (linenum int, message text)
    EXECUTE '/var/load_scripts/get_log_data.sh' ON HOST
    FORMAT 'TEXT' (DELIMITER '|');
```

IRS MeF XML Files (In demo Directory)

This example demonstrates loading a sample IRS Modernized eFile tax return using a Joost STX transformation. The data is in the form of a complex XML file.

The U.S. Internal Revenue Service (IRS) made a significant commitment to XML and specifies its use in its Modernized e-File (MeF) system. In MeF, each tax return is an XML document with a deep hierarchical structure that closely reflects the particular form of the underlying tax code.

XML, XML Schema and stylesheets play a role in their data representation and business workflow. The actual XML data is extracted from a ZIP file attached to a MIME "transmission file" message. For more information about MeF, see Modernized e-File (Overview) on the IRS web site.

The sample XML document, *RET990EZ_2006.xml*, is about 350KB in size with two elements:

- ReturnHeader
- ReturnData

The <ReturnHeader> element contains general details about the tax return such as the taxpayer's name, the tax year of the return, and the preparer. The <ReturnData> element contains multiple sections with specific details about the tax return and associated schedules.

The following is an abridged sample of the XML file.

```
<?xml version="1.0" encoding="UTF-8"?>
<Return returnVersion="2006v2.0"
   xmlns="https://www.irs.gov/efile"
   xmlns:efile="https://www.irs.gov/efile"
   xsi:schemaLocation="https://www.irs.gov/efile"
   xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
   <ReturnHeader binaryAttachmentCount="1">
     <ReturnId>AAAAAAAAAAAAAAAAAAAA</ReturnId>
     <Timestamp>1999-05-30T12:01:01+05:01</Timestamp>
     <ReturnType>990EZ</ReturnType>
     <TaxPeriodBeginDate>2005-01-01</TaxPeriodBeginDate>
     <TaxPeriodEndDate>2005-12-31</TaxPeriodEndDate>
     <Filer>
       <EIN>011248772</EIN>
       ... more data ...
     </Filer>
     <Preparer>
       <Name>Percy Polar</Name>
       ... more data ...
     </Preparer>
     <TaxYear>2005</TaxYear>
   </ReturnHeader>
   ... more data ..
```

The goal is to import all the data into a WarehousePG. First, convert the XML document into text with newlines "escaped", with two columns: `ReturnId` and a single column on the end for the entire MeF tax return. For example:

```
AAAAAAAAAAAAAAAAAAAA|<Return returnVersion="2006v2.0"...
```

Load the data into WarehousePG.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

WITSML™ Files (In demo Directory)

This example demonstrates loading sample data describing an oil rig using a Joost STX transformation. The data is in the form of a complex XML file downloaded from energistics.org.

The Wellsite Information Transfer Standard Markup Language (WITSML™) is an oil industry initiative to provide open, non-proprietary, standard interfaces for technology and software to share information among oil companies, service companies, drilling contractors, application vendors, and regulatory agencies. For more information about WITSML™, see https://www.energistics.org/.

The oil rig information consists of a top level `<rigs>` element with multiple child elements such as `<documentInfo>, <rig>`, and so on. The following excerpt from the file shows the type of information in the `<rig>` tag.

```
<?xml version="1.0" encoding="UTF-8"?>
<?xml-stylesheet href="../stylesheets/rig.xsl" type="text/xsl" media="screen"?>
<rigs
 xmlns="https://www.energistics.org/schemas/131"
 xmlns:xsi="https://www.w3.org/2001/XMLSchema-instance"
 xsi:schemaLocation="https://www.energistics.org/schemas/131 ../obj_rig.xsd"
 version="1.3.1.1">
 <documentInfo>
 ... misc data ...
 </documentInfo>
 <rig uidWell="W-12" uidWellbore="B-01" uid="xr31">
     <nameWell>6507/7-A-42</nameWell>
     <nameWellbore>A-42</nameWellbore>
     <name>Deep Drill #5</name>
     <owner>Deep Drilling Co.</owner>
     <typeRig>floater</typeRig>
     <manufacturer>Fitsui Engineering</manufacturer>
     <yearEntService>1980</yearEntService>
     <classRig>ABS Class A1 M CSDU AMS ACCU</classRig>
     <approvals>DNV</approvals>
 ... more data ...
```

The goal is to import the information for this rig into WarehousePG.

The sample document, *rig.xml*, is about 11KB in size. The input does not contain tabs so the relevant information can be converted into records delimited with a pipe (|).

```
W-12|6507/7-A-42|xr31|Deep Drill #5|Deep Drilling Co.|John Doe|John.Doe@example.com|
```

With the columns:

- `well_uid text`, -- e.g. W-12
- `well_name text`, -- e.g. 6507/7-A-42
- `rig_uid text`, -- e.g. xr31
- `rig_name text`, -- e.g. Deep Drill #5
- `rig_owner text`, -- e.g. Deep Drilling Co.
- `rig_contact text`, -- e.g. John Doe
- `rig_email text`, -- e.g. John.Doe@example.com
- `doc xml`

Then, load the data into WarehousePG.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.9.6 Loading Data with COPY

`COPY FROM` copies data from a file or standard input into a table and appends the data to the table contents. `COPY` is non-parallel: data is loaded in a single process using the WarehousePG coordinator instance. Using `COPY` is only recommended for very small data files.

The `COPY` source file must be accessible to the `postgres` process on the coordinator host. Specify the `COPY` source file name relative to the data directory on the coordinator host, or specify an absolute path.

WarehousePG copies data from `STDIN` or `STDOUT` using the connection between the client and the coordinator server.

Parent topic: Loading and Unloading Data

Loading From a File

The `COPY` command asks the `postgres` backend to open the specified file, read it and append it to the table. In order to be able to read the file, the backend needs to have read permissions on the file, and the file name must be specified using an absolute path on the coordinator host, or a relative path to the coordinator data directory.

```
COPY <table_name> FROM </path/to/filename>;
```

Loading From STDIN

To avoid the problem of copying the data file to the coordinator host before loading the data, `COPY FROM STDIN` uses the Standard Input channel and feeds data directly into the `postgres` backend. After the `COPY FROM STDIN` command started, the backend will accept lines of data until a single line only contains a backslash-period (\.).

```
COPY <table_name> FROM <STDIN>;
```

Loading Data Using \copy in psql

Do not confuse the psql `\copy` command with the `COPY` SQL command. The `\copy` invokes a regular `COPY FROM STDIN` and sends the data from the psql client to the backend. Therefore any file must reside on the host where the psql client runs, and must be accessible to the user which runs the client.

To avoid the problem of copying the data file to the coordinator host before loading the data, `COPY FROM STDIN` uses the Standard Input channel and feeds data directly into the `postgres` backend. After the `COPY FROM STDIN` command started, the backend will accept lines of data until a single line only contains a backslash-period (\.). psql is wrapping all of this into the handy `\copy` command.

```
\copy <table_name> FROM <filename>;
```

Input Format

`COPY FROM` accepts a `FORMAT` parameter, which specifies the format of the input data. The possible values are `TEXT`, `CSV` (Comma Separated Values), and `BINARY`.

```
COPY <table_name> FROM </path/to/filename> WITH (FORMAT csv);
```

The `FORMAT csv` will read comma-separated values. The `FORMAT text` by default uses tabulators to separate the values, the `DELIMITER` option specifies a different character as value delimiter.

```
COPY <table_name> FROM </path/to/filename> WITH (FORMAT text, DELIMITER '|');
```

By default, the default client encoding is used, this can be changed with the `ENCODING` option. This is useful if data is coming from another operating system.

```
COPY <table_name> FROM </path/to/filename> WITH (ENCODING 'latin1');
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.9.7 Running COPY in Single Row Error Isolation Mode

By default, `COPY` stops an operation at the first error: if the data contains an error, the operation fails and no data loads. If you run `COPY FROM` in *single row error isolation mode*, WarehousePG skips rows that contain format errors and loads properly formatted rows. Single row error isolation mode applies only to rows in the input file that contain format errors. If the data contains a constraint error such as violation of a `NOT NULL`, `CHECK`, or `UNIQUE` constraint, the operation fails and no data loads.

Specifying `SEGMENT REJECT LIMIT` runs the `COPY` operation in single row error isolation mode. Specify the acceptable number of error rows on each segment, after which the entire `COPY FROM` operation fails and no rows load. The error row count is for each WarehousePG segment, not for the entire load operation.

If the `COPY` operation does not reach the error limit, WarehousePG loads all correctly-formatted rows and discards the error rows. Use the `LOG ERRORS` clause to capture data formatting errors internally in WarehousePG. For example:

```
=> COPY country FROM '/data/gpdb/country_data'
   WITH DELIMITER '|' LOG ERRORS
   SEGMENT REJECT LIMIT 10 ROWS;
```

See Viewing Bad Rows in the Error Log for information about investigating error rows.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.9.8 Optimizing Data Load and Query Performance

Use the following tips to help optimize your data load and subsequent query performance.

- Drop indexes before loading data into existing tables.

  Creating an index on pre-existing data is faster than updating it incrementally as each row is loaded. You can temporarily increase the `maintenance_work_mem` server configuration parameter to help speed up `CREATE INDEX` commands, though load performance is affected. Drop and recreate indexes only when there are no active users on the system.

- Create indexes last when loading data into new tables. Create the table, load the data, and create any required indexes.

- Run `ANALYZE` after loading data. If you significantly altered the data in a table, run `ANALYZE` or `VACUUM ANALYZE` to update table statistics for the query optimizer. Current statistics ensure that the optimizer makes the best decisions during query planning and avoids poor performance due to inaccurate or nonexistent statistics.

- Run `VACUUM` after load errors. If the load operation does not run in single row error isolation mode, the operation stops at the first error. The target table contains the rows loaded before the error occurred. You cannot access these rows, but they occupy disk space. Use the `VACUUM` command to recover the wasted space.

Parent topic: Loading and Unloading Data

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.9.9 Unloading Data from WarehousePG

A writable external table allows you to select rows from other database tables and output the rows to files, named pipes, to applications. You can define file-based and web-based writable external tables.

This topic describes how to unload data from WarehousePG using parallel unload (writable external tables) and non-parallel unload (`COPY`).

- Defining a File-Based Writable External Table
- Defining a Command-Based Writable External Web Table
- Unloading Data Using a Writable External Table
- Unloading Data Using COPY

Parent topic: Loading and Unloading Data

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.9.9.1 Defining a File-Based Writable External Table

Writable external tables that output data to files can use the WarehousePG parallel file server program, gpfdist, or the WarehousePG Platform Extension Framework (PXF), WarehousePG's interface to Hadoop.

Use the `CREATE WRITABLE EXTERNAL TABLE` command to define the external table and specify the location and format of the output files. See Using the WarehousePG Parallel File Server (gpfdist) for instructions on setting up gpfdist for use with an external table and Accessing External Data with PXF for instructions on setting up PXF for use with an external table

- With a writable external table using the gpfdist protocol, the WarehousePG segments send their data to gpfdist, which writes the data to the named file. gpfdist must run on a host that the WarehousePG segments can access over the network. gpfdist points to a file location on the output host and writes data received from the WarehousePG segments to the file. To divide the output data among multiple files, list multiple gpfdist URIs in your writable external table definition.
- A writable external web table sends data to an application as a stream of data. For example, unload data from WarehousePG and send it to an application that connects to another database or ETL tool to load the data elsewhere. Writable external web tables use the `EXECUTE` clause to specify a shell command, script, or application to run on the segment hosts and accept an input stream of data. See Defining a Command-Based Writable External Web Table for more information about using `EXECUTE` commands in a writable external table definition.

You can optionally declare a distribution policy for your writable external tables. By default, writable external tables use a random distribution policy. If the source table you are exporting data from has a hash distribution policy, defining the same distribution key column(s) for the writable external table improves unload performance by eliminating the requirement to move rows over the interconnect. If you unload data from a particular table, you can use the `LIKE` clause to copy the column definitions and distribution policy from the source table.

- **Example 1—WarehousePG file server (gpfdist)**
- **Example 2—Hadoop file server (pxf)**

Parent topic: Unloading Data from WarehousePG

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.9.9.1.1 Example 1—WarehousePG file server (gpfdist)

```
=# CREATE WRITABLE EXTERNAL TABLE unload_expenses
   ( LIKE expenses )
   LOCATION ('gpfdist://etlhost-1:8081/expenses1.out',
             'gpfdist://etlhost-2:8081/expenses2.out')
 FORMAT 'TEXT' (DELIMITER ',')
 DISTRIBUTED BY (exp_id);
```

Parent topic: Defining a File-Based Writable External Table

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.9.9.1.2 Example 2—Hadoop file server (pxf)

```
=# CREATE WRITABLE EXTERNAL TABLE unload_expenses
   ( LIKE expenses )
   LOCATION ('pxf://dir/path?PROFILE=hdfs:text')
 FORMAT 'TEXT' (DELIMITER ',')
 DISTRIBUTED BY (exp_id);
```

You specify an HDFS directory for a writable external table that you create with the `pxf` protocol.

Parent topic: Defining a File-Based Writable External Table

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.9.9.2 Defining a Command-Based Writable External Web Table

You can define writable external web tables to send output rows to an application or script. The application must accept an input stream, reside in the same location on all of the WarehousePG segment hosts, and be executable by the `gpadmin` user. All segments in the WarehousePG cluster run the application or script, whether or not a segment has output rows to process.

Use `CREATE WRITABLE EXTERNAL WEB TABLE` to define the external table and specify the application or script to run on the segment hosts. Commands run from within the database and cannot access environment variables (such as `$PATH`). Set environment variables in the `EXECUTE` clause of your writable external table definition. For example:

```
=# CREATE WRITABLE EXTERNAL WEB TABLE output (output text)
    EXECUTE 'export PATH=$PATH:/home/`gpadmin`
            /programs;
    myprogram.sh'
    FORMAT 'TEXT'
    DISTRIBUTED RANDOMLY;
```

The following WarehousePG variables are available for use in OS commands run by a web or writable external table. Set these variables as environment variables in the shell that runs the command(s). They can be used to identify a set of requests made by an external table statement across the WarehousePG cluster of hosts and segment instances.

Variable	Description
$GP_CID	Command count of the transaction running the external table statement.
$GP_DATABASE	The database in which the external table definition resides.
$GP_DATE	The date on which the external table command ran.
$GP_COORDINATOR_HOST	The host name of the WarehousePG coordinator host from which the external table statement was dispatched.
$GP_COORDINATOR_PORT	The port number of the WarehousePG coordinator instance from which the external table statement was dispatched.
$GP_QUERY_STRING	The SQL command (DML or SQL query) run by WarehousePG.
$GP_SEG_DATADIR	The location of the data directory of the segment instance running the external table command.
$GP_SEG_PG_CONF	The location of the `postgresql.conf` file of the segment instance running the external table command.
$GP_SEG_PORT	The port number of the segment instance running the external table command.
$GP_SEGMENT_COUNT	The total number of primary segment instances in the WarehousePG cluster.
$GP_SEGMENT_ID	The ID number of the segment instance running the external table command (same as `content` in `gp_segment_configuration`).
$GP_SESSION_ID	The database session identifier number associated with the external table statement.
$GP_SN	Serial number of the external table scan node in the query plan of the external table statement.
$GP_TIME	The time the external table command was run.
$GP_USER	The database user running the external table statement.
$GP_XID	The transaction ID of the external table statement.

- Deactivating EXECUTE for Web or Writable External Tables

Parent topic: Unloading Data from WarehousePG

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.9.9.2.1 Deactivating EXECUTE for Web or Writable External Tables

There is a security risk associated with allowing external tables to run OS commands or scripts. To deactivate the use of `EXECUTE` in web and writable external table definitions, set the `gp_external_enable_exec` server configuration parameter to off in your coordinator postgresql.conf file:

```
gp_external_enable_exec = off
```

> **Note** You must restart the database in order for changes to the `gp_external_enable_exec` server configuration parameter to take effect.

Parent topic: Defining a Command-Based Writable External Web Table

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.9.9.3 Unloading Data Using a Writable External Table

Writable external tables allow only `INSERT` operations. You must grant `INSERT` permission on a table to enable access to users who are not the table owner or a superuser. For example:

```
GRANT INSERT ON writable_ext_table TO admin;
```

To unload data using a writable external table, select the data from the source table(s) and insert it into the writable external table. The resulting rows are output to the writable external table. For example:

```
INSERT INTO writable_ext_table SELECT * FROM regular_table;
```

Parent topic: Unloading Data from WarehousePG

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.9.9.4 Unloading Data Using COPY

`COPY TO` copies data from a table to a file (or standard input) on the WarehousePG coordinator host using a single process on the WarehousePG coordinator instance. Use `COPY` to output a table's entire contents, or filter the output using a `SELECT` statement. For example:

```
COPY (SELECT * FROM country WHERE country_name LIKE 'A%')
TO '/home/gpadmin/a_list_countries.out';
```

Parent topic: Unloading Data from WarehousePG

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.9.10 Formatting Data Files

When you use the WarehousePG tools for loading and unloading data, you must specify how your data is formatted. `COPY`, `CREATE EXTERNAL TABLE`, and `gpload` have clauses that allow you to specify how your data is formatted. Data can be delimited text (`TEXT`) or comma separated values (`CSV`) format. External data must be formatted correctly to be read by WarehousePG. This topic explains the format of data files expected by WarehousePG.

- Formatting Rows
- Formatting Columns
- Representing NULL Values
- Escaping
- Character Encoding

Parent topic: Loading and Unloading Data

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.9.10.1 Formatting Rows

WarehousePG expects rows of data to be separated by the `LF` character (Line feed, `0x0A`), `CR` (Carriage return, `0x0D`), or `CR` followed by `LF` (`CR+LF`, `0x0D 0x0A`). `LF` is the standard newline representation on UNIX or UNIX-like operating systems. Operating systems such as Windows or Mac OS X use `CR` or `CR+LF`. All of these representations of a newline are supported by WarehousePG as a row delimiter. For more information, see Importing and Exporting Fixed Width Data.

Parent topic: Formatting Data Files

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.9.10.2 Formatting Columns

The default column or field delimiter is the horizontal `TAB` character (`0x09`) for text files and the comma character (`0x2C`) for CSV files. You can declare a single character delimiter using the `DELIMITER` clause of `COPY` , `CREATE EXTERNAL TABLE` or `gpload` when you define your data format. The delimiter character must appear between any two data value fields. Do not place a delimiter at the beginning or end of a row. For example, if the pipe character (|) is your delimiter:

```
data value 1|data value 2|data value 3
```

The following command shows the use of the pipe character as a column delimiter:

```
=# CREATE EXTERNAL TABLE ext_table (name text, date date)
LOCATION ('gpfdist://<hostname>/filename.txt)
FORMAT 'TEXT' (DELIMITER '|');
```

Parent topic: Formatting Data Files

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.9.10.3 Representing NULL Values

`NULL` represents an unknown piece of data in a column or field. Within your data files you can designate a string to represent null values. The default string is `\N` (backslash-N) in `TEXT` mode, or an empty value with no quotations in `CSV` mode. You can also declare a different string using the `NULL` clause of `COPY`, `CREATE EXTERNAL TABLE` or `gpload` when defining your data format. For example, you can use an empty string if you do not want to distinguish nulls from empty strings. When using the WarehousePG loading tools, any data item that matches the designated null string is considered a null value.

Parent topic: Formatting Data Files

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.9.10.4 Escaping

There are two reserved characters that have special meaning to WarehousePG:

- The designated delimiter character separates columns or fields in the data file.
- The newline character designates a new row in the data file.

If your data contains either of these characters, you must escape the character so that WarehousePG treats it as data and not as a field separator or new row. By default, the escape character is a \ (backslash) for text-formatted files and a double quote (") for csv-formatted files.

- **Escaping in Text Formatted Files**
- **Escaping in CSV Formatted Files**

Parent topic: Formatting Data Files

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.9.10.4.1 Escaping in Text Formatted Files

By default, the escape character is a \ (backslash) for text-formatted files. You can declare a different escape character in the `ESCAPE` clause of `COPY`, `CREATE EXTERNAL TABLE` or `gpload`. If your escape character appears in your data, use it to escape itself.

For example, suppose you have a table with three columns and you want to load the following three fields:

- `backslash = \`
- `vertical bar = |`
- `exclamation point = !`

Your designated delimiter character is `|` (pipe character), and your designated escape character is `\` (backslash). The formatted row in your data file looks like this:

```
backslash = \\ | vertical bar = \| | exclamation point = !
```

Notice how the backslash character that is part of the data is escaped with another backslash character, and the pipe character that is part of the data is escaped with a backslash character.

You can use the escape character to escape octal and hexadecimal sequences. The escaped value is converted to the equivalent character when loaded into WarehousePG. For example, to load the ampersand character `&`), use the escape character to escape its equivalent hexadecimal (`\0x26`) or octal (`\046`) representation.

You can deactivate escaping in `TEXT` -formatted files using the `ESCAPE` clause of `COPY`, `CREATE EXTERNAL TABLE` or `gpload` as follows:

```
ESCAPE 'OFF'
```

This is useful for input data that contains many backslash characters, such as web log data.

Parent topic: Escaping

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.9.10.4.2 Escaping in CSV Formatted Files

By default, the escape character is a `"` (double quote) for CSV-formatted files. If you want to use a different escape character, use the `ESCAPE` clause of `COPY`, `CREATE EXTERNAL TABLE` or `gpload` to declare a different escape character. In cases where your selected escape character is present in your data, you can use it to escape itself.

For example, suppose you have a table with three columns and you want to load the following three fields:

- `Free trip to A,B`
- `5.89`
- `Special rate "1.79"`

Your designated delimiter character is `,` (comma), and your designated escape character is `"` (double quote). The formatted row in your data file looks like this:

```
"Free trip to A,B","5.89","Special rate ""1.79"""
```

The data value with a comma character that is part of the data is enclosed in double quotes. The double quotes that are part of the data are escaped with a double quote even though the field value is enclosed in double quotes.

Embedding the entire field inside a set of double quotes guarantees preservation of leading and trailing whitespace characters:

```
"Free trip to A,B ","5.89 ","Special rate ""1.79"" "
```

> **Note** In CSV mode, all characters are significant. A quoted value surrounded by white space, or any characters other than `DELIMITER`, includes those characters. This can cause errors if you import data from a system that pads CSV lines with white space to some fixed width. In this case, preprocess the CSV file to remove the trailing white space before importing the data into WarehousePG.

Parent topic: Escaping

4.9.10.5 Character Encoding

Character encoding systems consist of a code that pairs each character from a character set with something else, such as a sequence of numbers or octets, to facilitate data transmission and storage. WarehousePG supports a variety of character sets, including single-byte character sets such as the ISO 8859 series and multiple-byte character sets such as EUC (Extended UNIX Code), UTF-8, and Mule internal code. The server-side character set is defined during database initialization, UTF-8 is the default and can be changed. Clients can use all supported character sets transparently, but a few are not supported for use within the server as a server-side encoding. When loading or inserting data into WarehousePG, WarehousePG transparently converts the data from the specified client encoding into the server encoding. When sending data back to the client, WarehousePG converts the data from the server character encoding into the specified client encoding.

Data files must be in a character encoding recognized by WarehousePG. See the *WarehousePG Reference Guide* for the supported character sets.Data files that contain invalid or unsupported encoding sequences encounter errors when loading into WarehousePG.

> **Note** On data files generated on a Microsoft Windows operating system, run the `dos2unix` system command to remove any Windows-only characters before loading into WarehousePG.

> **Note** If you *change* the `ENCODING` value in an existing `gpload` control file, you must manually drop any external tables that were creating using the previous `ENCODING` configuration. `gpload` does not drop and recreate external tables to use the new `ENCODING` if `REUSE_TABLES` is set to `true`.

Parent topic: Formatting Data Files

Changing the Client-Side Character Encoding

The client-side character encoding can be changed for a session by setting the server configuration parameter `client_encoding`

```
SET client_encoding TO 'latin1';
```

Change the client-side character encoding back to the default value:

```
RESET client_encoding;
```

Show the current client-side character encoding setting:

```
SHOW client_encoding;
```

4.9.11 Example Custom Data Access Protocol

The following is the API for the WarehousePG custom data access protocol. The example protocol implementation gpextprotocal.c is written in C and shows how the API can be used. For information about accessing a custom data access protocol, see Using a Custom Protocol.

```
/* ---- Read/Write function API ------*/
CALLED_AS_EXTPROTOCOL(fcinfo)
EXTPROTOCOL_GET_URL(fcinfo)(fcinfo)
EXTPROTOCOL_GET_DATABUF(fcinfo)
EXTPROTOCOL_GET_DATALEN(fcinfo)
EXTPROTOCOL_GET_SCANQUALS(fcinfo)
EXTPROTOCOL_GET_USER_CTX(fcinfo)
EXTPROTOCOL_IS_LAST_CALL(fcinfo)
EXTPROTOCOL_SET_LAST_CALL(fcinfo)
EXTPROTOCOL_SET_USER_CTX(fcinfo, p)

/* ------ Validator function API ------*/
CALLED_AS_EXTPROTOCOL_VALIDATOR(fcinfo)
EXTPROTOCOL_VALIDATOR_GET_URL_LIST(fcinfo)
EXTPROTOCOL_VALIDATOR_GET_NUM_URLS(fcinfo)
EXTPROTOCOL_VALIDATOR_GET_NTH_URL(fcinfo, n)
EXTPROTOCOL_VALIDATOR_GET_DIRECTION(fcinfo)
```

Notes

The protocol corresponds to the example described in Using a Custom Protocol. The source code file name and shared object are `gpextprotocol.c` and `gpextprotocol.so`.

The protocol has the following properties:

- The name defined for the protocol is `myprot`.
- The protocol has the following simple form: the protocol name and a path, separated by `://`.

  `myprot://` `path`
- Three functions are implemented:
  - `myprot_import()` a read function
  - `myprot_export()` a write function
  - `myprot_validate_urls()` a validation function These functions are referenced in the `CREATE PROTOCOL` statement when the protocol is created and declared in the database.

The example implementation gpextprotocal.c uses `fopen()` and `fread()` to simulate a simple protocol that reads local files. In practice, however, the protocol would implement functionality such as a remote connection to some process over the network.

- **Installing the External Table Protocol**

Parent topic: Loading and Unloading Data

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.9.11.1 Installing the External Table Protocol

To use the example external table protocol, you use the C compiler `cc` to compile and link the source code to create a shared object that can be dynamically loaded by WarehousePG. The commands to compile and link the source code on a Linux system are similar to this:

```
cc -fpic -c gpextprotocal.c cc -shared -o gpextprotocal.so gpextprotocal.o
```

The option `-fpic` specifies creating position-independent code (PIC) and the `-c` option compiles the source code without linking and creates an object file. The object file needs to be created as position-independent code (PIC) so that it can be loaded at any arbitrary location in memory by WarehousePG.

The flag `-shared` specifies creating a shared object (shared library) and the `-o` option specifies the shared object file name `gpextprotocal.so`. Refer to the GCC manual for more information on the `cc` options.

The header files that are declared as include files in `gpextprotocal.c` are located in subdirectories of `$GPHOME/include/postgresql/.`

For more information on compiling and linking dynamically-loaded functions and examples of compiling C source code to create a shared library on other operating systems, see the PostgreSQL documentation at https://www.postgresql.org/docs/12/xfunc-c.html#DFUNC.

The manual pages for the C compiler `cc` and the link editor `ld` for your operating system also contain information on compiling and linking source code on your system.

The compiled code (shared object file) for the custom protocol must be placed in the same location on every host in your WarehousePG cluster (coordinator and all segments). This location must also be in the `LD_LIBRARY_PATH` so that the server can locate the files. It is recommended to locate shared libraries either relative to `$libdir` (which is located at `$GPHOME/lib`) or through the dynamic library path (set by the `dynamic_library_path` server configuration parameter) on all coordinator segment instances in the WarehousePG cluster. You can use the WarehousePG utilities gpssh and `gpsync` to update segments.

4.10 Managing Performance

The topics in this section cover WarehousePG performance management, including how to monitor performance and how to configure workloads to prioritize resource utilization.

- Defining Database Performance
  Managing system performance includes measuring performance, identifying the causes of performance problems, and applying the tools and techniques available to you to remedy the problems.
- Common Causes of Performance Issues
  This section explains the troubleshooting processes for common performance issues and potential solutions to these issues.
- WarehousePG Memory Overview
  Memory is a key resource for a WarehousePG cluster and, when used efficiently, can ensure high performance and throughput. This topic describes how segment host memory is allocated between segments and the options available to administrators to configure memory.
- Managing Resources
  WarehousePG provides features to help you prioritize and allocate resources to queries according to business requirements and to prevent queries from starting when resources are unavailable.
- Investigating a Performance Problem
  This section provides guidelines for identifying and troubleshooting performance problems in a WarehousePG cluster.

Parent topic: WarehousePG Administrator Guide

4.10.1 Defining Database Performance

Managing system performance includes measuring performance, identifying the causes of performance problems, and applying the tools and techniques available to you to remedy the problems.

WarehousePG measures database performance based on the rate at which the database management system (DBMS) supplies information to requesters.

Parent topic: Managing Performance

Understanding the Performance Factors

Several key performance factors influence database performance. Understanding these factors helps identify performance opportunities and avoid problems:

- System Resources
- Workload
- Throughput
- Contention
- Optimization

System Resources

Database performance relies heavily on disk I/O and memory usage. To accurately set performance expectations, you need to know the baseline performance of the hardware on which your DBMS is deployed. Performance of hardware components such as CPUs, hard disks, disk controllers, RAM, and network interfaces will significantly affect how fast your database performs.

> **Note** If you use endpoint security software on your WarehousePG hosts, it may affect your database performance and stability. SeeAbout Endpoint Security Sofware for more information.

Workload

The workload equals the total demand from the DBMS, and it varies over time. The total workload is a combination of user queries, applications, batch jobs, transactions, and system commands directed through the DBMS at any given time. For example, it can increase when month-end reports are run or decrease on weekends when most users are out of the office. Workload strongly influences database performance. Knowing your workload and peak demand times helps you plan for the most efficient use of your system resources and enables processing the largest possible workload.

Throughput

A system's throughput defines its overall capability to process data. DBMS throughput is measured in queries per second, transactions per second, or average response times. DBMS throughput is closely related to the processing capacity of the underlying systems (disk I/O, CPU speed, memory bandwidth, and so on), so it is important to know the throughput capacity of your hardware when setting DBMS throughput goals.

Contention

Contention is the condition in which two or more components of the workload attempt to use the system in a conflicting way — for example, multiple queries that try to update the same piece of data at the same time or multiple large workloads that compete for system resources. As contention increases, throughput decreases.

Optimization

DBMS optimizations can affect the overall system performance. SQL formulation, database configuration parameters, table design, data distribution, and so on enable the database query optimizer to create the most efficient access plans.

Determining Acceptable Performance

When approaching a performance tuning initiative, you should know your system's expected level of performance and define measurable performance requirements so you can accurately evaluate your system's performance. Consider the following when setting performance goals:

- Baseline Hardware Performance
- Performance Benchmarks

Baseline Hardware Performance

Most database performance problems are caused not by the database, but by the underlying systems on which the database runs. I/O bottlenecks, memory problems, and network issues can notably degrade database performance. Knowing the baseline capabilities of your hardware and operating system (OS) will help you identify and troubleshoot hardware-related problems before you explore database-level or query-level tuning initiatives.

See the *WarehousePG Reference Guide* for information about running the `gpcheckperf` utility to validate hardware and network performance.

Performance Benchmarks

To maintain good performance or fix performance issues, you should know the capabilities of your DBMS on a defined workload. A benchmark is a predefined workload that produces a known result set. Periodically run the same benchmark tests to help identify system-related performance degradation over time. Use benchmarks to compare workloads and identify queries or applications that need optimization.

Many third-party organizations, such as the Transaction Processing Performance Council (TPC), provide benchmark tools for the database industry. TPC provides TPC-H, a decision support system that examines large volumes of data, runs queries with a high degree of complexity, and gives answers to critical business questions. For more information about TPC-H, go to:

http://www.tpc.org/tpch

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4.10.2 Distribution and Skew

WarehousePG relies on even distribution of data across segments.

In an MPP shared nothing environment, overall response time for a query is measured by the completion time for all segments. The system is only as fast as the slowest segment. If the data is skewed, segments with more data will take more time to complete, so every segment must have an approximately equal number of rows and perform approximately the same amount of processing. Poor performance and out of memory conditions may result if one segment has significantly more data to process than other segments.

Optimal distributions are critical when joining large tables together. To perform a join, matching rows must be located together on the same segment. If data is not distributed on the same join column, the rows needed from one of the tables are dynamically redistributed to the other segments. In some cases a broadcast motion, in which each segment sends its individual rows to all other segments, is performed rather than a redistribution motion, where each segment rehashes the data and sends the rows to the appropriate segments according to the hash key.

Parent topic: WarehousePG Administrator Guide

Local (Co-located) Joins

Using a hash distribution that evenly distributes table rows across all segments and results in local joins can provide substantial performance gains. When joined rows are on the same segment, much of the processing can be accomplished within the segment instance. These are called *local* or *co-located* joins. Local joins minimize data movement; each segment operates independently of the other segments, without network traffic or communications between segments.

To achieve local joins for large tables commonly joined together, distribute the tables on the same column. Local joins require that both sides of a join be distributed on the same columns (and in the same order) *and* that all columns in the distribution clause are used when joining tables. The distribution columns must also be the same data type—although some values with different data types may appear to have the same representation, they are stored differently and hash to different values, so they are stored on different segments.

Data Skew

Data skew may be caused by uneven data distribution due to the wrong choice of distribution keys or single tuple table insert or copy operations. Present at the table level, data skew, is often the root cause of poor query performance and out of memory conditions. Skewed data affects scan (read) performance, but it also affects all other query execution operations, for instance, joins and group by operations.

It is very important to *validate* distributions to *ensure* that data is evenly distributed after the initial load. It is equally important to *continue* to validate distributions after incremental loads.

The following query shows the number of rows per segment as well as the variance from the minimum and maximum numbers of rows:

```
SELECT 'Example Table' AS "Table Name",
    max(c) AS "Max Seg Rows", min(c) AS "Min Seg Rows",
    (max(c)-min(c))*100.0/max(c) AS "Percentage Difference Between Max & Min"
FROM (SELECT count(*) c, gp_segment_id FROM facts GROUP BY 2) AS a;
```

The `gp_toolkit` schema has two views that you can use to check for skew.

- The `gp_toolkit.gp_skew_coefficients` view shows data distribution skew by calculating the coefficient of variation (CV) for the data stored on each segment. The `skccoeff` column shows the coefficient of variation (CV), which is calculated as the standard deviation divided by the average. It takes into account both the average and variability around the average of a data series. The lower the value, the better. Higher values indicate greater data skew.
- The `gp_toolkit.gp_skew_idle_fractions` view shows data distribution skew by calculating the percentage of the system that is idle during a table scan, which is an indicator of computational skew. The `siffraction` column shows the percentage of the system that is idle during a table scan. This is an indicator of uneven data distribution or query processing skew. For example, a value of 0.1 indicates 10% skew, a value of 0.5 indicates 50% skew, and so on. Tables that have more than10% skew should have their distribution policies evaluated.

Considerations for Replicated Tables

When you create a replicated table (with the `CREATE TABLE` clause `DISTRIBUTED REPLICATED`), WarehousePG distributes every table row to every segment instance. Replicated table data is evenly distributed because every segment has the same rows. A query that uses the `gp_segment_id` system column on a replicated table to verify evenly distributed data, will fail because WarehousePG does not allow queries to reference replicated tables' system columns.

Processing Skew

Processing skew results when a disproportionate amount of data flows to, and is processed by, one or a few segments. It is often the culprit behind WarehousePG performance and stability issues. It can happen with operations such join, sort, aggregation, and various OLAP operations. Processing skew happens in flight while a query is running and is not as easy to detect as data skew.

If single segments are failing, that is, not all segments on a host, it may be a processing skew issue. Identifying processing skew is currently a manual process. First look for spill files. If there is skew, but not enough to cause spill, it will not become a performance issue. If you determine skew exists, then find the query responsible for the skew.

The remedy for processing skew in almost all cases is to rewrite the query. Creating temporary tables can eliminate skew. Temporary tables can be randomly distributed to force a two-stage aggregation.

4.10.3 Common Causes of Performance Issues

This section explains the troubleshooting processes for common performance issues and potential solutions to these issues.

Parent topic: Managing Performance

Identifying Hardware and Segment Failures

The performance of WarehousePG depends on the hardware and IT infrastructure on which it runs. WarehousePG is comprised of several servers (hosts) acting together as one cohesive system (array); as a first step in diagnosing performance problems, ensure that all WarehousePG segments are online. WarehousePG's performance will be as fast as the slowest host in the array. Problems with CPU utilization, memory management, I/O processing, or network load affect performance. Common hardware-related issues are:

- **Disk Failure** – Although a single disk failure should not dramatically affect database performance if you are using RAID, disk resynchronization does consume resources on the host with failed disks. The `gpcheckperf` utility can help identify segment hosts that have disk I/O issues.
- **Host Failure** – When a host is offline, the segments on that host are nonoperational. This means other hosts in the array must perform twice their usual workload because they are running the primary segments and multiple mirrors. If mirrors are not enabled, service is interrupted. Service is temporarily interrupted to recover failed segments. The `gpstate` utility helps identify failed segments.
- **Network Failure** – Failure of a network interface card, a switch, or DNS server can bring down segments. If host names or IP addresses cannot be resolved within your WarehousePG cluster, these manifest themselves as interconnect errors in WarehousePG. The `gpcheckperf` utility helps identify segment hosts that have network issues.
- **Disk Capacity** – Disk capacity on your segment hosts should never exceed 70 percent full. WarehousePG needs some free space for runtime processing. To reclaim disk space that deleted rows occupy, run `VACUUM` after loads or updates.The *gp_toolkit* administrative schema has many views for checking the size of distributed database objects.

  See the *WarehousePG Reference Guide* for information about checking database object sizes and disk space.

Managing Workload

A database system has a limited CPU capacity, memory, and disk I/O resources. When multiple workloads compete for access to these resources, database performance degrades. Resource management maximizes system throughput while meeting varied business requirements. WarehousePG provides resource queues and resource groups to help you manage these system resources.

Resource queues and resource groups limit resource usage and the total number of concurrent queries running in the particular queue or group. By assigning database roles to the appropriate queue or group, administrators can control concurrent user queries and prevent system overload. For more information about resource queues and resource groups, including selecting the appropriate scheme for your WarehousePG environment, see Managing Resources.

WarehousePG administrators should run maintenance workloads such as data loads and `VACUUM ANALYZE` operations after business hours. Do not compete with database users for system resources; perform administrative tasks at low-usage times.

Avoiding Contention

Contention arises when multiple users or workloads try to use the system in a conflicting way; for example, contention occurs when two transactions try to update a table simultaneously. A transaction that seeks a table-level or row-level lock will wait indefinitely for conflicting locks to be released. Applications should not hold transactions open for long periods of time, for example, while waiting for user input.

Maintaining Database Statistics

WarehousePG uses a cost-based query optimizer that relies on database statistics. Accurate statistics allow the query optimizer to better estimate the number of rows retrieved by a query to choose the most efficient query plan. Without database statistics, the query optimizer cannot estimate how many records will be returned. The optimizer does not assume it has sufficient memory to perform certain operations such as aggregations, so it takes the most conservative action and does these operations by reading and writing from disk. This is significantly slower than doing them in memory. ANALYZE collects statistics about the database that the query optimizer needs.

> **Note** When running an SQL command with GPORCA, WarehousePG issues a warning if the command performance could be improved by collecting statistics on a column or set of columns referenced by the command. The warning is issued on the command line and information is added to the WarehousePG log file. For information about collecting statistics on table columns, see the ANALYZE command in the *WarehousePG Reference Guide*

Identifying Statistics Problems in Query Plans

Before you interpret a query plan for a query using EXPLAIN or `EXPLAIN ANALYZE`, familiarize yourself with the data to help identify possible statistics problems. Check the plan for the following indicators of inaccurate statistics:

- **Are the optimizer's estimates close to reality?** Run `EXPLAIN ANALYZE` and see if the number of rows the optimizer estimated is close to the number of rows the query operation returned.
- **Are selective predicates applied early in the plan?** The most selective filters should be applied early in the plan so fewer rows move up the plan tree.
- **Is the optimizer choosing the best join order?** When you have a query that joins multiple tables, make sure the optimizer chooses the most selective join order. Joins that eliminate the largest number of rows should be done earlier in the plan so fewer rows move up the plan tree.

See Query Profiling for more information about reading query plans.

Tuning Statistics Collection

The following configuration parameters control the amount of data sampled for statistics collection:

- `default_statistics_target`

These parameters control statistics sampling at the system level. It is better to sample only increased statistics for columns used most frequently in query predicates. You can adjust statistics for a particular column using the command:

`ALTER TABLE...SET STATISTICS`

For example:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
ALTER TABLE sales ALTER COLUMN region SET STATISTICS 50;
```

This is equivalent to changing `default_statistics_target` for a particular column. Subsequent `ANALYZE` operations will then gather more statistics data for that column and produce better query plans as a result.

Optimizing Data Distribution

When you create a table in WarehousePG, you must declare a distribution key that allows for even data distribution across all segments in the system. Because the segments work on a query in parallel, WarehousePG will always be as fast as the slowest segment. If the data is unbalanced, the segments that have more data will return their results slower and therefore slow down the entire system.

Optimizing Your Database Design

Many performance issues can be improved by database design. Examine your database design and consider the following:

- Does the schema reflect the way the data is accessed?
- Can larger tables be broken down into partitions?
- Are you using the smallest data type possible to store column values?
- Are columns used to join tables of the same datatype?
- Are your indexes being used?

WarehousePG Maximum Limits

To help optimize database design, review the maximum limits that WarehousePG supports:

Dimension	Limit
Database Size	Unlimited
Table Size	Unlimited, 128 TB per partition per segment
Row Size	1.6 TB (1600 columns * 1 GB)
Field Size	1 GB
Rows per Table	281474976710656 (2^48)
Columns per Table/View	1600
Indexes per Table	Unlimited
Columns per Index	32
Table-level Constraints per Table	Unlimited
Table Name Length	63 Bytes (Limited by *name* data type)

Dimensions listed as unlimited are not intrinsically limited by WarehousePG. However, they are limited in practice to available disk space and memory/swap space. Performance may degrade when these values are unusually large.

> **Note** There is a maximum limit on the number of objects (tables, indexes, and views, but not rows) that may exist at one time. This limit is 4294967296 (2^32).

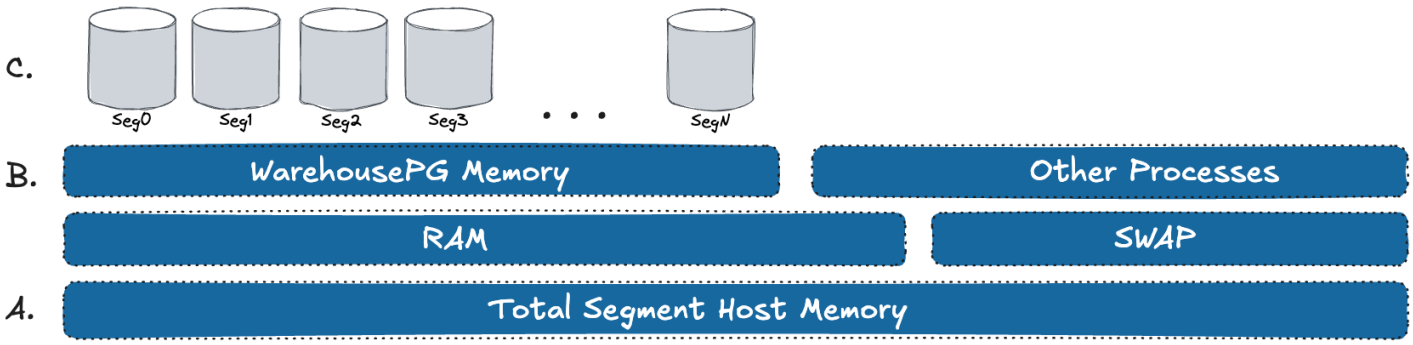
4.10.4 WarehousePG Memory Overview

Memory is a key resource for a WarehousePG cluster and, when used efficiently, can ensure high performance and throughput. This topic describes how segment host memory is allocated between segments and the options available to administrators to configure memory.

A WarehousePG segment host runs multiple PostgreSQL instances, all sharing the host's memory. The segments have an identical configuration and they consume similar amounts of memory, CPU, and disk IO simultaneously, while working on queries in parallel.

For best query throughput, the memory configuration should be managed carefully. There are memory configuration options at every level in WarehousePG, from operating system parameters, to managing resources with resource queues and resource groups, to setting the amount of memory allocated to an individual query.



Memory calculator tool

For an automated way to determine the required values based on your specific hardware, use the WarehousePG memory calculator. Input your system's RAM, swap, and segment count to get the optimized `gp_vmem_protect_limit` and `vm.overcommit_ratio` values.

Segment Host Memory Overview

On a WarehousePG segment host, the available host memory is shared among all the processes running on the computer, including the operating system, WarehousePG segment instances, and other application processes. Administrators must determine what WarehousePG and non-WarehousePG processes share the hosts' memory and configure the system to use the memory efficiently. It is equally important to monitor memory usage regularly to detect any changes in the way host memory is consumed by WarehousePG or other processes.

The following figure illustrates how memory is consumed on a WarehousePG segment host when resource queue-based resource management is active.

Beginning at the bottom of the illustration, the line labeled *A* represents the total host memory. The line directly above line *A* shows that the total host memory comprises both physical RAM and swap space.

The line labelled *B* shows that the total memory available must be shared by WarehousePG and all other processes on the host. Non-WarehousePG processes include the operating system and any other applications, for example system monitoring agents. Some applications may use a significant portion of memory and, as a result, you may have to adjust the number of segments per WarehousePG host or the amount of memory per segment.

Each segment on line labelled *C* gets an equal share of the WarehousePG Memory.

Within a segment, the currently active resource management scheme, Resource Queues or Resource Groups, governs how memory is allocated to run a SQL statement. These constructs allow you to translate business requirements into execution policies in your WarehousePG cluster and to guard against queries that could degrade performance. For an overview of resource groups and resource queues, refer to Managing Resources.

Configuring Segment Host Memory

Host memory is the total memory shared by all applications on the segment host. You can configure the amount of host memory using any of the following methods:

- Add more RAM to the nodes to increase the physical memory.
- Allocate swap space to increase the size of virtual memory.
- Adjust the kernel parameter `vm.overcommit_ratio` to configure how the operating system handles large memory allocation requests.

The physical RAM and OS configuration are usually managed by the platform team and system administrators. See the WarehousePG Installation Guide for the recommended kernel parameters and for how to set the `/etc/sysctl.conf` file parameters.

The amount of memory to reserve for the operating system and other processes is workload dependent. The minimum recommendation for operating system memory is 32GB, but if there is much concurrency in WarehousePG, increasing to 64GB of reserved memory may be required. The largest user of operating system memory is SLAB, which increases as WarehousePG concurrency and the number of sockets used increases.

The `vm.overcommit_memory` kernel parameter should always be set to 2, the only safe value for WarehousePG.

The `vm.overcommit_ratio` kernel parameter sets the percentage of RAM that is used for application processes, the remainder reserved for the operating system. The default for Red Hat is 50 (50%). Setting this parameter too high may result in insufficient memory reserved for the operating system, which can cause segment host failure or database failure. Leaving the setting at the default of 50 is generally safe, but conservative. Setting the value too low reduces the amount of concurrency and the complexity of queries you can run at the same time by reducing the amount of memory available to WarehousePG. When increasing `vm.overcommit_ratio`, it is important to remember to always reserve some memory for operating system activities.

To calculate a safe value for `vm.overcommit_ratio`, first determine the total memory available to WarehousePG processes, `gp_vmem`.

- If the total system memory is less than 256 GB, use this formula:

```
gp_vmem = ((SWAP + RAM) – (7.5GB + 0.05 * RAM)) / 1.7
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

- If the total system memory is equal to or greater than 256 GB, use this formula:

```
gp_vmem = ((SWAP + RAM) – (7.5GB + 0.05 * RAM)) / 1.17
```

where `SWAP` is the swap space on the host in GB, and `RAM` is the number of GB of RAM installed on the host.

Use `gp_vmem` to calculate the `vm.overcommit_ratio` value with this formula:

```
vm.overcommit_ratio = (RAM – 0.026 * gp_vmem) / RAM
```

Configuring WarehousePG Memory

WarehousePG Memory is the amount of memory available to all WarehousePG segment instances.

When you set up the WarehousePG cluster, you determine the number of primary segments to run per host and the amount of memory to allocate for each segment. Depending on the CPU cores, amount of physical RAM, and workload characteristics, the number of segments is usually a value between 4 and 8. With segment mirroring enabled, it is important to allocate memory for the maximum number of primary segments running on a host during a failure. For example, if you use the default grouping mirror configuration, a segment host failure doubles the number of acting primaries on the host that has the failed host's mirrors. Mirror configurations that spread each host's mirrors over multiple other hosts can lower the maximum, allowing more memory to be allocated for each segment. For example, if you use a block mirroring configuration with 4 hosts per block and 8 primary segments per host, a single host failure would cause other hosts in the block to have a maximum of 11 active primaries, compared to 16 for the default grouping mirror configuration.

The gp_vmem_protect_limit server configuration parameter value identifies the amount of memory to allocate to each segment. This value is estimated by calculating the memory available for all WarehousePG processes and dividing by the maximum number of primary segments during a failure. If `gp_vmem_protect_limit` is set too high, queries can fail. Use the following formula to calculate a safe value for `gp_vmem_protect_limit`, using the `gp_vmem` value that you calculated earlier.

```
gp_vmem_protect_limit = gp_vmem / max_acting_primary_segments
```

where `max_acting_primary_segments` is the maximum number of primary segments that could be running on a host when mirror segments are activated due to a host or segment failure.

Resource queues and resource groups expose additional configuration parameters that enable you to further control and refine the amount of memory allocated for queries.

Example Memory Configuration Calculations

This section provides example memory calculations for resource queues and resource groups for a WarehousePG cluster with the following specifications:

- Total RAM = 256GB
- Swap = 64GB
- 8 primary segments and 8 mirror segments per host, in blocks of 4 hosts
- Maximum number of primaries per host during failure is 11

The `vm.overcommit_ratio` calculation for this example system follows:

```
gp_vmem = ((SWAP + RAM) – (7.5GB + 0.05 * RAM)) / 1.7
        = ((64 + 256) – (7.5 + 0.05 * 256)) / 1.7
        = 176

vm.overcommit_ratio = (RAM – (0.026 * gp_vmem)) / RAM
                    = (256 – (0.026 * 176)) / 256
                    = .982
```

You would set `vm.overcommit_ratio` of the example system to 98.

The `gp_vmem_protect_limit` calculation follows:

```
gp_vmem_protect_limit = gp_vmem / maximum_acting_primary_segments
                      = 176 / 11
                      = 16GB
                      = 16384MB
```

You would set the `gp_vmem_protect_limit` server configuration parameter on the example system to 16384.

4.10.6 Managing Resources

WarehousePG provides features to help you prioritize and allocate resources to queries according to business requirements and to prevent queries from starting when resources are unavailable.

You can use resource management features to limit the number of concurrent queries, the amount of memory used to run a query, and the relative amount of CPU devoted to processing a query. WarehousePG provides two schemes to manage resources: Resource Queues and Resource Groups.

Either the resource queue or the resource group management scheme can be active in WarehousePG; both schemes cannot be active at the same time. Set the server configuration parameter gp_resource_manager to enable the preferred scheme in the WarehousePG cluster.

The following table summarizes some of the differences between resource queues and resource groups.

Metric	Resource Queues	Resource Groups
Concurrency	Defines the number of query slots available at a time	Defines the number of transaction slots available at a time
CPU	Specify query priority	Specify percentage of CPU resources or the specific number of CPU cores; uses Linux Control Groups
Memory	Managed at the queue and operator level; users can over-subscribe	Managed at the transaction level, with enhanced allocation and tracking; users can over-subscribe
Users	Limits are applied only to non-admin users	Limits are applied to `SUPERUSER`, non-admin users, and system processes of non-user classes
Disk I/O	None	Limit the maximum read/write disk I/O throughput, and maximum read/write I/O operations per second
Queueing	Queue when no slot available or not enough available memory	Queue only when no slot is available
Query Failure	Query may fail immediately if the allocated memory for the query surpasses the available system memory and spill limits	Query may fail if the allocated memory for the query surpasses the available system memory and spill limits
Limit Bypass	Limits are not enforced for `SUPERUSER` roles and certain operators and functions	Limits are not enforced on `SET`, `RESET`, and `SHOW` commands. Additionally, certain queries may be configured to bypass the concurrency limit
External Components	None	Manage PL/Container CPU resources

Parent topic: Managing Performance

4.10.6.1 About Changes to Resource Groups in WarehousePG 7

WarehousePG 7 introduces substantial changes to resource group-based resource management. This topic compares the differences between resource groups with WarehousePG 6 and WarehousePG 7. Visit Using Resource Groups for more information about how resource groups work in WarehousePG 7.

The following table compares the main concepts of resource management and how each version of WarehousePG implements them:

Metric	Resource Groups in WarehousePG 6	Resource Groups in WarehousePG 7
Concurrency	Managed at the transaction level	Managed at the transaction level
CPU	Specify percentage of CPU resources or the number of CPU cores; uses Linux Control Groups	Specify percentage of CPU resources or the number of CPU cores, as well as set upper limits per resource group; uses Linux Control Groups
Memory	Managed at the transaction level, with enhanced allocation and tracking; users cannot over-subscribe	Managed at the transaction level, with enhanced allocation and tracking; users can over-subscribe; simpler and more convenient configuration
Disk I/O	None	Limit the maximum read/write disk I/O throughput, and maximum read/write I/O operations per second
Users	Limits are applied to `SUPERUSER` and non-admin users alike There are two default resource groups: `admin_group` and `default_group`	Limits are applied to `SUPERUSER`, non-admin users, and system processes of non-user classes There are three default resource groups: `admin_group`, `default_group`, and `system_group`
Queueing	Queue when no slot is available or not enough available memory	Queue when no slot is available
Query Failure	Query may fail after reaching transaction fixed memory limit when no shared resource group memory exists and the transaction requests more memory	Query may fail if the allocated memory for the query surpasses the available system memory and spill limits
Limit Bypass	Limits are not enforced on `SET`, `RESET`, and `SHOW` commands	Limits are not enforced on `SET`, `RESET`, and `SHOW` commands. Additionally, certain queries may be configured to bypass the concurrency limit
External Components	Manage PL/Container CPU and memory resources	Manage PL/Container CPU resources

> **Note** Disk I/O limits are only available when you use Linux Control Groups v2. See Configuring and Using Resource Groups for more information.

Changes to Resource Groups Attributes

You may configure four new resource group attributes using the `CREATE RESOURCE GROUP` and `ALTER RESOURCE GROUP` SQL commands:

- `CPU_MAX_PERCENT`, which configures the maximum amount of CPU resources the resource group can use.
- `CPU_WEIGHT`, which configures the scheduling priority of the resource group.
- `MIN_COST`, which configures the minimum amount a query's query plan cost for the query to remain in the resource group.
- `IO_LIMIT`, which configures device I/O usage at the resource group level to manage the maximum throughput of read/write operations, and the maximum read/write operations per second.

The following resource group attributes have been removed:

- `CPU_RATE_LIMIT`
- `MEMORY_AUDITOR`
- `MEMORY_SPILL_RATIO`
- `MEMORY_SHARED_QUOTA`

Changes to Server Configuration Parameters

WarehousePG 7 resource group management introduces the following changes to server configuration parameters:

- The possible settings for the gp_resource_manager server configuration parameter have changed. They now include the following:
  - `none` - Configures WarehousePG to not use any resource manager. This is the default.
  - `group` - Configures WarehousePG to use resource groups and base resource group behavior on the cgroup v1 version of Linux cgroup functionality.
  - `group-v2` - Configures WarehousePG to use resource groups and base resource group behavior on the cgroup v2 version of Linux cgroup functionality.
  - `queue` - Configures WarehousePG to use resource queues.
- The new server configuration parameter gp_resgroup_memory_query_fixed_mem allows you to override at a session level the fixed amount of memory reserved for all queries in a resource group.
- The new server configuration parameter gp_resource_group_move_timeout cancels the `pg_resgroup_move_query()` function, which moves a running query from one resouce group to another, if it waits longer than the specified number of miliseconds.
- The new server configuration parameter gp_resource_group_bypass_direct_dispatch bypasses the resource group's limits for a direct dispatch query so it can run immediately. A direct dispatch query is a special type of query that only requires a single segment to participate in the execution.
- The server configuration parameter `gp_resource_group_cpu_ceiling_enforcement` has been removed.
- The server configuration parameter `gp_resource_group_enable_recalculate_query_mem` has been removed.
- The server configuration parameter `gp_resource_group_memory_limit` has been removed.

Changes to System Views

The following system views have changes:

- The fields `cpu_rate_limit`, `memory_shared_quota`, `memory_spill_ratio`, and `memory_auditor` have been replaced by `cpu_max_percent`, `cpu_weight`, `cpuset`, `min_cost`, and `io_limit` in the `gp_resgroups_config` system view.
- The field `rsgname` has been renamed to `groupname` in the `gp_resgroup_status` system view.
- The fields `cpu_usage` and `memory_usage` have been removed from the `gp_resgroup_status` system view to the `gp_resgroup_status_per_host` system view.
- The fields `hostname`, `cpu`, `memory_used`, `memory_available`, `memory_quota_used`, `memory_quota_available`, `memory_shared_used`, and `memory_shared_available` have been removed from the system view `gp_resgroup_status_per_host`. The fields `segment_id`, `cpu_usage` and `memory_usage` have been added to the view.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

- The fields `rsgname`, `hostname`, `cpu`, `memory_used`, `memory_available`, `memory_quota_used`, `memory_quota_available`, `memory_shared_used`, and `memory_shared_available` have been removed from the system view `gp_resgroup_status_per_segment`. The fields `groupname`, and `vmem_usage` have been added to the view.
- The `gp_resgroup_iostats_per_host` system view has been added.

4.10.6.2 Using Resource Groups

You use resource groups to manage and protect the resource allocation of CPU, memory, concurrent transaction limits, and disk I/O in WarehousePG. Once you define a resource group, you assign the group to one or more WarehousePG roles, or to an external component such as PL/Container, in order to control the resources used by them.

When you assign a resource group to a role, the resource limits that you define for the group apply to all of the roles to which you assign the group. For example, the memory limit for a resource group identifies the maximum memory usage for all running transactions submitted by WarehousePG users in all roles to which you assign the group.

WarehousePG uses Linux-based control groups for CPU resource management, and Runaway Detector for statistics, tracking and management of memory.

When using resource groups to control resources like CPU cores, review the Hyperthreading note in Hardware and Network.

Parent topic: Managing Resources

Understanding Role and Component Resource Groups

WarehousePG supports two types of resource groups: groups that manage resources for roles, and groups that manage resources for external components such as PL/Container.

The most common application for resource groups is to manage the number of active queries that different roles may run concurrently in your WarehousePG cluster. You can also manage the amount of CPU, memory resources, and disk I/O that WarehousePG allocates to each query.

When a user runs a query, WarehousePG evaluates the query against a set of limits defined for the resource group. WarehousePG runs the query immediately if the group's resource limits have not yet been reached and the query does not cause the group to exceed the concurrent transaction limit. If these conditions are not met, WarehousePG queues the query. For example, if the maximum number of concurrent transactions for the resource group has already been reached, a subsequent query is queued and must wait until other queries complete before it runs. WarehousePG may also run a pending query when the resource group's concurrency and memory limits are altered to large enough values.

Within a resource group for roles, transactions are evaluated on a first in, first out basis. WarehousePG periodically assesses the active workload of the system, reallocating resources and starting/queuing jobs as necessary.

You can also use resource groups to manage the CPU and memory resources of external components such as PL/Container. Resource groups for external components use Linux cgroups to manage the total CPU resources for the component.

Resource Group Attributes and Limits

When you create a resource group, you provide a set of limits that determine the amount of CPU and memory resources available to the group. The following table lists the available limits for resource groups:

Limit Type	Description	Value Range	Default
CONCURRENCY	The maximum number of concurrent transactions, including active and idle transactions, that are permitted in the resource group.	[0 - max_connections]	20
CPU_MAX_PERCENT	The maximum percentage of CPU resources the group can use.	[1 - 100]	-1 (not set)
CPU_WEIGHT	The scheduling priority of the resource group.	[1 - 500]	100
CPUSET	The specific CPU logical core (or logical thread in hyperthreading) reserved for this resource group.	It depends on system core configuration	-1
IO_LIMIT	The limit for the maximum read/write disk I/O throughput, and maximum read/write I/O operations per second. Set the value on a per-tablespace basis.	[2 - 4294967295 or `max`]	-1
MEMORY_QUOTA	The memory limit value specified for the resource group.	Integer (MB)	-1 (not set, use `statement_mem` as the memory limit for a single query)
MIN_COST	The minimum cost of a query plan to be included in the resource group.	Integer	0

> **Note** Resource limits are not enforced on `SET`, `RESET`, and `SHOW` commands.

Transaction Concurrency Limit

The `CONCURRENCY` limit controls the maximum number of concurrent transactions permitted for a resource group.

Each resource group is logically divided into a fixed number of slots equal to the `CONCURRENCY` limit. WarehousePG allocates these slots an equal, fixed percentage of memory resources.

The default `CONCURRENCY` limit value for a resource group for roles is 20. A value of 0 means that no query is allowed to run for this resource group.

WarehousePG queues any transactions submitted after the resource group reaches its `CONCURRENCY` limit. When a running transaction completes, WarehousePG un-queues and runs the earliest queued transaction if sufficient memory resources exist. Note that if a transaction is in `idle in transaction` state, even if no statement is running, the concurrency slot is still in use.

You can set the server configuration parameter gp_resource_group_queuing_timeout to specify the amount of time a transaction remains in the queue before WarehousePG cancels the transaction. The default timeout is zero, WarehousePG queues transactions indefinitely.

Bypass and Unassign from Resource Groups

A query bypasses the resource group concurrency limit if you set the server configuration parameter gp_resource_group_bypass. This parameter enables or disables the concurrent transaction limit for the resource group so a query can run immediately. The default value is false, which enforces the limit of the `CONCURRENCY` limit. You may only set this parameter for a single session, not within a transaction or a function. If you set `gp_resource_group_bypass` to true, the query no longer enforces the CPU or memory limits assigned to its resource group. Instead, the memory quota assigned to this query is `statement_mem` per query. If there is not enough memory to satisfy the memory allocation request, the query will fail.

You may bypass queries that only use catalog tables, such as the database Graphical User Interface (GUI) client, which runs catalog queries to obtain metadata. If the server configuration parameter gp_resource_group_bypass_catalog_query is set to true (the default), WarehousePG's resource group scheduler bypasses all queries that read exclusively from system catalogs, or queries that contain in their query text `pg_catalog` schema tables only. These queries are automatically unassigned from its current resource group; they do not enforce the limits of the resource group and do not account for resource usage. The query resources are assigned out of the resource groups and run immediately. The memory quota is `statement_mem` per the query.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

You may bypass direct dispatch queries with the server configuration parameter gp_resource_group_bypass_direct_dispatch. A direct dispatch query is a special type of query that only requires a single segment to participate in the execution. In order to improve efficiency, WarehousePG optimizes this type of query, using direct dispatch optimization. The system sends the query plan to the execution of a single segment that needs to execute the plan, instead of sending it to all segments for execution. If you set `gp_resource_group_bypass_direct_dispatch` to true, the query no longer enforces the CPU or memory limits assigned to its resource group, so it runs immediately. Instead, the memory quota assigned to this query is `statement_mem` per query. If there is not enough memory to satisfy the memory allocation request, the query will fail. You may only set this parameter for a single session, not within a transaction or a function.

Queries whose plan cost is less than the limit `MIN_COST` are automatically unassigned from their resource group and do not enforce any of its limits. The resources used by the query do not account for the resources of the resource group. The query has a memory quota of `statement_mem`. The default value of `MIN_COST` is 0.

CPU Limits

WarehousePG leverages Linux control groups to implement CPU resource management. WarehousePG allocates CPU resources in two ways:

- By assigning a percentage of CPU resources to resource groups.
- By assigning specific CPU cores to resource groups

When you set one of the allocation modes for a resource group, WarehousePG deactivates the other allocation mode. You may employ both modes of CPU resource allocation simultaneously for different resource groups on the same WarehousePG cluster. You may also change the CPU resource allocation mode for a resource group at runtime.

WarehousePG uses the server configuration parameter gp_resource_group_cpu_limit to identify the maximum percentage of system CPU resources to allocate to resource groups on each WarehousePG segment node. The remaining unreserved CPU resources are used for the operating system kernel and WarehousePG daemons. The amount of CPU available to WarehousePG queries per host is then divided equally among each segment on the WarehousePG node.

> **Note** The default `gp_resource_group_cpu_limit` value may not leave sufficient CPU resources if you are running other workloads on your WarehousePG cluster nodes, so be sure to adjust this server configuration parameter accordingly.

> **Caution** Avoid setting `gp_resource_group_cpu_limit` to a value higher than .9. Doing so may result in high workload queries taking near all CPU resources, potentially starving WarehousePG auxiliary processes.

Assigning CPU Resources by Core

You identify the CPU cores that you want to reserve for a resource group with the `CPUSET` property. The CPU cores that you specify must be available in the system and cannot overlap with any CPU cores that you reserved for other resource groups. Although WarehousePG uses the cores that you assign to a resource group exclusively for that group, note that those CPU cores may also be used by non-WarehousePG processes in the system. When you configure `CPUSET` for a resource group, WarehousePG deactivates `CPU_MAX_PERCENT` and `CPU_WEIGHT` for the group and sets their value to -1.

Specify CPU cores separately for the coordinator host and segment hosts, separated by a semicolon. Use a comma-separated list of single core numbers or number intervals when you configure cores for `CPUSET`. You must enclose the core numbers/intervals in single quotes, for example, '1;1,3-4' uses core 1 on the coordinator host, and cores 1, 3, and 4 on segment hosts.

When you assign CPU cores to `CPUSET` groups, consider the following:

- A resource group that you create with `CPUSET` uses the specified cores exclusively. If there are no running queries in the group, the reserved cores are idle and cannot be used by queries in other resource groups. Consider minimizing the number of `CPUSET` groups to avoid wasting system CPU resources.
- Consider keeping CPU core 0 unassigned. CPU core 0 is used as a fallback mechanism in the following cases:
  - `admin_group` and `default_group` require at least one CPU core. When all CPU cores are reserved, WarehousePG assigns CPU core 0 to these default groups. In this situation, the resource group to which you assigned CPU core 0 shares the core with `admin_group` and `default_group`.
  - If you restart your WarehousePG cluster with one node replacement and the node does not have enough cores to service all `CPUSET` resource groups, the groups are automatically assigned CPU core 0 to avoid system start failure.

- Use the lowest possible core numbers when you assign cores to resource groups. If you replace a WarehousePG node and the new node has fewer CPU cores than the original, or if you back up the database and want to restore it on a cluster with nodes with fewer CPU cores, the operation may fail. For example, if your WarehousePG cluster has 16 cores, assigning cores 1-7 is optimal. If you create a resource group and assign CPU core 9 to this group, database restore to an 8 core node will fail.

Resource groups that you configure with `CPUSET` have a higher priority on CPU resources. The maximum CPU resource usage percentage for all resource groups configured with `CPUSET` on a segment host is the number of CPU cores reserved divided by the number of all CPU cores, multiplied by 100.

> **Note** You must configure `CPUSET` for a resource group *after* you have enabled resource group-based resource management for your WarehousePG cluster with the gp_resource_manager server configuration parameter.

Assigning CPU Resources by Percentage

You configure a resource group with `CPU_MAX_PERCENT` in order to assign CPU resources by percentage. When you configure `CPU_MAX_PERCENT` for a resource group, WarehousePG deactivates `CPUSET` for the group.

The parameter `CPU_MAX_PERCENT` sets a hard upper limit for the percentage of the segment CPU for resource management. The minimum `CPU_MAX_PERCENT` percentage you can specify for a resource group is 1, the maximum is 100. The sum of `CPU_MAX_PERCENT` s specified for all resource groups that you define in your WarehousePG cluster can exceed 100. It specifies the total time ratio that all tasks in a resource group can run in a given CPU time period. Once the tasks in the resource group have used up all the time specified by the quota, they are throttled for the remainder of the time specified in that time period, and are not allowed to run until the next time period.

When tasks in a resource group are idle and not using any CPU time, the leftover time is collected in a global pool of unused CPU cycles. Other resource groups can borrow CPU cycles from this pool. The actual amount of CPU time available to a resource group may vary, depending on the number of resource groups present on the system.

The parameter `CPU_MAX_PERCENT` enforces a hard upper limit of CPU usage. For example, if it is set to 40%, it indicates that although the resource group can temporarily use some idle CPU resources from other groups, the maximum it can use is 40% of the CPU resources available to WarehousePG.

You set the parameter `CPU_WEIGHT` to assign the scheduling priority of the current group. The default value is 100, and the range of values is 1 to 500. The value specifies the relative share of CPU time available to tasks in the resource group. For example, if one resource group has a relative share of 100 and another two groups have a relative share of 50, when processes in all the resource groups try to use 100% of the CPU (that means, the value of `CPU_MAX_PERCENT` for all groups is set to 100), the first resource group gets 50% of all CPU time, and the other two get 25% each. However, if you add another group with a relative share of 100, the first group is only allowed to use 33% of the CPU, and the remaining groups get 16.5%, 16.5%, and 33% respectively.

For example, consider the following groups:

Group Name	CONCURRENCY	CPU_MAX_PERCENT	CPU_WEIGHT
default_group	20	50	10
admin_group	10	70	30
system_group	10	30	10
test	10	10	10

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Roles in `default_group` have an available CPU ratio (determined by `CPU_WEIGHT`) of 10/(10+30+10+10)=16%. This means that they can use at least 16% of the CPU when the system workload is high. When the system has idle CPU resources, they can use more resources, as the hard limit (set by `CPU_MAX_PERCENT`) is 50%.

Roles in `admin_group` have an available CPU ratio of 30/(10+30+10+10)=50% when the system workload is high. When the system has idle CPU resources, they can use resources up to the hard limit of 70%.

Roles in `test` have a CPU ratio of 10/(10+30+10+10)=16%. However, as the hard limit determined by `CPU_MAX_PERCENT` is 10%, they can only use up to 10% of the resources even when the system is idle.

Memory Limits

When you enable resource groups, memory usage is managed at the WarehousePG segment and resource group levels. You can also manage memory at the transaction level. See WarehousePG Memory Overview to estimate how much memory each WarehousePG segment has available to use. This will help you estimate how much memory to assign to the resource groups.

The amount of memory allocated to a query is determined by the following parameters:

The parameter `MEMORY_QUOTA` of a resource group sets the maximum amount of memory reserved for this resource group on a segment. This determines the total amount of memory that all worker processes for a query can consume on the segment host during query execution. The amount of memory allotted to a query is the group memory limit divided by the group concurrency limit: `MEMORY_QUOTA` / `CONCURRENCY`.

If a query requires a large amount of memory, you may use the server configuration parameter gp_resgroup_memory_query_fixed_mem to set a fixed memory amount for the query at the session level. This parameter overrides and can surpass the allocated memory of the resource group.

WarehousePG allocates memory for an incoming query using the `gp_resgroup_memory_query_fixed_mem` value, if set, to bypass the resource group settings. Otherwise, it uses `MEMORY_QUOTA` / `CONCURRENCY` as the memory allocated for the query. If `MEMORY_QUOTA` is not set, the value for the query memory allocation defaults to statement_mem.

For all queries, if there is not enough memory in the system, they spill to disk. When the limit gp_workfile_limit_files_per_query is reached, WarehousePG generates an out of memory (OOM) error.

For example, consider a resource group named `adhoc` with `MEMORY_QUOTA` set to 1.5 GB and `CONCURRENCY` set to 3. By default, each statement submitted to the group is allocated 500 MB of memory. Now consider the following series of events:

1. User `ADHOC_1` submits query `Q1`, overriding `gp_resgroup_memory_query_fixed_mem` to 800MB. The `Q1` statement is admitted into the system.
2. User `ADHOC_2` submits query `Q2`, using the default 500MB.
3. With `Q1` and `Q2` still running, user `ADHOC3` submits query `Q3`, using the default 500MB.

   Queries `Q1` and `Q2` have used 1300MB of the group's 1500MB. However, if there is enough system memory available for query `Q3` in the segment at that time, it can run normally.
4. User `ADHOC4` submits query `Q4`, using `gp_resgroup_memory_query_fixed_mem` set to 700 MB.

   Query `Q4` runs immediately as it bypasses the resource group limits.

There are some special usage considerations regarding memory limits:

- If you set the configuration parameters `gp_resource_group_bypass` or `gp_resource_group_bypass_catalog_query` to bypass the resource group limits, the memory limit for the query takes the value of `statement_mem`.
- When (`MEMORY_QUOTA` / `CONCURRENCY`) < `statement_mem`, WarehousePG uses `statement_mem` as the fixed amount of memory allocated by query.
- The maximum value of `statement_mem` is capped at max_statement_mem.
- Queries whose plan cost is less than the limit `MIN_COST` use a memory quota of `statement_mem`.

Disk I/O Limits

WarehousePG leverages Linux control groups to implement disk I/O limits. The parameter `IO_LIMIT` limits the maximum read/write disk I/O throughput, and the maximum read/write I/O operations per second for the queries assigned to a specific resource group. It allocates bandwidth, ensures the use of high-priority resource groups, and avoids excessive use of disk bandwidth. The value of the parameter is set on a per-tablespace basis.

> **Note** Disk I/O limits are only available when you use Linux Control Groups v2. See Configuring and Using Resource Groups for more information.

When you limit disk I/O you specify:

- The tablespace name or the tablespace object ID (OID) you set the limits for. Use `*` to set limits for all tablespaces.
- The values for `rbps` and `wbps` to limit the maximum read and write disk I/O throughput in the resource group, in MB/sec. The default value is `max`, which means there is no limit.
- The values for `riops` and `wiops` to limit the maximum read and write I/O operations per second in the resource group. The default value is `max`, which means there is no limit.

If the parameter `IO_LIMIT` is not set, the default value for `rbps`, `wpbs`, `riops`, and `wiops` s is set to `max`, which means that there are no disk I/O limits. In this scenario, the `gp_toolkit.gp_resgroup_config` system view displays its value as `-1`. If only some of the values of `IO_LIMIT` are set (for example. `rbps`), the parameters that are not set default to `max` (in this example, `wbps`, `riops`, wiops`).

Configuring and Using Resource Groups

Prerequisites

WarehousePG resource groups use Linux Control Groups (cgroups) to manage CPU resources and disk I/O. There are two versions of cgroups: cgroup v1 and cgroup v2. WarehousePG 7 supports both versions, but it only supports the parameter `IO_LIMIT` for cgroup v2. The version of Linux Control Groups shipped by default with your Linux distribution depends on the operating system version. For Enterprise Linux 8 and older, the default version is v1. For Enterprise Linux 9 and later, the default version is v2. For detailed information about cgroups, refer to the Control Groups documentation for your Linux distribution.

Verify what version of cgroup is configured in your environment by checking what filesystem is mounted by default during system boot:

```
stat -fc %T /sys/fs/cgroup/
```

For cgroup v1, the output is `tmpfs`. For cgroup v2, output is `cgroup2fs`.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

You do not need to change your version of cgroup, you can simply skip to Configuring cgroup v1 or Configuring cgroup v2 in order to complete the configuration prerequisites. However, if you prefer to switch from cgroup v1 to v2, run the following commands as root:

- Red Hat 8/Rocky 8/Oracle 8 systems:

```
grubby --update-kernel=/boot/vmlinuz-$(uname -r) --args="systemd.unified_cgroup_hierarchy=1"
```

- Ubuntu systems:

```
vim /etc/default/grub
# add or modify: GRUB_CMDLINE_LINUX="systemd.unified_cgroup_hierarchy=1"
update-grub
```

If you want to switch from cgroup v2 to v1, run the following commands as root:

- Red Hat 8/Rocky 8/Oracle 8 systems:

```
grubby --update-kernel=/boot/vmlinuz-$(uname -r) --args="systemd.unified_cgroup_hierarchy=0 systemd.legacy_systemd_cgroup_controller"
```

- Ubuntu systems:

```
vim /etc/default/grub
# add or modify: GRUB_CMDLINE_LINUX="systemd.unified_cgroup_hierarchy=0"
update-grub
```

After that, reboot your host in order for the changes to take effect.

Configuring cgroup v1

Complete the following tasks on each node in your WarehousePG cluster to set up cgroups v1 for use with resource groups:

1. Locate the cgroups configuration file `/etc/cgconfig.conf`. You must be the superuser or have `sudo` access to edit this file:

   ```
   vi /etc/cgconfig.conf
   ```

2. Add the following configuration information to the file:

   ```
   group gpdb {
        perm {
            task {
                uid = gpadmin;
                gid = gpadmin;
            }
            admin {
                uid = gpadmin;
                gid = gpadmin;
            }
        }
        cpu {
        }
        cpuacct {
        }
        cpuset {
        }
        memory {
        }
   }
   ```

   This content configures CPU, CPU accounting, CPU core set, and memory control groups managed by the `gpadmin` user. WarehousePG uses the memory control group only for monitoring the memory usage.

3. Start the cgroups service on each WarehousePG node. For Redhat/Oracle/Rocky 8.x and older, run the following as root:

   ```
   cgconfigparser -l /etc/cgconfig.conf
   ```

4. To automatically recreate WarehousePG required cgroup hierarchies and parameters when your system is restarted, configure your system to enable the Linux cgroup service daemon `cgconfig.service` at node start-up. To ensure the configuration is persisten after reboot, run the following commands as user root. For Redhat/Oracle/Rocky 8.x and older:

   ```
   systemctl enable cgconfig.service
   ```

   To start the service immediately (without having to reboot) enter:

   ```
   systemctl start cgconfig.service
   ```

5. Identify the `cgroup` directory mount point for the node. For Redhat/Oracle/Rocky 8.x and older, run the following as root:

   ```
   grep cgroup /proc/mounts
   ```

   The first line of output identifies the `cgroup` mount point.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

6. Verify that you set up the WarehousePG cgroups configuration correctly by running the following commands. Replace \<cgroup_mount_point> with the mount point that you identified in the previous step:

```
ls -l <cgroup_mount_point>/cpu/gpdb
ls -l <cgroup_mount_point>/cpuset/gpdb
ls -l <cgroup_mount_point>/memory/gpdb
```

   If these directories exist and are owned by `gpadmin:gpadmin`, you have successfully configured cgroups for WarehousePG resource management.

Configuring cgroup v2

1. Configure the system to mount `cgroups-v2` by default during system boot by the `systemd` system and service manager as user root.

```
grubby --update-kernel=ALL --args="systemd.unified_cgroup_hierarchy=1"
```

2. Reboot the system for the changes to take effect.

```
reboot now
```

3. Create the directory `/sys/fs/cgroup/gpdb`, add all the necessary controllers, and ensure `gpadmin` user has read and write permission on it.

```
mkdir -p /sys/fs/cgroup/gpdb
echo "+cpuset +io +cpu +memory" | tee -a /sys/fs/cgroup/cgroup.subtree_control
chown -R gpadmin:gpadmin /sys/fs/cgroup/gpdb
```

You may encounter the error `Invalid argument` after running the above commands. This is because cgroups v2 do not support control of real-time processes, and the `cpu` controller can only be enabled when all the real-time processes are in the root cgroup. In this situation, find all real-time processes and move them to the root cgroup before you re-enable the controllers.

1. Ensure that `gpadmin` has write permission on `/sys/fs/cgroup/cgroup.procs`. This is required to move the WarehousePG processes from the user slices to `/sys/fs/cgroup/gpdb/` after the cluster is started in order to manage the postmaster services and all its auxiliary processes.

```
```
chmod a+w /sys/fs/cgroup/cgroup.procs
```
```

   Since resource groups manually manage cgroup files, the above settings will become ineffective after a system reboot. Add the following bash script for systemd so it runs automatically during system startup. Perform the following steps as user root:

2. Create `gpdb.service`.

```
vim /etc/systemd/system/gpdb.service
```

3. Write the following content into `gpdb.service`, if the user is not `gpadmin`, replace it with the appropriate user.

```
[Unit]
Description=WarehousePG Cgroup v2 Configuration Service
[Service]
Type=simple
WorkingDirectory=/sys/fs/cgroup/gpdb.service
Delegate=yes
Slice=-.slice

# set hierarchies only if cgroup v2 mounted
ExecCondition=bash -c '[ xcgroup2fs = x$(stat -fc "%%T" /sys/fs/cgroup) ] || exit 1'
ExecStartPre=bash -ec " \
chown -R gpadmin:gpadmin .; \
chmod a+w ../cgroup.procs; \
mkdir -p helper.scope"
ExecStart=sleep infinity
ExecStartPost=bash -ec "echo $MAINPID > ./helper.scope/cgroup.procs;"
[Install]
WantedBy=basic.target
```

4. Reload systemd daemon and enable the service:

```
systemctl daemon-reload
systemctl enable gpdb.service
```

Enabling Resource Groups

When you install WarehousePG, no resource management policy is enabled by default. To use resource groups, set the gp_resource_manager server configuration parameter.

1. Set the `gp_resource_manager` server configuration parameter to the value `"group"` or `"group-v2"`, depending on the version of cgroup configured on your Linux distribution. For example:

```
gpconfig -c gp_resource_manager -v "group"
gpconfig -c gp_resource_manager -v "group-v2"
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

2. Restart WarehousePG:

```
gpstop
gpstart
```

Once enabled, any transaction submitted by a role is directed to the resource group assigned to the role, and is governed by that resource group's concurrency, memory, CPU, and disk I/O limits.

WarehousePG creates three default resource groups for roles named `admin_group`, `default_group`, and `system_group`. When you enable resources groups, any role that was not explicitly assigned a resource group is assigned the default group for the role's capability. `SUPERUSER` roles are assigned the `admin_group`, non-admin roles are assigned the group named `default_group`. The resources of the WarehousePG cluster processes are assigned to the `system_group`. You cannot manually assign any roles to the `system_group`.

The default resource groups `admin_group`, `default_group`, and `system_group` are created with the following resource limits:

Limit Type	admin_group	default_group	system_group
CONCURRENCY	10	5	0
CPU_MAX_PERCENT	10	20	10
CPU_WEIGHT	100	100	100
CPUSET	-1	-1	-1
IO_LIMIT	-1	-1	-1
MEMORY_LIMIT	-1	-1	-1
MIN_COST	0	0	0

Creating Resource Groups

When you create a resource group for a role, you provide a name and a CPU resource allocation mode (core or percentage). You can optionally provide a concurrent transaction limit, a memory limit, a CPU soft priority, disk I/O limits, and a minimum cost. Use the CREATE RESOURCE GROUP command to create a new resource group.

When you create a resource group for a role, you must provide a `CPU_MAX_PERCENT` or `CPUSET` limit value. These limits identify the percentage of WarehousePG CPU resources to allocate to this resource group. You may specify a `MEMORY_QUOTA` to reserve a fixed amount of memory for the resource group.

For example, to create a resource group named *rgroup1* with a CPU limit of 20, a memory limit of 25, a CPU soft priority of 500, a minimum cost of 50, and disk I/O limits for the `pg_default` tablespace:

```
CREATE RESOURCE GROUP rgroup1 WITH (CONCURRENCY=20, CPU_MAX_PERCENT=20, MEMORY_QUOTA=250, CPU_WEIGHT=500, MIN_COST=50,
  IO_LIMIT='pg_default: wbps=1000, rbps=1000, wiops=100, riops=100');
```

The CPU limit of 20 is shared by every role to which `rgroup1` is assigned. Similarly, the memory limit of 25 is shared by every role to which `rgroup1` is assigned. `rgroup1` utilizes the default `CONCURRENCY` setting of 20.

The ALTER RESOURCE GROUP command updates the limits of a resource group. To change the limits of a resource group, specify the new values that you want for the group. For example:

```
ALTER RESOURCE GROUP rg_role_light SET CONCURRENCY 7;
ALTER RESOURCE GROUP exec SET MEMORY_QUOTA 30;
ALTER RESOURCE GROUP rgroup1 SET CPUSET '1;2,4';
ALTER RESOURCE GROUP sales SET IO_LIMIT 'tablespace1:wbps=2000,wiops=2000;tablespace2:rbps=2024,riops=2024';
```

> **Note** You cannot set or alter the `CONCURRENCY` value for the `admin_group` to zero (0).

You can rename a resource group using the `name` option:

```
ALTER RESOURCE GROUP rgroup1 SET NAME rgroup1_renamed;
```

You can't rename the default resource groups `admin_group`, `default_group`, and `system_group`, and you can't use `none` as a new name.

The DROP RESOURCE GROUP command drops a resource group. To drop a resource group for a role, the group cannot be assigned to any role, nor can there be any transactions active or waiting in the resource group.

To drop a resource group:

```
DROP RESOURCE GROUP exec;
```

Configuring Automatic Query Termination Based on Memory Usage

WarehousePG supports the Runaway detector, which automatically terminates queries based on the amount of memory used by the query. For resource group-managed queries, WarehousePG terminates a running query based on the amount of memory used by the query. The relevant configuration parameters are:

- gp_vmem_protect_limit sets the amount of memory that all `postgres` processes of the active segment instance can consume. If a query causes this limit to be exceeded, no memory will be allocated and the query will fail.
- runaway_detector_activation_percent. When resource groups are enabled, if the used memory exceeds the specified value `gp_vmem_protect_limit` * `runaway_detector_activation_percent`, WarehousePG terminates queries based on memory usage, selecting queries from the queries managed by user resource groups (excluding those in the `system_group` resource group). WarehousePG starts with the query that consumes the largest amount of memory. The query will terminate until the percentage of memory used falls below the specified percentage.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Assigning a Resource Group to a Role

You assign a resource group to a database role using the `RESOURCE GROUP` clause of the CREATE ROLE or ALTER ROLE commands. If you do not specify a resource group for a role, the role is assigned the default group for the role's capability. `SUPERUSER` roles are assigned the `admin_group`, non-admin roles are assigned the group named `default_group`.

Use the `ALTER ROLE` or `CREATE ROLE` commands to assign a resource group to a role. For example:

```
ALTER ROLE bill RESOURCE GROUP rg_light;
CREATE ROLE mary RESOURCE GROUP exec;
```

You can assign a resource group to one or more roles. If you have defined a role hierarchy, assigning a resource group to a parent role does not propagate down to the members of that role group.

If you wish to remove a resource group assignment from a role and assign the role the default group, change the role's group name assignment to `NONE`. For example:

```
ALTER ROLE mary RESOURCE GROUP NONE;
```

Monitoring Resource Group Status

Monitoring the status of your resource groups and queries may involve the following tasks.

Viewing Resource Group Limits

The gp_resgroup_config `gp_toolkit` system view displays the current limits for a resource group. To view the limits of all resource groups:

```
SELECT * FROM gp_toolkit.gp_resgroup_config;
```

Viewing Resource Group Query Status

The gp_resgroup_status `gp_toolkit` system view enables you to view the status and activity of a resource group. The view displays the number of running and queued transactions. To view this information:

```
SELECT * FROM gp_toolkit.gp_resgroup_status;
```

Viewing Resource Group Memory Usage Per Host

The gp_resgroup_status_per_host `gp_toolkit` system view enables you to view the real-time memory usage of a resource group on a per-host basis. To view this information:

```
SELECT * FROM gp_toolkit.gp_resgroup_status_per_host;
```

Viewing the Resource Group Assigned to a Role

To view the resource group-to-role assignments, perform the following query on the pg_roles and pg_resgroup system catalog tables:

```
SELECT rolname, rsgname FROM pg_roles, pg_resgroup
WHERE pg_roles.rolresgroup=pg_resgroup.oid;
```

Viewing Resource Group Disk I/O Usage Per Host

The gp_resgroup_iostats_per_host `gp_toolkit` system view enables you to view the real-time disk I/O usage of a resource group on a per-host basis. To view this information:

```
SELECT * FROM gp_toolkit.gp_resgroup_iostats_per_host;
```

Viewing a Resource Group's Running and Pending Queries

To view a resource group's running queries, pending queries, and how long the pending queries have been queued, examine the pg_stat_activity system catalog table:

```
SELECT query, rsgname,wait_event_type, wait_event
FROM pg_stat_activity;
```

`pg_stat_activity` displays information about the user/role that initiated a query. A query that uses an external component such as PL/Container is composed of two parts: the query operator that runs in WarehousePG and the UDF that runs in a PL/Container instance. WarehousePG processes the query operators under the resource group assigned to the role that initiated the query. A UDF running in a PL/Container instance runs under the resource group assigned to the PL/Container runtime. The latter is not represented in the `pg_stat_activity` view; WarehousePG does not have any insight into how external components such as PL/Container manage memory in running instances.

Cancelling a Running or Queued Transaction in a Resource Group

There may be cases when you want to cancel a running or queued transaction in a resource group. For example, you may want to remove a query that is waiting in the resource group queue but has not yet been run. Or, you may want to stop a running query that is taking too long to run, or one that is sitting idle in a transaction and taking up resource group transaction slots that are needed by other users.

By default, transactions can remain queued in a resource group indefinitely. If you want WarehousePG to cancel a queued transaction after a specific amount of time, set the server configuration parameter gp_resource_group_queuing_timeout. When this parameter is set to a value (milliseconds) greater than 0, WarehousePG cancels any queued transaction when it has waited longer than the configured timeout.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

To manually cancel a running or queued transaction, you must first determine the process id (pid) associated with the transaction. Once you have obtained the process id, you can invoke `pg_cancel_backend()` to end that process, as shown below.

For example, to view the process information associated with all statements currently active or waiting in all resource groups, run the following query. If the query returns no results, then there are no running or queued transactions in any resource group.

```
SELECT rolname, g.rsgname, pid, waiting, state, query, datname
FROM pg_roles, gp_toolkit.gp_resgroup_status g, pg_stat_activity
WHERE pg_roles.rolresgroup=g.groupid
AND pg_stat_activity.usename=pg_roles.rolname;
```

Sample partial query output:

```
 rolname | rsgname  | pid     | waiting | state  |          query           | datname
---------+----------+---------+---------+--------+------------------------ -+---------
  sammy  | rg_light |  31861  |    f    | idle   | SELECT * FROM mytesttbl; | testdb
  billy  | rg_light |  31905  |    t    | active | SELECT * FROM topten;    | testdb
```

Use this output to identify the process id (`pid`) of the transaction you want to cancel, and then cancel the process. For example, to cancel the pending query identified in the sample output above:

```
SELECT pg_cancel_backend(31905);
```

You can provide an optional message in a second argument to `pg_cancel_backend()` to indicate to the user why the process was cancelled.

> **Note** Do not use an operating system `KILL` command to cancel any WarehousePG process.

Moving a Query to a Different Resource Group

A user with WarehousePG superuser privileges can run the `gp_toolkit.pg_resgroup_move_query()` function to move a running query from one resource group to another, without stopping the query. Use this function to expedite a long-running query by moving it to a resource group with a higher resource allotment or availability.

> **Note** You can move only an active or running query to a new resource group. You cannot move a queued or pending query that is in an idle state due to concurrency or memory limits.

`pg_resgroup_move_query()` requires the process id (pid) of the running query, as well as the name of the resource group to which you want to move the query. The signature of the function follows:

```
pg_resgroup_move_query( pid int4, group_name text );
```

You can obtain the pid of a running query from the `pg_stat_activity` system view as described in Cancelling a Running or Queued Transaction in a Resource Group. Use the `gp_toolkit.gp_resgroup_status` view to list the name, id, and status of each resource group.

When you invoke `pg_resgroup_move_query()`, the query is subject to the limits configured for the destination resource group:

- If the group has already reached its concurrent task limit, WarehousePG queues the query until a slot opens or for `gp_resource_group_queuing_timeout` milliseconds if set.
- If the group has a free slot, `pg_resgroup_move_query()` tries to give slot control away to the target process for up to `gp_resource_group_move_timeout` milliseconds. If target process can't handle movement request until `gp_resource_group_queuing_timeout` exceeds, WarehousePG returns the error: `target process failed to move to a new group`.
- If `pg_resgroup_move_query()` was cancelled, but target process already got all slot controls, segment's processes will not be moved to new group, and target process will hold the slot. Such inconsistent state will be fixed by the end of transaction or by any next command dispatched by target process inside same transaction.
- If the destination resource group does not have enough memory available to service the query's current memory requirements, WarehousePG returns the error: `group <group_name> doesn't have enough memory ...`. In this situation, you may choose to increase the group shared memory allotted to the destination resource group, or perhaps wait a period of time for running queries to complete and then invoke the function again.

After WarehousePG moves the query, there is no way to guarantee that a query currently running in the destination resource group does not exceed the group memory quota. In this situation, one or more running queries in the destination group may fail, including the moved query. Reserve enough resource group global shared memory to minimize the potential for this scenario to occur.

`pg_resgroup_move_query()` moves only the specified query to the destination resource group. WarehousePG assigns subsequent queries that you submit in the session to the original resource group.

Frequently Asked Questions

Why is CPU usage lower than the `CPU_MAX_PERCENT` configured for the resource group?

You may run into this situation when a low number of queries and slices are running in the resource group, and these processes are not utilizing all of the cores on the system.

**My resource group has a `CPU_WEIGHT` equivalent to 40%. Why is the CPU usage never reaching this limit?

The value of `CPU_MAX_PERCENT` might be lower than 40, hence it might be limiting the CPU usage even with idle resources.

Why is the number of running transactions lower than the `CONCURRENCY` limit configured for the resource group?

WarehousePG considers memory availability before running a transaction, and will queue the transaction if there is not enough memory available to serve it. If you use `ALTER RESOURCE GROUP` to increase the `CONCURRENCY` limit for a resource group but do not also adjust memory limits, currently running transactions may be consuming all allotted memory resources for the group. When in this state, WarehousePG queues subsequent transactions in the resource group.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Why is the number of running transactions in the resource group higher than the configured `CONCURRENCY` limit?

This behaviour is expected. There are several reasons why this may happen:

- Resource groups do not enforce resource restrictions on `SET`, `RESET` and `SHOW` commands
- The server configuration parameter `gp_resource_group_bypass` disables the concurrent transaction limit for the resource group so a query can run immediately.
- If the server configuration parameter `gp_resource_group_bypass_catalog_query` is set to true (the default), all queries that read exclusively from system catalogs, or queries that contain in their query text `pg_catalog` schema tables only will not enforce the limits of the resource group.
- Queries whose plan cost is less than the limit `MIN_COST` will be automatically unassigned from their resource group and will not enforce any of the limits set for this.

Why did my query return a "memory limit reached" error?

WarehousePG automatically adjusts transaction and group memory to the new settings when you use `ALTER RESOURCE GROUP` to change a resource group's memory and/or concurrency limits. An "out of memory" error may occur if you recently altered resource group attributes and there is no longer a sufficient amount of memory available for a currently running query.

My query cannot run due to insufficient memory, resulting in memory leak Out of Memory (OOM).

First, ensure that the resource group is allocating enough memory required by the query by tuning resource group parameters such as `CONCURRENCY` and `MEMORY_QUOTA`. Analyze the type of query, whether there will be a lot of intermediate results using memory. If it does exist, you can set a reasonable `gp_resgroup_memory_query_fixed_mem` to allocate more memory at the session level for this specific query.

After a memory leak OOM the system has a high concurrent load

When the system starts to clean up the sessions left over by the memory leak, the concurrent load of the system is high at this time, and the OOM error message may reappear. Due to the current design, we cannot expedite the cleanup process of the Runaway Session. The solution to this problem is to adjust the `runaway_detector_activation_percent` to 0.85 or 0.8, or even lower, in order to increase the available memory of the segment host.

Some transaction requests only run during a certain period of time, and do not run at other times.

You may change the configuration of resource groups can be changed dynamically at regular intervals to match the requirements of your workload, and customize resource allocation at different times to achieve higher efficiency. For example, change the configuration of resources within a group, add or delete resource groups.

After upgrading WarehousePG, the performance seems to be degraded.

There are many factors that can affect performance degradation. A possible cause is that after upgrading to WarehousePG 7, SWAP is enabled by default and hence affecting your performance. We recommend disabling SWAP and use RAM memory instead, in order to improve running speed and efficiency. If your memory configuration is sufficient, there is no need to use SWAP space. If you decide to use SWAP, be sure you understand how it takes part in the calculation of memory management allocation. See WarehousePG Memory Overview for more information.

4.10.6.3 Using Resource Queues

Use WarehousePG resource queues to prioritize and allocate resources to queries according to business requirements and to prevent queries from starting when resources are unavailable.

Resource queues are one tool to manage the degree of concurrency in a WarehousePG cluster. Resource queues are database objects that you create with the `CREATE RESOURCE QUEUE` SQL statement. You can use them to manage the number of active queries that may run concurrently, the amount of memory each type of query is allocated, and the relative priority of queries. Resource queues can also guard against queries that would consume too many resources and degrade overall system performance.

Each database role is associated with a single resource queue; multiple roles can share the same resource queue. Roles are assigned to resource queues using the `RESOURCE QUEUE` phrase of the `CREATE ROLE` or `ALTER ROLE` statements. If a resource queue is not specified, the role is associated with the default resource queue, `pg_default`.

When the user submits a query for execution, the query is evaluated against the resource queue's limits. If the query does not cause the queue to exceed its resource limits, then that query will run immediately. If the query causes the queue to exceed its limits (for example, if the maximum number of active statement slots are currently in use), then the query must wait until queue resources are free before it can run. Queries are evaluated on a first in, first out basis. If query prioritization is enabled, the active workload on the system is periodically assessed and processing resources are reallocated according to query priority (see How Priorities Work). Roles with the `SUPERUSER` attribute are exempt from resource queue limits. Superuser queries always run immediately regardless of limits imposed by their assigned resource queue.

Resource queues define classes of queries with similar resource requirements. Administrators should create resource queues for the various types of workloads in their organization. For example, you could create resource queues for the following classes of queries, corresponding to different service level agreements:

- ETL queries
- Reporting queries
- Executive queries

A resource queue has the following characteristics:

`MEMORY_LIMIT` The amount of memory used by all the queries in the queue (per segment). For example, setting `MEMORY_LIMIT` to 2GB on the ETL queue allows ETL queries to use up to 2GB of memory in each segment.

`ACTIVE_STATEMENTS` The number of *slots* for a queue; the maximum concurrency level for a queue. When all slots are used, new queries must wait. Each query uses an equal amount of memory by default.

For example, the `pg_default` resource queue has `ACTIVE_STATEMENTS` = 20.

`PRIORITY` The relative CPU usage for queries. This may be one of the following levels: `LOW`, `MEDIUM`, `HIGH`, `MAX`. The default level is `MEDIUM`. The query prioritization mechanism monitors the CPU usage of all the queries running in the system, and adjusts the CPU usage for each to conform to its priority level. For example, you could set `MAX` priority to the `executive` resource queue and `MEDIUM` to other queues to ensure that executive queries receive a greater share of CPU.

`MAX_COST` Query plan cost limit.

The WarehousePG optimizer assigns a numeric cost to each query. If the cost exceeds the `MAX_COST` value set for the resource queue, the query is rejected as too expensive.

> **Note** GPORCA and the Postgres-based planner utilize different query costing models and may compute different costs for the same query. The WarehousePG resource queue resource management scheme neither differentiates nor aligns costs between GPORCA and the Postgres-based planner; it uses the literal cost value returned from the optimizer to throttle queries.

When resource queue-based resource management is active, use the `MEMORY_LIMIT` and `ACTIVE_STATEMENTS` limits for resource queues rather than configuring cost-based limits. Even when using GPORCA, WarehousePG may fall back to using the Postgres-based planner for certain queries, so using cost-based limits can lead to unexpected results.

The default configuration for a WarehousePG cluster has a single default resource queue named `pg_default`. The `pg_default` resource queue has an `ACTIVE_STATEMENTS` setting of 20, no `MEMORY_LIMIT`, medium `PRIORITY`, and no set `MAX_COST`. This means that all queries are accepted and run immediately, at the same priority and with no memory limitations; however, only twenty queries may run concurrently.

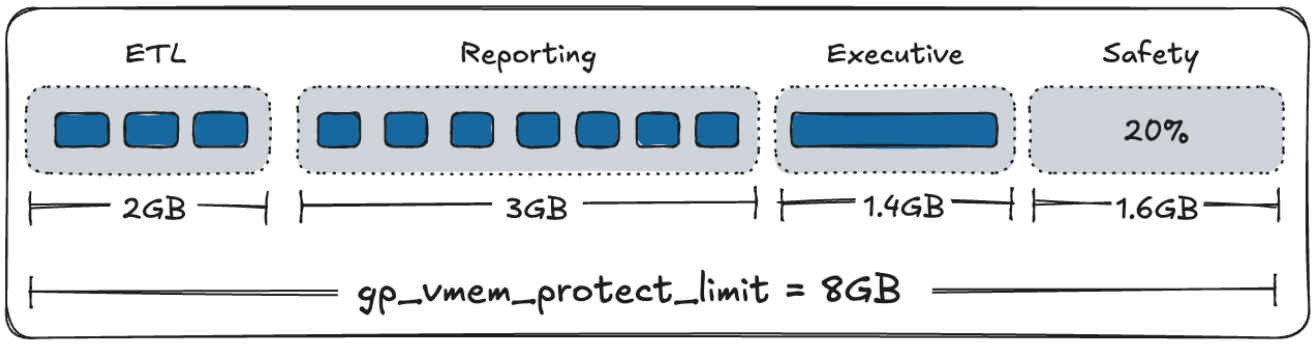
The number of concurrent queries a resource queue allows depends on whether the `MEMORY_LIMIT` parameter is set:

- If no `MEMORY_LIMIT` is set for a resource queue, the amount of memory allocated per query is the value of the statement_mem server configuration parameter. The maximum memory the resource queue can use is the product of `statement_mem` and `ACTIVE_STATEMENTS`.
- When a `MEMORY_LIMIT` is set on a resource queue, the number of queries that the queue can run concurrently is limited by the queue's available memory.

A query admitted to the system is allocated an amount of memory and a query plan tree is generated for it. Each node of the tree is an operator, such as a sort or hash join. Each operator is a separate execution thread and is allocated a fraction of the overall statement memory, at minimum 100KB. If the plan has a large number of operators, the minimum memory required for operators can exceed the available memory and the query will be rejected with an insufficient memory error. Operators determine if they can complete their tasks in the memory allocated, or if they must spill data to disk, in work files. The mechanism that allocates and controls the amount of memory used by each operator is called *memory quota*.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Not all SQL statements submitted through a resource queue are evaluated against the queue limits. By default only `SELECT`, `SELECT INTO`, `CREATE TABLE AS SELECT`, and `DECLARE CURSOR` statements are evaluated. If the server configuration parameter resource_select_only is set to `off`, then `INSERT`, `UPDATE`, and `DELETE` statements will be evaluated as well.



Also, an SQL statement that is run during the execution of an `EXPLAIN ANALYZE` command is excluded from resource queues.

Parent topic: Managing Resources

Resource Queue Example

The default resource queue, `pg_default`, allows a maximum of 20 active queries and allocates the same amount of memory to each. This is generally not adequate resource control for production systems. To ensure that the system meets performance expectations, you can define classes of queries and assign them to resource queues configured to run them with the concurrency, memory, and CPU resources best suited for that class of query.

The following illustration shows an example resource queue configuration for a WarehousePG cluster with `gp_vmem_protect_limit` set to 8GB:

This example has three classes of queries with different characteristics and service level agreements (SLAs). Three resource queues are configured for them. A portion of the segment memory is reserved as a safety margin.

Resource Queue Name	Active Statements	Memory Limit	Memory per Query
ETL	3	2GB	667MB
Reporting	7	3GB	429MB
Executive	1	1.4GB	1.4GB

The total memory allocated to the queues is 6.4GB, or 80% of the total segment memory defined by the `gp_vmem_protect_limit` server configuration parameter. Allowing a safety margin of 20% accommodates some operators and queries that are known to use more memory than they are allocated by the resource queue.

See the CREATE RESOURCE QUEUE, CREATE ROLE, and ALTER ROLE statements in the *WarehousePG Reference Guide* for help with command syntax and detailed reference information.

How Memory Limits Work

Setting `MEMORY_LIMIT` on a resource queue sets the maximum amount of memory that all active queries submitted through the queue can consume for a segment instance. The amount of memory allotted to a query is the queue memory limit divided by the active statement limit. (Use the memory limits in conjunction with statement-based queues rather than cost-based queues.) For example, if a queue has a memory limit of 2000MB and an active statement limit of 10, each query submitted through the queue is allotted 200MB of memory by default. The default memory allotment can be overridden on a per-query basis using the `statement_mem` server configuration parameter (up to the queue memory limit). Once a query has started running, it holds its allotted memory in the queue until it completes, even if during execution it actually consumes less than its allotted amount of memory.

You can use the `statement_mem` server configuration parameter to override memory limits set by the current resource queue. At the session level, you can increase `statement_mem` up to the resource queue's `MEMORY_LIMIT`. This will allow an individual query to use all of the memory allocated for the entire queue without affecting other resource queues.

The value of `statement_mem` is capped using the `max_statement_mem` configuration parameter (a superuser parameter). For a query in a resource queue with `MEMORY_LIMIT` set, the maximum value for `statement_mem` is `min(MEMORY_LIMIT, max_statement_mem)`. When a query is admitted, the memory allocated to it is subtracted from `MEMORY_LIMIT`. If `MEMORY_LIMIT` is exhausted, new queries in the same resource queue must wait. This happens even if `ACTIVE_STATEMENTS` has not yet been reached. Note that this can happen only when `statement_mem` is used to override the memory allocated by the resource queue.

For example, consider a resource queue named `adhoc` with the following settings:

- `MEMORY_LIMIT` is 1.5GB
- `ACTIVE_STATEMENTS` is 3

By default each statement submitted to the queue is allocated 500MB of memory. Now consider the following series of events:

1. User `ADHOC_1` submits query `Q1`, overriding `STATEMENT_MEM` to 800MB. The `Q1` statement is admitted into the system.
2. User `ADHOC_2` submits query `Q2`, using the default 500MB.
3. With `Q1` and `Q2` still running, user `ADHOC3` submits query `Q3`, using the default 500MB.

Queries `Q1` and `Q2` have used 1300MB of the queue's 1500MB. Therefore, `Q3` must wait for `Q1` or `Q2` to complete before it can run.

If `MEMORY_LIMIT` is not set on a queue, queries are admitted until all of the `ACTIVE_STATEMENTS` slots are in use, and each query can set an arbitrarily high `statement_mem`. This could lead to a resource queue using unbounded amounts of memory.

For more information on configuring memory limits on a resource queue, and other memory utilization controls, see Creating Queues with Memory Limits.

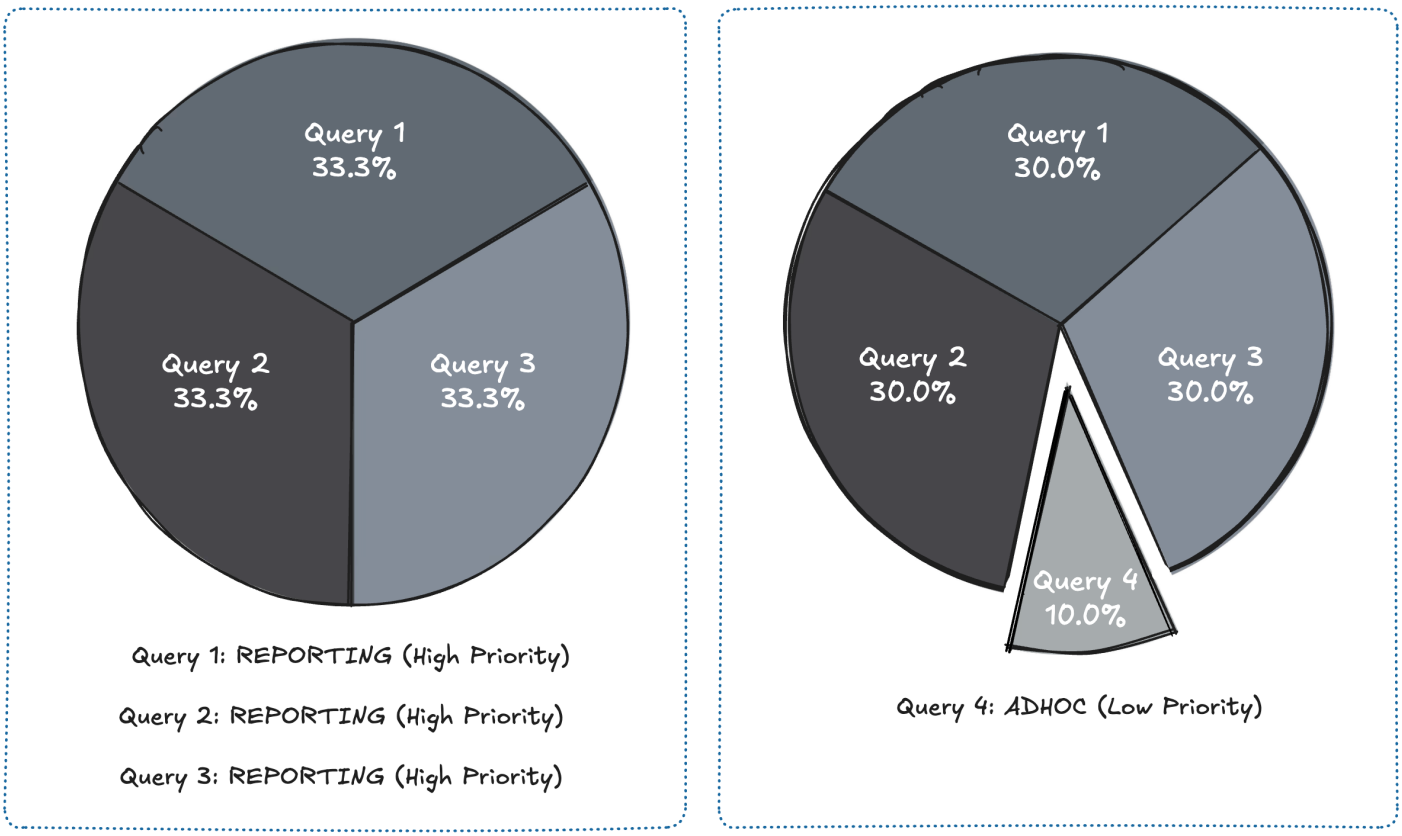
Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

statement_mem and Low Memory Queries

A low `statement_mem` setting (for example, in the 1-3MB range) has been shown to increase the performance of queries with low memory requirements. Use the `statement_mem` server configuration parameter to override the setting on a per-query basis. For example:

```
SET statement_mem='2MB';
```

How Priorities Work

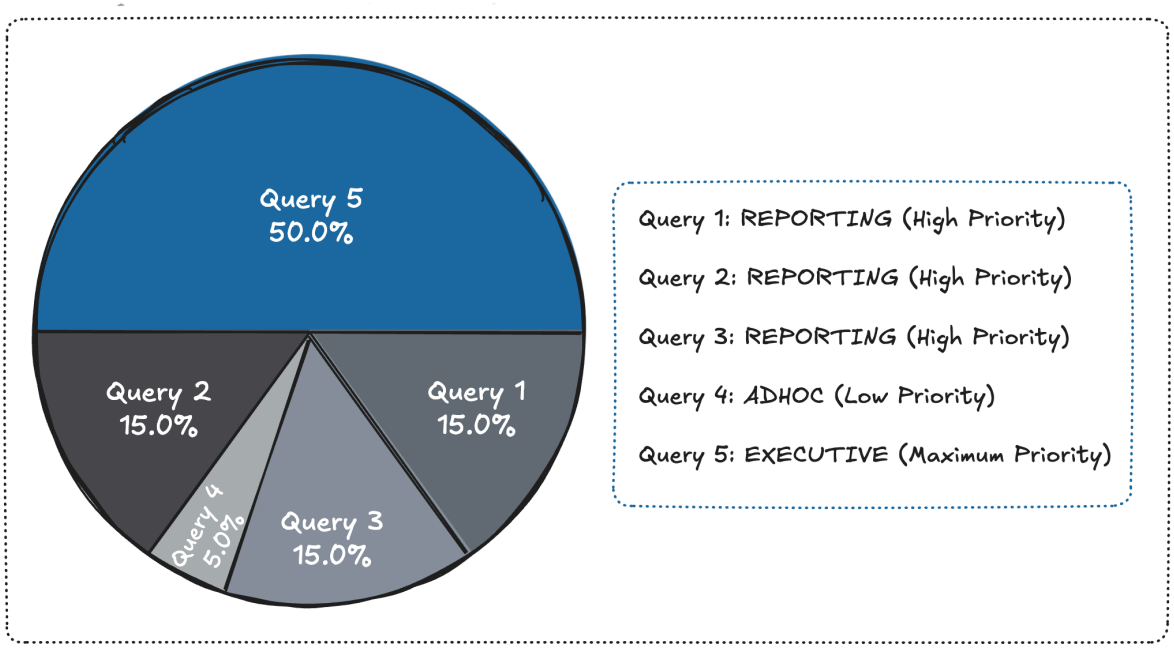


The `PRIORITY` setting for a resource queue differs from the `MEMORY_LIMIT` and `ACTIVE_STATEMENTS` settings, which determine whether a query will be admitted to the queue and eventually run. The `PRIORITY` setting applies to queries after they become active. Active queries share available CPU resources as determined by the priority settings for its resource queue. When a statement from a high-priority queue enters the group of actively running statements, it may claim a greater share of the available CPU, reducing the share allocated to already-running statements in queues with a lesser priority setting.

The comparative size or complexity of the queries does not affect the allotment of CPU. If a simple, low-cost query is running simultaneously with a large, complex query, and their priority settings are the same, they will be allocated the same share of available CPU resources. When a new query becomes active, the CPU shares will be recalculated, but queries of equal priority will still have equal amounts of CPU.

For example, an administrator creates three resource queues: *adhoc* for ongoing queries submitted by business analysts, *reporting* for scheduled reporting jobs, and *executive* for queries submitted by executive user roles. The administrator wants to ensure that scheduled reporting jobs are not heavily affected by unpredictable resource demands from ad-hoc analyst queries. Also, the administrator wants to make sure that queries submitted by executive roles are allotted a significant share of CPU. Accordingly, the resource queue priorities are set as shown:

- *adhoc* — Low priority
- *reporting* — High priority
- *executive* — Maximum priority



At runtime, the CPU share of active statements is determined by these priority settings. If queries 1, 2 and 3 from the **reporting** queue are running simultaneously, they have equal shares of CPU. When an **ad-hoc** query becomes active, it claims a smaller share of CPU. The exact share used by the reporting queries is adjusted, but remains equal due to their equal priority setting:

Note The percentages shown in these illustrations are approximate. CPU usage between high, low and maximum priority queues is not always calculated in precisely these proportions.

When an executive query enters the group of running statements, CPU usage is adjusted to account for its maximum priority setting. It may be a simple query compared to the analyst and reporting queries, but until it is completed, it will claim the largest share of CPU.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

For more information about commands to set priorities, see Setting Priority Levels.

Enabling Resource Queues

When you install WarehousePG, no resource management policy is enabled by default. To use resource queues, set the gp_resource_manager server configuration parameter:

1. Set the `gp_resource_manager` server configuration parameter to the value `"queue"`

   ```
   gpconfig -c gp_resource_manager -v "queue"
   ```

2. Restart WarehousePG:

   ```
   gpstop
   gpstart
   ```

Configuring Resource Queues

Before you create any resource groups, learn about the different resouce queue server configuration parameters and their usage. See Server Configuration Parameters for more information.

1. General configuration

   - `max_resource_queues` - Sets the maximum number of resource queues.
   - `max_resource_portals_per_transaction` - Sets the maximum number of simultaneously open cursors allowed per transaction. Note that an open cursor will hold an active query slot in a resource queue.
   - `resource_select_only` - If set to *on*, then `SELECT`, `SELECT INTO`, `CREATE TABLE AS``SELECT`, and `DECLARE CURSOR` commands are evaluated. If set to *off* `INSERT`, `UPDATE`, and `DELETE` commands will be evaluated as well.
   - `resource_cleanup_gangs_on_wait` - Cleans up idle segment worker processes before taking a slot in the resource queue.
   - `stats_queue_level` - Enables statistics collection on resource queue usage, which can then be viewed by querying the pg_stat_resqueues system view.

2. Memory utilization

   - `gp_resqueue_memory_policy` - Enables WarehousePG memory management features.

     In WarehousePG 4.2 and later, the distribution algorithm `eager_free` takes advantage of the fact that not all operators run at the same time. The query plan is divided into stages and WarehousePG eagerly frees memory allocated to a previous stage at the end of that stage's execution, then allocates the eagerly freed memory to the new stage.

     When set to `none`, memory management is the same as in WarehousePG releases prior to 4.1. When set to `auto`, query memory usage is controlled by `statement_mem` and resource queue memory limits.

   - `statement_mem` and `max_statement_mem` - Used to allocate memory to a particular query at runtime (override the default allocation assigned by the resource queue). `max_statement_mem` is set by database superusers to prevent regular database users from over-allocation.

   - `gp_vmem_protect_limit` - Sets the upper boundary that all query processes can consume and should not exceed the amount of physical memory of a segment host. When a segment host reaches this limit during query execution, the queries that cause the limit to be exceeded will be cancelled.

   - `gp_vmem_idle_resource_timeout` and `gp_vmem_protect_segworker_cache_limit` - used to free memory on segment hosts held by idle database processes. Administrators may want to adjust these settings on systems with lots of concurrency.

   - `shared_buffers` - Sets the amount of memory a WarehousePG server instance uses for shared memory buffers. This setting must be at least 128 kilobytes and at least 16 kilobytes times `max_connections`. The value must not exceed the operating system shared memory maximum allocation request size, `shmmax` on Linux. See the *WarehousePG Installation Guide* for recommended OS memory settings for your platform.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

3. Query prioritization. Note that the following parameters are all *local* parameters, meaning they must be set in the `postgresql.conf` files of the coordinator and all segments:

    - `gp_resqueue_priority` - The query prioritization feature is enabled by default.
    - `gp_resqueue_priority_sweeper_interval` - Sets the interval at which CPU usage is recalculated for all active statements. The default value for this parameter should be sufficient for typical database operations.
    - `gp_resqueue_priority_cpucores_per_segment` - Specifies the number of CPU cores allocated per segment instance on a segment host. If the segment is configured with primary-mirror segment instance pairs, use the number of primary segment instances on the host in the calculation. The default value is 4 for the coordinator and segment hosts.

      Each WarehousePG host checks its own `postgresql.conf` file for the value of this parameter. This parameter also affects the coordinator host, where it should be set to a value reflecting the higher ratio of CPU cores. For example, on a cluster that has 10 CPU cores per segment host and 4 primary segments per host, you would specify the following values for `gp_resqueue_priority_cpucores_per_segment`:

        - 10 on the coordinator and standby coordinator hosts. Typically, only a single coordinator segment instance runs on the coordinator host.
        - 2.5 on each segment host (10 cores divided by 4 primary segments).
          If the parameter value is not set correctly, either the CPU might not be fully utilized, or query prioritization might not work as expected. For example, if the WarehousePG cluster has fewer than one segment instance per CPU core on your segment hosts, make sure that you adjust this value accordingly.

      Actual CPU core utilization is based on the ability of WarehousePG to parallelize a query and the resources required to run the query.

      > **Note** Include any CPU core that is available to the operating system in the number of CPU cores, including virtual CPU cores.

Use the `gpconfig` utility to view or change any of the resource management parameter values. For example, to see the setting of a particular parameter:

```
gpconfig --show gp_vmem_protect_limit
```

To set one value on all segment instances and a different value on the coordinator:

```
gpconfig -c gp_resqueue_priority_cpucores_per_segment -v 2 -m 8
```

Restart WarehousePG to make the configuration changes effective:

```
gpstop -r
```

Creating Resource Queues

When you create a resource queue for a role, you provide a name, set an active query limit, and optionally a query priority for the resource queue. Use theCREATE RESOURCE QUEUE command to create new resource queues.

Creating Queues with an Active Query Limit

Resource queues with an `ACTIVE_STATEMENTS` setting limit the number of queries that can be run by roles assigned to that queue. For example, to create a resource queue named*adhoc* with an active query limit of three:

```
CREATE RESOURCE QUEUE adhoc WITH (ACTIVE_STATEMENTS=3);
```

This means that for all roles assigned to the *adhoc* resource queue, only three active queries can be running on the system at any given time. If this queue has three queries running, and a fourth query is submitted by a role in that queue, that query must wait until a slot is free before it can run.

Creating Queues with Memory Limits

Resource queues with a `MEMORY_LIMIT` setting control the amount of memory for all the queries submitted through the queue. The total memory should not exceed the physical memory available per-segment. Set `MEMORY_LIMIT` to 90% of memory available on a per-segment basis. For example, if a host has 48 GB of physical memory and 6 segment instances, then the memory available per segment instance is 8 GB. You can calculate the recommended `MEMORY_LIMIT` for a single queue as 0.90*8=7.2 GB. If there are multiple queues created on the system, their total memory limits must also add up to 7.2 GB.

When used in conjunction with `ACTIVE_STATEMENTS`, the default amount of memory allotted per query is: `MEMORY_LIMIT / ACTIVE_STATEMENTS`. When used in conjunction with `MAX_COST`, the default amount of memory allotted per query is: `MEMORY_LIMIT * (query_cost / MAX_COST)`. Use `MEMORY_LIMIT` in conjunction with `ACTIVE_STATEMENTS` rather than with `MAX_COST`.

For example, to create a resource queue with an active query limit of 10 and a total memory limit of 2000MB (each query will be allocated 200MB of segment host memory at execution time):

```
CREATE RESOURCE QUEUE myqueue WITH (ACTIVE_STATEMENTS=20,
MEMORY_LIMIT='2000MB');
```

The default memory allotment can be overridden on a per-query basis using the `statement_mem` server configuration parameter, provided that `MEMORY_LIMIT` or `max_statement_mem` is not exceeded. For example, to allocate more memory to a particular query:

```
SET statement_mem='2GB';
SELECT * FROM my_big_table WHERE column='value' ORDER BY id;
RESET statement_mem;
```

As a general guideline, `MEMORY_LIMIT` for all of your resource queues should not exceed the amount of physical memory of a segment host. If workloads are staggered over multiple queues, it may be OK to oversubscribe memory allocations, keeping in mind that queries may be cancelled during execution if the segment host memory limit (`gp_vmem_protect_limit`) is exceeded.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Setting Priority Levels

To control a resource queue's consumption of available CPU resources, an administrator can assign an appropriate priority level. When high concurrency causes contention for CPU resources, queries and statements associated with a high-priority resource queue will claim a larger share of available CPU than lower priority queries and statements.

Priority settings are created or altered using the `WITH` parameter of the commands `CREATE RESOURCE QUEUE` and `ALTER RESOURCE QUEUE`. For example, to specify priority settings for the *adhoc* and *reporting* queues, an administrator would use the following commands:

```
ALTER RESOURCE QUEUE adhoc WITH (PRIORITY=LOW);
ALTER RESOURCE QUEUE reporting WITH (PRIORITY=HIGH);
```

To create the *executive* queue with maximum priority, an administrator would use the following command:

```
CREATE RESOURCE QUEUE executive WITH (ACTIVE_STATEMENTS=3, PRIORITY=MAX);
```

When the query prioritization feature is enabled, resource queues are given a `MEDIUM` priority by default if not explicitly assigned. For more information on how priority settings are evaluated at runtime, see How Priorities Work.

> **Important** In order for resource queue priority levels to be enforced on the active query workload, you must enable the query prioritization feature by setting the associated server configuration parameters. SeeConfiguring Resource Queues.

Assigning Roles to a Resource Queue

Once a resource queue is created, you must assign roles (users) to their appropriate resource queue. If roles are not explicitly assigned to a resource queue, they will go to the default resource queue `pg_default`. The default resource queue has an active statement limit of 20, no cost limit, and a medium priority setting.

Use the `ALTER ROLE` or `CREATE ROLE` commands to assign a role to a resource queue. For example:

```
ALTER ROLE `name` RESOURCE QUEUE `queue_name`;
CREATE ROLE `name` WITH LOGIN RESOURCE QUEUE `queue_name`;
```

A role can only be assigned to one resource queue at any given time, so you can use the `ALTER ROLE` command to initially assign or change a role's resource queue.

Resource queues must be assigned on a user-by-user basis. If you have a role hierarchy (for example, a group-level role) then assigning a resource queue to the group does not propagate down to the users in that group.

Superusers are always exempt from resource queue limits. Superuser queries will always run regardless of the limits set on their assigned queue.

Removing a Role from a Resource Queue

All users *must* be assigned to a resource queue. If not explicitly assigned to a particular queue, users will go into the default resource queue, `pg_default`. If you wish to remove a role from a resource queue and put them in the default queue, change the role's queue assignment to `none`. For example:

```
ALTER ROLE `role_name` RESOURCE QUEUE none;
```

Modifying Resource Queues

After a resource queue has been created, you can change or reset the queue limits using the `ALTER RESOURCE QUEUE` command. You can remove a resource queue using the `DROP RESOURCE QUEUE` command. To change the roles (users) assigned to a resource queue, Assigning Roles to a Resource Queue.

Altering a Resource Queue

The `ALTER RESOURCE QUEUE` command changes the limits of a resource queue. To change the limits of a resource queue, specify the new values you want for the queue. For example:

```
ALTER RESOURCE QUEUE <adhoc> WITH (ACTIVE_STATEMENTS=5);
ALTER RESOURCE QUEUE <exec> WITH (PRIORITY=MAX);
```

To reset active statements or memory limit to no limit, enter a value of `-1`. To reset the maximum query cost to no limit, enter a value of `-1.0`. For example:

```
ALTER RESOURCE QUEUE <adhoc> WITH (MAX_COST=-1.0, MEMORY_LIMIT='2GB');
```

You can use the `ALTER RESOURCE QUEUE` command to change the priority of queries associated with a resource queue. For example, to set a queue to the minimum priority level:

```
ALTER RESOURCE QUEUE <webuser> WITH (PRIORITY=MIN);
```

Dropping a Resource Queue

The `DROP RESOURCE QUEUE` command drops a resource queue. To drop a resource queue, the queue cannot have any roles assigned to it, nor can it have any statements waiting in the queue. SeeRemoving a Role from a Resource Queue and Clearing a Waiting Statement From a Resource Queue for instructions on emptying a resource queue. To drop a resource queue:

```
DROP RESOURCE QUEUE <name>;
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Monitoring Resource Queue Status

Monitoring resource queue status involves the following tasks:

Viewing Queued Statements and Resource Queue Status

The gp_resqueue_status `gp_toolkit` view allows administrators to see status and activity for a resource queue. It shows how many queries are waiting to run and how many queries are currently active in the system from a particular resource queue. To see the resource queues created in the system, their limit attributes, and their current status:

```
SELECT * FROM gp_toolkit.gp_resqueue_status;
```

Viewing Resource Queue Statistics

If you want to track statistics and performance of resource queues over time, you can enable statistics collecting for resource queues. This is done by setting the following server configuration parameter in your coordinator `postgresql.conf` file:

```
stats_queue_level = on
```

Once this is enabled, you can use the `pg_stat_resqueue` system view to see the statistics collected on resource queue usage. Note that enabling this feature does incur slight performance overhead, as each query submitted through a resource queue must be tracked. It may be useful to enable statistics collecting on resource queues for initial diagnostics and administrative planning, and then deactivate the feature for continued use.

See the Statistics Collector section in the PostgreSQL documentation for more information about collecting statistics in WarehousePG.

Viewing the Roles Assigned to a Resource Queue

To see the roles assigned to a resource queue, perform the following query of the `pg_roles` and The gp_resqueue_status `gp_toolkit` system catalog tables:

```
SELECT rolname, rsqname FROM pg_roles,
       gp_toolkit.gp_resqueue_status
WHERE pg_roles.rolresqueue=gp_toolkit.gp_resqueue_status.queueid;
```

You may want to create a view of this query to simplify future inquiries. For example:

```
CREATE VIEW role2queue AS
SELECT rolname, rsqname FROM pg_roles, pg_resqueue
WHERE pg_roles.rolresqueue=gp_toolkit.gp_resqueue_status.queueid;
```

Then you can just query the view:

```
SELECT * FROM role2queue;
```

Viewing the Waiting Queries for a Resource Queue

When a slot is in use for a resource queue, it is recorded in the `pg_locks` system catalog table. This is where you can see all of the currently active and waiting queries for all resource queues. To check that statements are being queued (even statements that are not waiting), you can also use the gp_locks_on_resqueue `gp_toolkit` view. For example:

```
SELECT * FROM gp_toolkit.gp_locks_on_resqueue WHERE lorwaiting='true';
```

If this query returns no results, then that means there are currently no statements waiting in a resource queue.

Clearing a Waiting Statement From a Resource Queue

In some cases, you may want to clear a waiting statement from a resource queue. For example, you may want to remove a query that is waiting in the queue but has not been run yet. You may also want to stop a query that has been started if it is taking too long to run, or if it is sitting idle in a transaction and taking up resource queue slots that are needed by other users. To do this, you must first identify the statement you want to clear, determine its process id (pid), and then, use `pg_cancel_backend` with the process id to end that process, as shown below. An optional message to the process can be passed as the second parameter, to indicate to the user why the process was cancelled.

For example, to see process information about all statements currently active or waiting in all resource queues, run the following query:

```
SELECT rolname, rsqname, pg_locks.pid as pid, granted, state,
       query, datname
FROM pg_roles, gp_toolkit.gp_resqueue_status, pg_locks,
     pg_stat_activity
WHERE pg_roles.rolresqueue=pg_locks.objid
AND pg_locks.objid=gp_toolkit.gp_resqueue_status.queueid
AND pg_stat_activity.pid=pg_locks.pid
AND pg_stat_activity.usename=pg_roles.rolname;
```

If this query returns no results, then that means there are currently no statements in a resource queue. A sample of a resource queue with two statements in it looks something like this:

```
rolname | rsqname |  pid  | granted | state  |         query          | datname
--------+---------+-------+---------+--------+------------------------+---------
  sammy | webuser | 31861 | t       | idle   | SELECT * FROM testtbl; | namesdb
  daria | webuser | 31905 | f       | active | SELECT * FROM topten;  | namesdb
```

Use this output to identify the process id (pid) of the statement you want to clear from the resource queue. To clear the statement, you would then open a terminal window (as the `gpadmin` database superuser or as root) on the coordinator host and cancel the corresponding process. For example:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
pg_cancel_backend(31905)
```

> **Important** Do not use the operating system `KILL` command.

Viewing the Priority of Active Statements

The *gp_toolkit* administrative schema has a view called gp_resq_priority_statement, which lists all statements currently being run and provides the priority, session ID, and other information.

This view is only available through the `gp_toolkit` administrative schema. See the *WarehousePG Reference Guide* for more information.

Resetting the Priority of an Active Statement

Superusers can adjust the priority of a statement currently being run using the built-in function `gp_adjust_priority(session_id, statement_count, priority)`. Using this function, superusers can raise or lower the priority of any query. For example:

```
SELECT gp_adjust_priority(752, 24905, 'HIGH')`
```

To obtain the session ID and statement count parameters required by this function, superusers can use the `gp_toolkit` administrative schema view gp_resq_priority_statement. From the view, use these values for the function parameters.

- The value of the `rqpsession` column for the `session_id` parameter
- The value of the `rqpcommand` column for the `statement_count` parameter
- The value of `rqppriority` column is the current priority. You can specify a string value of `MAX`, `HIGH`, `MEDIUM`, or `LOW` as the `priority`.

> **Note** The `gp_adjust_priority()` function affects only the specified statement. Subsequent statements in the same resource queue are run using the queue's normally assigned priority.

4.10.7 Investigating a Performance Problem

This section provides guidelines for identifying and troubleshooting performance problems in a WarehousePG cluster.

This topic lists steps you can take to help identify the cause of a performance problem. If the problem affects a particular workload or query, you can focus on tuning that particular workload. If the performance problem is system-wide, then hardware problems, system failures, or resource contention may be the cause.

Parent topic: Managing Performance

Checking System State

Use the `gpstate` utility to identify failed segments. A WarehousePG cluster will incur performance degradation when segment instances are down because other hosts must pick up the processing responsibilities of the down segments.

Failed segments can indicate a hardware failure, such as a failed disk drive or network card. WarehousePG provides the hardware verification tool `gpcheckperf` to help identify the segment hosts with hardware issues.

Checking Database Activity

- Checking for Active Sessions (Workload)
- Checking for Locks (Contention)
- Checking Query Status and System Utilization

Checking for Active Sessions (Workload)

The *pg_stat_activity* system catalog view shows one row per server process; it shows the database OID, database name, process ID, user OID, user name, current query, time at which the current query began execution, time at which the process was started, client address, and port number. To obtain the most information about the current system workload, query this view as the database superuser. For example:

```
SELECT * FROM pg_stat_activity;
```

Note that the information does not update instantaneously.

Checking for Locks (Contention)

The *pg_locks* system catalog view allows you to see information about outstanding locks. If a transaction is holding a lock on an object, any other queries must wait for that lock to be released before they can continue. This may appear to the user as if a query is hanging.

Examine *pg_locks* for ungranted locks to help identify contention between database client sessions. *pg_locks* provides a global view of all locks in the database system, not only those relevant to the current database. You can join its relation column against `pg_class.oid` to identify locked relations (such as tables), but this works correctly only for relations in the current database. You can join the `pid` column to the `pg_stat_activity.pid` to see more information about the session holding or waiting to hold a lock. For example:

```
SELECT locktype, database, c.relname, l.relation,
l.transactionid, l.pid, l.mode, l.granted,
a.query
        FROM pg_locks l, pg_class c, pg_stat_activity a
        WHERE l.relation=c.oid AND l.pid=a.pid
        ORDER BY c.relname;
```

If you use resource groups, queries that are waiting will also show in *pg_locks*. To see how many queries are waiting to run in a resource group, use the *gp_resgroup_status* system catalog view. For example:

```
SELECT * FROM gp_toolkit.gp_resgroup_status;
```

Similarly, if you use resource queues, queries that are waiting in a queue also show in *pg_locks*. To see how many queries are waiting to run from a resource queue, use the *gp_resqueue_status* system catalog view. For example:

```
SELECT * FROM gp_toolkit.gp_resqueue_status;
```

Checking Query Status and System Utilization

You can use system monitoring utilities such as `ps`, `top`, `iostat`, `vmstat`, `netstat` and so on to monitor database activity on the hosts in your WarehousePG cluster. These tools can help identify WarehousePG processes (`postgres` processes) currently running on the system and the most resource intensive tasks with regards to CPU, memory, disk I/O, or network activity. Look at these system statistics to identify queries that degrade database performance by overloading the system and consuming excessive resources. WarehousePG's management tool `gpssh` allows you to run these system monitoring commands on several hosts simultaneously.

You can create and use the WarehousePG *session_level_memory_consumption* view that provides information about the current memory utilization and idle time for sessions that are running queries on WarehousePG. For information about the view, see Viewing Session Memory Usage Information.

Troubleshooting Problem Queries

If a query performs poorly, look at its query plan to help identify problems. The `EXPLAIN` command shows the query plan for a given query. See Query Profiling for more information about reading query plans and identifying problems.

When an out of memory event occurs during query execution, the WarehousePG memory accounting framework reports detailed memory consumption of every query running at the time of the event. The information is written to the WarehousePG segment logs.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Investigating Error Messages

WarehousePG log messages are written to files in the `log` directory within the coordinator's or segment's data directory. Because the coordinator log file contains the most information, you should always check it first. Log files roll over daily and use the naming convention: `gpdb- *YYYY - MM - DD_hhmmss.csv*`. To locate the log files on the coordinator host:

```
$ cd $COORDINATOR_DATA_DIRECTORY/log
```

Log lines have the format of:

```
<timestamp> | <user> | <database> | <statement_id> | <con#><cmd#>
|:-<LOG_LEVEL>: <log_message>
```

You may want to focus your search for `WARNING` , `ERROR` , `FATAL` or `PANIC` log level messages. You can use the WarehousePG utility `gplogfilter` to search through WarehousePG log files. For example, when you run the following command on the coordinator host, it checks for problem log messages in the standard logging locations:

```
$ gplogfilter -t
```

To search for related log entries in the segment log files, you can run `gplogfilter` on the segment hosts using `gpssh` . You can identify corresponding log entries by the `*statement_id*` or `*con #*` (session identifier). For example, to search for log messages in the segment log files containing the string `con6` and save output to a file:

```
gpssh -f seg_hosts_file -e 'source
/usr/edb/whpg7/greenplum_path.sh ; gplogfilter -f
con6 /gpdata/*/log/gpdb*.csv' > seglog.out
```

4.11 Retrieving Query Results with a Parallel Retrieve Cursor

A *parallel retrieve cursor* is an enhanced cursor implementation that you can use to create a special kind of cursor on the WarehousePG coordinator node, and retrieve query results, on demand and in parallel, directly from the WarehousePG segments.

About Parallel Retrieve Cursors

You use a cursor to retrieve a smaller number of rows at a time from a larger query. When you declare a parallel retrieve cursor, the WarehousePG Database Query Dispatcher (QD) dispatches the query plan to each Query Executor (QE), and creates an *endpoint* on each QE before it executes the query. An endpoint is a query result source for a parallel retrieve cursor on a specific QE. Instead of returning the query result to the QD, an endpoint retains the query result for retrieval via a different process: a direct connection to the endpoint. You open a special retrieve mode connection, called a *retrieve session*, and use the new `RETRIEVE` SQL command to retrieve query results from each parallel retrieve cursor endpoint. You can retrieve from parallel retrieve cursor endpoints on demand and in parallel.

You can use the following functions and views to examine and manage parallel retrieve cursors and endpoints:

Function, View Name	Description
gp_get_endpoints() gp_endpoints	List the endpoints associated with all active parallel retrieve cursors declared by the current user in the current database. When the WarehousePG superuser invokes this function, it returns a list of all endpoints for all parallel retrieve cursors declared by all users in the current database.
gp_get_session_endpoints() gp_session_endpoints	List the endpoints associated with all parallel retrieve cursors declared in the current session for the current user.
gp_get_segment_endpoints() gp_segment_endpoints	List the endpoints created in the QE for all active parallel retrieve cursors declared by the current user. When the WarehousePG superuser accesses this view, it returns a list of all endpoints on the QE created for all parallel retrieve cursors declared by all users.
gp_wait_parallel_retrieve_cursor(cursorname text, timeout_sec int4)	Return cursor status or block and wait for results to be retrieved from all endpoints associated with the specified parallel retrieve cursor.

> **Note:** Each of these functions and views is located in the `pg_catalog` schema, and each `RETURNS TABLE`.

Using a Parallel Retrieve Cursor

You will perform the following tasks when you use a WarehousePG parallel retrieve cursor to read query results in parallel from WarehousePG segments:

1. Declare the parallel retrieve cursor.
2. List the endpoints of the parallel retrieve cursor.
3. Open a retrieve connection to each endpoint.
4. Retrieve data from each endpoint.
5. Wait for data retrieval to complete.
6. Handle data retrieval errors.
7. Close the parallel retrieve cursor.

In addition to the above, you may optionally choose to List all parallel retrieve cursors in the system or List segment-specific retrieve session information.

Declaring a Parallel Retrieve Cursor

You DECLARE a cursor to retrieve a smaller number of rows at a time from a larger query. When you declare a parallel retrieve cursor, you can retrieve the query results directly from the WarehousePG segments.

The syntax for declaring a parallel retrieve cursor is similar to that of declaring a regular cursor; you must additionally include the `PARALLEL RETRIEVE` keywords in the command. You can declare a parallel retrieve cursor only within a transaction, and the cursor name that you specify when you declare the cursor must be unique within the transaction.

For example, the following commands begin a transaction and declare a parallel retrieve cursor named `prc1` to retrieve the results from a specific query:

```
BEGIN;
DECLARE prc1 PARALLEL RETRIEVE CURSOR FOR
<i>query</i>;
```

WarehousePG creates the endpoint(s) on the QD or QEs, depending on the *query* parameters:

- WarehousePG creates an endpoint on the QD when the query results must be gathered by the coordinator. For example, this `DECLARE` statement requires that the coordinator gather the query results:

  ```
  DECLARE c1 PARALLEL RETRIEVE CURSOR FOR SELECT * FROM t1 ORDER BY
  a;
  ```

  > **Note:** You may choose to run the `EXPLAIN` command on the parallel retrieve cursor query to identify when motion is involved. Consider using a regular cursor for such queries.

- When the query involves direct dispatch to a segment (the query is filtered on the distribution key), WarehousePG creates the endpoint(s) on specific segment host(s). For example, this `DECLARE` statement may result in the creation of single endpoint:

  ```
  DECLARE c2 PARALLEL RETRIEVE CURSOR FOR SELECT * FROM t1 WHERE
  a=1;
  ```

- WarehousePG creates the endpoints on all segment hosts when all hosts contribute to the query results. This example `DECLARE` statement results in all segments contributing query results:

  ```
  DECLARE c3 PARALLEL RETRIEVE CURSOR FOR SELECT * FROM
  t1;
  ```

The `DECLARE` command returns when the endpoints are ready and query execution has begun.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Listing a Parallel Retrieve Cursor's Endpoints

You can obtain the information that you need to initiate a retrieve connection to an endpoint by invoking the `gp_get_endpoints()` function or examining the `gp_endpoints` view in a session on the WarehousePG coordinator host:

```
SELECT * FROM
gp_get_endpoints();
SELECT * FROM gp_endpoints;
```

These commands return the list of endpoints in a table with the following columns:

Column Name	Description
gp_segment_id	The QE's endpoint `gp_segment_id`.
auth_token	The authentication token for a retrieve session.
cursorname	The name of the parallel retrieve cursor.
sessionid	The identifier of the session in which the parallel retrieve cursor was created.
hostname	The name of the host from which to retrieve the data for the endpoint.
port	The port number from which to retrieve the data for the endpoint.
username	The name of the current user; *you must initiate the retrieve session as this user.*
state	The state of the endpoint; the valid states are: READY: The endpoint is ready to be retrieved. ATTACHED: The endpoint is attached to a retrieve connection. RETRIEVING: A retrieve session is retrieving data from the endpoint at this moment. FINISHED: The endpoint has been fully retrieved. RELEASED: Due to an error, the endpoint has been released and the connection closed.
endpointname	The endpoint identifier; you provide this identifier to the `RETRIEVE` command.

Refer to the gp_endpoints view reference page for more information about the endpoint attributes returned by these commands.

You can similarly invoke the `gp_get_session_endpoints()` function or examine the `gp_session_endpoints` view to list the endpoints created for the parallel retrieve cursors declared in the current session and by the current user.

Opening a Retrieve Session

After you declare a parallel retrieve cursor, you can open a retrieve session to each endpoint. Only a single retrieve session may be open to an endpoint at any given time.

> **Note:** A retrieve session is independent of the parallel retrieve cursor itself and the endpoints.

Retrieve session authentication does not depend on the `pg_hba.conf` file, but rather on an authentication token (`auth_token`) generated by WarehousePG.

> **Note:** Because WarehousePG skips `pg_hba.conf`-controlled authentication for a retrieve session, for security purposes you may invoke only the `RETRIEVE` command in the session.

When you initiate a retrieve session to an endpoint:

- The user that you specify for the retrieve session must be the user that declared the parallel retrieve cursor (the `username` returned by `gp_endpoints`). This user must have WarehousePG login privileges.
- You specify the `hostname` and `port` returned by `gp_endpoints` for the endpoint.
- You authenticate the retrieve session by specifying the `auth_token` returned for the endpoint via the `PGPASSWORD` environment variable, or when prompted for the retrieve session `Password`.
- You must specify the gp_retrieve_conn server configuration parameter on the connection request, and set the value to `true`.

For example, if you are initiating a retrieve session via `psql`:

```
PGOPTIONS='-c gp_retrieve_conn=true' psql -h <hostname> -p <port> -U <username> -d <dbname>
```

To distinguish a retrieve session from other sessions running on a segment host, WarehousePG includes the `[retrieve]` tag on the `ps` command output display for the process.

Retrieving Data From the Endpoint

Once you establish a retrieve session, you retrieve the tuples associated with a query result on that endpoint using theRETRIEVE command.

You can specify a (positive) number of rows to retrieve, or `ALL` rows:

```
RETRIEVE 7 FROM ENDPOINT
prc10000003300000003;
RETRIEVE ALL FROM ENDPOINT
prc10000003300000003;
```

WarehousePG returns an empty set if there are no more rows to retrieve from the endpoint.

> **Note:** You can retrieve from multiple parallel retrieve cursors from the same retrieve session only when their `auth_token`s match.

Waiting for Data Retrieval to Complete

Use the `gp_wait_parallel_retrieve_cursor()` function to display the status of data retrieval from a parallel retrieve cursor, or to wait for all endpoints to finishing retrieving the data. You invoke this function in the transaction block in which you declared the parallel retrieve cursor.

`gp_wait_parallel_retrieve_cursor()` returns `true` only when all tuples are fully retrieved from all endpoints. In all other cases, the function returns `false` and may additionally throw an error.

The function signatures of `gp_wait_parallel_retrieve_cursor()` follow:

```
gp_wait_parallel_retrieve_cursor( cursorname text
)
gp_wait_parallel_retrieve_cursor( cursorname text, timeout_sec int4
)
```

You must identify the name of the cursor when you invoke this function. The timeout argument is optional:

- The default timeout is `0` seconds: WarehousePG checks the retrieval status of all endpoints and returns the result immediately.
- A timeout value of `-1` seconds instructs WarehousePG to block until all data from all endpoints has been retrieved, or block until an error occurs.
- The function reports the retrieval status after a timeout occurs for any other positive timeout value that you specify.

`gp_wait_parallel_retrieve_cursor()` returns when it encounters one of the following conditions:

- All data has been retrieved from all endpoints.
- A timeout has occurred.
- An error has occurred.

Handling Data Retrieval Errors

An error can occur in a retrieve sesson when:

- You cancel or interrupt the retrieve operation.
- The endpoint is only partially retrieved when the retrieve session quits.

When an error occurs in a specific retrieve session, WarehousePG removes the endpoint from the QE. Other retrieve sessions continue to function as normal.

If you close the transaction before fully retrieving from all endpoints, or if `gp_wait_parallel_retrieve_cursor()` returns an error, WarehousePG terminates all remaining open retrieve sessions.

Closing the Cursor

When you have completed retrieving data from the parallel retrieve cursor, close the cursor and end the transaction:

```
CLOSE prc1;
END;
```

> **Note:** When you close a parallel retrieve cursor, WarehousePG terminates any open retrieve sessions associated with the cursor.

On closing, WarehousePG frees all resources associated with the parallel retrieve cursor and its endpoints.

Listing All Parallel Retrieve Cursors

The pg_cursors view lists all declared cursors that are currently available in the system. You can obtain information about all parallel retrieve cursors by running the following command:

```
SELECT * FROM pg_cursors WHERE is_parallel =
true;
```

Listing Segment-Specific Retrieve Session Information

You can obtain information about all retrieve sessions to a specific QE endpoint by invoking the `gp_get_segment_endpoints()` function or examining the `gp_segment_endpoints` view:

```
SELECT * FROM gp_get_segment_endpoints();
SELECT * FROM
gp_segment_endpoints;
```

These commands provide information about the retrieve sessions associated with a QE endpoint for all active parallel retrieve cursors declared by the current user. When the WarehousePG superuser invokes the command, it returns the retrieve session information for all endpoints on the QE created for all parallel retrieve cursors declared by all users.

You can obtain segment-specific retrieve session information in two ways: from the QD, or via a utility-mode connection to the endpoint:

- QD example:

  ```
  SELECT * from gp_dist_random('gp_segment_endpoints');
  ```

  Display the information filtered to a specific segment:

  ```
  SELECT * from gp_dist_random('gp_segment_endpoints') WHERE gp_segment_id = 0;
  ```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

- Example utilizing a utility-mode connection to the endpoint:

```
$ PGOPTIONS='-c gp_session_role=utility' psql -h sdw3 -U localuser -p 6001 -d
testdb

testdb=> SELECT * FROM
gp_segment_endpoints;
```

The commands return endpoint and retrieve session information in a table with the following columns:

Column Name	Description
auth_token	The authentication token for a the retrieve session.
databaseid	The identifier of the database in which the parallel retrieve cursor was created.
senderpid	The identifier of the process sending the query results.
receiverpid	The process identifier of the retrieve session that is receiving the query results.
state	The state of the endpoint; the valid states are: READY: The endpoint is ready to be retrieved. ATTACHED: The endpoint is attached to a retrieve connection. RETRIEVING: A retrieve session is retrieving data from the endpoint at this moment. FINISHED: The endpoint has been fully retrieved. RELEASED: Due to an error, the endpoint has been released and the connection closed.
gp_segment_id	The QE's endpoint `gp_segment_id`.
sessionid	The identifier of the session in which the parallel retrieve cursor was created.
username	The name of the user that initiated the retrieve session.
endpointname	The endpoint identifier.
cursorname	The name of the parallel retrieve cursor.

Refer to the gp_segment_endpoints view reference page for more information about the endpoint attributes returned by these commands.

Limiting the Number of Concurrently Open Cursors

By default, WarehousePG does not limit the number of parallel retrieve cursors that are active in the cluster (up to the maximum value of 1024). The WarehousePG superuser can set the gp_max_parallel_cursors server configuration parameter to limit the number of open cursors.

Known Issues and Limitations

The parallel retrieve cursor implementation has the following limitations:

- The WarehousePG query optimizer (GPORCA) does not support queries on a parallel retrieve cursor.
- WarehousePG ignores the `BINARY` clause when you declare a parallel retrieve cursor.
- Parallel retrieve cursors cannot be declared `WITH HOLD`.
- Parallel retrieve cursors do not support the `FETCH` and `MOVE` cursor operations.
- Parallel retrieve cursors are not supported in SPI; you cannot declare a parallel retrieve cursor in a PL/pgSQL function.

Additional Documentation

Refer to the README in the WarehousePG `github` repository for additional information about the parallel retrieve cursor implementation. You can also find parallel retrieve cursor programming examples in the repository.

Example

Create a parallel retrieve cursor and use it to pull query results from a WarehousePG cluster:

1. Open a `psql` session to the WarehousePG coordinator host:

```
psql -d testdb
```

2. Start the transaction:

```
BEGIN;
```

3. Declare a parallel retrieve cursor named `prc1` for a `SELECT *` query on a table:

```
DECLARE prc1 PARALLEL RETRIEVE CURSOR FOR SELECT * FROM
t1;
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4. Obtain the endpoints for this parallel retrieve cursor:

```
SELECT * FROM gp_endpoints WHERE cursorname='prc1';
 gp_segment_id |            auth_token             | cursorname | sessionid | hostname | port | username | state |     endpointname
---------------+-----------------------------------+------------+-----------+----------+------+----------+-------+----------------------
             2 | 39a2dc90a82fca668e04d04e0338f105 | prc1       |        51 | sdw1     | 6000 | bill     | READY |
prc10000003300000003
             3 | 1a6b29f0f4cad514a8c3936f9239c50d | prc1       |        51 | sdw1     | 6001 | bill     | READY |
prc10000003300000003
             4 | 1ae948c8650ebd76bfa1a1a9fa535d93 | prc1       |        51 | sdw2     | 6000 | bill     | READY |
prc10000003300000003
             5 | f10f180133acff608275d87966f8c7d9 | prc1       |        51 | sdw2     | 6001 | bill     | READY |
prc10000003300000003
             6 | dda0b194f74a89ed87b592b27ddc0e39 | prc1       |        51 | sdw3     | 6000 | bill     | READY |
prc10000003300000003
             7 | 037f8c747a5dc1b75fb10524b676b9e8 | prc1       |        51 | sdw3     | 6001 | bill     | READY |
prc10000003300000003
             8 | c43ac67030dbc819da9d2fd8b576410c | prc1       |        51 | sdw4     | 6000 | bill     | READY |
prc10000003300000003
             9 | e514ee276f6b2863142aa2652cbccd85 | prc1       |        51 | sdw4     | 6001 | bill     | READY |
prc10000003300000003
(8 rows)
```

5. Wait until all endpoints are fully retrieved:

```
SELECT gp_wait_parallel_retrieve_cursor( 'prc1', -1 );
```

6. For each endpoint:

    1. Open a retrieve session. For example, to open a retrieve session to the segment instance running on `sdw3`, port number `6001`, run the following command in a *different terminal window*; when prompted for the password, provide the `auth_token` identified in row 7 of the `gp_endpoints` output:

    ```
    $ PGOPTIONS='-c gp_retrieve_conn=true' psql -h sdw3 -U localuser -p 6001 -d
    testdb
    Password:
    ```

    2. Retrieve data from the endpoint:

    ```
    -- Retrieve 7 rows of data from this
    session
    RETRIEVE 7 FROM ENDPOINT
    prc10000003300000003
    -- Retrieve the remaining rows of data from this
    session
    RETRIEVE ALL FROM ENDPOINT
    prc10000003300000003
    ```

    3. Exit the retrieve session:

    ```
    \q
    ```

7. In the original `psql` session (the session in which you declared the parallel retrieve cursor), verify that the `gp_wait_parallel_retrieve_cursor()` function returned `t`. Then close the cursor and complete the transaction:

```
CLOSE prc1;
END;
```

4.12 Backing up WarehousePG with gpbackup and gprestore

Associated Topics

- Incremental backups
- gpbackup syntax reference
- gprestore syntax reference

gpbackup and gprestore are WarehousePG utilities that create and restore backup sets in parallel for WarehousePG. By default, `gpbackup` stores only the object metadata files and DDL files for a backup in the WarehousePG Coordinator data directory. WarehousePG segments use the `COPY ... ON SEGMENT` command to store their data for backed-up tables in compressed CSV data files, located in each segment's backups directory.

Parallel Backup with gpbackup and gprestore

The backup metadata files contain all of the information that `gprestore` needs to restore a full backup set in parallel. Backup metadata also provides the framework for restoring only individual objects in the data set, along with any dependent objects, in future versions of `gprestore`. (See Understanding Backup Files for more information.) Storing the table data in CSV files also provides opportunities for using other restore utilities, such as gpload, to load the data either in the same cluster or another cluster. By default, one file is created for each table on the segment. You can specify the `--leaf-partition-data` option with `gpbackup` to create one data file per leaf partition of a partitioned table, instead of a single file. This option also enables you to filter backup sets by leaf partitions.

Each `gpbackup` task uses a single transaction in WarehousePG. During this transaction, metadata is backed up on the Coordinator host, and data for each table on each segment host is written to CSV backup files using COPY ... ON SEGMENT commands in parallel. The backup process acquires an ACCESS SHARE lock on each table that is backed up.

For additional documenation, visit thegpbackup and gprestore cluster utilities reference page.

Objects in a backup set

Objects Included in a Backup or Restore The following table lists the objects that are backed up and restored with `gpbackup` and `gprestore`.

Database objects are backed up for the database you specify with the `--dbname` option.

Global objects (WarehousePG Cluster objects) are also backed up by default, but they are restored only if you include the `--with-globals option` when calling `gprestore`. Conversely, the `gpbackup --without-globals` will skip the backup of global objects

Objects that are backed up and restored

Database objects	
Aggregates	Readable External Tables [1]
Casts	Rules
Comments	Schemas [4]
Conversions	Sequences
Domains	Session-level configuration parameter settings (GUCs)
Extensions	Table statistics [2]
Functions	Tables
Indexes	Text search parsers, dictionaries, templates, and configurations
Materialized Views [1]	Triggers [3]
Operators, operator families, and operator classes	Types
Owners	Views
Procedural language extensions	Writable External Tables [1]
Protocols	

1. DDL Only
2. when `--with-stats` flag is used
3. While WarehousePG does not support triggers, trigger definitions present in the database are backed up and restored
4. The following schemas are not part of the backup set: gp_toolkit, information_schema, pg_aoseg, pg_bitmapindex, pg_catalog, pg_toast*, pg_temp*

Global objects	_
Databases	Resource queue definitions
Database-wide configuration parameter settings (GUCs)	Roles
GRANT assignments of roles to databases	Tablespaces
Resource group definitions	

When restoring to an existing database, `gprestore` assumes the public schema exists when restoring objects to the public schema. When restoring to a new database (with the --create-db option), `gprestore` creates the public schema automatically when creating a database with the CREATE DATABASE command. The command uses the template0 database that contains the public schema.

Backup and Restore Workflow

Full Backup

This command will take a full backup (metadata and user data) using zstandard compression

```
$ gpbackup --dbname <database_name> --compression-type zstd
```

Example:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
[gpadmin@whpg_cdw ~]$ gpbackup --dbname ww_sales --compression-type zstd

20250514:20:27:23 gpbackup:gpadmin:whpg_cdw:027069-[INFO]:-/home/gpadmin/gp_email_contacts.yaml list found, /data/coordinator/gpseg-
1/backups/20250514/20250514202713/gpbackup_20250514202713_report will be sent
20250514:20:28:23 gpbackup:gpadmin:whpg_cdw:027069-[INFO]:-Beginning cleanup
20250514:20:28:23 gpbackup:gpadmin:whpg_cdw:027069-[INFO]:-Cleanup complete
20250514:20:28:23 gpbackup:gpadmin:whpg_cdw:027069-[INFO]:-Backup completed successfully
```

The above command creates a file that contains global and database-specific metadata on the WarehousePG Coordinator host in the default directory, `$COORDINATOR_DATA_DIRECTORY/backups/<YYYYMMDD>/<YYYYMMDDHHMMSS>/`.

For example:

```
[gpadmin@whpg_cdw 20250514202713]$ ls -ltr /data/coordinator/gpseg-1/backups/20250514/20250514202713
total 2112
-r--r--r-- 1 gpadmin gpadmin 2114041 May 14 20:27 gpbackup_20250514202713_metadata.sql
-r--r--r-- 1 gpadmin gpadmin   35787 May 14 20:27 gpbackup_20250514202713_toc.yaml
-r--r--r-- 1 gpadmin gpadmin    1437 May 14 20:27 gpbackup_20250514202713_config.yaml
-r--r--r-- 1 gpadmin gpadmin    1833 May 14 20:27 gpbackup_20250514202713_report
```

By default, each segment stores each table's data for the backup in a separate compressed CSV file in `<seg_dir>/backups/<YYYYMMDD>/<YYYYMMDDHHMMSS>/`:

```
[gpadmin@mdw 20250514202713]$ ls -ltr /data/primary/gpseg0/backups/20250514/20250514202713
total 125764

```

To consolidate all backup files into a single directory, include the `--backup-dir` option with an absolute path to the location you wish to backup to. Optionally, when performing a backup, the `--single-data-file` option may be used in situations where the additional overhead of multiple files might be prohibitive such as third party storage solutions.

The command below shows both options in use

Full Restore

To use `gprestore` to restore from a backup set, you must use the `--timestamp` option to specify the exact timestamp value (YYYYMMDDHHMMSS) to restore. Include the `--create-db` option if the database does not exist in the cluster. If you specified a custom --backup-dir to consolidate the backup files, include the same `--backup-dir` option when using `gprestore` to locate the backup files.

```

`gprestore` does not attempt to restore global metadata for the WarehousePG Cluster by default. If this is required, include the `--with-globals` option.

By default, `gprestore` uses 1 connection to restore table data and metadata. If you have a large backup set which **did not use** the `--single-data-file` option, restore duration can be decreased by specifiying the number of parallel processes using the `--jobs` option. Depending on system resourceds and database size, this number can be tuned for each specific environment.

```
[gpadmin@whpg_cdw ~]$ psql -c "DROP DATABASE ww_sales";

```

Report Files

When performing a backup or restore operation, `gpbackup` and `gprestore` generate a report file. When email notification is configured, the email sent contains the contents of the report file. For information about email notification, see Configuring Email Notifications.

The report file is placed in the WarehousePG Coordinator backup directory. The report file name contains the timestamp of the operation. These are the formats of the `gpbackup` and `gprestore` report file names.

- `gpbackup_<backup_timestamp>_report`
- `gprestore_<backup_timestamp>_<restore_timesamp>_report`

For these example report file names, `20250518010000` is the timestamp of the backup and `20250530234643` is the timestamp of the restore operation.

`gpbackup_20250518010000_report`

`gprestore_20250518010000_20180213115426_report`

This backup directory on a WarehousePG Coordinator host contains both a `gpbackup` and `gprestore` report file.

```
[gpadmin@cdw 20250530234643]$ ls -ltr
total 2124
-r--r--r-- 1 gpadmin gpadmin 2120143 May 30 23:46 gpbackup_20250530234643_metadata.sql
-r--r--r-- 1 gpadmin gpadmin   38064 May 30 23:46 gpbackup_20250530234643_toc.yaml
-r--r--r-- 1 gpadmin gpadmin    1499 May 30 23:46 gpbackup_20250530234643_config.yaml
-r--r--r-- 1 gpadmin gpadmin    1837 May 30 23:46 gpbackup_20250530234643_report
-r--r--r-- 1 gpadmin gpadmin     539 May 31 00:05 gprestore_20250530234643_20250531000515_report
```

The contents of the report files are similar. This is an example of the contents of a `gprestore` report file.

restore status:          Success
```

Backup History Database

`gpbackup` stores details of each backup operation in a SQLite database found in `$COORDINATOR_DATA_DIRECTORY/gpbackup_history.db`. Details such as timestamps, command line options, incremental backup details and status are stored in this database. `gpbackup_history.db` is not backed up my `gpbackup`, but can be copied to a secondary location if a backup copy is desired.

`gpbackup` uses the metadata in `gpbackup_history.db` to create the backup/restore plan for an incremental backup sets when you run `gpbackup` with the `--incremental` option and do not specify the `--from-timesamp` option to indicate the backup that you want to use as the base backup of the incremental backup set. For information about incremental backups, refer toIncremental Backups with `gpbackup` and `gprestore`.

Filtering the Contents of a Backup or Restore

`gpbackup` backs up all schemas and tables in the specified database, unless you exclude or include individual schema or table objects with schema level or table level filter options.

The schema level options are

- `--include-schema`
- `--include-schema-file`
- `--exclude-schema`
- `--exclude-schema-file`

command-line options to `gpbackup`. For example, if the `ww_customer` database contains three schemas, `na_customer`, `apac_customer`, `emea_customer`, the following commands back up only the `apac_customer` and `emea_customer` schemas:

```
$ gpbackup --dbname ww_customer --exclude-schema na_customer
```

Multiple `--include-schema` options may be used in a `gpbackup` or multiple `--exclude-schema` options to filter 2 or many schemas

```
$ gpbackup --dbname ww_customer --include-schema apac_customer --include-schema emea_customer
```

An alternative to multiple command line options is to use `--include-schema-file` or `--exclude-schema-file`. Each line in the file defines a single schema, and the file cannot contain trailing lines.

`/tmp/nw_states.schema` contents

```
[gpadmin@whpg_cdw tmp]$ cat nw_states.schema
Washington
Oregon
Idaho
Montana
Wyoming
[gpadmin@whpg_cdw tmp]$
```

Example of the command:

```
gpbackup --dbname ww_customer --include-schema-file /tmp/nw_states.schema
```

Filtering included or excluded tables is similar process to schemas.

- `--include-table`
- `--exclude-table`
- `--include-table-file`
- `--exclude-table-file`

Options use the `schema-name.table-name` format as input on the command line, and in the text file. The individual table filtering options can be used multiple times, but `--include-table` and `--exclude-table` cannot both be used in the same command.

You can create a list of qualified table names in a text file. Each line in the file defines a single `schema-name.table-name`, and the file cannot contain trailing lines.

```
gpbackup --dbname ww_customer --include-table apac_customer.customer_fact
```

or

```
gpbackup --dbname ww_customer --exclude-table-file /tmp/exclude_tables.file
```

where `/tmp/include_tables.file` contents

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
[gpadmin@whpg_cdw tmp]$ cat exclude_tables.file
emea_customer.customer_fact
na_customer.customer_fact
[gpadmin@whpg_cdw tmp]$
```

Table and schema names containing upper case letters or spaces must be enclosed with double quotes.

```
[gpadmin@whpg_cdw tmp]$ cat exclude_tables_2.file
emea_customer.customer_fact
na_customer.customer_fact
na_customer."ZipCodes"
"WW_GEO".holidays
"WW_GEO"."time zones"
[gpadmin@whpg_cdw tmp]$
```

When `--include-table` or `--include-table-file` is specified on the command line, dependent objects are not automatically backed up or restored. Depenedent objects must be specified in your filter string or file. For example, if you back up or restore a view or materialized view, you must also list the table(s) the view or the materialized view require. If you backup or restore a table containing a sequence, you must also specify the sequence name.

Filtering by Leaf Partition

By default, `gpbackup` creates one file for each table on a data segment. When the `--leaf-partition-data` option is used, `gpbackup` will create one data file per leaf partition of a partitioned table, instead of a single file data file for the root table. You can also filter backups to specific leaf partitions by including the names of the leaf partitions names as you would a stand along table, using the `schema_name.table_name` format.

```
gpadmin=# \d+ ww_inventory
                                Table "WW_GEO.ww_inventory"
        Column         |       Type        | Modifiers | Storage  | Stats target | Description
-----------------------+-------------------+-----------+----------+--------------+-------------
 prod_id               | integer           |           | plain    |              |
 prod_sku              | character varying |           | extended |              |

              ww_inventory_1_prt_27,
              ww_inventory_1_prt_28,
              ww_inventory_1_prt_29,
              ww_inventory_1_prt_3,
              ww_inventory_1_prt_30,
              ww_inventory_1_prt_4,
              ww_inventory_1_prt_5,
              ww_inventory_1_prt_6,
              ww_inventory_1_prt_7,
              ww_inventory_1_prt_8,
              ww_inventory_1_prt_9
Distributed by: (prod_id)
Partition by: (prod_date_inventoried)
```

The following file `/tmp/may_week1.include` contains the partitions for the first week of May which will be included in our `gpbackup`

```
[gpadmin@whpg_cdw ~]$ cat /tmp/may_week1.include
"WW_GEO".ww_inventory_1_prt_1
"WW_GEO".ww_inventory_1_prt_2
"WW_GEO".ww_inventory_1_prt_3
"WW_GEO".ww_inventory_1_prt_4
"WW_GEO".ww_inventory_1_prt_5
"WW_GEO".ww_inventory_1_prt_6
"WW_GEO".ww_inventory_1_prt_7
```

Using the `--include-table-file` and `--leaf-partition-data` options, `gpbackup` will create one data file for each leaf partition specified in the input file

```
$ gpbackup --dbname ww_sales --include-table-file /tmp/may_week1.include --leaf-partition-data
```

The `--exclude-table-file` option and `--leaf-partition-data` are not compatible. Although you can specify leaf partition names in a file specified with `--exclude-table-file`, `gpbackup` ignores the partition names.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Filtering with `gprestore`

After creating a backup set with `gpbackup`, you can filter the schemas and tables that you want to restore from the backup set using the `gprestore --include-schema` and `--include-table-file` options. These options work in the same way as their `gpbackup` counterparts, but have the following restrictions:

The tables that you attempt to restore must not already exist in the database.

If you attempt to restore a schema or table that does not exist in the backup set, the `gprestore` does not run.

If you use the `--include-schema` option, `gprestore` cannot restore objects that have dependencies on multiple schemas.

If you use the `--include-table-file` option, `gprestore` does not create roles or set the owner of the tables. The utility restores table indexes and rules. Triggers are also restored but are not supported in WarehousePG.

The file that you specify with `--include-table-file` cannot include a leaf partition name, as it can when you specify this option with `gpbackup`. If you specified leaf partitions in the backup set, specify the partitioned table to restore the leaf partition data.

When restoring a backup set that contains data from some leaf partitions of a partitioned table, the partitioned table is restored along with the data for the leaf partitions. For example, you create a backup with the `gpbackup` option `--include-table-file` and the text file lists some leaf partitions of a partitioned table. Restoring the backup creates the partitioned table and restores the data only for the leaf partitions listed in the file.

Setting Up Email Alerts

`gpbackup` and `gprestore` can send email notifications via `sendmail` after a backup or restore run completes.

To have `gpbackup` or `gprestore` send out status email notifications, a `gp_email_contacts.yaml` file must exist in either home directory of the user running `gpbackup` or `gprestore` or the same directory as the utilities ($GPHOME/bin).

If the `gp_email_contacts.yaml` file is not present, the gpbackup/gprestore log file will have a message similar to:

```
20250530:23:46:52 gpbackup:gpadmin:cdw:022290-[INFO]:-Data backup complete
20250530:23:46:52 gpbackup:gpadmin:cdw:022290-[INFO]:-Skipped data backup of 24 external/foreign table(s).
20250530:23:46:52 gpbackup:gpadmin:cdw:022290-[INFO]:-See /home/gpadmin/gpAdminLogs/gpbackup_20250530.log for a complete list of skipped tables.
20250530:23:46:53 gpbackup:gpadmin:cdw:022290-[INFO]:-Found neither /usr/local/greenplum-db-6.27.1/bin/gp_email_contacts.yaml nor
/home/gpadmin/gp_email_contacts.yaml
20250530:23:46:53 gpbackup:gpadmin:cdw:022290-[INFO]:-Email containing gpbackup report /data/coordinator/gpseg-
1/backups/20250530/20250530234643/gpbackup_20250530234643_report will not be sent
20250530:23:46:53 gpbackup:gpadmin:cdw:022290-[INFO]:-Beginning cleanup
20250530:23:46:53 gpbackup:gpadmin:cdw:022290-[INFO]:-Cleanup complete
20250530:23:46:53 gpbackup:gpadmin:cdw:022290-[INFO]:-Backup completed successfully
```

If the `gp_email_contacts.yaml` file is present, can configured properly, a similar message will be printed to the logs:

```
20250514:20:27:23 gpbackup:gpadmin:whpg_cdw:027069-[INFO]:-/home/gpadmin/gp_email_contacts.yaml list found, /data/coordinator/gpseg-
1/backups/20250514/20250514202713/gpbackup_20250514202713_report will be sent```
```

The `$HOME/gp_email_contacts.yaml` file will override any configurations found in the `$GPHOME/bin/gp_email_contacts.yaml`

The email subject line includes the utility name, timestamp, status, and the name of the WarehousePG Coordinator. This is an example subject line for a `gpbackup` email.

```
gpbackup 20250514202713 on whpg_cdw completed: Success
```

or

```
gprestore 20250515182209 on whpg_cdw completed: Failure
```

The email contains summary information about the operation including options, duration, and number of objects backed up or restored. For information about the contents of a notification email, see Report Files.

gp_email_contacts.yaml file format

The `gpbackup` and `gprestore` email notification YAML file gp_email_contacts.yaml uses indentation (spaces) to determine the document hierarchy and the relationships of the sections to one another. The use of white space is significant. White space should not be used simply for formatting purposes, and tabs should not be used at all.

Note: If the status parameters are not specified correctly, the utility does not issue a warning. For example, if the success parameter is misspelled and is set to true, a warning is not issued and an email is not sent to the email address after a successful operation. To ensure email notification is configured correctly, run tests with email notifications configured.

This is the format of the gp_email_contacts.yaml YAML file for `gpbackup` email notifications:

```
contacts:
  gpbackup:
  - address: name@domain
    status:
         success: [true | false]
         success_with_errors: [true | false]
         failure: [true | false]
  gprestore:
  - address: name@domain
    status:
         success: [true | false]
         success_with_errors: [true | false]
         failure: [true | false]
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Email YAML File Sections

contacts: Required. The section that contains the `gpbackup` and `gprestore` sections. The YAML file can contain a `gpbackup` section, a `gprestore` section, or one of each.

gpbackup : Optional. Begins the gpbackup email section.

address : Required. At least one email address must be specified. Multiple email address parameters can be specified. Each address requires a status section.

> **Note**
>
> name@domainis a single, valid email address.

status : Required. Specify when the utility sends an email to the specified email address. The default is to not send email notification.

You specify sending email notifications based on the completion status of a backup or restore operation. At least one of these parameters must be specified and each parameter can appear at most once.

success : Optional. Specify if an email is sent if the operation completes without errors. If the value is true, an email is sent if the operation completes without errors. If the value is false (the default), an email is not sent.

success_with_errors : Optional. Specify if an email is sent if the operation completes with errors. If the value is true, an email is sent if the operation completes with errors. If the value is false (the default), an email is not sent.

failure : Optional. Specify if an email is sent if the operation fails. If the value is true, an email is sent if the operation fails. If the value is false (the default), an email is not sent.

gprestore : Optional. Begins the gprestore email section. This section contains the address and status parameters that are used to send an email notification after a `gprestore` operation. The syntax is the same as the gpbackup section.

Examples

This example YAML file specifies sending email to email addresses depending on the success or failure of an operation. For a backup operation, an email is sent to a different address depending on the success or failure of the backup operation. For a restore operation, an email is sent to single address only when the operation succeeds or completes with errors.

```
contacts:
  gpbackup:
  - address: dba_backup_success@whpg.io
    status:
      success:true
  - address: dba_backup_failure@whpg.io
    status:
      success_with_errors: true
      failure: true
  gprestore:
  - address: dba_restore_status@example.com
    status:
      success: true
      success_with_errors: true
```

Backup Files Details

A complete backup set for `gpbackup` includes multiple metadata files, supporting files, and CSV data files, each designated with the timestamp at which the backup was created.

By default, metadata and supporting files are stored on the WarehousePG coordinator host in the directory `$COORDINATOR_DATA_DIRECTORY/backups/YYYYMMDD/YYYYMMDDHHMMSS/` . If you specify a custom backup directory, this same file path is created as a subdirectory of the backup directory. The following table describes the names and contents of the metadata and supporting files.

> **Warning:**
>
> All `gpbackup` metadata files are created with read-only permissions. Never delete or modify the metadata files for a `gpbackup` backup set. Doing so may render the backup files non-functional.

Coordinator Metadata Files

`gpbackup_<YYYYMMDDHHMMSS>_metadata.sql`

Contains global and database-specific metadata:

- DDL for objects that are global to the WarehousePG cluster, and not owned by a specific database within the cluster.
- DDL for objects in the backed-up database (specified with --dbname) that must be created before to restoring the actual data, and DDL for objects that must be created after restoring the data.

Global objects include:

- Tablespaces
- Databases
- Database-wide configuration parameter settings (GUCs)
- Resource group definitions
- Resource queue definitions
- Roles
- GRANT assignments of roles to databases

> **Note**
>
> Note: Global metadata is not restored by default. You must include the --with-globals option to the `gprestore` command to restore global metadata.

Database-specific objects that must be created before to restoring the actual data include:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

- Session-level configuration parameter settings (GUCs)
- Schemas
- Procedural language extensions
- Types
- Sequences
- Functions
- Tables
- Protocols
- Operators and operator classes
- Conversions
- Aggregates
- Casts
- Views
- Materialized Views (only view definition is backed up / restored, not data)
- Constraints
- Database-specific objects that must be created after restoring the actual data include:
- Indexes
- Rules
- Triggers. (While WarehousePG does not support triggers, any trigger definitions that are present are backed up and restored.)

example:

```
CREATE TABLE uat.refund (
        returned_date_sk integer,
        returned_time_sk integer,
        item_sk integer,
        refunded_customer_sk integer,
        refunded_cdemo_sk integer,
        refunded_hdemo_sk integer,
) DISTRIBUTED RANDOMLY;

ALTER TABLE uat.refund OWNER TO gpadmin;

CREATE INDEX item_sk_cr_fee_idx ON uat.refund USING btree (item_sk, fee);

CREATE INDEX item_sk_idx ON uat.refund USING btree (item_sk);
```

`gpbackup_<YYYYMMDDHHMMSS>_toc.yaml`

Table of contents file, containing location information of the various object DDL in the `gpbackup_<YYYYMMDDHHMMSS>_metadata.sql` files

This file also contains the table names and OIDs used for locating the corresponding table data in CSV data files that are created on each segment.

example:

```
- schema: tpcds
  name: household_demographics
  oid: 37231
  attributestring: (hd_demo_sk,hd_income_band_sk,hd_buy_potential,hd_dep_count,hd_vehicle_count)
  rowscopied: 7200
  partitionroot: ""
  isreplicated: false
  distbyenum: false
- schema: tpcds
  name: income_band
  oid: 37238
  attributestring: (ib_income_band_sk,ib_lower_bound,ib_upper_bound)
  rowscopied: 20
  partitionroot: ""
  isreplicated: false
  distbyenum: false
- schema: tpcds
  name: inventory
  oid: 37245
  attributestring: (inv_date_sk,inv_item_sk,inv_warehouse_sk,inv_quantity_on_hand)
  rowscopied: 11745000
  partitionroot: ""
  isreplicated: false
  distbyenum: false
```

See Segment Data Files

`gpbackup_<YYYYMMDDHHMMSS>_report`

Contains information about the backup operation that is used to populate the email notice (if configured) that is sent after the backup completes. This file contains information such as:

- Command-line options that were provided
- Database that was backed up
- Database version
- Backup type

example:

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
WarehousePG Backup Report

timestamp key:         20250530232002

  - tpcds.customer_address
  - tpcds.customer_demographics
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Segment Data Files

By default, each segment creates one compressed CSV file for each table that is backed up on the segment. You can optionally specify the `--single-data-file` option to create a single data file on each segment. The files are stored in `<seg_dir>/backups/YYYYMMDD/YYYYMMDDHHMMSS/`.

If you specify a custom backup directory, segment data files are copied to this same file path as a subdirectory of the backup directory. If you include the `--leaf-partition-data` option, `gpbackup` creates one data file for each leaf partition of a partitioned table, instead of just one table for file.

By default, each table is backed up into a distinct file on the segment hosts: The file uses a name format `gpbackup_<content_id>_<YYYYMMDDHHMMSS>_<oid>.gz` where:

`<content_id>` is the content ID of the segment. `<YYYYMMDDHHMMSS>` is the timestamp of the `gpbackup` operation. `<oid>` is the object ID of the table.

default multiple data file example

```
-rw------- 1 gpadmin gpadmin      216 May 30 23:46 gpbackup_1_20250530234643_32812.zst

```

`--single-data-file` example

All table data for a particular segment is written to a single file:

- `gpbackup_<content_id>_<YYYYMMDDHHMMSS>`

With a corresponding table of contents files:

- `gpbackup_<content_id>_<YYYYMMDDHHMMSS>_toc.yaml`

```
-rw-rw-r-- 1 gpadmin gpadmin 417025744 May 30 23:20 gpbackup_0_20250530232002
-r--r--r-- 1 gpadmin gpadmin      2035 May 30 23:20 gpbackup_0_20250530232002_toc.yaml
```

The metadata file `gpbackup_<YYYYMMDDHHMMSS>_toc.yaml` references this `<oid>` to locate the data for a specific table in a schema.

You can optionally specify the gzip compression level (from 1-9) using the `--compression-level` option, or disable compression entirely with `--no-compression`. If you do not specify a compression level, `gpbackup` uses compression level 1 by default.

Return Codes

One of these codes is returned after `gpbackup` or `gprestore` completes.

0 – Backup or restore completed with no problems
1 – Backup or restore completed with non-fatal errors. See log file for more information.
2 – Backup or restore failed with a fatal error. See log file for more information.

Supported WHPG versions

The WarehousePG provided `gpbackup` and `gprestore` utilities are compatible with WarehousePG versions

- 6.27.1 or later
- 7.2.1-WHPG or later

Limitations

`gpbackup` and `gprestore` have the following limitations:

If you create an index on a parent partitioned table, `gpbackup` does not back up that same index on child partitioned tables of the parent, as creating the same index on a child would cause an error. However, if you exchange a partition, `gpbackup` does not detect that the index on the exchanged partition is inherited from the new parent table. In this case, `gpbackup` backs up conflicting CREATE INDEX statements, which causes an error when you restore the backup set.

You can execute multiple instances of `gpbackup`, but each execution requires a distinct timestamp.

Database object filtering is currently limited to schemas and tables.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

When backing up a partitioned table where some or all leaf partitions are in different schemas from the root partition, the leaf partition table definitions, including the schemas, are backed up as metadata. This occurs even if the backup operation specifies that schemas that contain the leaf partitions should be excluded. To control data being backed up for this type of partitioned table in this situation, use the `--leaf-partition-data` option.

If the `--leaf-partition-data` option is not specified, the leaf partition data is also backed up even if the backup operation specifies that the leaf partition schemas should excluded. If the `--leaf-partition-data` option is specified, the leaf partition data is not be backed up if the backup operation specifies that the leaf partition schemas should excluded. Only the metadata for leaf partition tables are backed up. If you use the `gpbackup` --single-data-file option to combine table backups into a single file per segment, you cannot perform a parallel restore operation with `gprestore` (cannot set --jobs to a value higher than 1).

You cannot use the `--exclude-table-file` with `--leaf-partition-data`. Although you can specify leaf partition names in a file specified with `--exclude-table-file`, `gpbackup` ignores the partition names.

Backing up a database with `gpbackup` while simultaneously running DDL commands might cause `gpbackup` to fail, in order to ensure consistency within the backup set. For example, if a table is dropped after the start of the backup operation, `gpbackup` exits and displays the error message ERROR: relation `<schema.table>` does not exist.

`gpbackup` might fail when a table is dropped during a backup operation due to table locking issues. `gpbackup` generates a list of tables to back up and acquires an ACCESS SHARED lock on the tables. If an `EXCLUSIVE LOCK` is held on a table, `gpbackup` acquires the `ACCESS SHARED` lock after the existing lock is released. If the table no longer exists when `gpbackup` attempts to acquire a lock on the table, `gpbackup` exits with the error message.

For tables that might be dropped during a backup, you can exclude the tables from a backup with a `gpbackup` table filtering option such as `--exclude-table` or --exclude-schema.

A backup created with `gpbackup` can only be restored to a WarehousePG cluster with the same number of segment instances as the source cluster. If you run gpexpand to add segments to the cluster, backups you made before starting the expand cannot be restored after the expansion has completed.

4.12.1 Incremental Backups using gpbackup and gprestore

> **Associated Topics**
>
> - gpbackup & gprestore user guide
> - gpbackup syntax reference
> - gprestore syntax reference

The gpbackup and gprestore utilities support creating incremental backups of append-optimized tables and restoring from incremental backups. An incremental backup backs up all specified heap tables and backs up append-optimized tables (including append-optimized, column-oriented tables) only if the tables have changed.

For example, if a row of an append-optimized table has changed, the table is backed up. For partitioned append-optimized tables, only the changed leaf partitions are backed up.

Incremental backups are efficient when the total amount of data in append-optimized tables or table partitions that changed is small compared to the data that has not changed since the last backup.

An incremental backup backs up an append-optimized table only if one of the following operations was performed on the table after the last full or incremental backup:

- `ALTER TABLE`
- `DELETE`
- `INSERT`
- `TRUNCATE`
- `UPDATE`
- `DROP` and then re-create the table

Restoring data from incremental backups requires a complete incremental backup file set.

Understanding Incremental Backup Sets

An incremental backup set includes the following backups:

- A full backup. This is the full backup that the incremental backups are based on.
- The set of incremental backups that capture the changes to the database from the time of the full backup.

For example, you can create a full backup (Sunday) and then create three daily incremental backups(Monday, Wednesday, Friday). The full backup and all three incremental backups are the backup set.

> **Incremental Backup Set**
>
> - Full: Sunday
> - Incremental: Monday
> - Incremental: Wednesday
> - Incremental: Friday

When you create or add to an incremental backup set, `gpbackup` ensures that the backups in the set are created with a consistent set of backup options to ensure that the backup set can be used in a restore operation.

When you create an incremental backup you include these options with the other `gpbackup` options to create a backup:

`--leaf-partition-data`

- Required for all backups in the incremental backup set.
- Required when you create a full backup that will be the base backup for an incremental backup set.

`--incremental`

- Required when you create an incremental backup.

> **Note**
>
> `--data-only` and `--metadata-only` are not compatible with the `--incremental` option

`--from-timestamp`

- Optional. This option can be used with `--incremental`. The timestamp you specify if of an existing backup. The timestamp can be either an incremental backup or the initial full backup of the set.

The backup being created must be have the same command line options as the with the backup specified with the `--from-timestamp` option.

If you do not specify `--from-timestamp`, `gpbackup` attempts to find a compatible backup based on information in the `gpbackup` history database.

When you add an incremental backup to a backup set, `gpbackup` ensures that the full backup and the incremental backups are consistent by checking these `gpbackup` options:

`--dbname` - The database must be the same.

`--backup-dir` - The directory must be the same. The backup set, the

full backup and the incremental backups, must be in the same location.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

`--single-data-file` - This option must be either specified or absent

for all backups in the set.

`--plugin-config` - If this option is specified, it must be specified

for all backups in the backup set. The configuration must reference the same plugin binary.

`--include-table-file` , `--include-schema` , or any other

options that filter tables and schemas must be the same.

When checking schema filters, only the schema names are checked, not the objects contained in the schemas.

`--no-compression` - If this option is specified, it must be specified

for all backups in the backup set.

If compression is used on the on the full backup, compression must be used on the incremental backups. Different compression levels are allowed for the backups in the backup set. For a backup, the default is compression level 1.

> **Warning**
>
> If you try to add an `--incremental` backup to a backup set, the backup operation fails if the `gpbackup` command line options options are not consistent.

Examples

The following example shows a backup strategy using weekly Full + daily Incremental backups.

The following command creates the first full backup of the backup set:

Sunday

```
$ gpbackup --dbname ww_sales --backup-dir /nfsmount/whpg_backups/ww_sales --leaf-partition-data
```

Resulting in the example backup set

```
20250518010000 (full backup, Sunday 1am)
```

> **Tip**
>
> Each backup has a timestamp taken when the backup is created, and is used in the naming of the backup set files.
>
> `YYYYMMDDhhmmss` is the format.
>
> For example, a backup on May 18,2025 at 1:00:00am local time, the backup file names contain `20250527` for the day and `010000` representing 1:00:00am.
>
> Resulting in a naming convention of `20250518010000` for the backup file set
>
> When you specify the `--backup-dir` option, the backups are created in the corresponding directory on each WarehousePG host, `/nfsmount/whpg_backups/ww_sales` in this example.

The next backup will be an incremental backup, based on the full backup above

Monday

```
$ gpbackup --dbname ww_sales --incremental --backup-dir /nfsmount/whpg_backups/ww_sales --leaf-partition-data
```

Resulting in a second backup belonging to the backup set.

```
20250518010000 (full backup, Sunday 1am)
20250519020000 (incremental backup, Monday 2am)
```

Subsequent backups are run on

- **Tuesday**
- **Wednesday**
- **Thursday**
- **Friday**
- **Saturday**

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

resulting in this complete set.

```
20250518010000 (full backup, Sunday 1am)
20250519020000 (incremental backup, Monday 2am)
20250520030000 (incremental backup, Tuesday 3am)
20250521040000 (incremental backup, Wedndesday 4am)
20250522050000 (incremental backup, Thursday 5am)
20250523060000 (incremental backup, Friday 6am)
20250524070000 (incremental backup, Saturday 7am)
```

Full vs Incremental Backup Strategy

The advantage of Full backups is that they contain every object in the database, allowing for a simple restore (filtered, or complete). One disadvantage may be the size & duration of this backup.

Incremental backups decrease the time and volume of data backed up, but they will backup `HEAP` tables every time. To mitigate this, using a partitioned `AO/CO` table approach will greatly reduce incremental backups to only those partitions which have seen changes since the previous backup.

Given the Sunday-Saturday example above, the user has a choice of how to handle the next round of backups.

Weekly Full Backup + Incrementals Example

The user / DBA may choose to run a full backup again on Sunday (no `--incremental` flag)

```
$ gpbackup --dbname ww_sales --backup-dir /nfsmount/whpg_backups/ww_sales --leaf-partition-data
```

Resulting in a new full backup.

```
20250518010000 (full backup, Sunday 1am)
20250519020000 (incremental backup, Monday 2am)
20250520030000 (incremental backup, Tuesday 3am)
20250521040000 (incremental backup, Wedndesday 4am)
20250522050000 (incremental backup, Thursday 5am)
20250523060000 (incremental backup, Friday 6am)
20250524070000 (incremental backup, Saturday 7am)
20250525010000 (full backup, Sunday 1am)
```

The choice then could be made to retain the prior seven backups, or purge the data to convserve disk space.

Aggregated Incrementals Example using --from-timestamp

An alternative approach would be to take an incremental backup on the next Sunday using `--from-timestamp` which creates a single incremental backup set from the basis of the initial full backup on the previous Sunday.

For example:

```
$ gpbackup --dbname ww_sales --incremental --from-timestamp 20250518010000 --backup-dir /nfsmount/whpg_backups/ww_sales --leaf-partition-data
```

Resulting in the following backup sets

```
20250518010000 (full backup, Sunday 1am)
20250519020000 (incremental backup, Monday 2am)
20250520030000 (incremental backup, Tuesday 3am)
20250521040000 (incremental backup, Wedndesday 4am)
20250522050000 (incremental backup, Thursday 5am)
20250523060000 (incremental backup, Friday 6am)
20250524070000 (incremental backup, Saturday 7am)
20250525010000 (incremental backup, Sunday 1am)
```

While this last backup was incremental, it was incremental from the last full backup's timestamp.
This means all the previous incremental backup sets are now redundant, and not required.

> **redundant backup sets**
>
> These backup sets can now be deleted to reclaim storage space
>
> ```
> 20250519020000 (incremental backup, Monday 2am)
> 20250520030000 (incremental backup, Tuesday 3am)
> 20250521040000 (incremental backup, Wedndesday 4am)
> 20250522050000 (incremental backup, Thursday 5am)
> 20250523060000 (incremental backup, Friday 6am)
> 20250524070000 (incremental backup, Saturday 7am)
> ```

Resulting in the following two backups covering the entire week

```
20250518010000 (full backup, Sunday 1am)
20250525010000 (incremental backup, Sunday 1am)
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Restoring Incremental Backup Sets

Based on the previous examples of full and incremental backups

```
20250518010000 (full backup, Sunday 1am)
20250519020000 (incremental backup, Monday 2am)
20250520030000 (incremental backup, Tuesday 3am)
20250521040000 (incremental backup, Wedndesday 4am)
20250522050000 (incremental backup, Thursday 5am)
20250523060000 (incremental backup, Friday 6am)
20250524070000 (incremental backup, Saturday 7am)
```

The following `gprestore` command specifies the timestamp `20250521040000` (Wednesday) as the restore to point.

```
$ gprestore --timestamp 20250521040000 --redirect-db www_sales_pitr --create-db
```

The incremental backup with the timestamps

- `20250520030000` (Tuesday)
- `20250519020000` (Monday)

And the full backup

- `20250518010000` (Sunday)

must be available to perform a succesful restore.

Tips & Notes

> **Choices**
>
> - The amount of backups (full or incremental) retained is a choice for each user. Some enterprises may have regulatory requirements to keep `x of days` of backups.
> - `RPO` (Recovery Point Objective) 1 day, 1 week, 1 month for example, may play a role in how you develop your backup strategy.
> - Using `--incremental` backups, effective partitioning of `AO/CO` tables, and the use of the `--include` and `--exclude` table and schema filters, allow for a flexible and performant approach to your backup strategy.

To create an incremental backup, or to restore data from an incremental backup set, you need the complete backup set. When you archive incremental backups, the complete backup set must be archived. You must archive all the files created on the coordinator and all segments.

Each time `gpbackup` runs, the utility adds backup information to the backup history database `gpbackup_history.db` located in the WarehousePG `$COORDINATORY_DATA_DIRECTORY`. This sqlite database contains metadata details of the backup set, such as timestamp, flags used, object contents. To bypass the inserting of this metadata into the history database, the `--no-history` flag can be included in your `gpbakcup` command.

When using the `--incremental` flag without the `--from-timestamp` option, `gpbackup` will attempt to find the most recent backup with the same command line options, in the `gpbackup_history.db`. If `gpbackup` cannot find a backup with a consistent set of options, `gpbackup` displays a warning indicating a full backup must be created before an incremental can be created.

When using the `--from-timestamp` option with `--incremental`, `gpbackup` ensures that the command line options of the current backup match the options of the previously created incremental backup with the specified timestamp.

The `gpbackup` option `--with-stats` is not required to be the same for all backups in the backup set. However, to perform a restore operation with the `gprestore` option `--with-stats` to restore statistics, the backup you specify must have must have used the `--with-stats` when taking the backup.

Restore operations can be performed from any backup in the backup set. However, changes captured in incremental backups later than the backup use to restore database data will not be restored.

When restoring from an incremental backup set, `gprestore` checks the backups and restores each append-optimized table from the most recent version of the append-optimized table in the backup set.

Heap tables are always restored from the latest backup in the incremental backup set.

The incremental back up set, a full backup and associated incremental backups, must be on a single device. For example, the backups in a backup set must all be on the local filesystem, S3 compatible bucket or a NFS mount point accessible my all hosts in the WarehousePG cluster.

> **Warning**
>
> Changes to the WarehousePG segment configuration invalidate incremental backups. After you change the segment configuration (add or remove segment instances), you must create a full backup before you can create an incremental backup.

5 WarehousePG security configuration guide

This guide describes how to secure a WarehousePG cluster. The guide assumes knowledge of Linux/UNIX system administration and database management systems. Familiarity with structured query language (SQL) is helpful.

> **Important** Because WarehousePG is based on PostgreSQL, certain commercial security scanning software, when trying to identify WarehousePG vulnerabilities, may use a PostgreSQL database profile. The reports generated by these tools can produce misleading results, and cannot be trusted as an accurate assessment of vulnerabilities that may exist in WarehousePG.

Because WarehousePG is based on PostgreSQL 9.4, this guide assumes some familiarity with PostgreSQL. References to PostgreSQL documentation are provided throughout this guide for features that are similar to those in WarehousePG.

This information is intended for system administrators responsible for administering a WarehousePG cluster.

- Securing the Database
  Introduces WarehousePG security topics.
- WarehousePG Ports and Protocols
  Lists network ports and protocols used within the WarehousePG cluster.
- Configuring Client Authentication
  Describes the available methods for authenticating WarehousePG clients.
- Configuring Database Authorization
  Describes how to restrict authorization access to database data at the user level by using roles and permissions.
- Auditing
  Describes WarehousePG events that are logged and should be monitored to detect security threats.
- Encrypting Data and Database Connections
  Describes how to encrypt data at rest in the database or in transit over the network, to protect from eavesdroppers or man-in-the-middle attacks.
- Security Best Practices
  Describes basic security best practices that you should follow to ensure the highest level of system security.

About Endpoint Security Software

If you install any endpoint security software on your WarehousePG hosts, such as anti-virus, data protection, network security, or other security related software, the additional CPU, IO, network or memory load can interfere with WarehousePG operations and may affect database performance and stability.

Refer to your endpoint security vendor and perform careful testing in a non-production environment to ensure it does not have any negative impact on WarehousePG operations.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

5.1 Securing the Database

Introduces WarehousePG security topics.

The intent of security configuration is to configure the WarehousePG server to eliminate as many security vulnerabilities as possible. This guide provides a baseline for minimum security requirements, and is supplemented by additional security documentation.

The essential security requirements fall into the following categories:

- Authentication covers the mechanisms that are supported and that can be used by the WarehousePG server to establish the identity of a client application.
- Authorization pertains to the privilege and permission models used by the database to authorize client access.
- Auditing, or log settings, covers the logging options available in WarehousePG to track successful or failed user actions.
- Data Encryption addresses the encryption capabilities that are available for protecting data at rest and data in transit. This includes the security certifications that are relevant to the WarehousePG.

Accessing a Kerberized Hadoop Cluster

You can use the WarehousePG Platform Extension Framework (PXF) to read or write external tables referencing files in a Hadoop file system. If the Hadoop cluster is secured with Kerberos ("Kerberized"), you must configure WarehousePG and PXF to allow users accessing external tables to authenticate with Kerberos. Refer to Configuring PXF for Secure HDFS for the procedure to perform this setup.

Platform Hardening

Platform hardening involves assessing and minimizing system vulnerability by following best practices and enforcing federal security standards. Hardening the product is based on the US Department of Defense (DoD) guidelines Security Template Implementation Guides (STIG). Hardening removes unnecessary packages, deactivates services that are not required, sets up restrictive file and directory permissions, removes unowned files and directories, performs authentication for single-user mode, and provides options for end users to configure the package to be compliant to the latest STIGs.

5.2 WarehousePG Ports and Protocols

Lists network ports and protocols used within the WarehousePG cluster.

WarehousePG clients connect with TCP to the WarehousePG coordinator instance at the client connection port, 5432 by default. The listen port can be reconfigured in the postgresql.conf configuration file. Client connections use the PostgreSQL libpq API. The `psql` command-line interface, several WarehousePG utilities, and language-specific programming APIs all either use the libpq library directly or implement the libpq protocol internally.

Each segment instance also has a client connection port, used solely by the coordinator instance to coordinate database operations with the segments. The `gpstate -p` command, run on the WarehousePG coordinator, lists the port assignments for the WarehousePG coordinator and the primary segments and mirrors. For example:

```
[gpadmin@cdw ~]$ gpstate -p
20190403:02:57:04:011030 gpstate:cdw:gpadmin-[INFO]:-Starting gpstate with args: -p

20190403:02:57:05:011030 gpstate:cdw:gpadmin-[INFO]:-   sdw1   /data/mirror/gpseg6    21000
20190403:02:57:05:011030 gpstate:cdw:gpadmin-[INFO]:-   sdw3   /data/primary/gpseg7   20001
20190403:02:57:05:011030 gpstate:cdw:gpadmin-[INFO]:-   sdw1   /data/mirror/gpseg7    21001
20190403:02:57:05:011030 gpstate:cdw:gpadmin-[INFO]:-   sdw3   /data/primary/gpseg8   20002
20190403:02:57:05:011030 gpstate:cdw:gpadmin-[INFO]:-   sdw1   /data/mirror/gpseg8    21002
```

Additional WarehousePG network connections are created for features such as standby replication, segment mirroring, statistics collection, and data exchange between segments. Some persistent connections are established when the database starts up and other transient connections are created during operations such as query execution. Transient connections for query execution processes, data movement, and statistics collection use available ports in the range 1025 to 65535 with both TCP and UDP protocols.

> **Note** To avoid port conflicts between WarehousePG and other applications when initializing WarehousePG, do not specify WarehousePG ports in the range specified by the operating system parameter `net.ipv4.ip_local_port_range`. For example, if `net.ipv4.ip_local_port_range = 10000 65535`, you could set the WarehousePG base port numbers to values outside of that range:

```
PORT_BASE = 6000
MIRROR_PORT_BASE = 7000
```

Some add-on products and services that work with WarehousePG have additional networking requirements. The following table lists ports and protocols used within the WarehousePG cluster, and includes services and applications that integrate with WarehousePG.

Service	Protocol/Port	Description
Coordinator SQL client connection	TCP 5432, libpq	SQL client connection port on the WarehousePG coordinator host. Supports clients using the PostgreSQL libpq API. Configurable.
Segment SQL client connection	varies, libpq	The SQL client connection port for a segment instance. Each primary and mirror segment on a host must have a unique port. Ports are assigned when the WarehousePG cluster is initialized or expanded. The `gp_segment_configuration` system catalog records port numbers for each primary (p) or mirror (m) segment in the `port` column. Run `gpstate -p` to view the ports in use.
Segment mirroring port	varies, libpq	The port where a segment receives mirrored blocks from its primary. The port is assigned when the mirror is set up. The `gp_segment_configuration` system catalog records port numbers for each primary (p) or mirror (m) segment in the `port` column. Run `gpstate -p` to view the ports in use.
WarehousePG Interconnect	UDP 1025-65535, dynamically allocated	The Interconnect transports database tuples between WarehousePG segments during query execution.
Standby coordinator client listener	TCP 5432, libpq	SQL client connection port on the standby coordinator host. Usually the same as the coordinator client connection port. Configure with the `gpinitstandby` utility `-P` option.
Standby coordinator replicator	TCP 1025-65535, gpsyncmaster	The `gpsyncmaster` process on the coordinator host establishes a connection to the secondary coordinator host to replicate the coordinator's log to the standby coordinator.
WarehousePG file load and transfer utilities: gpfdist, gpload.	TCP 8080, HTTP TCP 9000, HTTPS	The gpfdist file serving utility can run on WarehousePG hosts or external hosts. Specify the connection port with the `-p` option when starting the server. The gpload utility runs one or more instances of gpfdist with ports or port ranges specified in a configuration file.
Backup completion notification	TCP 25, TCP 587, SMTP	The `gpbackup` backup utility can optionally send email to a list of email addresses at completion of a backup. The SMTP service must be enabled on the WarehousePG coordinator host.
WarehousePG secure shell (SSH): gpssh, gpsync, gpssh-exkeys	TCP 22, SSH	Many WarehousePG utilities use rsync and ssh to transfer files between hosts and manage the WarehousePG cluster within the cluster.
WarehousePG Platform Extension Framework (PXF)	TCP 5888	The PXF Java service runs on port number 5888 on each WarehousePG segment host.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Service	Protocol/Port	Description
Dell PowerProtect (Data Domain)	TCP/UDP 111, NFS portmapper	Used to assign a random port for the mountd service used by NFS. The mountd service port can be statically assigned on the Data Domain server.
Dell PowerProtect (Data Domain)	TCP 2052	Main port used by NFS mountd. This port can be set on the Data Domain system using the `nfs set mountd-port` command .
Dell PowerProtect (Data Domain)	TCP 2049, NFS	Main port used by NFS. This port can be configured using the `nfs set server-port` command on the Data Domain server.
Dell PowerProtect (Data Domain)	TCP 2051, replication	Used when replication is configured on the Data Domain system. This port can be configured using the `replication modify` command on the Data Domain server.
Pgbouncer connection pooler	TCP, libpq	The pgbouncer connection pooler runs between libpq clients and WarehousePG (or PostgreSQL) databases. While you can run it on the WarehousePG coordinator host, running pgbouncer on a host outside of the WarehousePG cluster is recommended. When it runs on a separate host, pgbouncer can act as a warm standby mechanism for the WarehousePG coordinator host, switching to the WarehousePG standby host without requiring clients to reconfigure. Set the client connection port and the WarehousePG coordinator host address and port in the pgbouncer.ini configuration file.

5.3 Configuring Client Authentication

Describes the available methods for authenticating WarehousePG clients.

When a WarehousePG cluster is first initialized, the system contains one predefined superuser role. This role will have the same name as the operating system user who initialized the WarehousePG cluster. This role is referred to as gpadmin. By default, the system is configured to only allow local connections to the database from the gpadmin role. If you want to allow any other roles to connect, or if you want to allow connections from remote hosts, you have to configure WarehousePG to allow such connections. This section explains how to configure client connections and authentication to WarehousePG.

- Allowing Connections to WarehousePG
- Editing the pg_hba.conf File
- Authentication Methods
- Limiting Concurrent Connections
- Encrypting Client/Server Connections

Parent topic: WarehousePG Security Configuration Guide

Allowing Connections to WarehousePG

Client access and authentication is controlled by a configuration file named `pg_hba.conf` (the standard PostgreSQL host-based authentication file). For detailed information about this file, see The pg_hba.conf File in the PostgreSQL documentation.

In WarehousePG, the `pg_hba.conf` file of the coordinator instance controls client access and authentication to your WarehousePG cluster. The segments also have `pg_hba.conf` files, but these are already correctly configured to only allow client connections from the coordinator host. The segments never accept outside client connections, so there is no need to alter the `pg_hba.conf` file on segments.

The general format of the `pg_hba.conf` file is a set of records, one per line. Blank lines are ignored, as is any text after a # comment character. A record is made up of a number of fields which are separated by spaces and/or tabs. Fields can contain white space if the field value is quoted. Records cannot be continued across lines.

A record can have one of seven formats:

```
local      <database>  <user>  <auth-method>  [<auth-options>]
host       <database>  <user>  <address>  <auth-method>  [<auth-options>]
hostssl    <database>  <user>  <address>  <auth-method>  [<auth-options>]
hostnossl  <database>  <user>  <address>  <auth-method>  [<auth-options>]
host       <database>  <user>  <IP-address>  <IP-mask>  <auth-method>  [<auth-options>]
hostssl    <database>  <user>  <IP-address>  <IP-mask>  <auth-method>  [<auth-options>]
hostnossl  <database>  <user>  <IP-address>  <IP-mask>  <auth-method>  [<auth-options>]
```

The meaning of the `pg_hba.conf` fields is as follows:

`local` Matches connection attempts using UNIX-domain sockets. Without a record of this type, UNIX-domain socket connections are disallowed.

`host` Matches connection attempts made using TCP/IP. Remote TCP/IP connections will not be possible unless the server is started with an appropriate value for the `listen_addresses` server configuration parameter. WarehousePG by default allows connections from all hosts (`'*'`).

`hostssl` Matches connection attempts made using TCP/IP, but only when the connection is made with SSL encryption. SSL must be enabled at server start time by setting the `ssl` configuration parameter to on. Requires SSL authentication be configured in `postgresql.conf` . See Configuring postgresql.conf for SSL Authentication.

`hostnossl` Matches connection attempts made over TCP/IP that do not use SSL.

`database` Specifies which database names this record matches. The value `all` specifies that it matches all databases. Multiple database names can be supplied by separating them with commas. A separate file containing database names can be specified by preceding the file name with `@` .

`user` Specifies which database role names this record matches. The value `all` specifies that it matches all roles. If the specified role is a group and you want all members of that group to be included, precede the role name with a `+` . Multiple role names can be supplied by separating them with commas. A separate file containing role names can be specified by preceding the file name with `@` .

`address` Specifies the client machine addresses that this record matches. This field can contain either a host name, an IP address range, or one of the special key words mentioned below.

An IP address range is specified using standard numeric notation for the range's starting address, then a slash (`/`) and a CIDR mask length. The mask length indicates the number of high-order bits of the client IP address that must match. Bits to the right of this should be zero in the given IP address. There must not be any white space between the IP address, the `/` , and the CIDR mask length.

Typical examples of an IPv4 address range specified this way are `172.20.143.89/32` for a single host, or `172.20.143.0/24` for a small network, or `10.6.0.0/16` for a larger one. An IPv6 address range might look like `::1/128` for a single host (in this case the IPv6 loopback address) or `fe80::7a31:c1ff:0000:0000/96` for a small network. `0.0.0.0/0` represents all IPv4 addresses, and `::0/0` represents all IPv6 addresses. To specify a single host, use a mask length of 32 for IPv4 or 128 for IPv6. In a network address, do not omit trailing zeroes.

An entry given in IPv4 format will match only IPv4 connections, and an entry given in IPv6 format will match only IPv6 connections, even if the represented address is in the IPv4-in-IPv6 range.

> **Note** Entries in IPv6 format will be rejected if the host system C library does not have support for IPv6 addresses.

You can also write `all` to match any IP address, `samehost` to match any of the server's own IP addresses, or `samenet` to match any address in any subnet to which the server is directly connected.

If a host name is specified (an address that is not an IP address, IP range, or special key word is treated as a host name), that name is compared with the result of a reverse name resolution of the client IP address (for example, reverse DNS lookup, if DNS is used). Host name comparisons are case insensitive. If there is a match, then a forward name resolution (for example, forward DNS lookup) is performed on the host name to check whether any of the addresses it resolves to are equal to the client IP address. If both directions match, then the entry is considered to match.

The host name that is used in `pg_hba.conf` should be the one that address-to-name resolution of the client's IP address returns, otherwise the line won't be matched. Some host name databases allow associating an IP address with multiple host names, but the operating system will only return one host name when asked to resolve an IP address.

A host name specification that starts with a dot (.) matches a suffix of the actual host name. So `.example.com` would match `foo.example.com` (but not just `example.com`).

When host names are specified in `pg_hba.conf` , you should ensure that name resolution is reasonably fast. It can be advantageous to set up a local name resolution cache such as `nscd` . Also, you can enable the server configuration parameter `log_hostname` to see the client host name instead of the IP address in the log.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

`IP-address` `IP-mask` These two fields can be used as an alternative to the CIDR address notation. Instead of specifying the mask length, the actual mask is specified in a separate column. For example, `255.0.0.0` represents an IPv4 CIDR mask length of 8, and `255.255.255.255` represents a CIDR mask length of 32.

`auth-method` Specifies the authentication method to use when a connection matches this record. See Authentication Methods for options.

`auth-options` After the `auth-method` field, there can be field(s) of the form `name=value` that specify options for the authentication method. Details about which options are available for which authentication methods are described in Authentication Methods.

Files included by @ constructs are read as lists of names, which can be separated by either whitespace or commas. Comments are introduced by #, just as in `pg_hba.conf`, and nested @ constructs are allowed. Unless the file name following @ is an absolute path, it is taken to be relative to the directory containing the referencing file.

The `pg_hba.conf` records are examined sequentially for each connection attempt, so the order of the records is significant. Typically, earlier records will have tight connection match parameters and weaker authentication methods, while later records will have looser match parameters and stronger authentication methods. For example, you might wish to use `trust` authentication for local TCP/IP connections but require a password for remote TCP/IP connections. In this case a record specifying `trust` authentication for connections from 127.0.0.1 would appear before a record specifying `password` authentication for a wider range of allowed client IP addresses.

The `pg_hba.conf` file is read on start-up and when the main server process receives a SIGHUP signal. If you edit the file on an active system, you must reload the file using this command:

```
$ gpstop -u
```

CAUTION: For a more secure system, remove records for remote connections that use `trust` authentication from the `pg_hba.conf` file. `trust` authentication grants any user who can connect to the server access to the database using any role they specify. You can safely replace `trust` authentication with `ident` authentication for local UNIX-socket connections. You can also use `ident` authentication for local and remote TCP clients, but the client host must be running an ident service and you must `trust` the integrity of that machine.

Editing the pg_hba.conf File

Initially, the `pg_hba.conf` file is set up with generous permissions for the gpadmin user and no database access for other WarehousePG roles. You will need to edit the `pg_hba.conf` file to enable users' access to databases and to secure the gpadmin user. Consider removing entries that have `trust` authentication, since they allow anyone with access to the server to connect with any role they choose. For local (UNIX socket) connections, use `ident` authentication, which requires the operating system user to match the role specified. For local and remote TCP connections, `ident` authentication requires the client's host to run an indent service. You could install an ident service on the coordinator host and then use `ident` authentication for local TCP connections, for example `127.0.0.1/28`. Using `ident` authentication for remote TCP connections is less secure because it requires you to trust the integrity of the ident service on the client's host.

This example shows how to edit the `pg_hba.conf` file on the coordinator host to allow remote client access to all databases from all roles using encrypted password authentication.

To edit `pg_hba.conf`:

1. Open the file `$COORDINATOR_DATA_DIRECTORY/pg_hba.conf` in a text editor.
2. Add a line to the file for each type of connection you want to allow. Records are read sequentially, so the order of the records is significant. Typically, earlier records will have tight connection match parameters and weaker authentication methods, while later records will have looser match parameters and stronger authentication methods. For example:

   ```
   # allow the gpadmin user local access to all databases
   # using ident authentication
   local   all   gpadmin   ident         sameuser
   host    all   gpadmin   127.0.0.1/32  ident
   host    all   gpadmin   ::1/128       ident
   # allow the 'dba' role access to any database from any
   # host with IP address 192.168.x.x and use md5 encrypted
   # passwords to authenticate the user
   # Note that to use SHA-256 encryption, replace md5 with
   # password in the line below
   host    all   dba   192.168.0.0/32  md5
   ```

Authentication Methods

- Basic Authentication
- GSSAPI Authentication
- LDAP Authentication
- SSL Client Authentication
- PAM-Based Authentication
- Radius Authentication

Basic Authentication

Trust Allows the connection unconditionally, without the need for a password or any other authentication. This entry is required for the `gpadmin` role, and for WarehousePG utilities (for example `gpinitsystem`, `gpstop`, or `gpstart` amongst others) that need to connect between nodes without prompting for input or a password.

> **Important** For a more secure system, remove records for remote connections that use `trust` authentication from the `pg_hba.conf` file. `trust` authentication grants any user who can connect to the server access to the database using any role they specify. You can safely replace `trust` authentication with `ident` authentication for local UNIX-socket connections. You can also use `ident` authentication for local and remote TCP clients, but the client host must be running an ident service and you must `trust` the integrity of that machine.

Reject Reject the connections with the matching parameters. You should typically use this to restrict access from specific hosts or insecure connections.

Ident Authenticates based on the client's operating system user name. This is secure for local socket connections. Using `ident` for TCP connections from remote hosts requires that the client's host is running an ident service. The `ident` authentication method should only be used with remote hosts on a trusted, closed network.

md5 Require the client to supply a double-MD5-hashed password for authentication.

password Require the client to supply an unencrypted password for authentication. Since the password is sent in clear text over the network, this should not be used on untrusted networks.

The password-based authentication methods are `md5` and `password`. These methods operate similarly except for the way that the password is sent across the connection: MD5-hashed and clear-text respectively.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

If you are at all concerned about password "sniffing" attacks then `md5` is preferred. Plain `password` should always be avoided if possible. If the connection is protected by SSL encryption then `password` can be used safely (although SSL certificate authentication might be a better choice if you are depending on using SSL).

Following are some sample `pg_hba.conf` basic authentication entries:

```
hostnossl    all   all        0.0.0.0   reject
hostssl      all   testuser   0.0.0.0/0 md5
local        all   gpuser               ident
```

Or:

```

local    all           gpadmin         ident
host     all           gpadmin         localhost      trust
host     all           gpadmin         cdw            trust
local    replication   gpadmin         ident
host     replication   gpadmin         samenet       trust
host     all           all             0.0.0.0/0     md5
```

GSSAPI Authentication

GSSAPI is an industry-standard protocol for secure authentication defined in RFC 2743. WarehousePG supports GSSAPI with Kerberos authentication according to RFC 1964. GSSAPI provides automatic authentication (single sign-on) for systems that support it. The authentication itself is secure, but the data sent over the database connection will be sent unencrypted unless SSL is used.

The `gss` authentication method is only available for TCP/IP connections.

When GSSAPI uses Kerberos, it uses a standard principal in the format `servicename/hostname@realm`. The WarehousePG server will accept any principal that is included in the keytab file used by the server, but care needs to be taken to specify the correct principal details when making the connection from the client using the `krbsrvname` connection parameter. (See Connection Parameter Key Words in the PostgreSQL documentation.) In most environments, this parameter never needs to be changed. Some Kerberos implementations might require a different service name, such as Microsoft Active Directory, which requires the service name to be in upper case (POSTGRES).

`hostname` is the fully qualified host name of the server machine. The service principal's realm is the preferred realm of the server machine.

Client principals must have their WarehousePG user name as their first component, for example `gpusername@realm`. Alternatively, you can use a user name mapping to map from the first component of the principal name to the database user name. By default, WarehousePG does not check the realm of the client. If you have cross-realm authentication enabled and need to verify the realm, use the `krb_realm` parameter, or enable `include_realm` and use user name mapping to check the realm.

Make sure that your server keytab file is readable (and preferably only readable) by the `gpadmin` server account. The location of the key file is specified by the krb_server_keyfile configuration parameter. For security reasons, it is recommended to use a separate keytab just for the WarehousePG server rather than opening up permissions on the system keytab file.

The keytab file is generated by the Kerberos software; see the Kerberos documentation for details. The following example is for MIT-compatible Kerberos 5 implementations:

```
kadmin% **ank -randkey postgres/server.my.domain.org**
kadmin% **ktadd -k krb5.keytab postgres/server.my.domain.org**
```

When connecting to the database make sure you have a ticket for a principal matching the requested database user name. For example, for database user name `fred`, principal `fred@EXAMPLE.COM` would be able to connect. To also allow principal `fred/users.example.com@EXAMPLE.COM`, use a user name map, as described in User Name Maps in the PostgreSQL documentation.

The following configuration options are supported for GSSAPI:

`include_realm` If set to 1, the realm name from the authenticated user principal is included in the system user name that is passed through user name mapping. This is the recommended configuration as, otherwise, it is impossible to differentiate users with the same username who are from different realms. The default for this parameter is 0 (meaning to not include the realm in the system user name) but may change to 1 in a future version of WarehousePG. You can set it explicitly to avoid any issues when upgrading.

`map` Allows for mapping between system and database user names. For a GSSAPI/Kerberos principal, such as `username@EXAMPLE.COM` (or, less commonly, `username/hostbased@EXAMPLE.COM`), the default user name used for mapping is `username` (or `username/hostbased`, respectively), unless `include_realm` has been set to 1 (as recommended, see above), in which case `username@EXAMPLE.COM` (or `username/hostbased@EXAMPLE.COM`) is what is seen as the system username when mapping.

`krb_realm` Sets the realm to match user principal names against. If this parameter is set, only users of that realm will be accepted. If it is not set, users of any realm can connect, subject to whatever user name mapping is done.

LDAP Authentication

You can authenticate against an LDAP directory.

- LDAPS and LDAP over TLS options encrypt the connection to the LDAP server.
- The connection from the client to the server is not encrypted unless SSL is enabled. Configure client connections to use SSL to encrypt connections from the client.
- To configure or customize LDAP settings, set the `LDAPCONF` environment variable with the path to the `ldap.conf` file and add this to the `greenplum_path.sh` script.

Following are the recommended steps for configuring your system for LDAP authentication:

1. Set up the LDAP server with the database users/roles to be authenticated via LDAP.
2. On the database:
    1. Verify that the database users to be authenticated via LDAP exist on the database. LDAP is only used for verifying username/password pairs, so the roles should exist in the database.
    2. Update the `pg_hba.conf` file in the `$COORDINATOR_DATA_DIRECTORY` to use LDAP as the authentication method for the respective users. Note that the first entry to match the user/role in the `pg_hba.conf` file will be used as the authentication mechanism, so the position of the entry in the file is important.
    3. Reload the server for the `pg_hba.conf` configuration settings to take effect (`gpstop -u`).

Specify the following parameter `auth-options`.

ldapserver Names or IP addresses of LDAP servers to connect to. Multiple servers may be specified, separated by spaces.

ldapprefix String to prepend to the user name when forming the DN to bind as, when doing simple bind authentication.

ldapsuffix String to append to the user name when forming the DN to bind as, when doing simple bind authentication.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

ldapport Port number on LDAP server to connect to. If no port is specified, the LDAP library's default port setting will be used.

ldaptls Set to 1 to make the connection between PostgreSQL and the LDAP server use TLS encryption. Note that this only encrypts the traffic to the LDAP server — the connection to the client will still be unencrypted unless SSL is used.

ldapbasedn Root DN to begin the search for the user in, when doing search+bind authentication.

ldapbinddn DN of user to bind to the directory with to perform the search when doing search+bind authentication.

ldapbindpasswd Password for user to bind to the directory with to perform the search when doing search+bind authentication.

ldapsearchattribute Attribute to match against the user name in the search when doing search+bind authentication.

ldapsearchfilter Beginning with WarehousePG 6.22, this attribute enables you to provide a search filter to use when doing search+bind authentication. Occurrences of `$username` will be replaced with the user name. This allows for more flexible search filters than `ldapsearchattribute`. Note that you can specify *either* `ldapsearchattribute` or `ldapsearchattribute`, but not both.

When using search+bind mode, the search can be performed using a single attribute specified with `ldapsearchattribute`, or using a custom search filter specified with `ldapsearchfilter`. Specifying `ldapsearchattribute=foo` is equivalent to specifying `ldapsearchfilter="(foo=$username)"`. If neither option is specified the default is `ldapsearchattribute=uid`.

Here is an example for a search+bind configuration that uses `ldapsearchfilter` instead of `ldapsearchattribute` to allow authentication by user ID or email address:

```
host ... ldap ldapserver=ldap.example.net ldapbasedn="dc=example, dc=net" ldapsearchfilter="(|(uid=$username)(mail=$username))"
```

Following are additional sample `pg_hba.conf` file entries for LDAP authentication:

```
host all testuser 0.0.0.0/0 ldap ldap
ldapserver=ldapserver.greenplum.com ldapport=389 ldapprefix="cn=" ldapsuffix=",ou=people,dc=greenplum,dc=com"
hostssl   all   ldaprole   0.0.0.0/0   ldap
ldapserver=ldapserver.greenplum.com ldaptls=1 ldapprefix="cn=" ldapsuffix=",ou=people,dc=greenplum,dc=com"
```

SSL Client Authentication

SSL authentication compares the Common Name (cn) attribute of an SSL certificate provided by the connecting client during the SSL handshake to the requested database user name. The database user should exist in the database. A map file can be used for mapping between system and database user names.

SSL Authentication Parameters

Authentication method:

- Cert

  Authentication options:

  Hostssl Connection type must be hostssl.

  map=mapping mapping.

  This is specified in the `pg_ident.conf`, or in the file specified in the `ident_file` server setting.

  Following are sample `pg_hba.conf` entries for SSL client authentication:

  ```
  Hostssl testdb certuser 192.168.0.0/16 cert
  Hostssl testdb all 192.168.0.0/16 cert map=gpuser
  ```

OpenSSL Configuration

You can make changes to the OpenSSL configuration by updating the `openssl.cnf` file under your OpenSSL installation directory, or the file referenced by `$OPENSSL_CONF`, if present, and then restarting the WarehousePG server.

Creating a Self-Signed Certificate

A self-signed certificate can be used for testing, but a certificate signed by a certificate authority (CA) (either one of the global CAs or a local one) should be used in production so that clients can verify the server's identity. If all the clients are local to the organization, using a local CA is recommended.

To create a self-signed certificate for the server:

1. Enter the following `openssl` command:

   ```
   openssl req -new -text -out server.req
   ```

2. Enter the requested information at the prompts.

   Make sure you enter the local host name for the Common Name. The challenge password can be left blank.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

3. The program generates a key that is passphrase-protected; it does not accept a passphrase that is less than four characters long. To remove the passphrase (and you must if you want automatic start-up of the server), run the following command:

```
openssl rsa -in privkey.pem -out server.key
rm privkey.pem
```

4. Enter the old passphrase to unlock the existing key. Then run the following command:

```
openssl req -x509 -in server.req -text -key server.key -out server.crt
```

   This turns the certificate into a self-signed certificate and copies the key and certificate to where the server will look for them.

5. Finally, run the following command:

```
chmod og-rwx server.key
```

For more details on how to create your server private key and certificate, refer to the OpenSSL documentation.

Configuring postgresql.conf for SSL Authentication

The following Server settings need to be specified in the `postgresql.conf` configuration file:

- `ssl` *boolean*. Enables SSL connections.
- `ssl_renegotiation_limit` *integer*. Specifies the data limit before key renegotiation.
- `ssl_ciphers` *string*. Configures the list SSL ciphers that are allowed. `ssl_ciphers` *overrides* any ciphers string specified in `/etc/openssl.cnf`. The default value `ALL:!ADH:!LOW:!EXP:!MD5:@STRENGTH` enables all ciphers except for ADH, LOW, EXP, and MD5 ciphers, and prioritizes ciphers by their strength.

  > **Note** With TLS 1.2 some ciphers in MEDIUM and HIGH strength still use NULL encryption (no encryption for transport), which the default `ssl_ciphers` string allows. To bypass NULL ciphers with TLS 1.2 use a string such as `TLSv1.2:!eNULL:!aNULL`.

  It is possible to have authentication without encryption overhead by using `NULL-SHA` or `NULL-MD5` ciphers. However, a man-in-the-middle could read and pass communications between client and server. Also, encryption overhead is minimal compared to the overhead of authentication. For these reasons, NULL ciphers should not be used.

The default location for the following SSL server files is the WarehousePG coordinator data directory (`$COORDINATOR_DATA_DIRECTORY`):

- `server.crt` - Server certificate.
- `server.key` - Server private key.
- `root.crt` - Trusted certificate authorities.
- `root.crl` - Certificates revoked by certificate authorities.

If WarehousePG coordinator mirroring is enabled with SSL client authentication, the SSL server files *should not be placed* in the default directory `$COORDINATOR_DATA_DIRECTORY`. If a `gpinitstandby` operation is performed, the contents of `$COORDINATOR_DATA_DIRECTORY` is copied from the coordinator to the standby coordinator and the incorrect SSL key, and cert files (the coordinator files, and not the standby coordinator files) will prevent standby coordinator start up.

You can specify a different directory for the location of the SSL server files with the `postgresql.conf` parameters `sslcert`, `sslkey`, `sslrootcert`, and `sslcrl`.

Configuring the SSL Client Connection

SSL options:

sslmode Specifies the level of protection.

`require` Only use an SSL connection. If a root CA file is present, verify the certificate in the same way as if `verify-ca` was specified.

`verify-ca` Only use an SSL connection. Verify that the server certificate is issued by a trusted CA.

`verify-full` Only use an SSL connection. Verify that the server certificate is issued by a trusted CA and that the server host name matches that in the certificate.

sslcert The file name of the client SSL certificate. The default is `$COORDINATOR_DATA_DIRECTORY/postgresql.crt`.

sslkey The secret key used for the client certificate. The default is `$COORDINATOR_DATA_DIRECTORY/postgresql.key`.

sslrootcert The name of a file containing SSL Certificate Authority certificate(s). The default is `$COORDINATOR_DATA_DIRECTORY/root.crt`.

sslcrl The name of the SSL certificate revocation list. The default is `$COORDINATOR_DATA_DIRECTORY/root.crl`.

The client connection parameters can be set using the following environment variables:

- `sslmode` - `PGSSLMODE`
- `sslcert` - `PGSSLCERT`
- `sslkey` - `PGSSLKEY`
- `sslrootcert` - `PGSSLROOTCERT`
- `sslcrl` - `PGSSLCRL`

For example, run the following command to connect to the `postgres` database from `localhost` and verify the certificate present in the default location under `$COORDINATOR_DATA_DIRECTORY`:

```
psql "sslmode=verify-ca host=localhost dbname=postgres"
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

PAM-Based Authentication

The "PAM" (Pluggable Authentication Modules) authentication method validates username/password pairs, similar to basic authentication. To use PAM authentication, the user must already exist as a WarehousePG role name.

WarehousePG uses the `pamservice` authentication parameter to identify the service from which to obtain the PAM configuration.

> **Note** If PAM is set up to read `/etc/shadow`, authentication will fail because the PostgreSQL server is started by a non-root user. This is not an issue when PAM is configured to use LDAP or another authentication method.

WarehousePG does not install a PAM configuration file. If you choose to use PAM authentication with WarehousePG, you must identify the PAM service name for WarehousePG and create the associated PAM service configuration file and configure WarehousePG to use PAM authentication as described below:

1. Log in to the WarehousePG coordinator host and set up your environment. For example:

   ```
   $ ssh gpadmin@<gpcoord>
   gpadmin@gpcoord$ . /usr/edb/whpg7/greenplum_path.sh
   ```

2. Identify the `pamservice` name for WarehousePG. In this procedure, we choose the name `greenplum`.

3. Create the PAM service configuration file, `/etc/pam.d/greenplum`, and add the text below. You must have operating system superuser privileges to create the `/etc/pam.d` directory (if necessary) and the `greenplum` PAM configuration file.

   ```
   #%PAM-1.0
   auth        include     password-auth
   account     include     password-auth
   ```

   This configuration instructs PAM to authenticate the local operating system user.

4. Ensure that the `/etc/pam.d/greenplum` file is readable by all users:

   ```
   sudo chmod 644 /etc/pam.d/greenplum
   ```

5. Add one or more entries to the `pg_hba.conf` configuration file to enable PAM authentication in WarehousePG. These entries must specify the `pam` *auth-method*. You must also specify the `pamservice=greenplum` *auth-option*. For example:

   ```
   host     <user-name>     <db-name>     <address>     pam     pamservice=greenplum
   ```

6. Reload the WarehousePG configuration:

   ```
   $ gpstop -u
   ```

Radius Authentication

RADIUS (Remote Authentication Dial In User Service) authentication works by sending an Access Request message of type 'Authenticate Only' to a configured RADIUS server. It includes parameters for user name, password (encrypted), and the Network Access Server (NAS) Identifier. The request is encrypted using the shared secret specified in the `radiussecret` option. The RADIUS server responds with either `Access Accept` or `Access Reject`.

> **Note** RADIUS accounting is not supported.

RADIUS authentication only works if the users already exist in the database.

The RADIUS encryption vector requires SSL to be enabled in order to be cryptographically strong.

RADIUS Authentication Options

radiusserver The name of the RADIUS server.

radiussecret The RADIUS shared secret.

radiusport The port to connect to on the RADIUS server.

radiusidentifier NAS identifier in RADIUS requests.

Following are sample `pg_hba.conf` entries for RADIUS client authentication:

```
hostssl  all all 0.0.0.0/0 radius radiusserver=servername radiussecret=sharedsecret
```

Limiting Concurrent Connections

To limit the number of active concurrent sessions to your WarehousePG cluster, you can configure the `max_connections` server configuration parameter. This is a local parameter, meaning that you must set it in the `postgresql.conf` file of the coordinator, the standby coordinator, and each segment instance (primary and mirror). The value of `max_connections` on segments must be 5-10 times the value on the coordinator.

When you set `max_connections`, you must also set the dependent parameter `max_prepared_transactions`. This value must be at least as large as the value of `max_connections` on the coordinator, and segment instances should be set to the same value as the coordinator.

In `$COORDINATOR_DATA_DIRECTORY/postgresql.conf` (including standby coordinator):

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
max_connections=100
max_prepared_transactions=100
```

In `SEGMENT_DATA_DIRECTORY/postgresql.conf` for all segment instances:

```
max_connections=500
max_prepared_transactions=100
```

> **Note** Raising the values of these parameters may cause WarehousePG to request more shared memory. To mitigate this effect, consider decreasing other memory-related parameters such as `gp_cached_segworkers_threshold`.

To change the number of allowed connections:

1. Stop your WarehousePG cluster:

   ```
   $ gpstop
   ```

2. On the coordinator host, edit `$COORDINATOR_DATA_DIRECTORY/postgresql.conf` and change the following two parameters:

   - `max_connections` – the number of active user sessions you want to allow plus the number of `superuser_reserved_connections`.
   - `max_prepared_transactions` – must be greater than or equal to `max_connections`.

3. On each segment instance, edit `SEGMENT_DATA_DIRECTORY/postgresql.conf` and change the following two parameters:

   - `max_connections` – must be 5-10 times the value on the coordinator.
   - `max_prepared_transactions` – must be equal to the value on the coordinator.

4. Restart your WarehousePG cluster:

   ```
   $ gpstart
   ```

Encrypting Client/Server Connections

WarehousePG has native support for SSL connections between the client and the coordinator server. SSL connections prevent third parties from snooping on the packets, and also prevent man-in-the-middle attacks. SSL should be used whenever the client connection goes through an insecure link, and must be used whenever client certificate authentication is used.

> **Note** For information about encrypting data between the `gpfdist` server and WarehousePG segment hosts, see Encrypting gpfdist Connections.

To enable SSL requires that OpenSSL be installed on both the client and the coordinator server systems. WarehousePG can be started with SSL enabled by setting the server configuration parameter `ssl=on` in the coordinator `postgresql.conf`. When starting in SSL mode, the server will look for the files `server.key` (server private key) and `server.crt` (server certificate) in the coordinator data directory. These files must be set up correctly before an SSL-enabled WarehousePG cluster can start.

> **Important** Do not protect the private key with a passphrase. The server does not prompt for a passphrase for the private key, and the database startup fails with an error if one is required.

A self-signed certificate can be used for testing, but a certificate signed by a certificate authority (CA) should be used in production, so the client can verify the identity of the server. Either a global or local CA can be used. If all the clients are local to the organization, a local CA is recommended. See Creating a Self-Signed Certificate for steps to create a self-signed certificate.

5.4 Configuring Database Authorization

Describes how to restrict authorization access to database data at the user level by using roles and permissions.

Parent topic: WarehousePG Security Configuration Guide

Access Permissions and Roles

WarehousePG manages database access permissions using *roles*. The concept of roles subsumes the concepts of users and groups. A role can be a database user, a group, or both. Roles can own database objects (for example, tables) and can assign privileges on those objects to other roles to control access to the objects. Roles can be members of other roles, thus a member role can inherit the object privileges of its parent role.

Every WarehousePG cluster contains a set of database roles (users and groups). Those roles are separate from the users and groups managed by the operating system on which the server runs. However, for convenience you may want to maintain a relationship between operating system user names and WarehousePG role names, since many of the client applications use the current operating system user name as the default.

In WarehousePG, users log in and connect through the coordinator instance, which verifies their role and access privileges. The coordinator then issues out commands to the segment instances behind the scenes using the currently logged in role.

Roles are defined at the system level, so they are valid for all databases in the system.

To bootstrap the WarehousePG cluster, a freshly initialized system always contains one predefined superuser role (also referred to as the system user). This role will have the same name as the operating system user that initialized the WarehousePG cluster. Customarily, this role is named `gpadmin`. To create more roles you first must connect as this initial role.

Managing Object Privileges

When an object (table, view, sequence, database, function, language, schema, or tablespace) is created, it is assigned an owner. The owner is normally the role that ran the creation statement. For most kinds of objects, the initial state is that only the owner (or a superuser) can do anything with the object. To allow other roles to use it, privileges must be granted. WarehousePG supports the following privileges for each object type:

Object Type	Privileges

Tables, Views, Sequences	`SELECT`
	`INSERT`
	`UPDATE`
	`DELETE`
	`RULE`
	`ALL`

External Tables	`SELECT`
	`RULE`
	`ALL`

Databases	`CONNECT`
	`CREATE`
	`TEMPORARY` or `TEMP`
	`ALL`

Functions	`EXECUTE`
Procedural Languages	`USAGE`

Schemas	`CREATE`
	`USAGE`
	`ALL`

Privileges must be granted for each object individually. For example, granting `ALL` on a database does not grant full access to the objects within that database. It only grants all of the database-level privileges (`CONNECT`, `CREATE`, `TEMPORARY`) to the database itself.

Use the `GRANT` SQL command to give a specified role privileges on an object. For example:

```
=# GRANT INSERT ON mytable TO jsmith;
```

To revoke privileges, use the `REVOKE` command. For example:

```
=# REVOKE ALL PRIVILEGES ON mytable FROM jsmith;
```

You can also use the `DROP OWNED` and `REASSIGN OWNED` commands for managing objects owned by deprecated roles. (Note: only an object's owner or a superuser can drop an object or reassign ownership.) For example:

```
=# REASSIGN OWNED BY sally TO bob;
=# DROP OWNED BY visitor;
```

Restricting Access by Time

WarehousePG enables the administrator to restrict access to certain times by role. Use the `CREATE ROLE` or `ALTER ROLE` commands to specify time-based constraints.

Access can be restricted by day or by day and time. The constraints are removable without deleting and recreating the role.

Time-based constraints only apply to the role to which they are assigned. If a role is a member of another role that contains a time constraint, the time constraint is not inherited.

Time-based constraints are enforced only during login. The `SET ROLE` and `SET SESSION AUTHORIZATION` commands are not affected by any time-based constraints.

Superuser or `CREATEROLE` privileges are required to set time-based constraints for a role. No one can add time-based constraints to a superuser.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

There are two ways to add time-based constraints. Use the keyword `DENY` in the `CREATE ROLE` or `ALTER ROLE` command followed by one of the following.

- A day, and optionally a time, when access is restricted. For example, no access on Wednesdays.
- An interval—that is, a beginning and ending day and optional time—when access is restricted. For example, no access from Wednesday 10 p.m. through Thursday at 8 a.m.

You can specify more than one restriction; for example, no access Wednesdays at any time and no access on Fridays between 3:00 p.m. and 5:00 p.m.

There are two ways to specify a day. Use the word `DAY` followed by either the English term for the weekday, in single quotation marks, or a number between 0 and 6, as shown in the table below.

English Term	Number
DAY 'Sunday'	DAY 0
DAY 'Monday'	DAY 1
DAY 'Tuesday'	DAY 2
DAY 'Wednesday'	DAY 3
DAY 'Thursday'	DAY 4
DAY 'Friday'	DAY 5
DAY 'Saturday'	DAY 6

A time of day is specified in either 12- or 24-hour format. The word `TIME` is followed by the specification in single quotation marks. Only hours and minutes are specified and are separated by a colon (:). If using a 12-hour format, add `AM` or `PM` at the end. The following examples show various time specifications.

```
TIME '14:00'     # 24-hour time implied
TIME '02:00 PM'  # 12-hour time specified by PM
TIME '02:00'     # 24-hour time implied. This is equivalent to TIME '02:00 AM'.
```

> **Important** Time-based authentication is enforced with the server time. Timezones are disregarded.

To specify an interval of time during which access is denied, use two day/time specifications with the words `BETWEEN` and `AND`, as shown. `DAY` is always required.

```
BETWEEN DAY 'Monday' AND DAY 'Tuesday'

BETWEEN DAY 'Monday' TIME '00:00' AND
        DAY 'Monday' TIME '01:00'

BETWEEN DAY 'Monday' TIME '12:00 AM' AND
        DAY 'Tuesday' TIME '02:00 AM'

BETWEEN DAY 'Monday' TIME '00:00' AND
        DAY 'Tuesday' TIME '02:00'
        DAY 2 TIME '02:00'
```

The last three statements are equivalent.

> **Note** Intervals of days cannot wrap past Saturday.

The following syntax is not correct:

```
DENY BETWEEN DAY 'Saturday' AND DAY 'Sunday'
```

The correct specification uses two DENY clauses, as follows:

```
DENY DAY 'Saturday'
DENY DAY 'Sunday'
```

The following examples demonstrate creating a role with time-based constraints and modifying a role to add time-based constraints. Only the statements needed for time-based constraints are shown. For more details on creating and altering roles see the descriptions of `CREATE ROLE` and `ALTER ROLE` in the *WarehousePG Reference Guide*.

Example 1 – Create a New Role with Time-based Constraints

No access is allowed on weekends.

```
CREATE ROLE generaluser
DENY DAY 'Saturday'
DENY DAY 'Sunday'
...
```

Example 2 – Alter a Role to Add Time-based Constraints

No access is allowed every night between 2:00 a.m. and 4:00 a.m.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

```
ALTER ROLE generaluser
 DENY BETWEEN DAY 'Monday' TIME '02:00' AND DAY 'Monday' TIME '04:00'
 DENY BETWEEN DAY 'Tuesday' TIME '02:00' AND DAY 'Tuesday' TIME '04:00'
 DENY BETWEEN DAY 'Wednesday' TIME '02:00' AND DAY 'Wednesday' TIME '04:00'
 DENY BETWEEN DAY 'Thursday' TIME '02:00' AND DAY 'Thursday' TIME '04:00'
 DENY BETWEEN DAY 'Friday' TIME '02:00' AND DAY 'Friday' TIME '04:00'
 DENY BETWEEN DAY 'Saturday' TIME '02:00' AND DAY 'Saturday' TIME '04:00'
 DENY BETWEEN DAY 'Sunday' TIME '02:00' AND DAY 'Sunday' TIME '04:00'
  ...
```

Excample 3 – Alter a Role to Add Time-based Constraints

No access is allowed Wednesdays or Fridays between 3:00 p.m. and 5:00 p.m.

```
ALTER ROLE generaluser
 DENY DAY 'Wednesday'
 DENY BETWEEN DAY 'Friday' TIME '15:00' AND DAY 'Friday' TIME '17:00'
```

Dropping a Time-based Restriction

To remove a time-based restriction, use the ALTER ROLE command. Enter the keywords DROP DENY FOR followed by a day/time specification to drop.

```
DROP DENY FOR DAY 'Sunday'
```

Any constraint containing all or part of the conditions in a DROP clause is removed. For example, if an existing constraint denies access on Mondays and Tuesdays, and the DROP clause removes constraints for Mondays, the existing constraint is completely dropped. The DROP clause completely removes all constraints that overlap with the constraint in the drop clause. The overlapping constraints are completely removed even if they contain more restrictions that the restrictions mentioned in the DROP clause.

Example 1 - Remove a Time-based Restriction from a Role

```
ALTER ROLE generaluser
DROP DENY FOR DAY 'Monday'
   ...
```

This statement would remove all constraints that overlap with a Monday constraint for the role `generaluser` in Example 2, even if there are additional constraints.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

5.5 Auditing

Describes WarehousePG events that are logged and should be monitored to detect security threats.

WarehousePG is capable of auditing a variety of events, including startup and shutdown of the system, segment database failures, SQL statements that result in an error, and all connection attempts and disconnections. WarehousePG also logs SQL statements and information regarding SQL statements, and can be configured in a variety of ways to record audit information with more or less detail. The `log_error_verbosity` configuration parameter controls the amount of detail written in the server log for each message that is logged. Similarly, the `log_min_error_statement` parameter allows administrators to configure the level of detail recorded specifically for SQL statements, and the `log_statement` parameter determines the kind of SQL statements that are audited. WarehousePG records the username for all auditable events, when the event is initiated by a subject outside the WarehousePG.

WarehousePG prevents unauthorized modification and deletion of audit records by only allowing administrators with an appropriate role to perform any operations on log files. Logs are stored in a proprietary format using comma-separated values (CSV). Each segment and the coordinator stores its own log files, although these can be accessed remotely by an administrator. WarehousePG also authorizes overwriting of old log files via the `log_truncate_on_rotation` parameter. This is a local parameter and must be set on each segment and coordinator configuration file.

WarehousePG provides an administrative schema called `gp_toolkit` that you can use to query log files, as well as system catalogs and operating environment for system status information. For more information, including usage, refer to *The gp_tookit Administrative Schema* appendix in the *WarehousePG Reference Guide*.

Viewing the Database Server Log Files

Every database instance in WarehousePG (coordinator and segments) is a running PostgreSQL database server with its own server log file. Daily log files are created in the `log` directory of the coordinator and each segment data directory.

The server log files are written in comma-separated values (CSV) format. Not all log entries will have values for all of the log fields. For example, only log entries associated with a query worker process will have the `slice_id` populated. Related log entries of a particular query can be identified by its session identifier (`gp_session_id`) and command identifier (`gp_command_count`).

#	Field Name	Data Type	Description
1	event_time	timestamp with time zone	Time that the log entry was written to the log
2	user_name	varchar(100)	The database user name
3	database_name	varchar(100)	The database name
4	process_id	varchar(10)	The system process id (prefixed with "p")
5	thread_id	varchar(50)	The thread count (prefixed with "th")
6	remote_host	varchar(100)	On the coordinator, the hostname/address of the client machine. On the segment, the hostname/address of the coordinator.
7	remote_port	varchar(10)	The segment or coordinator port number
8	session_start_time	timestamp with time zone	Time session connection was opened
9	transaction_id	int	Top-level transaction ID on the coordinator. This ID is the parent of any subtransactions.
10	gp_session_id	text	Session identifier number (prefixed with "con")
11	gp_command_count	text	The command number within a session (prefixed with "cmd")
12	gp_segment	text	The segment content identifier (prefixed with "seg" for primaries or "mir" for mirrors). The coordinator always has a content id of -1.
13	slice_id	text	The slice id (portion of the query plan being run)
14	distr_tranx_id text	Distributed transaction ID	
15	local_tranx_id	text	Local transaction ID
16	sub_tranx_id	text	Subtransaction ID
17	event_severity	varchar(10)	Values include: LOG, ERROR, FATAL, PANIC, DEBUG1, DEBUG2
18	sql_state_code	varchar(10)	SQL state code associated with the log message
19	event_message	text	Log or error message text
20	event_detail	text	Detail message text associated with an error or warning message
21	event_hint	text	Hint message text associated with an error or warning message
22	internal_query	text	The internally-generated query text
23	internal_query_pos	int	The cursor index into the internally-generated query text
24	event_context	text	The context in which this message gets generated
25	debug_query_string	text	User-supplied query string with full detail for debugging. This string can be modified for internal use.
26	error_cursor_pos	int	The cursor index into the query string
27	func_name	text	The function in which this message is generated
28	file_name	text	The internal code file where the message originated
29	file_line	int	The line of the code file where the message originated
30	stack_trace	text	Stack trace text associated with this message

WarehousePG provides a utility called `gplogfilter` that can be used to search through a WarehousePG log file for entries matching the specified criteria. By default, this utility searches through the WarehousePG coordinator log file in the default logging location. For example, to display the last three lines of the coordinator log file:

```
$ gplogfilter -n 3
```

You can also use `gplogfilter` to search through all segment log files at once by running it through the `gpssh` utility. For example, to display the last three lines of each segment log file:

```
$ gpssh -f seg_host_file
  => source /usr/edb/whpg7/greenplum_path.sh
  => gplogfilter -n 3 /data*/*/gp*/pg_log/gpdb*.csv
```

The following are the WarehousePG security-related audit (or logging) server configuration parameters that are set in the postgresql.conf configuration file:

Field Name	Value Range	Default	Description
log_connections	Boolean	off	This outputs a line to the server log detailing each successful connection. Some client programs, like psql, attempt to connect twice while determining if a password is required, so duplicate “connection received” messages do not always indicate a problem.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Field Name	Value Range	Default	Description
log_disconnections	Boolean	off	This outputs a line in the server log at termination of a client session, and includes the duration of the session.
log_statement	NONE DDL MOD ALL	ALL	Controls which SQL statements are logged. DDL logs all data definition commands like CREATE, ALTER, and DROP commands. MOD logs all DDL statements, plus INSERT, UPDATE, DELETE, TRUNCATE, and COPY FROM. PREPARE and EXPLAIN ANALYZE statements are also logged if their contained command is of an appropriate type.
log_hostname	Boolean	off	By default, connection log messages only show the IP address of the connecting host. Turning on this option causes logging of the host name as well. Note that depending on your host name resolution setup this might impose a non-negligible performance penalty.
log_duration	Boolean	off	Causes the duration of every completed statement which satisfies log_statement to be logged.
log_error_verbosity	TERSE DEFAULT VERBOSE	DEFAULT	Controls the amount of detail written in the server log for each message that is logged.
log_min_duration_statement	number of milliseconds, 0, -1	-1	Logs the statement and its duration on a single log line if its duration is greater than or equal to the specified number of milliseconds. Setting this to 0 will print all statements and their durations. -1 deactivates the feature. For example, if you set it to 250 then all SQL statements that run 250ms or longer will be logged. Enabling this option can be useful in tracking down unoptimized queries in your applications.
log_min_messages	DEBUG5 DEBUG4 DEBUG3 DEBUG2 DEBUG1 INFO NOTICE WARNING ERROR LOG FATAL PANIC	NOTICE	Controls which message levels are written to the server log. Each level includes all the levels that follow it. The later the level, the fewer messages are sent to the log.
log_rotation_size	0 - INT_MAX/1024 kilobytes	1048576	When greater than 0, a new log file is created when this number of kilobytes have been written to the log. Set to zero to deactivate size-based creation of new log files.
log_rotation_age	Any valid time expression (number and unit)	1d	Determines the lifetime of an individual log file. When this amount of time has elapsed since the current log file was created, a new log file will be created. Set to zero to deactivate time-based creation of new log files.
log_statement_stats	Boolean	off	For each query, write total performance statistics of the query parser, planner, and executor to the server log. This is a crude profiling instrument.
log_truncate_on_rotation	Boolean	off	Truncates (overwrites), rather than appends to, any existing log file of the same name. Truncation will occur only when a new file is being opened due to time-based rotation. For example, using this setting in combination with a log_filename such as gpseg#-%H.log would result in generating twenty-four hourly log files and then cyclically overwriting them. When off, pre-existing files will be appended to in all cases.

5.6 Encrypting Data and Database Connections

This topic describes how to encrypt data at rest in the database or in transit over the network, to protect from eavesdroppers or man-in-the-middle attacks.

- Connections between clients and the coordinator database can be encrypted with SSL. This is enabled with the `ssl` server configuration parameter, which is `off` by default. Setting the `ssl` parameter to `on` allows client communications with the coordinator to be encrypted. The coordinator database must be set up for SSL. See OpenSSL Configuration for more about encrypting client connections with SSL.
- WarehousePG allows SSL encryption of data in transit between the WarehousePG parallel file distribution server, `gpfdist` , and segment hosts. See Encrypting gpfdist Connections for more information.
- The `pgcrypto` module of encryption/decryption functions protects data at rest in the database. Encryption at the column level protects sensitive information, such as social security numbers or credit card numbers. See Encrypting Data at Rest with pgcrypto for more information.

Parent topic: WarehousePG Security Configuration Guide

Encrypting gpfdist Connections

The `gpfdists` protocol is a secure version of the `gpfdist` protocol that securely identifies the file server and the WarehousePG and encrypts the communications between them. Using `gpfdists` protects against eavesdropping and man-in-the-middle attacks.

The `gpfdists` protocol implements client/server SSL security with the following notable features:

- Client certificates are required.
- Multilingual certificates are not supported.
- A Certificate Revocation List (CRL) is not supported.
- A minimum TLS version of 1.2 is required.
- SSL renegotiation is supported.
- The SSL ignore host mismatch parameter is set to false.
- Private keys containing a passphrase are not supported for the `gpfdist` file server (server.key) or for the WarehousePG (client.key).
- It is the user's responsibility to issue certificates that are appropriate for the operating system in use. Generally, converting certificates to the required format is supported, for example using the SSL Converter at https://www.sslshopper.com/ssl-converter.html.

A `gpfdist` server started with the `--ssl` option can only communicate with the `gpfdists` protocol. A `gpfdist` server started without the `--ssl` option can only communicate with the `gpfdist` protocol. For more detail about `gpfdist` refer to the *WarehousePG Administrator Guide*.

There are two ways to enable the `gpfdists` protocol:

- Run `gpfdist` with the `--ssl` option and then use the `gpfdists` protocol in the `LOCATION` clause of a `CREATE EXTERNAL TABLE` statement.
- Use a YAML control file with the SSL option set to true and run `gpload` . Running `gpload` starts the `gpfdist` server with the `--ssl` option and then uses the `gpfdists` protocol.

When using gpfdists, the following client certificates must be located in the `$PGDATA/gpfdists` directory on each segment:

- The client certificate file, `client.crt`
- The client private key file, `client.key`
- The trusted certificate authorities, `root.crt`

> **Important** Do not protect the private key with a passphrase. The server does not prompt for a passphrase for the private key, and loading data fails with an error if one is required.

When using `gpload` with SSL you specify the location of the server certificates in the YAML control file. When using `gpfdist` with SSL, you specify the location of the server certificates with the --ssl option.

The following example shows how to securely load data into an external table. The example creates a readable external table named `ext_expenses` from all files with the `txt` extension, using the `gpfdists` protocol. The files are formatted with a pipe (`|`) as the column delimiter and an empty space as null.

1. Run `gpfdist` with the `--ssl` option on the segment hosts.
2. Log into the database and run the following command:

```
=# CREATE EXTERNAL TABLE ext_expenses
   ( name text, date date, amount float4, category text, desc1 text )
LOCATION ('gpfdists://etlhost-1:8081/*.txt', 'gpfdists://etlhost-2:8082/*.txt')
FORMAT 'TEXT' ( DELIMITER '|' NULL ' ') ;
```

Encrypting Data at Rest with pgcrypto

The pgcrypto module for WarehousePG provides functions for encrypting data at rest in the database. Administrators can encrypt columns with sensitive information, such as social security numbers or credit card numbers, to provide an extra layer of protection. Database data stored in encrypted form cannot be read by users who do not have the encryption key, and the data cannot be read directly from disk.

pgcrypto is installed by default when you install WarehousePG. You must explicitly enable pgcrypto in each database in which you want to use the module.

pgcrypto allows PGP encryption using symmetric and asymmetric encryption. Symmetric encryption encrypts and decrypts data using the same key and is faster than asymmetric encryption. It is the preferred method in an environment where exchanging secret keys is not an issue. With asymmetric encryption, a public key is used to encrypt data and a private key is used to decrypt data. This is slower then symmetric encryption and it requires a stronger key.

Using pgcrypto always comes at the cost of performance and maintainability. It is important to use encryption only with the data that requires it. Also, keep in mind that you cannot search encrypted data by indexing the data.

Before you implement in-database encryption, consider the following PGP limitations.

- No support for signing. That also means that it is not checked whether the encryption sub-key belongs to the coordinator key.
- No support for encryption key as coordinator key. This practice is generally discouraged, so this limitation should not be a problem.
- No support for several subkeys. This may seem like a problem, as this is common practice. On the other hand, you should not use your regular GPG/PGP keys with pgcrypto, but create new ones, as the usage scenario is rather different.

WarehousePG is compiled with zlib by default; this allows PGP encryption functions to compress data before encrypting. When compiled with OpenSSL, more algorithms will be available.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Because pgcrypto functions run inside the database server, the data and passwords move between pgcrypto and the client application in clear-text. For optimal security, you should connect locally or use SSL connections and you should trust both the system and database administrators.

pgcrypto configures itself according to the findings of the main PostgreSQL configure script.

When compiled with `zlib`, pgcrypto encryption functions are able to compress data before encrypting.

Pgcrypto has various levels of encryption ranging from basic to advanced built-in functions. The following table shows the supported encryption algorithms.

Value Functionality	Built-in	With OpenSSL
MD5	yes	yes
SHA1	yes	yes
SHA224/256/384/512	yes	yes [^1]
Other digest algorithms	no	yes [^2]
Blowfish	yes	yes
AES	yes	yes [^3]
DES/3DES/CAST5	no	yes
Raw Encryption	yes	yes
PGP Symmetric-Key	yes	yes
PGP Public Key	yes	yes

Creating PGP Keys

To use PGP asymmetric encryption in WarehousePG, you must first create public and private keys and install them.

This section assumes you are installing WarehousePG on a Linux machine with the Gnu Privacy Guard (`gpg`) command line tool. Use the latest version of GPG to create keys. Download and install Gnu Privacy Guard (GPG) for your operating system from https://www.gnupg.org/download/. On the GnuPG website you will find installers for popular Linux distributions and links for Windows and Mac OS X installers.

1. As root, run the following command and choose option 1 from the menu:

```
# gpg --gen-key
gpg (GnuPG) 2.0.14; Copyright (C) 2009 Free Software Foundation, Inc.
This is free software: you are free to change and redistribute it.
There is NO WARRANTY, to the extent permitted by law.

gpg: directory '/root/.gnupg' created
gpg: new configuration file '/root/.gnupg/gpg.conf' created
gpg: WARNING: options in '/root/.gnupg/gpg.conf' are not yet active during this run
gpg: keyring '/root/.gnupg/secring.gpg' created
gpg: keyring '/root/.gnupg/pubring.gpg' created
Please select what kind of key you want:
 (1) RSA and RSA (default)
 (2) DSA and Elgamal
 (3) DSA (sign only)
 (4) RSA (sign only)
Your selection? **1**
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

2. Respond to the prompts and follow the instructions, as shown in this example:

```
RSA keys may be between 1024 and 4096 bits long.
What keysize do you want? (2048) Press enter to accept default key size
Requested keysize is 2048 bits
Please specify how long the key should be valid.
 0 = key does not expire
 <n> = key expires in n days
 <n>w = key expires in n weeks
 <n>m = key expires in n months
 <n>y = key expires in n years
 Key is valid for? (0) **365**
Key expires at Wed 13 Jan 2016 10:35:39 AM PST
Is this correct? (y/N) **y**

GnuPG needs to construct a user ID to identify your key.

Real name: **John Doe**
Email address: **jdoe@email.com**
Comment:
You selected this USER-ID:
 "John Doe <jdoe@email.com>"

Change (N)ame, (C)omment, (E)mail or (O)kay/(Q)uit? **O**
You need a Passphrase to protect your secret key.
*\(For this demo the passphrase is blank.\)*
can't connect to '/root/.gnupg/S.gpg-agent': No such file or directory
You don't want a passphrase - this is probably a *bad* idea!
I will do it anyway.  You can change your passphrase at any time,
using this program with the option "--edit-key".

We need to generate a lot of random bytes. It is a good idea to perform
some other action (type on the keyboard, move the mouse, utilize the
disks) during the prime generation; this gives the random number
generator a better chance to gain enough entropy.
We need to generate a lot of random bytes. It is a good idea to perform
some other action (type on the keyboard, move the mouse, utilize the
disks) during the prime generation; this gives the random number
generator a better chance to gain enough entropy.
gpg: /root/.gnupg/trustdb.gpg: trustdb created
gpg: key 2027CC30 marked as ultimately trusted
public and secret key created and signed.

gpg:  checking the trustdbgpg:
      3 marginal(s) needed, 1 complete(s) needed, PGP trust model
gpg:  depth: 0  valid1  signed0  trust: 0-, 0q, 0n, 0m, 0f, 1u
gpg:  next trustdb check due at 2016-01-13
pub   2048R/2027CC30 2015-01-13 [expires: 2016-01-13]
      Key fingerprint = 7EDA 6AD0 F5E0 400F 4D45   3259 077D 725E 2027 CC30
uid                  John Doe <jdoe@email.com>
sub   2048R/4FD2EFBB 2015-01-13 [expires: 2016-01-13]
```

3. List the PGP keys by entering the following command:

```
gpg --list-secret-keys
/root/.gnupg/secring.gpg
------------------------
sec   2048R/2027CC30 2015-01-13 [expires: 2016-01-13]
uid                  John Doe <jdoe@email.com>
ssb   2048R/4FD2EFBB 2015-01-13
```

2027CC30 is the public key and will be used to *encrypt* data in the database. 4FD2EFBB is the private (secret) key and will be used to *decrypt* data.

4. Export the keys using the following commands:

```
# gpg -a --export 4FD2EFBB > public.key
# gpg -a --export-secret-keys 2027CC30 > secret.key
```

See the pgcrypto documentation for more information about PGP encryption functions.

Encrypting Data in Tables using PGP

This section shows how to encrypt data inserted into a column using the PGP keys you generated.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

1. Dump the contents of the `public.key` file and then copy it to the clipboard:

```
# cat public.key
-----BEGIN PGP PUBLIC KEY BLOCK-----

-----END PGP PUBLIC KEY BLOCK-----'));

pgp_key_id | 9D4D255F4FD2EFBB
```

This shows that the PGP key ID used to encrypt the `ssn` column is 9D4D255F4FD2EFBB. It is recommended to perform this step whenever a new key is created and then store the ID for tracking.

You can use this key to see which key pair was used to encrypt the data:

```
SELECT username, pgp_key_id(ssn) As key_used
FROM userssn;
username | Bob
key_used | 9D4D255F4FD2EFBB
---------+-----------------
username | Alice
key_used | 9D4D255F4FD2EFBB
```

> **Note** Different keys may have the same ID. This is rare, but is a normal event. The client application should try to decrypt with each one to see which fits — like handling `ANYKEY`. See pgp_key_id() in the pgcrypto documentation.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

5. Decrypt the data using the private key.

```
SELECT username, pgp_pub_decrypt(ssn, keys.privkey)
                AS decrypted_ssn FROM userssn
                CROSS JOIN
                (SELECT dearmor('-----BEGIN PGP PRIVATE KEY BLOCK-----

```

If you created a key with passphrase, you may have to enter it here. However for the purpose of this example, the passphrase is blank.

Key Management

Whether you are using symmetric (single private key) or asymmetric (public and private key) cryptography, it is important to store the coordinator or private key securely. There are many options for storing encryption keys, for example, on a file system, key vault, encrypted USB, trusted platform module (TPM), or hardware security module (HSM).

Consider the following questions when planning for key management:

- Where will the keys be stored?
- When should keys expire?
- How are keys protected?
- How are keys accessed?
- How can keys be recovered and revoked?

The Open Web Application Security Project (OWASP) provides a very comprehensive guide to securing encryption keys.

[^1]: SHA2 algorithms were added to OpenSSL in version 0.9.8. For older versions, pgcrypto will use built-in code.

[^2]: Any digest algorithm OpenSSL supports is automatically picked up. This is not possible with ciphers, which need to be supported explicitly.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

[^3]: AES is included in OpenSSL since version 0.9.7. For older versions, pgcrypto will use built-in code.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

5.7 Security Best Practices

Describes basic security best practices that you should follow to ensure the highest level of system security.

In the default WarehousePG security configuration:

- Only local connections are allowed.
- Basic authentication is configured for the superuser (`gpadmin`).
- The superuser is authorized to do anything.
- Only database role passwords are encrypted.

System User (gpadmin)

Secure and limit access to the `gpadmin` system user.

WarehousePG requires a UNIX user id to install and initialize the WarehousePG cluster. This system user is referred to as `gpadmin` in the WarehousePG documentation. The `gpadmin` user is the default database superuser in WarehousePG, as well as the file system owner of the WarehousePG installation and its underlying data files. The default administrator account is fundamental to the design of WarehousePG. The system cannot run without it, and there is no way to limit the access of the `gpadmin` user id.

The `gpadmin` user can bypass all security features of WarehousePG. Anyone who logs on to a WarehousePG host with this user id can read, alter, or delete any data, including system catalog data and database access rights. Therefore, it is very important to secure the `gpadmin` user id and only allow essential system administrators access to it.

Administrators should only log in to WarehousePG as `gpadmin` when performing certain system maintenance tasks (such as upgrade or expansion).

Database users should never log on as `gpadmin` , and ETL or production workloads should never run as `gpadmin` .

Superusers

Roles granted the `SUPERUSER` attribute are superusers. Superusers bypass all access privilege checks and resource queues. Only system administrators should be given superuser rights.

See "Altering Role Attributes" in the *WarehousePG Administrator Guide*.

Login Users

Assign a distinct role to each user who logs in and set the `LOGIN` attribute.

For logging and auditing purposes, each user who is allowed to log in to WarehousePG should be given their own database role. For applications or web services, consider creating a distinct role for each application or service. See "Creating New Roles (Users)" in the *WarehousePG Administrator Guide*.

Each login role should be assigned to a single, non-default resource queue.

Groups

Use groups to manage access privileges.

Create a group for each logical grouping of object/access permissions.

Every login user should belong to one or more roles. Use the `GRANT` statement to add group access to a role. Use the `REVOKE` statement to remove group access from a role.

The `LOGIN` attribute should not be set for group roles.

See "Creating Groups (Role Membership)" in the *WarehousePG Administrator Guide*.

Object Privileges

Only the owner and superusers have full permissions to new objects. Permission must be granted to allow other rules (users or groups) to access objects. Each type of database object has different privileges that may be granted. Use the `GRANT` statement to add a permission to a role and the `REVOKE` statement to remove the permission.

You can change the owner of an object using the `REASSIGN OWNED BY` statement. For example, to prepare to drop a role, change the owner of the objects that belong to the role. Use the `DROP OWNED BY` to drop objects, including dependent objects, that are owned by a role.

Schemas can be used to enforce an additional layer of object permissions checking, but schema permissions do not override object privileges set on objects contained within the schema.

Operating System Users and File System

> **Note** Commands shown in this section should be run as the root user.

To protect the network from intrusion, system administrators should verify the passwords used within an organization are sufficiently strong. The following recommendations can strengthen a password:

- Minimum password length recommendation: At least 9 characters. MD5 passwords should be 15 characters or longer.
- Mix upper and lower case letters.
- Mix letters and numbers.
- Include non-alphanumeric characters.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

- Pick a password you can remember.

The following are recommendations for password cracker software that you can use to determine the strength of a password.

- John The Ripper. A fast and flexible password cracking program. It allows the use of multiple word lists and is capable of brute-force password cracking. It is available online at http://www.openwall.com/john/.
- Crack. Perhaps the most well-known password cracking software, Crack is also very fast, though not as easy to use as John The Ripper. It can be found online at https://dropsafe.crypticide.com/alecm/software/crack/c50-faq.html.

The security of the entire system depends on the strength of the root password. This password should be at least 12 characters long and include a mix of capitalized letters, lowercase letters, special characters, and numbers. It should not be based on any dictionary word.

Password expiration parameters should be configured. The following commands must be run as `root` or using `sudo`.

Ensure the following line exists within the file `/etc/libuser.conf` under the `[import]` section.

```
login_defs = /etc/login.defs
```

Ensure no lines in the `[userdefaults]` section begin with the following text, as these words override settings from `/etc/login.defs`:

- `LU_SHADOWMAX`
- `LU_SHADOWMIN`
- `LU_SHADOWWARNING`

Ensure the following command produces no output. Any accounts listed by running this command should be locked.

```
grep "^+:" /etc/passwd /etc/shadow /etc/group
```

Note: We strongly recommend that customers change their passwords after initial setup.

```
cd /etc
chown root:root passwd shadow group gshadow
chmod 644 passwd group
chmod 400 shadow gshadow
```

Find all the files that are world-writable and that do not have their sticky bits set.

```
find / -xdev -type d \( -perm -0002 -a ! -perm -1000 \) -print
```

Set the sticky bit (`# chmod +t {dir}`) for all the directories that result from running the previous command.

Find all the files that are world-writable and fix each file listed.

```
find / -xdev -type f -perm -0002 -print
```

Set the right permissions (`# chmod o-w {file}`) for all the files generated by running the aforementioned command.

Find all the files that do not belong to a valid user or group and either assign an owner or remove the file, as appropriate.

```
find / -xdev \( -nouser -o -nogroup \) -print
```

Find all the directories that are world-writable and ensure they are owned by either root or a system account (assuming only system accounts have a User ID lower than 500). If the command generates any output, verify the assignment is correct or reassign it to root.

```
find / -xdev -type d -perm -0002 -uid +500 -print
```

Authentication settings such as password quality, password expiration policy, password reuse, password retry attempts, and more can be configured using the Pluggable Authentication Modules (PAM) framework. PAM looks in the directory `/etc/pam.d` for application-specific configuration information. Running `authconfig` or `system-config-authentication` will re-write the PAM configuration files, destroying any manually made changes and replacing them with system defaults.

The default `pam_cracklib` PAM module provides strength checking for passwords. To configure `pam_cracklib` to require at least one uppercase character, lowercase character, digit, and special character, as recommended by the U.S. Department of Defense guidelines, edit the file `/etc/pam.d/system-auth` to include the following parameters in the line corresponding to password requisite `pam_cracklib.so try_first_pass`.

```
retry=3:
dcredit=-1. Require at least one digit
ucredit=-1. Require at least one upper case character
ocredit=-1. Require at least one special character
lcredit=-1. Require at least one lower case character
minlen=14. Require a minimum password length of 14.
```

For example:

```
password required pam_cracklib.so try_first_pass retry=3\minlen=14 dcredit=-1 ucredit=-1 ocredit=-1 lcredit=-1
```

These parameters can be set to reflect your security policy requirements. Note that the password restrictions are not applicable to the root password.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

The `pam_tally2` PAM module provides the capability to lock out user accounts after a specified number of failed login attempts. To enforce password lockout, edit the file `/etc/pam.d/system-auth` to include the following lines:

- The first of the auth lines should include:

```
auth required pam_tally2.so deny=5 onerr=fail unlock_time=900
```

- The first of the account lines should include:

```
account required pam_tally2.so
```

Here, the deny parameter is set to limit the number of retries to 5 and the `unlock_time` has been set to 900 seconds to keep the account locked for 900 seconds before it is unlocked. These parameters may be configured appropriately to reflect your security policy requirements. A locked account can be manually unlocked using the `pam_tally2` utility:

```
/sbin/pam_tally2 --user {username} --reset
```

You can use PAM to limit the reuse of recent passwords. The remember option for the `pam_ unix` module can be set to remember the recent passwords and prevent their reuse. To accomplish this, edit the appropriate line in `/etc/pam.d/system-auth` to include the remember option.

For example:

```
password sufficient pam_unix.so [ … existing_options …]
remember=5
```

You can set the number of previous passwords to remember to appropriately reflect your security policy requirements.

```
cd /etc
chown root:root passwd shadow group gshadow
chmod 644 passwd group
chmod 400 shadow gshadow
```

6 WarehousePG best practices

A best practice is a method or technique that has consistently shown results superior to those achieved with other means. Best practices are found through experience and are proven to reliably lead to a desired result. Best practices are a commitment to use any product correctly and optimally, by leveraging all the knowledge and expertise available to ensure success.

This document does not teach you how to use WarehousePG features. Links are provided to other relevant parts of the WarehousePG documentation for information on how to use and implement specific WarehousePG features. This document addresses the most important best practices to follow when designing, implementing, and using WarehousePG.

It is not the intent of this document to cover the entire product or compendium of features, but rather to provide a summary of *what matters most* in WarehousePG. This document does not address *edge* use cases. While edge use cases can further leverage and benefit from WarehousePG features, they require a proficient knowledge and expertise with these features, as well as a deep understanding of your environment, including SQL access, query execution, concurrency, workload, and other factors.

By following these best practices, you will increase the success of your WarehousePG clusters in the areas of maintenance, support, performance, and scalability.

- Best Practices Summary
  A summary of best practices for WarehousePG.
- System Configuration
  Requirements and best practices for system administrators who are configuring WarehousePG cluster hosts.
- Schema Design
  Best practices for designing WarehousePG schemas.
- Memory and Resource Management with Resource Groups
  Managing WarehousePG resources with resource groups.
- Memory and Resource Management with Resource Queues
  Avoid memory errors and manage WarehousePG resources.
- System Monitoring and Maintenance
  Best practices for regular maintenance that will ensure WarehousePG high availability and optimal performance.
- Loading Data
  Description of the different ways to add data to WarehousePG.
- Security
  Best practices to ensure the highest level of system security.
- Encrypting Data and Database Connections
  Best practices for implementing encryption and managing keys.
- Tuning SQL Queries
  The WarehousePG cost-based optimizer evaluates many strategies for running a query and chooses the least costly method.
- High Availability
  WarehousePG supports highly available, fault-tolerant database services when you enable and properly configure WarehousePG high availability features. To guarantee a required level of service, each component must have a standby ready to take its place if it should fail.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

6.1 Best Practices Summary

A summary of best practices for WarehousePG.

Data Model

WarehousePG is an analytical MPP shared-nothing database. This model is significantly different from a highly normalized/transactional SMP database. Because of this, the following best practices are recommended.

- WarehousePG performs best with a denormalized schema design suited for MPP analytical processing for example, Star or Snowflake schema, with large fact tables and smaller dimension tables.
- Use the same data types for columns used in joins between tables.

See Schema Design.

Heap vs. Append-Optimized Storage

- Use heap storage for tables and partitions that will receive iterative batch and singleton `UPDATE`, `DELETE`, and `INSERT` operations.
- Use heap storage for tables and partitions that will receive concurrent `UPDATE`, `DELETE`, and `INSERT` operations.
- Use append-optimized storage for tables and partitions that are updated infrequently after the initial load and have subsequent inserts only performed in large batch operations.
- Avoid performing singleton `INSERT`, `UPDATE`, or `DELETE` operations on append-optimized tables.
- Avoid performing concurrent batch `UPDATE` or `DELETE` operations on append-optimized tables. Concurrent batch `INSERT` operations are acceptable.

See Heap Storage or Append-Optimized Storage.

Row vs. Column Oriented Storage

- Use row-oriented storage for workloads with iterative transactions where updates are required and frequent inserts are performed.
- Use row-oriented storage when selects against the table are wide.
- Use row-oriented storage for general purpose or mixed workloads.
- Use column-oriented storage where selects are narrow and aggregations of data are computed over a small number of columns.
- Use column-oriented storage for tables that have single columns that are regularly updated without modifying other columns in the row.

See Row or Column Orientation.

Compression

- Use compression on large append-optimized and partitioned tables to improve I/O across the system.
- Set the column compression settings at the level where the data resides.
- Balance higher levels of compression with the time and CPU cycles needed to compress and uncompress data.

See Compression.

Distributions

- Explicitly define a column or random distribution for all tables. Do not use the default.
- Use a single column that will distribute data across all segments evenly.
- Do not distribute on columns that will be used in the `WHERE` clause of a query.
- Do not distribute on dates or timestamps.
- Never distribute and partition tables on the same column.
- Achieve local joins to significantly improve performance by distributing on the same column for large tables commonly joined together.
- To ensure there is no data skew, validate that data is evenly distributed after the initial load and after incremental loads.

See Distributions.

Resource Queue Memory Management

- Set `vm.overcommit_memory` to 2.
- Do not configure the OS to use huge pages.
- Use `gp_vmem_protect_limit` to set the maximum memory that the instance can allocate for *all* work being done in each segment database.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

- You can use `gp_vmem_protect_limit` by calculating:
  - `gp_vmem` – the total memory available to WarehousePG
    - If the total system memory is less than 256 GB, use this formula:

      ```
      gp_vmem = ((SWAP + RAM) – (7.5GB + 0.05 * RAM)) / 1.7
      ```

    - If the total system memory is equal to or greater than 256 GB, use this formula:

      ```
      gp_vmem = ((SWAP + RAM) – (7.5GB + 0.05 * RAM)) / 1.17
      ```

    where `SWAP` is the host's swap space in GB, and `RAM` is the host's RAM in GB.
  - `max_acting_primary_segments` – the maximum number of primary segments that could be running on a host when mirror segments are activated due to a host or segment failure.
  - `gp_vmem_protect_limit`

    ```
    gp_vmem_protect_limit = gp_vmem / acting_primary_segments
    ```

    Convert to MB to set the value of the configuration parameter.
- In a scenario where a large number of workfiles are generated calculate the `gp_vmem` factor with this formula to account for the workfiles.
  - If the total system memory is less than 256 GB:

    ```
    gp_vmem = ((SWAP + RAM) – (7.5GB + 0.05 * RAM – (300KB *
          total_#_workfiles))) / 1.7
    ```

  - If the total system memory is equal to or greater than 256 GB:

    ```
    gp_vmem = ((SWAP + RAM) – (7.5GB + 0.05 * RAM – (300KB *
          total_#_workfiles))) / 1.17
    ```

- Never set `gp_vmem_protect_limit` too high or larger than the physical RAM on the system.
- Use the calculated `gp_vmem` value to calculate the setting for the `vm.overcommit_ratio` operating system parameter:

  ```
  vm.overcommit_ratio = (RAM – 0.026 * gp_vmem) / RAM
  ```

- Use `statement_mem` to allocate memory used for a query per segment db.
- Use resource queues to set both the numbers of active queries (`ACTIVE_STATEMENTS`) and the amount of memory (`MEMORY_LIMIT`) that can be utilized by queries in the queue.
- Associate all users with a resource queue. Do not use the default queue.
- Set `PRIORITY` to match the real needs of the queue for the workload and time of day. Avoid using MAX priority.
- Ensure that resource queue memory allocations do not exceed the setting for `gp_vmem_protect_limit`.
- Dynamically update resource queue settings to match daily operations flow.

See Setting the WarehousePG Recommended OS Parameters and Memory and Resource Management with Resource Queues.

Partitioning

- Partition large tables only. Do not partition small tables.
- Use partitioning only if partition elimination (partition pruning) can be achieved based on the query criteria.
- Choose range partitioning over list partitioning.
- Partition the table based on a commonly-used column, such as a date column.
- Never partition and distribute tables on the same column.
- Do not use default partitions.
- Do not use multi-level partitioning; create fewer partitions with more data in each partition.
- Validate that queries are selectively scanning partitioned tables (partitions are being eliminated) by examining the query `EXPLAIN` plan.
- Do not create too many partitions with column-oriented storage because of the total number of physical files on every segment: `physical files = segments x columns x partitions`

See Partitioning.

Indexes

- In general indexes are not needed in WarehousePG.
- Create an index on a single column of a columnar table for drill-through purposes for high cardinality tables that require queries with high selectivity.
- Do not index columns that are frequently updated.
- Consider dropping indexes before loading data into a table. After the load, re-create the indexes for the table.
- Create selective B-tree indexes.
- Do not create bitmap indexes on columns that are updated.
- Avoid using bitmap indexes for unique columns, very high or very low cardinality data. Bitmap indexes perform best when the column has a low cardinality—100 to 100,000 distinct values.
- Do not use bitmap indexes for transactional workloads.
- In general do not index partitioned tables. If indexes are needed, the index columns must be different than the partition columns.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

See Indexes.

Resource Queues

- Use resource queues to manage the workload on the cluster.
- Associate all roles with a user-defined resource queue.
- Use the `ACTIVE_STATEMENTS` parameter to limit the number of active queries that members of the particular queue can run concurrently.
- Use the `MEMORY_LIMIT` parameter to control the total amount of memory that queries running through the queue can utilize.
- Alter resource queues dynamically to match the workload and time of day.

See Configuring Resource Queues.

Monitoring and Maintenance

- Implement the "Recommended Monitoring and Maintenance Tasks" in the *WarehousePG Administrator Guide*.
- Run `gpcheckperf` at install time and periodically thereafter, saving the output to compare system performance over time.
- Use all the tools at your disposal to understand how your system behaves under different loads.
- Examine any unusual event to determine the cause.
- Monitor query activity on the system by running explain plans periodically to ensure the queries are running optimally.
- Review plans to determine whether index are being used and partition elimination is occurring as expected.
- Know the location and content of system log files and monitor them on a regular basis, not just when problems arise.

See System Monitoring and Maintenance, Query Profiling and Monitoring WarehousePG Log Files.

ANALYZE

- Determine if analyzing the database is actually needed. Analyzing is not needed if `gp_autostats_mode` is set to `on_no_stats` (the default) and the table is not partitioned.
- Use `analyzedb` in preference to `ANALYZE` when dealing with large sets of tables, as it does not require analyzing the entire database. The `analyzedb` utility updates statistics data for the specified tables incrementally and concurrently. For append optimized tables, `analyzedb` updates statistics incrementally only if the statistics are not current. For heap tables, statistics are always updated. `ANALYZE` does not update the table metadata that the `analyzedb` utility uses to determine whether table statistics are up to date.
- Selectively run `ANALYZE` at the table level when needed.
- Always run `ANALYZE` after `INSERT`, `UPDATE`. and `DELETE` operations that significantly changes the underlying data.
- Always run `ANALYZE` after `CREATE INDEX` operations.
- If `ANALYZE` on very large tables takes too long, run `ANALYZE` only on the columns used in a join condition, `WHERE` clause, `SORT`, `GROUP BY`, or `HAVING` clause.
- When dealing with large sets of tables, use `analyzedb` instead of `ANALYZE.`
- Run `analyzedb` on the root partition any time that you add a new partition(s) to a partitioned table. This operation both analyzes the leaf partitions in parallel and merges any updated statistics into the root partition.

See Updating Statistics with ANALYZE.

Vacuum

- Run `VACUUM` after large `UPDATE` and `DELETE` operations.
- Do not run `VACUUM FULL`. Instead run a `CREATE TABLE...AS` operation, then rename and drop the original table.
- Frequently run `VACUUM` on the system catalogs to avoid catalog bloat and the need to run `VACUUM FULL` on catalog tables.
- Never issue a `kill` command against `VACUUM` on catalog tables.

See Managing Bloat in a Database.

Loading

- Maximize the parallelism as the number of segments increase.
- Spread the data evenly across as many ETL nodes as possible.
  - Split very large data files into equal parts and spread the data across as many file systems as possible.
  - Run two `gpfdist` instances per file system.
  - Run `gpfdist` on as many interfaces as possible.
  - Use `gp_external_max_segs` to control the number of segments that will request data from the `gpfdist` process.
  - Always keep `gp_external_max_segs` and the number of `gpfdist` processes an even factor.

- Always drop indexes before loading into existing tables and re-create the index after loading.
- Run `VACUUM` after load errors to recover space.

See Loading Data.

Security

- Secure the `gpadmin` user id and only allow essential system administrators access to it.
- Administrators should only log in to WarehousePG as `gpadmin` when performing certain system maintenance tasks (such as upgrade or expansion).
- Limit users who have the `SUPERUSER` role attribute. Roles that are superusers bypass all access privilege checks in WarehousePG, as well as resource queuing. Only system administrators should be given superuser rights. See "Altering Role Attributes" in the *WarehousePG Administrator Guide*.
- Database users should never log on as `gpadmin`, and ETL or production workloads should never run as `gpadmin`.
- Assign a distinct WarehousePG role to each user, application, or service that logs in.
- For applications or web services, consider creating a distinct role for each application or service.
- Use groups to manage access privileges.
- Protect the root password.
- Enforce a strong password password policy for operating system passwords.
- Ensure that important operating system files are protected.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

See Security.

Encryption

- Encrypting and decrypting data has a performance cost; only encrypt data that requires encryption.
- Do performance testing before implementing any encryption solution in a production system.
- Server certificates in a production WarehousePG cluster should be signed by a certificate authority (CA) so that clients can authenticate the server. The CA may be local if all clients are local to the organization.
- Client connections to WarehousePG should use SSL encryption whenever the connection goes through an insecure link.
- A symmetric encryption scheme, where the same key is used to both encrypt and decrypt, has better performance than an asymmetric scheme and should be used when the key can be shared safely.
- Use cryptographic functions to encrypt data on disk. The data is encrypted and decrypted in the database process, so it is important to secure the client connection with SSL to avoid transmitting unencrypted data.
- Use the gpfdists protocol to secure ETL data as it is loaded into or unloaded from the database.

See Encrypting Data and Database Connections

High Availability

> **Note** The following guidelines apply to actual hardware deployments, but not to public cloud-based infrastructure, where high availability solutions may already exist.

- Use a hardware RAID storage solution with 8 to 24 disks.
- Use RAID 1, 5, or 6 so that the disk array can tolerate a failed disk.
- Configure a hot spare in the disk array to allow rebuild to begin automatically when disk failure is detected.
- Protect against failure of the entire disk array and degradation during rebuilds by mirroring the RAID volume.
- Monitor disk utilization regularly and add additional space when needed.
- Monitor segment skew to ensure that data is distributed evenly and storage is consumed evenly at all segments.
- Set up a standby coordinator instance to take over if the primary coordinator fails.
- Plan how to switch clients to the new coordinator instance when a failure occurs, for example, by updating the coordinator address in DNS.
- Set up monitoring to send notifications in a system monitoring application or by email when the primary fails.
- Set up mirrors for all segments.
- Locate primary segments and their mirrors on different hosts to protect against host failure.
- Recover failed segments promptly, using the `gprecoverseg` utility, to restore redundancy and return the system to optimal balance.
- Consider a Dual Cluster configuration to provide an additional level of redundancy and additional query processing throughput.
- Backup WarehousePGs regularly unless the data is easily restored from sources.
- If backups are saved to local cluster storage, move the files to a safe, off-cluster location when the backup is complete.
- If backups are saved to NFS mounts, use a scale-out NFS solution such as Dell PowerScale (Isilon) to prevent IO bottlenecks.

See High Availability.

Parent topic: WarehousePG Best Practices

6.2 System Configuration

Requirements and best practices for system administrators who are configuring WarehousePG cluster hosts.

Configuration of the WarehousePG cluster is usually performed as root.

Configuring the Timezone

WarehousePG selects a timezone to use from a set of internally stored PostgreSQL timezones. The available PostgreSQL timezones are taken from the Internet Assigned Numbers Authority (IANA) Time Zone Database, and WarehousePG updates its list of available timezones as necessary when the IANA database changes for PostgreSQL.

WarehousePG selects the timezone by matching a PostgreSQL timezone with the user specified time zone, or the host system time zone if no time zone is configured. For example, when selecting a default timezone, WarehousePG uses an algorithm to select a PostgreSQL timezone based on the host system timezone files. If the system timezone includes leap second information, WarehousePG cannot match the system timezone with a PostgreSQL timezone. In this case, WarehousePG calculates a "best match" with a PostgreSQL timezone based on information from the host system.

As a best practice, configure WarehousePG and the host systems to use a known, supported timezone. This sets the timezone for the WarehousePG coordinator and segment instances, and prevents WarehousePG from recalculating a "best match" timezone each time the cluster is restarted, using the current system timezone and WarehousePG timezone files (which may have been updated from the IANA database since the last restart). Use the `gpconfig` utility to show and set the WarehousePG timezone. For example, these commands show the WarehousePG timezone and set the timezone to `US/Pacific`.

```
# gpconfig -s TimeZone
# gpconfig -c TimeZone -v 'US/Pacific'
```

You must restart WarehousePG after changing the timezone. The command `gpstop -ra` restarts WarehousePG. The catalog view `pg_timezone_names` provides WarehousePG timezone information.

File System

XFS is the file system used for WarehousePG data directories. Use the mount options described in Configure Operating System.

Port Configuration

See the recommended OS parameter settings in the *WarehousePG Installation Guide* for further details.

Set up `ip_local_port_range` so it does not conflict with the WarehousePG port ranges. For example, setting this range in `/etc/sysctl.conf`:

```
net.ipv4.ip_local_port_range = 10000  65535
```

you could set the WarehousePG base port numbers to these values.

```
PORT_BASE = 6000
MIRROR_PORT_BASE = 7000
```

See the Recommended OS Parameters Settings in the *WarehousePG Installation Guide* for further details.

I/O Configuration

Set the blockdev read-ahead size to 16384 on the devices that contain data directories. This command sets the read-ahead size for `/dev/sdb`.

```
# /sbin/blockdev --setra 16384 /dev/sdb
```

This command returns the read-ahead size for `/dev/sdb`.

```
# /sbin/blockdev --getra /dev/sdb
16384
```

See the Recommended OS Parameters Settings in the *WarehousePG Installation Guide* for further details.

The deadline IO scheduler should be set for all data directory devices.

```
 # cat /sys/block/sdb/queue/scheduler
 noop anticipatory [deadline] cfq
```

The maximum number of OS files and processes should be increased in the `/etc/security/limits.conf` file.

```
* soft  nofile 524288
* hard  nofile 524288
* soft  nproc 131072
* hard  nproc 131072
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

OS Memory Configuration

The Linux sysctl `vm.overcommit_memory` and `vm.overcommit_ratio` variables affect how the operating system manages memory allocation. See the `/etc/sysctl.conf` file parameters guidelines in the *WarehousePG Datatabase Installation Guide* for further details.

`vm.overcommit_memory` determines the method the OS uses for determining how much memory can be allocated to processes. This should be always set to 2, which is the only safe setting for the database.

> **Note** For information on configuration of overcommit memory, refer to:

- https://en.wikipedia.org/wiki/Memory_overcommitment
- https://www.kernel.org/doc/Documentation/vm/overcommit-accounting

`vm.overcommit_ratio` is the percent of RAM that is used for application processes. The default is 50 on Red Hat Enterprise Linux. See Resource Queue Segment Memory Configuration for a formula to calculate an optimal value.

Do not enable huge pages in the operating system.

See also Memory and Resource Management with Resource Queues.

Shared Memory Settings

WarehousePG uses shared memory to communicate between `postgres` processes that are part of the same `postgres` instance. The following shared memory settings should be set in `sysctl` and are rarely modified. See the `sysctl.conf` file parameters in the *WarehousePG Installation Guide* for further details.

```
kernel.shmmax = 810810728448
kernel.shmmni = 4096
kernel.shmall = 197951838
```

See Setting the WarehousePG Recommended OS Parameters for more details.

Number of Segments per Host

Determining the number of segments to run on each segment host has immense impact on overall system performance. The segments share the host's CPU cores, memory, and NICs with each other and with other processes running on the host. Over-estimating the number of segments a server can accommodate is a common cause of suboptimal performance.

The factors that must be considered when choosing how many segments to run per host include the following:

- Number of cores
- Amount of physical RAM installed in the server
- Number of NICs
- Amount of storage attached to server
- Mixture of primary and mirror segments
- ETL processes that will run on the hosts
- Non-WarehousePG processes running on the hosts

Resource Queue Segment Memory Configuration

The `gp_vmem_protect_limit` server configuration parameter specifies the amount of memory that all active postgres processes for a single segment can consume at any given time. Queries that exceed this amount will fail. Use the following calculations to estimate a safe value for `gp_vmem_protect_limit`.

1. Calculate `gp_vmem`, the host memory available to WarehousePG.
    - If the total system memory is less than 256 GB, use this formula:

      ```
      gp_vmem = ((SWAP + RAM) – (7.5GB + 0.05 * RAM)) / 1.7
      ```

    - If the total system memory is equal to or greater than 256 GB, use this formula:

      ```
      gp_vmem = ((SWAP + RAM) – (7.5GB + 0.05 * RAM)) / 1.17
      ```

    where `SWAP` is the host's swap space in GB and `RAM` is the RAM installed on the host in GB.
2. Calculate `max_acting_primary_segments`. This is the maximum number of primary segments that can be running on a host when mirror segments are activated due to a segment or host failure on another host in the cluster. With mirrors arranged in a 4-host block with 8 primary segments per host, for example, a single segment host failure would activate two or three mirror segments on each remaining host in the failed host's block. The `max_acting_primary_segments` value for this configuration is 11 (8 primary segments plus 3 mirrors activated on failure).
3. Calculate `gp_vmem_protect_limit` by dividing the total WarehousePG memory by the maximum number of acting primaries:

    ```
    gp_vmem_protect_limit = gp_vmem / max_acting_primary_segments
    ```

    Convert to megabytes to find the value to set for the `gp_vmem_protect_limit` system configuration parameter.

For scenarios where a large number of workfiles are generated, adjust the calculation for `gp_vmem` to account for the workfiles.

- If the total system memory is less than 256 GB:

  ```
  gp_vmem = ((SWAP + RAM) – (7.5GB + 0.05 * RAM – (300KB * total_#_workfiles))) / 1.7
  ```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

- If the total system memory is equal to or greater than 256 GB:

```
gp_vmem = ((SWAP + RAM) – (7.5GB + 0.05 * RAM – (300KB * total_#_workfiles))) / 1.17
```

For information about monitoring and managing workfile usage, see the *WarehousePG Administrator Guide*.

You can calculate the value of the `vm.overcommit_ratio` operating system parameter from the value of `gp_vmem`:

```
vm.overcommit_ratio = (RAM – 0.026 * gp_vmem) / RAM
```

See OS Memory Configuration for more about about `vm.overcommit_ratio`.

See also Memory and Resource Management with Resource Queues.

Resource Queue Statement Memory Configuration

The `statement_mem` server configuration parameter is the amount of memory to be allocated to any single query in a segment database. If a statement requires additional memory it will spill to disk. Calculate the value for `statement_mem` with the following formula:

```
(gp_vmem_protect_limit * .9) / max_expected_concurrent_queries
```

For example, for 40 concurrent queries with `gp_vmem_protect_limit` set to 8GB (8192MB), the calculation for `statement_mem` would be:

```
(8192MB * .9) / 40 = 184MB
```

Each query would be allowed 184MB of memory before it must spill to disk.

To increase `statement_mem` safely you must either increase `gp_vmem_protect_limit` or reduce the number of concurrent queries. To increase `gp_vmem_protect_limit`, you must add physical RAM and/or swap space, or reduce the number of segments per host.

Note that adding segment hosts to the cluster cannot help out-of-memory errors unless you use the additional hosts to decrease the number of segments per host.

Spill files are created when there is not enough memory to fit all the mapper output, usually when 80% of the buffer space is occupied.

Also, see Resource Management for best practices for managing query memory using resource queues.

Resource Queue Spill File Configuration

WarehousePG creates *spill files* (also called *workfiles*) on disk if a query is allocated insufficient memory to run in memory. A single query can create no more than 100,000 spill files, by default, which is sufficient for the majority of queries.

You can control the maximum number of spill files created per query and per segment with the configuration parameter `gp_workfile_limit_files_per_query`. Set the parameter to 0 to allow queries to create an unlimited number of spill files. Limiting the number of spill files permitted prevents run-away queries from disrupting the system.

A query could generate a large number of spill files if not enough memory is allocated to it or if data skew is present in the queried data. If a query creates more than the specified number of spill files, WarehousePG returns this error:

```
ERROR: number of workfiles per query limit exceeded
```

Before raising the `gp_workfile_limit_files_per_query`, try reducing the number of spill files by changing the query, changing the data distribution, or changing the memory configuration.

The `gp_toolkit` schema includes views that allow you to see information about all the queries that are currently using spill files. This information can be used for troubleshooting and for tuning queries:

- The `gp_workfile_entries` view contains one row for each operator using disk space for workfiles on a segment at the current time. See How to Read Explain Plans for information about operators.
- The `gp_workfile_usage_per_query` view contains one row for each query using disk space for workfiles on a segment at the current time.
- The `gp_workfile_usage_per_segment` view contains one row for each segment. Each row displays the total amount of disk space used for workfiles on the segment at the current time.

See the *WarehousePG Reference Guide* for descriptions of the columns in these views.

The `gp_workfile_compression` configuration parameter specifies whether the spill files are compressed. It is `off` by default. Enabling compression can improve performance when spill files are used.

6.3 Schema Design

Best practices for designing WarehousePG schemas.

WarehousePG is an analytical, shared-nothing database, which is much different than a highly normalized, transactional SMP database. WarehousePG performs best with a denormalized schema design suited for MPP analytical processing, a star or snowflake schema, with large centralized fact tables connected to multiple smaller dimension tables.

Parent topic: WarehousePG Best Practices

Data Types

Use Types Consistently

Use the same data types for columns used in joins between tables. If the data types differ, WarehousePG must dynamically convert the data type of one of the columns so the data values can be compared correctly. With this in mind, you may need to increase the data type size to facilitate joins to other common objects.

Choose Data Types that Use the Least Space

You can increase database capacity and improve query execution by choosing the most efficient data types to store your data.

Use `TEXT` or `VARCHAR` rather than `CHAR`. There are no performance differences among the character data types, but using `TEXT` or `VARCHAR` can decrease the storage space used.

Use the smallest numeric data type that will accommodate your data. Using `BIGINT` for data that fits in `INT` or `SMALLINT` wastes storage space.

Storage Model

WarehousePG provides an array of storage options when creating tables. It is very important to know when to use heap storage versus append-optimized (AO) storage, and when to use row-oriented storage versus column-oriented storage. The correct selection of heap versus AO and row versus column is extremely important for large fact tables, but less important for small dimension tables.

The best practices for determining the storage model are:

1. Design and build an insert-only model, truncating a daily partition before load.
2. For large partitioned fact tables, evaluate and use optimal storage options for different partitions. One storage option is not always right for the entire partitioned table. For example, some partitions can be row-oriented while others are column-oriented.
3. When using column-oriented storage, every column is a separate file on *every* WarehousePG segment. For tables with a large number of columns consider columnar storage for data often accessed (hot) and row-oriented storage for data not often accessed (cold).
4. Storage options should be set at the partition level.
5. Compress large tables to improve I/O performance and to make space in the cluster.

Heap Storage or Append-Optimized Storage

Heap storage is the default model, and is the model PostgreSQL uses for all database tables. Use heap storage for tables and partitions that will receive iterative `UPDATE`, `DELETE`, and singleton `INSERT` operations. Use heap storage for tables and partitions that will receive concurrent `UPDATE`, `DELETE`, and `INSERT` operations.

Use append-optimized storage for tables and partitions that are updated infrequently after the initial load and have subsequent inserts performed only in batch operations. Avoid performing singleton `INSERT`, `UPDATE`, or `DELETE` operations on append-optimized tables. Concurrent batch `INSERT` operations are acceptable, but *never* perform concurrent batch `UPDATE` or `DELETE` operations.

The append-optimized storage model is inappropriate for frequently updated tables, because space occupied by rows that are updated and deleted in append-optimized tables is not recovered and reused as efficiently as with heap tables. Append-optimized storage is intended for large tables that are loaded once, updated infrequently, and queried frequently for analytical query processing.

Row or Column Orientation

Row orientation is the traditional way to store database tuples. The columns that comprise a row are stored on disk contiguously, so that an entire row can be read from disk in a single I/O.

Column orientation stores column values together on disk. A separate file is created for each column. If the table is partitioned, a separate file is created for each column and partition. When a query accesses only a small number of columns in a column-oriented table with many columns, the cost of I/O is substantially reduced compared to a row-oriented table; any columns not referenced do not have to be retrieved from disk.

Row-oriented storage is recommended for transactional type workloads with iterative transactions where updates are required and frequent inserts are performed. Use row-oriented storage when selects against the table are wide, where many columns of a single row are needed in a query. If the majority of columns in the `SELECT` list or `WHERE` clause is selected in queries, use row-oriented storage. Use row-oriented storage for general purpose or mixed workloads, as it offers the best combination of flexibility and performance.

Column-oriented storage is optimized for read operations but it is not optimized for write operations; column values for a row must be written to different places on disk. Column-oriented tables can offer optimal query performance on large tables with many columns where only a small subset of columns are accessed by the queries.

Another benefit of column orientation is that a collection of values of the same data type can be stored together in less space than a collection of mixed type values, so column-oriented tables use less disk space (and consequently less disk I/O) than row-oriented tables. Column-oriented tables also compress better than row-oriented tables.

Use column-oriented storage for data warehouse analytic workloads where selects are narrow or aggregations of data are computed over a small number of columns. Use column-oriented storage for tables that have single columns that are regularly updated without modifying other columns in the row. Reading a complete row in a wide columnar table requires more time than reading the same row from a row-oriented table. It is important to understand that each column is a separate physical file on *every* segment in WarehousePG.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Compression

WarehousePG offers a variety of options to compress append-optimized tables and partitions. Use compression to improve I/O across the system by allowing more data to be read with each disk read operation. The best practice is to set the column compression settings at the partition level.

Note that new partitions added to a partitioned table do not automatically inherit compression defined at the table level; you must *specifically* define compression when you add new partitions.

Run-length encoding (RLE) compression provides the best levels of compression. Higher levels of compression usually result in more compact storage on disk, but require additional time and CPU cycles when compressing data on writes and uncompressing on reads. Sorting data, in combination with the various compression options, can achieve the highest level of compression.

Data compression should never be used for data that is stored on a compressed file system.

Test different compression types and ordering methods to determine the best compression for your specific data. For example, you might start zstd compression at level 8 or 9 and adjust for best results. RLE compression works best with files that contain repetitive data.

Distributions

An optimal distribution that results in evenly distributed data is the most important factor in WarehousePG. In an MPP shared nothing environment overall response time for a query is measured by the completion time for all segments. The system is only as fast as the slowest segment. If the data is skewed, segments with more data will take more time to complete, so every segment must have an approximately equal number of rows and perform approximately the same amount of processing. Poor performance and out of memory conditions may result if one segment has significantly more data to process than other segments.

Consider the following best practices when deciding on a distribution strategy:

- Explicitly define a column or random distribution for all tables. Do not use the default.
- Ideally, use a single column that will distribute data across all segments evenly.
- Do not distribute on columns that will be used in the `WHERE` clause of a query.
- Do not distribute on dates or timestamps.
- The distribution key column data should contain unique values or very high cardinality.
- If a single column cannot achieve an even distribution, use a multi-column distribution key with a maximum of two columns. Additional column values do not typically yield a more even distribution and they require additional time in the hashing process.
- If a two-column distribution key cannot achieve an even distribution of data, use a random distribution. Multi-column distribution keys in most cases require motion operations to join tables, so they offer no advantages over a random distribution.

WarehousePG random distribution is not round-robin, so there is no guarantee of an equal number of records on each segment. Random distributions typically fall within a target range of less than ten percent variation.

Optimal distributions are critical when joining large tables together. To perform a join, matching rows must be located together on the same segment. If data is not distributed on the same join column, the rows needed from one of the tables are dynamically redistributed to the other segments. In some cases a broadcast motion, in which each segment sends its individual rows to all other segments, is performed rather than a redistribution motion, where each segment rehashes the data and sends the rows to the appropriate segments according to the hash key.

Local (Co-located) Joins

Using a hash distribution that evenly distributes table rows across all segments and results in local joins can provide substantial performance gains. When joined rows are on the same segment, much of the processing can be accomplished within the segment instance. These are called *local* or *co-located* joins. Local joins minimize data movement; each segment operates independently of the other segments, without network traffic or communications between segments.

To achieve local joins for large tables commonly joined together, distribute the tables on the same column. Local joins require that both sides of a join be distributed on the same columns (and in the same order) *and* that all columns in the distribution clause are used when joining tables. The distribution columns must also be the same data type—although some values with different data types may appear to have the same representation, they are stored differently and hash to different values, so they are stored on different segments.

Data Skew

Data skew is often the root cause of poor query performance and out of memory conditions. Skewed data affects scan (read) performance, but it also affects all other query execution operations, for instance, joins and group by operations.

It is very important to *validate* distributions to *ensure* that data is evenly distributed after the initial load. It is equally important to *continue* to validate distributions after incremental loads.

The following query shows the number of rows per segment as well as the variance from the minimum and maximum numbers of rows:

```
SELECT 'Example Table' AS "Table Name",
    max(c) AS "Max Seg Rows", min(c) AS "Min Seg Rows",
    (max(c)-min(c))*100.0/max(c) AS "Percentage Difference Between Max & Min"
FROM (SELECT count(*) c, gp_segment_id FROM facts GROUP BY 2) AS a;
```

The `gp_toolkit` schema has two views that you can use to check for skew.

- The `gp_toolkit.gp_skew_coefficients` view shows data distribution skew by calculating the coefficient of variation (CV) for the data stored on each segment. The `skccoeff` column shows the coefficient of variation (CV), which is calculated as the standard deviation divided by the average. It takes into account both the average and variability around the average of a data series. The lower the value, the better. Higher values indicate greater data skew.
- The `gp_toolkit.gp_skew_idle_fractions` view shows data distribution skew by calculating the percentage of the system that is idle during a table scan, which is an indicator of computational skew. The `siffraction` column shows the percentage of the system that is idle during a table scan. This is an indicator of uneven data distribution or query processing skew. For example, a value of 0.1 indicates 10% skew, a value of 0.5 indicates 50% skew, and so on. Tables that have more than10% skew should have their distribution policies evaluated.

Processing Skew

Processing skew results when a disproportionate amount of data flows to, and is processed by, one or a few segments. It is often the culprit behind WarehousePG performance and stability issues. It can happen with operations such join, sort, aggregation, and various OLAP operations. Processing skew happens in flight while a query is running and is not as easy to detect as data skew, which is caused by uneven data distribution due to the wrong choice of distribution keys. Data skew is present at the table level, so it can be easily detected and avoided by choosing optimal distribution keys.

If single segments are failing, that is, not all segments on a host, it may be a processing skew issue. Identifying processing skew is currently a manual process. First look for spill files. If there is skew, but not enough to cause spill, it will not become a performance issue. If you determine skew exists, then find the query responsible for the skew.

The remedy for processing skew in almost all cases is to rewrite the query. Creating temporary tables can eliminate skew. Temporary tables can be randomly distributed to force a two-stage aggregation.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Partitioning

A good partitioning strategy reduces the amount of data to be scanned by reading only the partitions needed to satisfy a query.

Each partition is a separate physical file or set of files (in the case of column-oriented tables) on *every* segment. Just as reading a complete row in a wide columnar table requires more time than reading the same row from a heap table, *reading all partitions in a partitioned table requires more time than reading the same data from a non-partitioned table*.

Following are partitioning best practices:

- Partition large tables only, do not partition small tables.
- Use partitioning on large tables *only* when partition elimination (partition pruning) can be achieved based on query criteria and is accomplished by partitioning the table based on the query predicate. Whenever possible, use range partitioning instead of list partitioning.
- The query planner can selectively scan partitioned tables only when the query contains a direct and simple restriction of the table using immutable operators, such as `=`, `<`, `<=`, `>`, `>=`, and `<>`.
- Selective scanning recognizes `STABLE` and `IMMUTABLE` functions, but does not recognize `VOLATILE` functions within a query. For example, `WHERE` clauses such as

  ```
  date > CURRENT_DATE
  ```

  cause the query planner to selectively scan partitioned tables, but a `WHERE` clause such as

  ```
  time > TIMEOFDAY
  ```

  does not. It is important to validate that queries are selectively scanning partitioned tables (partitions are being eliminated) by examining the query `EXPLAIN` plan.
- Do not use default partitions. The default partition is always scanned but, more importantly, in many environments they tend to overfill resulting in poor performance.
- *Never* partition and distribute tables on the same column.
- Do not use multi-level partitioning. While sub-partitioning is supported, it is not recommended because typically sub-partitions contain little or no data. It is a myth that performance increases as the number of partitions or sub-partitions increases; the administrative overhead of maintaining many partitions and sub-partitions will outweigh any performance benefits. For performance, scalability and manageability, balance partition scan performance with the number of overall partitions.
- Beware of using too many partitions with column-oriented storage.
- Consider workload concurrency and the average number of partitions opened and scanned for all concurrent queries.

Number of Partition and Columnar Storage Files

The only hard limit for the number of files WarehousePG supports is the operating system's open file limit. It is important, however, to consider the total number of files in the cluster, the number of files on every segment, and the total number of files on a host. In an MPP shared nothing environment, every node operates independently of other nodes. Each node is constrained by its disk, CPU, and memory. CPU and I/O constraints are not common with WarehousePG, but memory is often a limiting factor because the query execution model optimizes query performance in memory.

The optimal number of files per segment also varies based on the number of segments on the node, the size of the cluster, SQL access, concurrency, workload, and skew. There are generally six to eight segments per host, but large clusters should have fewer segments per host. When using partitioning and columnar storage it is important to balance the total number of files in the cluster, but it is *more* important to consider the number of files per segment and the total number of files on a node.

Example with 64GB Memory per Node

- Number of nodes: 16
- Number of segments per node: 8
- Average number of files per segment: 10,000

The total number of files per node is `8*10,000 = 80,000` and the total number of files for the cluster is `8*16*10,000 = 1,280,000`. The number of files increases quickly as the number of partitions and the number of columns increase.

As a general best practice, limit the total number of files per node to under 100,000. As the previous example shows, the optimal number of files per segment and total number of files per node depends on the hardware configuration for the nodes (primarily memory), size of the cluster, SQL access, concurrency, workload and skew.

Indexes

Indexes are not generally needed in WarehousePG. Most analytical queries operate on large volumes of data, while indexes are intended for locating single rows or small numbers of rows of data. In WarehousePG, a sequential scan is an efficient method to read data as each segment contains an equal portion of the data and all segments work in parallel to read the data.

If adding an index does not produce performance gains, drop it. Verify that every index you create is used by the optimizer.

For queries with high selectivity, indexes may improve query performance. Create an index on a single column of a columnar table for drill through purposes for high cardinality columns that are required for highly selective queries.

Do not index columns that are frequently updated. Creating an index on a column that is frequently updated increases the number of writes required on updates.

Indexes on expressions should be used only if the expression is used frequently in queries.

An index with a predicate creates a partial index that can be used to select a small number of rows from large tables.

Avoid overlapping indexes. Indexes that have the same leading column are redundant.

Indexes can improve performance on compressed append-optimized tables for queries that return a targeted set of rows. For compressed data, an index access method means only the necessary pages are uncompressed.

Create selective B-tree indexes. Index selectivity is a ratio of the number of distinct values a column has divided by the number of rows in a table. For example, if a table has 1000 rows and a column has 800 distinct values, the selectivity of the index is 0.8, which is considered good.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

As a general rule, drop indexes before loading data into a table. The load will run an order of magnitude faster than loading data into a table with indexes. After the load, re-create the indexes.

Bitmap indexes are suited for querying and not updating. Bitmap indexes perform best when the column has a low cardinality—100 to 100,000 distinct values. Do not use bitmap indexes for unique columns, very high, or very low cardinality data. Do not use bitmap indexes for transactional workloads.

If indexes are needed on partitioned tables, the index columns must be different than the partition columns. A benefit of indexing partitioned tables is that because the b-tree performance degrades exponentially as the size of the b-tree grows, creating indexes on partitioned tables creates smaller b-trees that perform better than with non-partitioned tables.

Column Sequence and Byte Alignment

For optimum performance lay out the columns of a table to achieve data type byte alignment. Lay out the columns in heap tables in the following order:

1. Distribution and partition columns
2. Fixed numeric types
3. Variable data types

Lay out the data types from largest to smallest, so that `BIGINT` and `TIMESTAMP` come before `INT` and `DATE`, and all of these types come before `TEXT`, `VARCHAR`, or `NUMERIC(x,y)`. For example, 8-byte types first (`BIGINT`, `TIMESTAMP`), 4-byte types next (`INT`, `DATE`), 2-byte types next (`SMALLINT`), and variable data type last (`VARCHAR`).

Instead of defining columns in this sequence:

`Int`, `Bigint`, `Timestamp`, `Bigint`, `Timestamp`, `Int` (distribution key), `Date` (partition key), `Bigint`, `Smallint`

define the columns in this sequence:

`Int` (distribution key), `Date` (partition key), `Bigint`, `Bigint`, `Timestamp`, `Bigint`, `Timestamp`, `Int`, `Smallint`

6.4 Memory and Resource Management with Resource Groups

Managing WarehousePG resources with resource groups.

Memory, CPU, and concurrent transaction management have a significant impact on performance in a WarehousePG cluster. Resource groups are a newer resource management scheme that enforce memory, CPU, and concurrent transaction limits in WarehousePG.

- Configuring Memory for WarehousePG
- Memory Considerations when using Resource Groups
- Configuring Resource Groups
- Low Memory Queries
- Administrative Utilities and admin_group Concurrency

Configuring Memory for WarehousePG

While it is not always possible to increase system memory, you can avoid many out-of-memory conditions by configuring resource groups to manage expected workloads.

The following operating system and WarehousePG memory settings are significant when you manage WarehousePG resources with resource groups:

- **vm.overcommit_memory**

  This Linux kernel parameter, set in `/etc/sysctl.conf`, identifies the method that the operating system uses to determine how much memory can be allocated to processes. `vm.overcommit_memory` must always be set to 2 for WarehousePG clusters.

- **vm.overcommit_ratio**

  This Linux kernel parameter, set in `/etc/sysctl.conf`, identifies the percentage of RAM that is used for application processes; the remainder is reserved for the operating system. Tune the setting as necessary. If your memory utilization is too low, increase the value; if your memory or swap usage is too high, decrease the setting.

- **gp_workfile_limit_files_per_query**

  Set `gp_workfile_limit_files_per_query` to limit the maximum number of temporary spill files (workfiles) allowed per query. Spill files are created when a query requires more memory than it is allocated. When the limit is exceeded the query is terminated. The default is zero, which allows an unlimited number of spill files and may fill up the file system.

- **gp_workfile_compression**

  If there are numerous spill files then set `gp_workfile_compression` to compress the spill files. Compressing spill files may help to avoid overloading the disk subsystem with IO operations.

- **statement_mem**

  WarehousePG uses the `statement_mem` setting to determine the amount of memory to allocate to a query.

Other considerations:

- Do not configure the operating system to use huge pages. See the Recommended OS Parameters Settings in the *WarehousePG Installation Guide*.
- When you configure resource group memory, consider memory requirements for mirror segments that become primary segments during a failure to ensure that database operations can continue when primary segments or segment hosts fail.

Memory Considerations when using Resource Groups

Available memory for resource groups may be limited on systems that use low or no swap space, and that use the default `vm.overcommit_ratio`. To ensure that WarehousePG has a reasonable per-segment-host memory limit, you may be required to increase one or more of the following configuration settings:

1. The swap size on the system.
2. The system's `vm.overcommit_ratio` setting.

Configuring Resource Groups

WarehousePG resource groups provide a powerful mechanism for managing the workload of the cluster. Consider these general guidelines when you configure resource groups for your system:

- A transaction submitted by any WarehousePG role with `SUPERUSER` privileges runs under the default resource group named `admin_group`. Keep this in mind when scheduling and running WarehousePG administration utilities.
- Ensure that you assign each non-admin role a resource group. If you do not assign a resource group to a role, queries submitted by the role are handled by the default resource group named `default_group`.
- Use the `CONCURRENCY` resource group parameter to limit the number of active queries that members of a particular resource group can run concurrently.
- Use the `MEMORY_QUOTA` parameter to control the maximum amount of memory that queries running in the resource group can consume.
- WarehousePG assigns unreserved memory (100 - (sum of all resource group `MEMORY_QUOTA`s) to a global shared memory pool. This memory is available to all queries on a first-come, first-served basis.
- Alter resource groups dynamically to match the real requirements of the group for the workload and the time of day.
- Use the `gp_toolkit` views to examine resource group resource usage and to monitor how the groups are working.

Low Memory Queries

A low `statement_mem` setting (for example, in the 10MB range) has been shown to increase the performance of queries with low memory requirements. Use the `statement_mem` server configuration parameter to override the setting on a per-query basis. For example:

```
SET statement_mem='10 MB';
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Administrative Utilities and admin_group Concurrency

The default resource group for database transactions initiated by WarehousePG `SUPERUSER` s is the group named `admin_group`. The default `CONCURRENCY` value for the `admin_group` resource group is 10.

Certain WarehousePG administrative utilities may use more than one `CONCURRENCY` slot at runtime, such as `gpbackup` that you invoke with the `--jobs` option. If the utility(s) you run require more concurrent transactions than that configured for `admin_group`, consider temporarily increasing the group's `MEMORY_QUOTA` and `CONCURRENCY` values to meet the utility's requirement, making sure to return these parameters back to their original settings when the utility completes.

> **Note** Memory allocation changes that you initiate with `ALTER RESOURCE GROUP` may not take affect immediately due to resource consumption by currently running queries. Be sure to alter resource group parameters in advance of your maintenance window.

6.5 Memory and Resource Management with Resource Queues

Avoid memory errors and manage WarehousePG resources.

> **Note** Resource groups are a newer resource management scheme that enforces memory, CPU, and concurrent transaction limits in WarehousePG. TheManaging Resources topic provides a comparison of the resource queue and the resource group management schemes. Refer to Using Resource Groups for configuration and usage information for this resource management scheme.

Memory management has a significant impact on performance in a WarehousePG cluster. The default settings are suitable for most environments. Do not change the default settings until you understand the memory characteristics and usage on your system.

- Resolving Out of Memory Errors
- Low Memory Queries
- Configuring Memory for WarehousePG
- Configuring Resource Queues

Resolving Out of Memory Errors

An out of memory error message identifies the WarehousePG segment, host, and process that experienced the out of memory error. For example:

```
Out of memory (seg27 host.example.com pid=47093)
VM Protect failed to allocate 4096 bytes, 0 MB available
```

Some common causes of out-of-memory conditions in WarehousePG are:

- Insufficient system memory (RAM) available on the cluster
- Improperly configured memory parameters
- Data skew at the segment level
- Operational skew at the query level

Following are possible solutions to out of memory conditions:

- Tune the query to require less memory
- Reduce query concurrency using a resource queue
- Validate the `gp_vmem_protect_limit` configuration parameter at the database level. See calculations for the maximum safe setting in Configuring Memory for WarehousePG.
- Set the memory quota on a resource queue to limit the memory used by queries run within the resource queue
- Use a session setting to reduce the `statement_mem` used by specific queries
- Decrease `statement_mem` at the database level
- Decrease the number of segments per host in the WarehousePG cluster. This solution requires a re-initializing WarehousePG and reloading your data.
- Increase memory on the host, if possible. (Additional hardware may be required.)

Adding segment hosts to the cluster will not in itself alleviate out of memory problems. The memory used by each query is determined by the `statement_mem` parameter and it is set when the query is invoked. However, if adding more hosts allows decreasing the number of segments per host, then the amount of memory allocated in `gp_vmem_protect_limit` can be raised.

Low Memory Queries

A low `statement_mem` setting (for example, in the 1-3MB range) has been shown to increase the performance of queries with low memory requirements. Use the `statement_mem` server configuration parameter to override the setting on a per-query basis. For example:

```
SET statement_mem='2MB';
```

Configuring Memory for WarehousePG

Most out of memory conditions can be avoided if memory is thoughtfully managed.

It is not always possible to increase system memory, but you can prevent out-of-memory conditions by configuring memory use correctly and setting up resource queues to manage expected workloads.

It is important to include memory requirements for mirror segments that become primary segments during a failure to ensure that the cluster can continue when primary segments or segment hosts fail.

The following are recommended operating system and WarehousePG memory settings:

- Do not configure the OS to use huge pages.
- **vm.overcommit_memory**

  This is a Linux kernel parameter, set in `/etc/sysctl.conf` and it should always be set to 2. It determines the method the OS uses for determining how much memory can be allocated to processes and 2 is the only safe setting for WarehousePG. Please review the sysctl parameters in the WarehousePG Installation Guide.
- **vm.overcommit_ratio**

  This is a Linux kernel parameter, set in `/etc/sysctl.conf`. It is the percentage of RAM that is used for application processes. The remainder is reserved for the operating system. The default on Red Hat is 50.

  Setting `vm.overcommit_ratio` too high may result in not enough memory being reserved for the operating system, which can result in segment host failure or database failure. Setting the value too low reduces the amount of concurrency and query complexity that can be run by reducing the amount of memory available to WarehousePG. When increasing the setting it is important to remember to always reserve some memory for operating system activities.

  See WarehousePG Memory Overview for instructions to calculate a value for `vm.overcommit_ratio`.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

- **gp_vmem_protect_limit**

  Use `gp_vmem_protect_limit` to set the maximum memory that the instance can allocate for *all* work being done in each segment database. Never set this value larger than the physical RAM on the system. If `gp_vmem_protect_limit` is too high, it is possible for memory to become exhausted on the system and normal operations may fail, causing segment failures. If `gp_vmem_protect_limit` is set to a safe lower value, true memory exhaustion on the system is prevented; queries may fail for hitting the limit, but system disruption and segment failures are avoided, which is the desired behavior.

  See Resource Queue Segment Memory Configuration for instructions to calculate a safe value for `gp_vmem_protect_limit`.

- **runaway_detector_activation_percent**

  Runaway Query Termination, prevents out of memory conditions. The `runaway_detector_activation_percent` system parameter controls the percentage of `gp_vmem_protect_limit` memory utilized that triggers termination of queries. It is set on by default at 90%. If the percentage of `gp_vmem_protect_limit` memory that is utilized for a segment exceeds the specified value, WarehousePG terminates queries based on memory usage, beginning with the query consuming the largest amount of memory. Queries are terminated until the utilized percentage of `gp_vmem_protect_limit` is below the specified percentage.

- **statement_mem**

  Use `statement_mem` to allocate memory used for a query per segment database. If additional memory is required it will spill to disk. Set the optimal value for `statement_mem` as follows:

  ```
  (vmprotect * .9) / max_expected_concurrent_queries
  ```

  The default value of `statement_mem` is 125MB. For example, on a system that is configured with 8 segments per host, a query uses 1GB of memory on each segment server (8 segments ⨯ 125MB) with the default `statement_mem` setting. Set `statement_mem` at the session level for specific queries that require additional memory to complete. This setting works well to manage query memory on clusters with low concurrency. For clusters with high concurrency also use resource queues to provide additional control on what and how much is running on the system.

- **gp_workfile_limit_files_per_query**

  Set `gp_workfile_limit_files_per_query` to limit the maximum number of temporary spill files (workfiles) allowed per query. Spill files are created when a query requires more memory than it is allocated. When the limit is exceeded the query is terminated. The default is zero, which allows an unlimited number of spill files and may fill up the file system.

- **gp_workfile_compression**

  If there are numerous spill files then set `gp_workfile_compression` to compress the spill files. Compressing spill files may help to avoid overloading the disk subsystem with IO operations.

Configuring Resource Queues

WarehousePG resource queues provide a powerful mechanism for managing the workload of the cluster. Queues can be used to limit both the numbers of active queries and the amount of memory that can be used by queries in the queue. When a query is submitted to WarehousePG, it is added to a resource queue, which determines if the query should be accepted and when the resources are available to run it.

- Associate all roles with an administrator-defined resource queue.

  Each login user (role) is associated with a single resource queue; any query the user submits is handled by the associated resource queue. If a queue is not explicitly assigned the user's queries are handed by the default queue, `pg_default`.

- Do not run queries with the gpadmin role or other superuser roles.

  Superusers are exempt from resource queue limits, therefore superuser queries always run regardless of the limits set on their assigned queue.

- Use the `ACTIVE_STATEMENTS` resource queue parameter to limit the number of active queries that members of a particular queue can run concurrently.

- Use the `MEMORY_LIMIT` parameter to control the total amount of memory that queries running through the queue can utilize. By combining the `ACTIVE_STATEMENTS` and `MEMORY_LIMIT` attributes an administrator can fully control the activity emitted from a given resource queue.

  The allocation works as follows: Suppose a resource queue, `sample_queue`, has `ACTIVE_STATEMENTS` set to 10 and `MEMORY_LIMIT` set to 2000MB. This limits the queue to approximately 2 gigabytes of memory per segment. For a cluster with 8 segments per server, the total usage per server is 16 GB for `sample_queue` (2GB * 8 segments/server). If a segment server has 64GB of RAM, there could be no more than four of this type of resource queue on the system before there is a chance of running out of memory (4 queues * 16GB per queue).

  Note that by using `STATEMENT_MEM`, individual queries running in the queue can allocate more than their "share" of memory, thus reducing the memory available for other queries in the queue.

- Resource queue priorities can be used to align workloads with desired outcomes. Queues with `MAX` priority throttle activity in all other queues until the `MAX` queue completes running all queries.

- Alter resource queues dynamically to match the real requirements of the queue for the workload and time of day. You can script an operational flow that changes based on the time of day and type of usage of the system and add `crontab` entries to run the scripts.

- Use gptoolkit to view resource queue usage and to understand how the queues are working.

6.6 System Monitoring and Maintenance

Best practices for regular maintenance that will ensure WarehousePG high availability and optimal performance.

- Updating Statistics with ANALYZE
- Managing Bloat in a Database
- Monitoring WarehousePG Log Files

Parent topic: WarehousePG Best Practices

Monitoring

WarehousePG includes utilities that are useful for monitoring the system.

The `gp_toolkit` schema contains several views that can be accessed using SQL commands to query system catalogs, log files, and operating environment for system status information.

The `gp_stats_missing` view shows tables that do not have statistics and require `ANALYZE` to be run.

For additional information on `gpstate` and `gpcheckperf` refer to the *WarehousePG Utility Guide*. For information about the `gp_toolkit` schema, see the *WarehousePG Reference Guide*.

gpstate

The `gpstate` utility program displays the status of the WarehousePG cluster, including which segments are down, coordinator and segment configuration information (hosts, data directories, etc.), the ports used by the system, and mapping of primary segments to their corresponding mirror segments.

Run `gpstate -Q` to get a list of segments that are marked "down" in the coordinator system catalog.

To get detailed status information for the WarehousePG cluster, run `gpstate -s`.

gpcheckperf

The `gpcheckperf` utility tests baseline hardware performance for a list of hosts. The results can help identify hardware issues. It performs the following checks:

- disk I/O test – measures I/O performance by writing and reading a large file using the `dd` operating system command. It reports read and write rates in megabytes per second.
- memory bandwidth test – measures sustainable memory bandwidth in megabytes per second using the STREAM benchmark.
- network performance test – runs the `gpnetbench` network benchmark program (optionally `netperf)` to test network performance. The test is run in one of three modes: parallel pair test (`-r N`), serial pair test (`-r n`), or full-matrix test (`-r M)` . The minimum, maximum, average, and median transfer rates are reported in megabytes per second.

To obtain valid numbers from `gpcheckperf`, the database system must be stopped. The numbers from `gpcheckperf` can be inaccurate even if the system is up and running with no query activity.

`gpcheckperf` requires a trusted host setup between the hosts involved in the performance test. It calls `gpssh` and `gpsync`, so these utilities must also be in your `PATH`. Specify the hosts to check individually (`-h *host1* -h *host2* ...`) or with `-f *hosts_file*`, where `*hosts_file*` is a text file containing a list of the hosts to check. If you have more than one subnet, create a separate host file for each subnet so that you can test the subnets separately.

By default, `gpcheckperf` runs the disk I/O test, the memory test, and a serial pair network performance test. With the disk I/O test, you must use the `-d` option to specify the file systems you want to test. The following command tests disk I/O and memory bandwidth on hosts listed in the `subnet_1_hosts` file:

```
$ gpcheckperf -f subnet_1_hosts -d /data1 -d /data2 -r ds
```

The `-r` option selects the tests to run: disk I/O (`d`), memory bandwidth (`s`), network parallel pair (`N`), network serial pair test (`n`), network full-matrix test (`M`). Only one network mode can be selected per execution. See the *WarehousePG Reference Guide* for the detailed `gpcheckperf` reference.

Monitoring with Operating System Utilities

The following Linux/UNIX utilities can be used to assess host performance:

- `iostat` allows you to monitor disk activity on segment hosts.
- `top` displays a dynamic view of operating system processes.
- `vmstat` displays memory usage statistics.

You can use `gpssh` to run utilities on multiple hosts.

Best Practices

- Implement the "Recommended Monitoring and Maintenance Tasks" in the *WarehousePG Administrator Guide*.
- Run `gpcheckperf` at install time and periodically thereafter, saving the output to compare system performance over time.
- Use all the tools at your disposal to understand how your system behaves under different loads.
- Examine any unusual event to determine the cause.
- Monitor query activity on the system by running explain plans periodically to ensure the queries are running optimally.
- Review plans to determine whether index are being used and partition elimination is occurring as expected.

6.6.1 Updating Statistics with ANALYZE

The most important prerequisite for good query performance is to begin with accurate statistics for the tables. Updating statistics with the `ANALYZE` statement enables the query planner to generate optimal query plans. When a table is analyzed, information about the data is stored in the system catalog tables. If the stored information is out of date, the planner can generate inefficient plans.

Generating Statistics Selectively

Running ANALYZE with no arguments updates statistics for all tables in the database. This can be a very long-running process and it is not recommended. You should `ANALYZE` tables selectively when data has changed or use the analyzedb utility.

Running `ANALYZE` on a large table can take a long time. If it is not feasible to run `ANALYZE` on all columns of a very large table, you can generate statistics for selected columns only using `ANALYZE table(column, ...)`. Be sure to include columns used in joins, `WHERE` clauses, `SORT` clauses, `GROUP BY` clauses, or `HAVING` clauses.

For a partitioned table, you can run `ANALYZE` just on partitions that have changed, for example, if you add a new partition. Note that for partitioned tables, you can run `ANALYZE` on the root partitioned table, or on the leaf partitions (files where data and statistics are actually stored). The intermediate files for sub-partitioned tables store no data or statistics, so running `ANALYZE` on them does not work. You can find the names of the leaf partitions using the `pg_partition_tree()` function:

```
SELECT * FROM pg_partition_tree( 'parent_table' );
```

Improving Statistics Quality

There is a trade-off between the amount of time it takes to generate statistics and the quality, or accuracy, of the statistics.

To allow large tables to be analyzed in a reasonable amount of time, `ANALYZE` takes a random sample of the table contents, rather than examining every row. To increase the number of sample values for all table columns adjust the `default_statistics_target` configuration parameter. The target value ranges from 1 to 1000; the default target value is 100. The `default_statistics_target` variable applies to all columns by default, and specifies the number of values that are stored in the list of common values. A larger target may improve the quality of the query planner's estimates, especially for columns with irregular data patterns. `default_statistics_target` can be set at the coordinator/session level and requires a reload.

When to Run ANALYZE

Run `ANALYZE`:

- after loading data,
- after `CREATE INDEX` operations,
- and after `INSERT`, `UPDATE`, and `DELETE` operations that significantly change the underlying data.

`ANALYZE` requires only a read lock on the table, so it may be run in parallel with other database activity, but do not run `ANALYZE` while performing loads, `INSERT`, `UPDATE`, `DELETE`, and `CREATE INDEX` operations.

Configuring Automatic Statistics Collection

The `gp_autostats_mode` configuration parameter, together with the `gp_autostats_on_change_threshold` parameter, determines when an automatic analyze operation is triggered. When automatic statistics collection is triggered, the planner adds an `ANALYZE` step to the query.

By default, `gp_autostats_mode` is `on_no_stats`, which triggers statistics collection for `CREATE TABLE AS SELECT`, `INSERT`, or `COPY` operations invoked by the table owner on any table that has no existing statistics.

Setting `gp_autostats_mode` to `on_change` triggers statistics collection only when the number of rows affected exceeds the threshold defined by `gp_autostats_on_change_threshold`, which has a default value of 2147483647. The following operations invoked on a table by its owner can trigger automatic statistics collection with `on_change`: `CREATE TABLE AS SELECT`, `UPDATE`, `DELETE`, `INSERT`, and `COPY`.

Setting the `gp_autostats_allow_nonowner` server configuration parameter to `true` also instructs WarehousePG to trigger automatic statistics collection on a table when:

- `gp_autostats_mode=on_change` and the table is modified by a non-owner.
- `gp_autostats_mode=on_no_stats` and the first user to `INSERT` or `COPY` into the table is a non-owner.

Setting `gp_autostats_mode` to `none` deactivates automatics statistics collection.

For partitioned tables, automatic statistics collection is not triggered if data is inserted from the top-level parent table of a partitioned table. But automatic statistics collection *is* triggered if data is inserted directly in a leaf table (where the data is stored) of the partitioned table.

6.6.2 Managing Bloat in a Database

Database bloat occurs in heap tables, append-optimized tables, indexes, and system catalogs and affects database performance and disk usage. You can detect database bloat and remove it from the database.

- About Bloat
- Detecting Bloat
- Removing Bloat from Database Tables
- Removing Bloat from Append-Optimized Tables
- Removing Bloat from Indexes
- Removing Bloat from System Catalogs

About Bloat

Database bloat is disk space that was used by a table or index and is available for reuse by the database but has not been reclaimed. Bloat is created when updating tables or indexes.

Because WarehousePG heap tables use the PostgreSQL Multiversion Concurrency Control (MVCC) storage implementation, a deleted or updated row is logically deleted from the database, but a non-visible image of the row remains in the table. Moreover, if the table has an index, index entries to these non-visible rows also remain. Running `VACUUM` marks the expired rows as free space that is available for reuse by subsequent inserts, and removes the corresponding index entries if any exist.

It is normal for tables that have frequent updates to have a small or moderate amount of expired rows and free space that will be reused as new data is added. But when the table is allowed to grow so large that active data occupies just a small fraction of the space, the table has become significantly bloated. Bloated tables require more disk storage and additional I/O that can slow down query execution. It can also slow down data ingest if a bloated table has a unique index, as uniqueness validation checks will read the aforementioned index entries.

> **Important** It is very important to run `VACUUM` on individual tables after large `UPDATE` and `DELETE` operations to avoid the necessity of ever running `VACUUM FULL`.

Running the `VACUUM` command regularly on tables prevents them from growing too large. If the table does become significantly bloated, the `VACUUM FULL` command must be used to compact the table data.

If the free space map is not large enough to accommodate all of the expired rows, the `VACUUM` command is unable to reclaim space for expired rows that overflowed the free space map. The disk space may only be recovered by running `VACUUM FULL`, which locks the table, creates a new table, copies the table data to the new table, and then drops old table. This is an expensive operation that can take an exceptional amount of time to complete with a large table.

> **Caution** `VACUUM FULL` acquires an `ACCESS EXCLUSIVE` lock on tables. You should not run `VACUUM FULL`. If you run `VACUUM FULL` on tables, run it during a time when users and applications do not require access to the tables, such as during a time of low activity, or during a maintenance window.

Detecting Bloat

The statistics collected by the `ANALYZE` statement can be used to calculate the expected number of disk pages required to store a table. The difference between the expected number of pages and the actual number of pages is a measure of bloat. The `gp_toolkit` schema provides the gp_bloat_diag view that identifies table bloat by comparing the ratio of expected to actual pages. To use it, make sure statistics are up to date for all of the tables in the database, then run the following SQL:

```
gpadmin=# SELECT * FROM gp_toolkit.gp_bloat_diag;
 bdirelid | bdinspname | bdirelname | bdirelpages | bdiexppages |                bdidiag
----------+------------+------------+-------------+-------------+----------------------------------------
    21488 | public     | t1         |          97 |           1 | significant amount of bloat suspected
(1 row)
```

The results include only tables with moderate or significant bloat. Moderate bloat is reported when the ratio of actual to expected pages is greater than four and less than ten. Significant bloat is reported when the ratio is greater than ten.

The `gp_toolkit.gp_bloat_expected_pages` view lists the actual number of used pages and expected number of used pages for each database object.

```
gpadmin=# SELECT * FROM gp_toolkit.gp_bloat_expected_pages LIMIT 5;
 btdrelid | btdrelpages | btdexppages
----------+-------------+-------------
    10789 |           1 |           1
    10794 |           1 |           1
    10799 |           1 |           1
     5004 |           1 |           1
     7175 |           1 |           1
(5 rows)
```

The `btdrelid` is the object ID of the table. The `btdrelpages` column reports the number of pages the table uses; the `btdexppages` column is the number of pages expected. Again, the numbers reported are based on the table statistics, so be sure to run `ANALYZE` on tables that have changed.

Removing Bloat from Database Tables

The `VACUUM` command adds expired rows to the free space map so that the space can be reused. When `VACUUM` is run regularly on a table that is frequently updated, the space occupied by the expired rows can be promptly reused, preventing the table file from growing larger. It is also important to run `VACUUM` before the free space map is filled. For heavily updated tables, you may need to run `VACUUM` at least once a day to prevent the table from becoming bloated.

> **Caution** When a table is significantly bloated, it is better to run `VACUUM` before running `ANALYZE`. Analyzing a severely bloated table can generate poor statistics if the sample contains empty pages, so it is good practice to vacuum a bloated table before analyzing it.

When a table accumulates significant bloat, running the `VACUUM` command is insufficient. For small tables, running `VACUUM FULL <table_name>` can reclaim space used by rows that overflowed the free space map and reduce the size of the table file. However, a `VACUUM FULL` statement is an expensive operation that requires an `ACCESS EXCLUSIVE` lock and may take an exceptionally long and unpredictable amount of time to finish for large tables. You should run `VACUUM FULL` on tables during a time when users and applications do not require access to the tables being vacuumed, such as during a time of low activity, or during a maintenance window.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Removing Bloat from Append-Optimized Tables

Append-optimized tables are handled much differently than heap tables. Although append-optimized tables allow update, insert, and delete operations, these operations are not optimized and are not recommended with append-optimized tables. If you heed this advice and use append-optimized for *load-once/read-many* workloads, `VACUUM` on an append-optimized table runs almost instantaneously.

If you do run `UPDATE` or `DELETE` commands on an append-optimized table, expired rows are tracked in an auxiliary bitmap instead of the free space map. `VACUUM` is the only way to recover the space. Running `VACUUM` on an append-optimized table with expired rows compacts a table by rewriting the entire table without the expired rows. However, no action is performed if the percentage of expired rows in the table exceeds the value of the `gp_appendonly_compaction_threshold` configuration parameter, which is 10 (10%) by default. The threshold is checked on each segment, so it is possible that a `VACUUM` statement will compact an append-only table on some segments and not others. Compacting append-only tables can be deactivated by setting the `gp_appendonly_compaction` parameter to `no`.

Removing Bloat from Indexes

The `VACUUM` command only recovers space from tables. To recover the space from indexes, recreate them using the `REINDEX` command.

To rebuild all indexes on a table run `REINDEX *table_name*;`. To rebuild a particular index, run `REINDEX *index_name*;`. `REINDEX` sets the `reltuples` and `relpages` to 0 (zero) for the index, To update those statistics, run `ANALYZE` on the table after reindexing.

Removing Bloat from System Catalogs

WarehousePG cluster catalog tables are heap tables and can become bloated over time. As database objects are created, altered, or dropped, expired rows are left in the system catalogs. Using `gpload` to load data contributes to the bloat since `gpload` creates and drops external tables. (Rather than use `gpload`, it is recommended to use `gpfdist` to load data.)

Bloat in the system catalogs increases the time require to scan the tables, for example, when creating explain plans. System catalogs are scanned frequently and if they become bloated, overall system performance is degraded.

It is recommended to run `VACUUM` on system catalog tables nightly and at least weekly. At the same time, running `REINDEX SYSTEM` on system catalog tables removes bloat from the indexes. Alternatively, you can reindex system tables using the `reindexdb` utility with the `-s` (`--system`) option. After removing catalog bloat, run `ANALYZE` to update catalog table statistics.

These are WarehousePG cluster catalog maintenance steps.

1. Perform a `REINDEX` on the system catalog tables to rebuild the system catalog indexes. This removes bloat in the indexes and improves `VACUUM` performance.

   > **Note** When performing `REINDEX` on the system catalog tables, locking will occur on the tables and might have an impact on currently running queries. You can schedule the `REINDEX` operation during a period of low activity to avoid disrupting ongoing business operations.

2. Perform a `VACUUM` on system catalog tables.

3. Perform an `ANALYZE` on the system catalog tables to update the table statistics.

If you are performing system catalog maintenance during a maintenance period and you need to stop a process due to time constraints, run the WarehousePG function `pg_cancel_backend(<PID>)` to safely stop a WarehousePG process.

The following script runs `REINDEX`, `VACUUM`, and `ANALYZE` on the system catalogs.

```
#!/bin/bash
DBNAME="<database_name>"
SYSTABLES="' pg_catalog.' || relname || ';' from pg_class a, pg_namespace b \
where a.relnamespace=b.oid and b.nspname='pg_catalog' and a.relkind='r'"

reindexdb -s -d $DBNAME
psql -tc "SELECT 'VACUUM' || $SYSTABLES" $DBNAME | psql -a $DBNAME
analyzedb -a -s pg_catalog -d $DBNAME
```

If the system catalogs become significantly bloated, you must run `VACUUM FULL` during a scheduled downtime period. During this period, stop all catalog activity on the system; `VACUUM FULL` takes `ACCESS EXCLUSIVE` locks against the system catalog. Running `VACUUM` regularly on system catalog tables can prevent the need for this more costly procedure.

These are steps for intensive system catalog maintenance.

1. Stop all catalog activity on the WarehousePG cluster.
2. Perform a `VACUUM FULL` on the system catalog tables. See the following Note.
3. Perform an `ANALYZE` on the system catalog tables to update the catalog table statistics.

> **Note** The system catalog table `pg_attribute` is usually the largest catalog table. If the `pg_attribute` table is significantly bloated, a `VACUUM FULL` operation on the table might require a significant amount of time and might need to be performed separately. The presence of both of these conditions indicate a significantly bloated `pg_attribute` table that might require a long `VACUUM FULL` time:

- The `pg_attribute` table contains a large number of records.
- The diagnostic message for `pg_attribute` is `significant amount of bloat` in the `gp_toolkit.gp_bloat_diag` view.

6.6.3 Monitoring WarehousePG Log Files

Know the location and content of system log files and monitor them on a regular basis and not just when problems arise.

The following table shows the locations of the various WarehousePG log files. In file paths:

- `$GPADMIN_HOME` refers to the home directory of the `gpadmin` operating system user.
- `$COORDINATOR_DATA_DIRECTORY` refers to the coordinator data directory on the WarehousePG coordinator host.
- `$GPDATA_DIR` refers to a data directory on the WarehousePG segment host.
- `host` identifies the WarehousePG segment host name.
- `segprefix` identifies the segment prefix.
- `N` identifies the segment instance number.
- `date` is a date in the format `YYYYMMDD`.

Path	Description
`$GPADMIN_HOME/gpAdminLogs/*`	Many different types of log files, directory on each server. `$GPADMIN_HOME` is the default location for the `gpAdminLogs/` directory. You can specify a different location when you run an administrative utility command.
`$GPADMIN_HOME/gpAdminLogs/gpinitsystem_date.log`	system initialization log
`$GPADMIN_HOME/gpAdminLogs/gpstart_date.log`	start log
`$GPADMIN_HOME/gpAdminLogs/gpstop_date.log`	stop log
`$GPADMIN_HOME/gpAdminLogs/gpsegstart.py_host:gpadmin_date.log`	segment host start log
`$GPADMIN_HOME/gpAdminLogs/gpsegstop.py_host:gpadmin_date.log`	segment host stop log
`$COORDINATOR_DATA_DIRECTORY/log/startup.log`, `$GPDATA_DIR/segprefixN/log/startup.log`	segment instance start log
`$COORDINATOR_DATA_DIRECTORY/log/*.csv`, `$GPDATA_DIR/segprefixN/log/*.csv`	coordinator and segment database logs
`$GPDATA_DIR/mirror/segprefixN/log/*.csv`	mirror segment database logs
`$GPDATA_DIR/primary/segprefixN/log/*.csv`	primary segment database logs
`/var/log/messages`	Global Linux system messages

> **Note** If you manually set the server configuration parameter log_directory to specify a different directory for log files, the items on the table above whose path is under `$COORDINATOR_DATA_DIRECTORY` or `$GPDATA_DIR` should point to the value of `log_directory` instead. Note that when you specify the value as an absolute path, or as a relative path that is outside the data directory, WarehousePG appends a subdirectory with a unique identifier (DBID) to the directory specified by this parameter. The unique identifier matches the value of `dbid` from `gp_segment_configuration`. For example, if you set `log_directory` as `/tmp/logs`, WarehousePG creates the directories: `/tmp/logs/1` for the coordinator, `/tmp/logs/2` for seg0, `/tmp/logs/3` for seg1, etcetera.

Use `gplogfilter -t` (`--trouble`) first to search the coordinator log for messages beginning with `ERROR:`, `FATAL:`, or `PANIC:`. Messages beginning with `WARNING` may also provide useful information.

To search log files on the segment hosts, use the WarehousePG `gplogfilter` utility with `gpssh` to connect to segment hosts from the coordinator host. You can identify corresponding log entries in segment logs by the `statement_id`.

WarehousePG can be configured to rotate database logs based on the size and/or age of the current log file. The `log_rotation_size` configuration parameter sets the size of an individual log file that triggers rotation. When the current log file size is equal to or greater than this size, the file is closed and a new log file is created. The `log_rotation_age` configuration parameter specifies the age of the current log file that triggers rotation. When the specified time has elapsed since the current log file was created, a new log file is created. The default `log_rotation_age`, `1d`, creates a new log file 24 hours after the current log file was created.

6.7 Loading Data

Description of the different ways to add data to WarehousePG.

Parent topic: WarehousePG Best Practices

INSERT Statement with Column Values

A singleton `INSERT` statement with values adds a single row to a table. The row flows through the coordinator and is distributed to a segment. This is the slowest method and is not suitable for loading large amounts of data.

COPY Statement

The PostgreSQL `COPY` statement copies data from an external file into a database table. It can insert multiple rows more efficiently than an `INSERT` statement, but the rows are still passed through the coordinator. All of the data is copied in one command; it is not a parallel process.

Data input to the `COPY` command is from a file or the standard input. For example:

```
COPY table FROM '/data/mydata.csv' WITH CSV HEADER;
```

Use `COPY` to add relatively small sets of data, for example dimension tables with up to ten thousand rows, or one-time data loads.

Use `COPY` when scripting a process that loads small amounts of data, less than 10 thousand rows.

Since COPY is a single command, there is no need to deactivate autocommit when you use this method to populate a table.

You can run multiple concurrent `COPY` commands to improve performance.

External Tables

External tables provide access to data in sources outside of WarehousePG. They can be accessed with `SELECT` statements and are commonly used with the Extract, Load, Transform (ELT) pattern, a variant of the Extract, Transform, Load (ETL) pattern that takes advantage of WarehousePG's fast parallel data loading capability.

With ETL, data is extracted from its source, transformed outside of the database using external transformation tools, such as Datastage, and then loaded into the database.

With ELT, WarehousePG external tables provide access to data in external sources, which could be read-only files (for example, text, CSV, or XML files), Web servers, Hadoop file systems, executable OS programs, or the WarehousePG `gpfdist` file server, described in the next section. External tables support SQL operations such as select, sort, and join so the data can be loaded and transformed simultaneously, or loaded into a*load table* and transformed in the database into target tables.

The external table is defined with a `CREATE EXTERNAL TABLE` statement, which has a `LOCATION` clause to define the location of the data and a `FORMAT` clause to define the formatting of the source data so that the system can parse the input data. Files use the `file://` protocol, and must reside on a segment host in a location accessible by the WarehousePG superuser. The data can be spread out among the segment hosts with no more than one file per primary segment on each host. The number of files listed in the `LOCATION` clause is the number of segments that will read the external table in parallel.

External Tables with Gpfdist

The fastest way to load large fact tables is to use external tables with `gpfdist`. `gpfdist` is a file server program using an HTTP protocol that serves external data files to WarehousePG segments in parallel. A `gpfdist` instance can serve 200 MB/second and many `gpfdist` processes can run simultaneously, each serving up a portion of the data to be loaded. When you begin the load using a statement such as `INSERT INTO <table> SELECT * FROM <external_table>`, the `INSERT` statement is parsed by the coordinator and distributed to the primary segments. The segments connect to the `gpfdist` servers and retrieve the data in parallel, parse and validate the data, calculate a hash from the distribution key data and, based on the hash key, send the row to its destination segment. By default, each `gpfdist` instance will accept up to 64 connections from segments. With many segments and `gpfdist` servers participating in the load, data can be loaded at very high rates.

Primary segments access external files in parallel when using `gpfdist` up to the value of `gp_external_max_segs`. When optimizing `gpfdist` performance, maximize the parallelism as the number of segments increase. Spread the data evenly across as many ETL nodes as possible. Split very large data files into equal parts and spread the data across as many file systems as possible.

Run two `gpfdist` instances per file system. `gpfdist` tends to be CPU bound on the segment nodes when loading. But if, for example, there are eight racks of segment nodes, there is lot of available CPU on the segments to drive more `gpfdist` processes. Run `gpfdist` on as many interfaces as possible. Be aware of bonded NICs and be sure to start enough `gpfdist` instances to work them.

It is important to keep the work even across all these resources. The load is as fast as the slowest node. Skew in the load file layout will cause the overall load to bottleneck on that resource.

The `gp_external_max_segs` configuration parameter controls the number of segments each `gpfdist` process serves. The default is 64. You can set a different value in the `postgresql.conf` configuration file on the coordinator. Always keep `gp_external_max_segs` and the number of `gpfdist` processes an even factor; that is, the `gp_external_max_segs` value should be a multiple of the number of `gpfdist` processes. For example, if there are 12 segments and 4 `gpfdist` processes, the planner round robins the segment connections as follows:

```
Segment 1  - gpfdist 1
Segment 2  - gpfdist 2
Segment 3  - gpfdist 3
Segment 4  - gpfdist 4
Segment 5  - gpfdist 1
Segment 6  - gpfdist 2
Segment 7  - gpfdist 3
Segment 8  - gpfdist 4
Segment 9  - gpfdist 1
Segment 10 - gpfdist 2
Segment 11 - gpfdist 3
Segment 12 - gpfdist 4
```

Drop indexes before loading into existing tables and re-create the index after loading. Creating an index on pre-existing data is faster than updating it incrementally as each row is loaded.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Run `ANALYZE` on the table after loading. Deactivate automatic statistics collection during loading by setting `gp_autostats_mode` to `NONE`. Run `VACUUM` after load errors to recover space.

Performing small, high frequency data loads into heavily partitioned column-oriented tables can have a high impact on the system because of the number of physical files accessed per time interval.

Gpload

`gpload` is a data loading utility that acts as an interface to the WarehousePG external table parallel loading feature.

Beware of using `gpload` as it can cause catalog bloat by creating and dropping external tables. Use `gpfdist` instead, since it provides the best performance.

`gpload` runs a load using a specification defined in a YAML-formatted control file. It performs the following operations:

- Invokes `gpfdist` processes
- Creates a temporary external table definition based on the source data defined
- Runs an `INSERT`, `UPDATE`, or `MERGE` operation to load the source data into the target table in the database
- Drops the temporary external table
- Cleans up `gpfdist` processes

The load is accomplished in a single transaction.

Best Practices

- Drop any indexes on an existing table before loading data and recreate the indexes after loading. Newly creating an index is faster than updating an index incrementally as each row is loaded.
- Deactivate automatic statistics collection during loading by setting the `gp_autostats_mode` configuration parameter to `NONE`.
- External tables are not intended for frequent or ad hoc access.
- When using `gpfdist`, maximize network bandwidth by running one `gpfdist` instance for each NIC on the ETL server. Divide the source data evenly between the `gpfdist` instances.
- When using `gpload`, run as many simultaneous `gpload` instances as resources allow. Take advantage of the CPU, memory, and networking resources available to increase the amount of data that can be transferred from ETL servers to the WarehousePG.
- Use the `SEGMENT REJECT LIMIT` clause of the `COPY` statement to set a limit for the number or percentage of rows that can have errors before the `COPY FROM` command is cancelled. The reject limit is per segment; when any one segment exceeds the limit, the command is cancelled and no rows are added. Use the `LOG ERRORS` clause to save error rows. If a row has errors in the formatting—for example missing or extra values, or incorrect data types—WarehousePG stores the error information and row internally. Use the `gp_read_error_log()` built-in SQL function to access this stored information.
- If the load has errors, run `VACUUM` on the table to recover space.
- After you load data into a table, run `VACUUM` on heap tables, including system catalogs, and `ANALYZE` on all tables. It is not necessary to run `VACUUM` on append-optimized tables. If the table is partitioned, you can vacuum and analyze just the partitions affected by the data load. These steps clean up any rows from prematurely ended loads, deletes, or updates and update statistics for the table.
- Recheck for segment skew in the table after loading a large amount of data. You can use a query like the following to check for skew:

```
SELECT gp_segment_id, count(*)
FROM schema.table
GROUP BY gp_segment_id ORDER BY 2;
```

- By default, `gpfdist` assumes a maximum record size of 32K. To load data records larger than 32K, you must increase the maximum row size parameter by specifying the `-m <*bytes*>` option on the `gpfdist` command line. If you use `gpload`, set the `MAX_LINE_LENGTH` parameter in the `gpload` control file.

Additional Information

See the *WarehousePG Reference Guide* for detailed instructions for loading data using `gpfdist` and `gpload`.

6.8 Identifying and Mitigating Heap Table Performance Issues

Symptom:

The first scan of tuples after bulk data load, modification, or deletion jobs on heap tables are running slow or hanging.

Potential Cause:

When a workload involves a bulk load, modification, or deletion of data in a heap table, the first scan post-operation may generate a large amount of WAL data when checksums are enabled (`data_check_sums=true`) or hint bits are logged (`wal_log_hints=true`), leading to slow or hung jobs.

Affected workloads include: restoring from a backup, loading data with or `COPY`, cluster expansion, `CTAS` / `INSERT` / `UPDATE` / `DELETE` operations, and `ALTER TABLE` operations that modify tuples.

Explanation:

WarehousePG uses hint bits to mark tuples as created and/or deleted by transactions. Hint bits, when set, can help in determining visibility of tuples without expensive `pg_xact` and `pg_subtrans` commit log lookups.

Hint bits are updated for every tuple on the first scan of the tuple after its creation or deletion. Because hint bits are checked and set on a per-tuple basis, even a read can result in heavy writes. When data checksums are enabled for heap tables (the default), hint bit updates are always WAL-logged.

Solution:

If you have restored or loaded a complete database comprised primarily of heap tables, you may choose to run `VACUUM` against the entire database.

Alternatively, if you can identify the individual tables affected, you have two options:

1. Schedule and take a maintenance window and run `VACUUM` on the specific tables that have been loaded, updated, or deleted in bulk. This operation should scan all of the tuples and set and WAL-log the hint bits, taking the performance hit up-front.
2. Run `SELECT count(*) FROM <table-name>` on each table. This operation similarly scans all of the tuples and sets and WAL-logs the hint bits.

All subsequent scans as part of regular workloads on the tables should not be required to generate hints or their accompanying full page image WAL records.

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

6.9 Security

Best practices to ensure the highest level of system security.

Basic Security Best Practices

- Secure the `gpadmin` system user. WarehousePG requires a UNIX user id to install and initialize the WarehousePG cluster. This system user is referred to as `gpadmin` in the WarehousePG documentation. The `gpadmin` user is the default database superuser in WarehousePG, as well as the file system owner of the WarehousePG installation and its underlying data files. The default administrator account is fundamental to the design of WarehousePG. The system cannot run without it, and there is no way to limit the access of the `gpadmin` user id. This `gpadmin` user can bypass all security features of WarehousePG. Anyone who logs on to a WarehousePG host with this user id can read, alter, or delete any data, including system catalog data and database access rights. Therefore, it is very important to secure the `gpadmin` user id and only allow essential system administrators access to it. Administrators should only log in to WarehousePG as `gpadmin` when performing certain system maintenance tasks (such as upgrade or expansion). Database users should never log on as `gpadmin`, and ETL or production workloads should never run as `gpadmin`.
- Assign a distinct role to each user who logs in. For logging and auditing purposes, each user who is allowed to log in to WarehousePG should be given their own database role. For applications or web services, consider creating a distinct role for each application or service. See "Creating New Roles (Users)" in the *WarehousePG Administrator Guide*.
- Use groups to manage access privileges. See "Creating Groups (Role Membership)" in the *WarehousePG Administrator Guide*.
- Limit users who have the `SUPERUSER` role attribute. Roles that are superusers bypass all access privilege checks in WarehousePG, as well as resource queuing. Only system administrators should be given superuser rights. See "Altering Role Attributes" in the *WarehousePG Administrator Guide*.

Password Strength Guidelines

To protect the network from intrusion, system administrators should verify the passwords used within an organization are strong ones. The following recommendations can strengthen a password:

- Minimum password length recommendation: At least 9 characters. MD5 passwords should be 15 characters or longer.
- Mix upper and lower case letters.
- Mix letters and numbers.
- Include non-alphanumeric characters.
- Pick a password you can remember.

The following are recommendations for password cracker software that you can use to determine the strength of a password.

- John The Ripper. A fast and flexible password cracking program. It allows the use of multiple word lists and is capable of brute-force password cracking. It is available online at http://www.openwall.com/john/.
- Crack. Perhaps the most well-known password cracking software, Crack is also very fast, though not as easy to use as John The Ripper. It can be found online at http://www.crypticide.com/alecm/security/crack/c50-faq.html.

The security of the entire system depends on the strength of the root password. This password should be at least 12 characters long and include a mix of capitalized letters, lowercase letters, special characters, and numbers. It should not be based on any dictionary word.

Password expiration parameters should be configured. The following commands must be run as `root` or using `sudo`.

Ensure the following line exists within the file `/etc/libuser.conf` under the `[import]` section.

```
login_defs = /etc/login.defs
```

Ensure no lines in the `[userdefaults]` section begin with the following text, as these words override settings from `/etc/login.defs`:

- `LU_SHADOWMAX`
- `LU_SHADOWMIN`
- `LU_SHADOWWARNING`

Ensure the following command produces no output. Any accounts listed by running this command should be locked.

```
grep "^+:" /etc/passwd /etc/shadow /etc/group
```

Note: We strongly recommend that customers change their passwords after initial setup.

```
cd /etc
chown root:root passwd shadow group gshadow
chmod 644 passwd group
chmod 400 shadow gshadow
```

Find all the files that are world-writable and that do not have their sticky bits set.

```
find / -xdev -type d \( -perm -0002 -a ! -perm -1000 \) -print
```

Set the sticky bit (`# chmod +t {dir}`) for all the directories that result from running the previous command.

Find all the files that are world-writable and fix each file listed.

```
find / -xdev -type f -perm -0002 -print
```

Set the right permissions (`# chmod o-w {file}`) for all the files generated by running the aforementioned command.

Find all the files that do not belong to a valid user or group and either assign an owner or remove the file, as appropriate.

```
find / -xdev \( -nouser -o -nogroup \) -print
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Find all the directories that are world-writable and ensure they are owned by either root or a system account (assuming only system accounts have a User ID lower than 500). If the command generates any output, verify the assignment is correct or reassign it to root.

```
find / -xdev -type d -perm -0002 -uid +500 -print
```

Authentication settings such as password quality, password expiration policy, password reuse, password retry attempts, and more can be configured using the Pluggable Authentication Modules (PAM) framework. PAM looks in the directory `/etc/pam.d` for application-specific configuration information. Running `authconfig` or `system-config-authentication` will re-write the PAM configuration files, destroying any manually made changes and replacing them with system defaults.

The default `pam_cracklib` PAM module provides strength checking for passwords. To configure `pam_cracklib` to require at least one uppercase character, lowercase character, digit, and special character, as recommended by the U.S. Department of Defense guidelines, edit the file `/etc/pam.d/system-auth` to include the following parameters in the line corresponding to password requisite `pam_cracklib.so try_first_pass`.

```
retry=3:
dcredit=-1. Require at least one digit
ucredit=-1. Require at least one upper case character
ocredit=-1. Require at least one special character
lcredit=-1. Require at least one lower case character
minlen=14. Require a minimum password length of 14.
```

For example:

```
password required pam_cracklib.so try_first_pass retry=3\minlen=14 dcredit=-1 ucredit=-1 ocredit=-1 lcredit=-1
```

These parameters can be set to reflect your security policy requirements. Note that the password restrictions are not applicable to the root password.

The `pam_tally2` PAM module provides the capability to lock out user accounts after a specified number of failed login attempts. To enforce password lockout, edit the file `/etc/pam.d/system-auth` to include the following lines:

- The first of the auth lines should include:

  ```
  auth required pam_tally2.so deny=5 onerr=fail unlock_time=900
  ```

- The first of the account lines should include:

  ```
  account required pam_tally2.so
  ```

Here, the deny parameter is set to limit the number of retries to 5 and the `unlock_time` has been set to 900 seconds to keep the account locked for 900 seconds before it is unlocked. These parameters may be configured appropriately to reflect your security policy requirements. A locked account can be manually unlocked using the `pam_tally2` utility:

```
/sbin/pam_tally2 --user {username} --reset
```

You can use PAM to limit the reuse of recent passwords. The remember option for the `pam_unix` module can be set to remember the recent passwords and prevent their reuse. To accomplish this, edit the appropriate line in `/etc/pam.d/system-auth` to include the remember option.

For example:

```
password sufficient pam_unix.so [ … existing_options …]
remember=5
```

You can set the number of previous passwords to remember to appropriately reflect your security policy requirements.

```
cd /etc
chown root:root passwd shadow group gshadow
chmod 644 passwd group
chmod 400 shadow gshadow
```

6.10 Encrypting Data and Database Connections

Best practices for implementing encryption and managing keys.

Encryption can be used to protect data in a WarehousePG cluster in the following ways:

- Connections between clients and the coordinator database can be encrypted with SSL. This is enabled by setting the `ssl` server configuration parameter to `on` and editing the `pg_hba.conf` file. See "Encrypting Client/Server Connections" in the *WarehousePG Administrator Guide* for information about enabling SSL in WarehousePG.
- WarehousePG 4.2.1 and above allow SSL encryption of data in transit between the WarehousePG parallel file distribution server, `gpfdist`, and segment hosts. See Encrypting gpfdist Connections for more information.
- Network communications between hosts in the WarehousePG cluster can be encrypted using IPsec. An authenticated, encrypted VPN is established between every pair of hosts in the cluster. Check your operating system documentation for IPsec support, or consider a third-party solution such as that provided by Zettaset.
- The `pgcrypto` module of encryption/decryption functions protects data at rest in the database. Encryption at the column level protects sensitive information, such as passwords, Social Security numbers, or credit card numbers. See Encrypting Data in Tables using PGP for an example.

Best Practices

- Encryption ensures that data can be seen only by users who have the key required to decrypt the data.
- Encrypting and decrypting data has a performance cost; only encrypt data that requires encryption.
- Do performance testing before implementing any encryption solution in a production system.
- Server certificates in a production WarehousePG cluster should be signed by a certificate authority (CA) so that clients can authenticate the server. The CA may be local if all clients are local to the organization.
- Client connections to WarehousePG should use SSL encryption whenever the connection goes through an insecure link.
- A symmetric encryption scheme, where the same key is used to both encrypt and decrypt, has better performance than an asymmetric scheme and should be used when the key can be shared safely.
- Use functions from the pgcrypto module to encrypt data on disk. The data is encrypted and decrypted in the database process, so it is important to secure the client connection with SSL to avoid transmitting unencrypted data.
- Use the gpfdists protocol to secure ETL data as it is loaded into or unloaded from the database. SeeEncrypting gpfdist Connections.

Key Management

Whether you are using symmetric (single private key) or asymmetric (public and private key) cryptography, it is important to store the coordinator or private key securely. There are many options for storing encryption keys, for example, on a file system, key vault, encrypted USB, trusted platform module (TPM), or hardware security module (HSM).

Consider the following questions when planning for key management:

- Where will the keys be stored?
- When should keys expire?
- How are keys protected?
- How are keys accessed?
- How can keys be recovered and revoked?

The Open Web Application Security Project (OWASP) provides a very comprehensive guide to securing encryption keys.

Encrypting Data at Rest with pgcrypto

The pgcrypto module for WarehousePG provides functions for encrypting data at rest in the database. Administrators can encrypt columns with sensitive information, such as social security numbers or credit card numbers, to provide an extra layer of protection. Database data stored in encrypted form cannot be read by users who do not have the encryption key, and the data cannot be read directly from disk.

pgcrypto is installed by default when you install WarehousePG. You must explicitly enable pgcrypto in each database in which you want to use the module.

pgcrypto allows PGP encryption using symmetric and asymmetric encryption. Symmetric encryption encrypts and decrypts data using the same key and is faster than asymmetric encryption. It is the preferred method in an environment where exchanging secret keys is not an issue. With asymmetric encryption, a public key is used to encrypt data and a private key is used to decrypt data. This is slower then symmetric encryption and it requires a stronger key.

Using pgcrypto always comes at the cost of performance and maintainability. It is important to use encryption only with the data that requires it. Also, keep in mind that you cannot search encrypted data by indexing the data.

Before you implement in-database encryption, consider the following PGP limitations.

- No support for signing. That also means that it is not checked whether the encryption sub-key belongs to the coordinator key.
- No support for encryption key as coordinator key. This practice is generally discouraged, so this limitation should not be a problem.
- No support for several subkeys. This may seem like a problem, as this is common practice. On the other hand, you should not use your regular GPG/PGP keys with pgcrypto, but create new ones, as the usage scenario is rather different.

WarehousePG is compiled with zlib by default; this allows PGP encryption functions to compress data before encrypting. When compiled with OpenSSL, more algorithms will be available.

Because pgcrypto functions run inside the database server, the data and passwords move between pgcrypto and the client application in clear-text. For optimal security, you should connect locally or use SSL connections and you should trust both the system and database administrators.

pgcrypto configures itself according to the findings of the main PostgreSQL configure script.

When compiled with `zlib`, pgcrypto encryption functions are able to compress data before encrypting.

Pgcrypto has various levels of encryption ranging from basic to advanced built-in functions. The following table shows the supported encryption algorithms.

Value Functionality	Built-in	With OpenSSL
MD5	yes	yes
SHA1	yes	yes
SHA224/256/384/512	yes	yes
Other digest algorithms	no	yes
Blowfish	yes	yes
AES	yes	yes
DES/3DES/CAST5	no	yes
Raw Encryption	yes	yes

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

Value Functionality	Built-in	With OpenSSL
PGP Symmetric-Key	yes	yes
PGP Public Key	yes	yes

Creating PGP Keys

To use PGP asymmetric encryption in WarehousePG, you must first create public and private keys and install them.

This section assumes you are installing WarehousePG on a Linux machine with the Gnu Privacy Guard (`gpg`) command line tool. It is recomended to use the latest version of GPG to create keys. Download and install Gnu Privacy Guard (GPG) for your operating system from https://www.gnupg.org/download/. On the GnuPG website you will find installers for popular Linux distributions and links for Windows and Mac OS X installers.

1. As root, run the following command and choose option 1 from the menu:

```
# gpg --gen-key
gpg (GnuPG) 2.0.14; Copyright (C) 2009 Free Software Foundation, Inc.
This is free software: you are free to change and redistribute it.
There is NO WARRANTY, to the extent permitted by law.

gpg: directory `/root/.gnupg' created
gpg: new configuration file `/root/.gnupg/gpg.conf' created
gpg: WARNING: options in `/root/.gnupg/gpg.conf' are not yet active during this run
gpg: keyring `/root/.gnupg/secring.gpg' created
gpg: keyring `/root/.gnupg/pubring.gpg' created
Please select what kind of key you want:
 (1) RSA and RSA (default)
 (2) DSA and Elgamal
 (3) DSA (sign only)
 (4) RSA (sign only)
Your selection? 1
```

2. Respond to the prompts and follow the instructions, as shown in this example:

```
RSA keys may be between 1024 and 4096 bits long.
What keysize do you want? (2048) Press enter to accept default key size
Requested keysize is 2048 bits
Please specify how long the key should be valid.
 0 = key does not expire
 <n> = key expires in n days
 <n>w = key expires in n weeks
 <n>m = key expires in n months
 <n>y = key expires in n years
 Key is valid for? (0) 365
Key expires at Wed 13 Jan 2016 10:35:39 AM PST
Is this correct? (y/N) y

GnuPG needs to construct a user ID to identify your key.

Real name: John Doe
Email address: jdoe@email.com
Comment:
You selected this USER-ID:
 "John Doe <jdoe@email.com>"

Change (N)ame, (C)omment, (E)mail or (O)kay/(Q)uit? O
You need a Passphrase to protect your secret key.
(For this demo the passphrase is blank.)
can't connect to `/root/.gnupg/S.gpg-agent': No such file or directory
You don't want a passphrase - this is probably a *bad* idea!
I will do it anyway.  You can change your passphrase at any time,
using this program with the option "--edit-key".

We need to generate a lot of random bytes. It is a good idea to perform
some other action (type on the keyboard, move the mouse, utilize the
disks) during the prime generation; this gives the random number
generator a better chance to gain enough entropy.
We need to generate a lot of random bytes. It is a good idea to perform
some other action (type on the keyboard, move the mouse, utilize the
disks) during the prime generation; this gives the random number
generator a better chance to gain enough entropy.
gpg: /root/.gnupg/trustdb.gpg: trustdb created
gpg: key 2027CC30 marked as ultimately trusted
public and secret key created and signed.

gpg:  checking the trustdbgpg:
      3 marginal(s) needed, 1 complete(s) needed, PGP trust model
gpg:  depth: 0  valid1  signed0  trust: 0-, 0q, 0n, 0m, 0f, 1u
gpg:  next trustdb check due at 2016-01-13
pub   2048R/2027CC30 2015-01-13 [expires: 2016-01-13]
      Key fingerprint = 7EDA 6AD0 F5E0 400F 4D45   3259 077D 725E 2027 CC30
uid                  John Doe <jdoe@email.com>
sub   2048R/4FD2EFBB 2015-01-13 [expires: 2016-01-13]
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

3. List the PGP keys by entering the following command:

```
gpg --list-secret-keys
/root/.gnupg/secring.gpg
------------------------
sec   2048R/2027CC30 2015-01-13 [expires: 2016-01-13]
uid                  John Doe <jdoe@email.com>
ssb   2048R/4FD2EFBB 2015-01-13
```

`2027CC30 is the public key and will be used to *encrypt* data in the database. 4FD2EFBB is the private (secret) key and will be used to *decrypt* data.`

4. Export the keys using the following commands:

```
# gpg -a --export 4FD2EFBB > public.key
# gpg -a --export-secret-keys 2027CC30 > secret.key
```

See the pgcrypto documentation for more information about PGP encryption functions.

Encrypting Data in Tables using PGP

This section shows how to encrypt data inserted into a column using the PGP keys you generated.

1. Dump the contents of the `public.key` file and then copy it to the clipboard:

```
# cat public.key
-----BEGIN PGP PUBLIC KEY BLOCK-----
Version: GnuPG v2.0.14 (GNU/Linux)

mQENBFS1Zf0BCADNw8Qvk1V1C36Kfcwd3Kpm/dijPfRyyEwB6PqKyA05jtWiXZTh
2His1ojSP6LI0cSkIqMU9LAlncecZhRIhBhuVgKlGSgd9texg2nnSL9Admqik/yX
R5syVKG+qcdWuvyZg9oOOmeyjhc3n+kkbRTEMuM3flbMs8shOwzMvstCUVmuHU/V
. . .
WH+N2lasoUaoJjb2kQGhLOnFbJuevkyBylRz+hI/+8rJKcZOjQkmmK8Hkk8qb5x/
HMUc55H0g2qQAY0BpnJHgOOQ45Q6pk3G2/7Dbek5WJ6K1wUrFy51sNlGWE8pvgEx
/UUZB+dYqCwtvX0nnBu1KNCmk2AkEcFK3YoliCxomdOxhFOv9AKjjojDyC65KJci
Pv2MikPS2fKOAg1R3LpMa8zDEtl4w3vckPQNrQNnYuUtfj6ZoCxv
=XZ8J
-----END PGP PUBLIC KEY BLOCK-----
```

2. Enable the `pgcrypto` extension:

```
CREATE EXTENSION pgcrypto;
```

3. Create a table called `userssn` and insert some sensitive data, social security numbers for Bob and Alice, in this example. Paste the public.key contents after "dearmor(".

```
CREATE TABLE userssn( ssn_id SERIAL PRIMARY KEY,
    username varchar(100), ssn bytea);

INSERT INTO userssn(username, ssn)
SELECT robotccs.username, pgp_pub_encrypt(robotccs.ssn, keys.pubkey) AS
ssn
FROM (
VALUES ('Alice', '123-45-6788'), ('Bob', '123-45-6799'))
AS robotccs(username, ssn)
CROSS JOIN (SELECT dearmor('-----BEGIN PGP PUBLIC KEY BLOCK-----
Version: GnuPG v2.0.22 (GNU/Linux)

=xdQf
-----END PGP PUBLIC KEY BLOCK-----')  as pubkey) AS keys;
```

Copyright © 2009 - 2026 EnterpriseDB Corporation. All rights reserved.

4. Verify that the `ssn` column is encrypted.

```
test_db=# select * from userssn;
ssn_id   | 1
username | Alice
ssn      | \301\300L\003\235M%_O\322\357\273\001\010\000\272\227\010\341\216\360\217C\020\261)_\367

. . .
WH+N2lasoUaoJjb2kQGhLOnFbJuevkyBylRz+hI/+8rJKcZOjQkmmK8Hkk8qb5x/
HMUc55H0g2qQAY0BpnJHgOOQ45Q6pk3G2/7Dbek5WJ6K1wUrFy51sNlGWE8pvgEx
/UUZB+dYqCwtvX0nnBu1KNCmk2AkEcFK3YoliCxomdOxhFOv9AKjjojDyC65KJci
Pv2MikPS2fKOAg1R3LpMa8zDEtl4w3vckPQNrQNnYuUtfj6ZoCxv
=XZ8J
-----END PGP PUBLIC KEY BLOCK-----'));

pgp_key_id | 9D4D255F4FD2EFBB
```

This shows that the PGP key ID used to encrypt the `ssn` column is 9D4D255F4FD2EFBB. It is recommended to perform this step whenever a new key is created and then store the ID for tracking.
