10 ECPGPlus 122
Database Compatibility for Oracle means that an application runs in an Oracle environment as well as in
the EDB Postgres Advanced Server (Advanced Server) environment with minimal or no changes to the
application code. Developing an application that is compatible with Oracle databases in the Advanced
Server requires special attention to which features are used in the construction of the application. For
example, developing a compatible application means choosing compatible:

- System and built-in functions for use in SQL statements and procedural logic.
- Stored Procedure Language (SPL) when creating database server-side application logic for stored
  procedures, functions, triggers, and packages.
- Data types that are compatible with Oracle databases
- SQL statements that are compatible with Oracle SQL
- System catalog views that are compatible with Oracle’s data dictionary

For detailed information about the compatible SQL syntax, data types, and views, see the Database Com-
patibility for Oracle Developers SQL Guide.

The compatibility offered by the procedures and functions that are part of the Built-in packages is docu-
mented in the Database Compatibility for Oracle Developers Built-in Packages Guide.

For information about using the compatible tools and utilities (EDB*Plus, EDB*Loader, DRITA, and
EDB*Wrap) that are included with an Advanced Server installation, see the Database Compatibility for
Oracle Developers Tools and Utilities Guide.

For applications written using the Oracle Call Interface (OCI), EDB’s Open Client Library (OCL) provides
interoperability with these applications. For detailed information about using the Open Client Library, see
the EDB Postgres Advanced Server OCL Connector Guide.

Advanced Server contains a rich set of features that enables development of database applications for either
PostgreSQL or Oracle. For more information about all of the features of Advanced Server, see the user
documentation available at the EDB website.

Advanced Server documentation is available at:

https://www.enterprisedb.com/edb-docs
1.1 Configuration Parameters Compatible with Oracle Databases

EDB Postgres Advanced Server supports the development and execution of applications compatible with PostgreSQL and Oracle. Some system behaviors can be altered to act in a more PostgreSQL or in a more Oracle compliant manner; these behaviors are controlled by configuration parameters. Modifying the parameters in the postgresql.conf file changes the behavior for all databases in the cluster, while a user or group can set the parameter value on the command line, effecting only their session. These parameters are:

- **edb_redwood_date** – Controls whether or not a time component is stored in DATE columns. For behavior compatible with Oracle databases, set edb_redwood_date to TRUE. See [edb_redwood_date](#).

- **edb_redwood_raw_names** – Controls whether database object names appear in uppercase or lowercase letters when viewed from Oracle system catalogs. For behavior compatible with Oracle databases, edb_redwood_raw_names is set to its default value of FALSE. To view database object names as they are actually stored in the PostgreSQL system catalogs, set edb_redwood_raw_names to TRUE. See [edb_redwood_raw_names](#).

- **edb_redwood_strings** – Equates NULL to an empty string for purposes of string concatenation operations. For behavior compatible with Oracle databases, set edb_redwood_strings to TRUE. See [edb_redwood_strings](#).

- **edb_stmt_level_tx** – Isolates automatic rollback of an aborted SQL command to statement level rollback only – the entire, current transaction is not automatically rolled back as is the case for default PostgreSQL behavior. For behavior compatible with Oracle databases, set edb_stmt_level_tx to TRUE; however, use only when absolutely necessary. See [edb_stmt_level_tx](#).

- **oracle_home** – Point Advanced Server to the correct Oracle installation directory. See [oracle_home](#).

### 1.1.1 edb_redwood_date

When DATE appears as the data type of a column in the commands, it is translated to TIMESTAMP at the time the table definition is stored in the database if the configuration parameter edb_redwood_date is set to TRUE. Thus, a time component will also be stored in the column along with the date. This is consistent with Oracle’s DATE data type.

If edb_redwood_date is set to FALSE the column’s data type in a CREATE TABLE or ALTER TABLE command remains as a native PostgreSQL DATE data type and is stored as such in the database. The PostgreSQL DATE data type stores only the date without a time component in the column.

Regardless of the setting of edb_redwood_date, when DATE appears as a data type in any other context such as the data type of a variable in an SPL declaration section, or the data type of a formal parameter in an SPL procedure or SPL function, or the return type of an SPL function, it is always internally translated to a TIMESTAMP and thus, can handle a time component if present.

See the *Database Compatibility for Oracle Developers Reference Guide* for more information about date/time data types.
1.1.2 edb_redwood_raw_names

When edb_redwood_raw_names is set to its default value of FALSE, database object names such as table names, column names, trigger names, program names, user names, etc. appear in uppercase letters when viewed from Oracle catalogs (for a complete list of supported catalog views, see the Database Compatibility for Oracle Catalog Views Guide). In addition, quotation marks enclose names that were created with enclosing quotation marks.

When edb_redwood_raw_names is set to TRUE, the database object names are displayed exactly as they are stored in the PostgreSQL system catalogs when viewed from the Oracle catalogs. Thus, names created without enclosing quotation marks appear in lowercase as expected in PostgreSQL. Names created with enclosing quotation marks appear exactly as they were created, but without the quotation marks.

For example, the following user name is created, and then a session is started with that user.

```
CREATE USER reduser IDENTIFIED BY password;
edb=# \c - reduser
Password for user reduser:
You are now connected to database "edb" as user "reduser".
```

When connected to the database as reduser, the following tables are created.

```
CREATE TABLE all_lower (col INTEGER);
CREATE TABLE ALL_UPPER (COL INTEGER);
CREATE TABLE "Mixed_Case" ("Col" INTEGER);
```

When viewed from the Oracle catalog, USER_TABLES, with edb_redwood_raw_names set to the default value FALSE, the names appear in uppercase except for the Mixed_Case name, which appears as created and also with enclosing quotation marks.

```
edb=> SELECT * FROM USER_TABLES;
schema_name | table_name | tablespace_name | status | temporary
--------------+-------------+-----------------+--------+-----------
REDUSER       | ALL_LOWER   |                 | VALID  | N         
REDUSER       | ALL_UPPER   |                 | VALID  | N         
REDUSER       | "Mixed_Case"|                 | VALID  | N         
(3 rows)
```

When viewed with edb_redwood_raw_names set to TRUE, the names appear in lowercase except for the Mixed_Case name, which appears as created, but now without the enclosing quotation marks.

```
edb=> SET edb_redwood_raw_names TO true;
SET
edb=> SELECT * FROM USER_TABLES;
schema_name | table_name | tablespace_name | status | temporary
--------------+-------------+-----------------+--------+-----------
reduser       | all_lower   |                 | VALID  | N         
reduser       | all_upper   |                 | VALID  | N         
reduser       | Mixed_Case  |                 | VALID  | N         
(3 rows)
```

These names now match the case when viewed from the PostgreSQL pg_tables catalog.
EDB Postgres™ Advanced Server, Release 13

1.1.3 edb_redwood_strings

In Oracle, when a string is concatenated with a null variable or null column, the result is the original string; however, in PostgreSQL concatenation of a string with a null variable or null column gives a null result. If the edb_redwood_strings parameter is set to TRUE, the aforementioned concatenation operation results in the original string as done by Oracle. If edb_redwood_strings is set to FALSE, the native PostgreSQL behavior is maintained.

The following example illustrates the difference.

The sample application introduced in the next section contains a table of employees. This table has a column named `comm` that is null for most employees. The following query is run with `edb_redwood_strings` set to FALSE. The concatenation of a null column with non-empty strings produces a final result of null, so only employees that have a commission appear in the query result. The output line for all other employees is null.

```
SET edb_redwood_strings TO off;

SELECT RPAD(ename,10) || ' ' || TO_CHAR(sal,'99,999.99') || ' ' ||
      TO_CHAR(comm,'99,999.99') "EMPLOYEE COMPENSATION" FROM emp;
```

<table>
<thead>
<tr>
<th>EMPLOYEE COMPENSATION</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALLEN 1,600.00 300.00</td>
</tr>
<tr>
<td>WARD 1,250.00 500.00</td>
</tr>
<tr>
<td>MARTIN 1,250.00 1,400.00</td>
</tr>
<tr>
<td>TURNER 1,500.00 .00</td>
</tr>
</tbody>
</table>

(14 rows)

The following is the same query executed when `edb_redwood_strings` is set to TRUE. Here, the value of a null column is treated as an empty string. The concatenation of an empty string with a non-empty string produces a null result. The output line for all other employees is null.

```
SELECT RPAD(ename,10) || ' ' || TO_CHAR(sal,'99,999.99') || ' ' ||
      TO_CHAR(comm,'99,999.99') "EMPLOYEE COMPENSATION" FROM emp;
```

<table>
<thead>
<tr>
<th>EMPLOYEE COMPENSATION</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALLEN 1,600.00 300.00</td>
</tr>
<tr>
<td>WARD 1,250.00 500.00</td>
</tr>
<tr>
<td>MARTIN 1,250.00 1,400.00</td>
</tr>
<tr>
<td>TURNER 1,500.00 .00</td>
</tr>
</tbody>
</table>

(14 rows)
produces the non-empty string. This result is consistent with the results produced by Oracle for the same query.

```sql
SET edb_redwood_strings TO on;

SELECT RPAD(ename,10) || ' ' || TO_CHAR(sal,'99,999.99') || ' ' ||
TO_CHAR(comm,'99,999.99') "EMPLOYEE COMPENSATION" FROM emp;
```

```
EMPLOYEE COMPENSATION
---------------------
SMITH     800.00
ALLEN    1,600.00  300.00
WARD     1,250.00  500.00
JONES     2,975.00
MARTIN   1,250.00  1,400.00
BLAKE     2,850.00
CLARK     2,450.00
SCOTT     3,000.00
KING      5,000.00
TURNER    1,500.00 .00
ADAMS     1,100.00
JAMES      950.00
FORD      3,000.00
MILLER    1,300.00
(14 rows)
```

### 1.1.4 edb_stmt_level_tx

In Oracle, when a runtime error occurs in a SQL command, all the updates on the database caused by that single command are rolled back. This is called **statement level transaction isolation**. For example, if a single `UPDATE` command successfully updates five rows, but an attempt to update a sixth row results in an exception, the updates to all six rows made by this `UPDATE` command are rolled back. The effects of prior SQL commands that have not yet been committed or rolled back are pending until a `COMMIT` or `ROLLBACK` command is executed.

In PostgreSQL, if an exception occurs while executing a SQL command, all the updates on the database since the start of the transaction are rolled back. In addition, the transaction is left in an aborted state and either a `COMMIT` or `ROLLBACK` command must be issued before another transaction can be started.

If `edb_stmt_level_tx` is set to `TRUE`, then an exception will not automatically roll back prior uncommitted database updates, emulating the Oracle behavior. If `edb_stmt_level_tx` is set to `FALSE`, then an exception will roll back uncommitted database updates.

**Note:** Use `edb_stmt_level_tx` set to `TRUE` only when absolutely necessary, as this may cause a negative performance impact.

The following example run in PSQL shows that when `edb_stmt_level_tx` is `FALSE`, the abort of the second `INSERT` command also rolls back the first `INSERT` command. Note that in PSQL, the command `\set AUTOCOMMIT off` must be issued, otherwise every statement commits automatically defeating the

---

1.1. Configuration Parameters Compatible with Oracle Databases
The purpose of this demonstration is to show the effect of `edb_stmt_level_tx`.

```sql
\set AUTOCOMMIT off
SET edb_stmt_level_tx TO off;

INSERT INTO emp (empno, ename, deptno) VALUES (9001, 'JONES', 40);
INSERT INTO emp (empno, ename, deptno) VALUES (9002, 'JONES', 00);
ERROR: insert or update on table "emp" violates foreign key constraint
"emp_ref_dept_fk"
DETAIL:  Key (deptno)=(0) is not present in table "dept".

COMMIT;
SELECT empno, ename, deptno FROM emp WHERE empno > 9000;

empno | ename | deptno
-------+-------+--------
(0 rows)
```

In the following example, with `edb_stmt_level_tx` set to TRUE, the first INSERT command has not been rolled back after the error on the second INSERT command. At this point, the first INSERT command can either be committed or rolled back.

```sql
\set AUTOCOMMIT off
SET edb_stmt_level_tx TO on;

INSERT INTO emp (empno, ename, deptno) VALUES (9001, 'JONES', 40);
INSERT INTO emp (empno, ename, deptno) VALUES (9002, 'JONES', 00);
ERROR: insert or update on table "emp" violates foreign key constraint
"emp_ref_dept_fk"
DETAIL:  Key (deptno)=(0) is not present in table "dept".

SELECT empno, ename, deptno FROM emp WHERE empno > 9000;

empno | ename | deptno
-------+-------+--------
9001 | JONES | 40
(1 row)

COMMIT;
```

A `ROLLBACK` command could have been issued instead of the `COMMIT` command in which case the insert of employee number 9001 would have been rolled back as well.

1.1. Configuration Parameters Compatible with Oracle Databases
1.1.5 oracle_home

Before creating a link to an Oracle server, you must direct Advanced Server to the correct Oracle home directory. Set the LD_LIBRARY_PATH environment variable on Linux (or PATH on Windows) to the lib directory of the Oracle client installation directory.

For Windows only, you can instead set the value of the oracle_home configuration parameter in the postgresql.conf file. The value specified in the oracle_home configuration parameter will override the Windows PATH environment variable.

The LD_LIBRARY_PATH environment variable on Linux (PATH environment variable or oracle_home configuration parameter on Windows) must be set properly each time you start Advanced Server.

When using a Linux service script to start Advanced Server, be sure LD_LIBRARY_PATH has been set within the service script so it is in effect when the script invokes the pg_ctl utility to start Advanced Server.

For Windows only: To set the oracle_home configuration parameter in the postgresql.conf file, edit the file, adding the following line:

```plaintext
oracle_home = 'lib_directory'
```

Substitute the name of the Windows directory that contains oci.dll for lib_directory.

After setting the oracle_home configuration parameter, you must restart the server for the changes to take effect. Restart the server from the Windows Services console.
1.2 About the Examples Used in this Guide

The examples shown in this guide are illustrated using the PSQL program. The prompt that normally appears when using PSQL is omitted in these examples to provide extra clarity for the point being demonstrated.

Examples and output from examples are shown in fixed-width, grey font on a light background.

Also note the following points:

• During installation of the EDB Postgres Advanced Server the selection for configuration and defaults compatible with Oracle databases must be chosen in order to reproduce the same results as the examples shown in this guide. A default compatible configuration can be verified by issuing the following commands in PSQL and obtaining the same results as shown below.

```sql
SHOW edb_redwood_date;

edb_redwood_date
------------------
on
SHOW datestyle;

DateStyle
----------
Redwood, DMY
SHOW edb_redwood_strings;

edb_redwood_strings
---------------------
on
```

• The examples use the sample tables, dept, emp, and jobhist, created and loaded when Advanced Server is installed. The emp table is installed with triggers that must be disabled in order to reproduce the same results as shown in this guide. Log onto Advanced Server as the enterprise db superuser and disable the triggers by issuing the following command.

```sql
ALTER TABLE emp DISABLE TRIGGER USER;
```

The triggers on the emp table can later be re-activated with the following command.

```sql
ALTER TABLE emp ENABLE TRIGGER USER;
```
Advanced Server is a *relational database management system* (RDBMS). That means it is a system for managing data stored in *relations*. A relation is essentially a mathematical term for a *table*. The notion of storing data in tables is so commonplace today that it might seem inherently obvious, but there are a number of other ways of organizing databases. Files and directories on Unix-like operating systems form an example of a hierarchical database. A more modern development is the object-oriented database.

Each table is a named collection of *rows*. Each row of a given table has the same set of named *columns*, and each column is of a specific *data type*. Whereas columns have a fixed order in each row, it is important to remember that SQL does not guarantee the order of the rows within the table in any way (although they can be explicitly sorted for display).

Tables are grouped into *databases*, and a collection of databases managed by a single Advanced Server instance constitutes a database *cluster*. 
2.1 Sample Database

Throughout this documentation we will be working with a sample database to help explain some basic to advanced level database concepts.

2.1.1 Sample Database Installation

When Advanced Server is installed a sample database named, `edb`, is automatically created. This sample database contains the tables and programs used throughout this document by executing the script, `edb-sample.sql`, located in the `/usr/edb/as13/share` directory.

This script does the following:

- Creates the sample tables and programs in the currently connected database
- Grants all permissions on the tables to the `PUBLIC` group

The tables and programs will be created in the first schema of the search path in which the current user has permission to create tables and procedures. You can display the search path by issuing the command:

```
SHOW SEARCH_PATH;
```

Altering the search path can be done using commands in PSQL.

2.1.2 Sample Database Description

The sample database represents employees in an organization.

It contains three types of records: employees, departments, and historical records of employees.

Each employee has an identification number, name, hire date, salary, and manager. Some employees earn a commission in addition to their salary. All employee-related information is stored in the `emp` table.

The sample company is regionally diverse, so the database keeps track of the location of the departments. Each company employee is assigned to a department. Each department is identified by a unique department number and a short name. Each department is associated with one location. All department-related information is stored in the `dept` table.

The company also tracks information about jobs held by the employees. Some employees have been with the company for a long time and have held different positions, received raises, switched departments, etc. When a change in employee status occurs, the company records the end date of the former position. A new job record is added with the start date and the new job title, department, salary, and the reason for the status change. All employee history is maintained in the `jobhist` table.

The following is an entity relationship diagram of the sample database tables.
The following is the *edb-sample.sql* script.

```sql
--
-- Script that creates the 'sample' tables, views, procedures,
-- functions, triggers, etc.
--
-- Start new transaction - commit all or nothing
--
BEGIN;
/
--
-- Create and load tables used in the documentation examples.
--
-- Create the 'dept' table
--
CREATE TABLE dept (
  deptno NUMBER(2) NOT NULL CONSTRAINT dept_pk PRIMARY KEY,
  dname VARCHAR2(14) CONSTRAINT dept_dname_uq UNIQUE,
  loc VARCHAR2(13)
);
--
-- Create the 'emp' table
--
CREATE TABLE emp (
  empno NUMBER(4) NOT NULL CONSTRAINT emp_pk PRIMARY KEY,
```

(continues on next page)
CREATE TABLE emp (
  empno NUMBER(4) NOT NULL,
  ename VARCHAR2(10),
  job VARCHAR2(9),
  mgr NUMBER(4),
  hiredate DATE,
  sal NUMBER(7,2) CONSTRAINT emp_sal_ck CHECK (sal > 0),
  comm NUMBER(7,2),
  deptno NUMBER(2) CONSTRAINT emp_ref_dept_fk
    REFERENCES dept(deptno)
);
--
-- Create the 'jobhist' table
--
CREATE TABLE jobhist (
  empno NUMBER(4) NOT NULL,
  startdate DATE NOT NULL,
  enddate DATE,
  job VARCHAR2(9),
  sal NUMBER(7,2),
  comm NUMBER(7,2),
  deptno NUMBER(2),
  chgdesc VARCHAR2(80),
  CONSTRAINT jobhist_pk PRIMARY KEY (empno, startdate),
  CONSTRAINT jobhist_ref_emp_fk FOREIGN KEY (empno)
    REFERENCES emp(empno) ON DELETE CASCADE,
  CONSTRAINT jobhist_ref_dept_fk FOREIGN KEY (deptno)
    REFERENCES dept (deptno) ON DELETE SET NULL,
  CONSTRAINT jobhist_date_chk CHECK (startdate <= enddate)
);
--
-- Create the 'salesemp' view
--
CREATE OR REPLACE VIEW salesemp AS
  SELECT empno, ename, hiredate, sal, comm FROM emp WHERE job = 'SALESMAN';
--
-- Sequence to generate values for function 'new_empno'.
--
CREATE SEQUENCE next_empno START WITH 8000 INCREMENT BY 1;
--
-- Issue PUBLIC grants
--
GRANT ALL ON emp TO PUBLIC;
GRANT ALL ON dept TO PUBLIC;
GRANT ALL ON jobhist TO PUBLIC;
GRANT ALL ON salesemp TO PUBLIC;
GRANT ALL ON next_empno TO PUBLIC;
--
-- Load the 'dept' table
--
INSERT INTO dept VALUES (10,'ACCOUNTING','NEW YORK');
INSERT INTO dept VALUES (20,'RESEARCH','DALLAS');

2.2 Creating a New Table

A new table is created by specifying the table name, along with all column names and their types. The following is a simplified version of the emp sample table with just the minimal information needed to define a table.

```sql
CREATE TABLE emp (  
    empno NUMBER(4),  
    ename VARCHAR2(10),  
    job VARCHAR2(9),  
    mgr NUMBER(4),  
    hiredate DATE,  
    sal NUMBER(7,2),  
    comm NUMBER(7,2),  
    deptno NUMBER(2)
);
```

You can enter this into PSQL with line breaks. PSQL will recognize that the command is not terminated until the semicolon.

White space (i.e., spaces, tabs, and newlines) may be used freely in SQL commands. That means you can type the command aligned differently than the above, or even all on one line. Two dashes (“–”) introduce comments. Whatever follows them is ignored up to the end of the line. SQL is case insensitive about key words and identifiers, except when identifiers are double-quoted to preserve the case (not done above).

`VARCHAR2(10)` specifies a data type that can store arbitrary character strings up to 10 characters in length. `NUMBER(7,2)` is a fixed point number with precision 7 and scale 2. `NUMBER(4)` is an integer number with precision 4 and scale 0.

Advanced Server supports the usual SQL data types `INTEGER`, `SMALLINT`, `NUMBER`, `REAL`, `DOUBLE PRECISION`, `CHAR`, `VARCHAR2`, `DATE`, and `TIMESTAMP` as well as various synonyms for these types.

If you don’t need a table any longer or want to recreate it differently you can remove it using the following command:

```sql
DROP TABLE tablename;
```
2.3 Populating a Table With Rows

The `INSERT` statement is used to populate a table with rows:

```
INSERT INTO emp VALUES (7369,'SMITH','CLERK',7902,'17-DEC-80',800,NULL,20);
```

Note that all data types use rather obvious input formats. Constants that are not simple numeric values usually must be surrounded by single quotes ("'), as in the example. The `DATE` type is actually quite flexible in what it accepts, but for this tutorial we will stick to the unambiguous format shown here.

The syntax used so far requires you to remember the order of the columns. An alternative syntax allows you to list the columns explicitly:

```
INSERT INTO emp(empno,ename,job,mgr,hiredate,sal,comm,deptno)
    VALUES (7499,'ALLEN','SALESMAN',7698,'20-FEB-81',1600,300,30);
```

You can list the columns in a different order if you wish or even omit some columns, e.g., if the commission is unknown:

```
INSERT INTO emp(empno,ename,job,mgr,hiredate,sal,deptno)
    VALUES (7369,'SMITH','CLERK',7902,'17-DEC-80',800,20);
```

Many developers consider explicitly listing the columns better style than relying on the order implicitly.
2.4 Querying a Table

To retrieve data from a table, the table is queried. An SQL SELECT statement is used to do this. The statement is divided into a select list (the part that lists the columns to be returned), a table list (the part that lists the tables from which to retrieve the data), and an optional qualification (the part that specifies any restrictions). The following query lists all columns of all employees in the table in no particular order.

```
SELECT * FROM emp;
```

Here, "*" in the select list means all columns. The following is the output from this query.

```
<table>
<thead>
<tr>
<th>empno</th>
<th>ename</th>
<th>job</th>
<th>mgr</th>
<th>hiredate</th>
<th>sal</th>
<th>comm</th>
<th>deptno</th>
</tr>
</thead>
<tbody>
<tr>
<td>7369</td>
<td>SMITH</td>
<td>CLERK</td>
<td>7902</td>
<td>17-DEC-80</td>
<td>800.00</td>
<td></td>
<td>20</td>
</tr>
<tr>
<td>7499</td>
<td>ALLEN</td>
<td>SALESMAN</td>
<td>7698</td>
<td>20-FEB-81</td>
<td>1600.00</td>
<td>300.00</td>
<td>30</td>

<td>1250.00</td>
<td>1400.00</td>
<td>30</td>
</tr>
<tr>
<td>7698</td>
<td>BLAKE</td>
<td>MANAGER</td>
<td>7839</td>
<td>01-MAY-81</td>
<td>2850.00</td>
<td></td>
<td>30</td>
</tr>
<tr>
<td>7782</td>
<td>CLARK</td>
<td>MANAGER</td>
<td>7839</td>
<td>09-JUN-81</td>
<td>2450.00</td>
<td></td>
<td>10</td>
</tr>
<tr>
<td>7788</td>
<td>SCOTT</td>
<td>ANALYST</td>
<td>7566</td>
<td>19-APR-87</td>
<td>3000.00</td>
<td></td>
<td>20</td>
</tr>
<tr>
<td>7839</td>
<td>KING</td>
<td>PRESIDENT</td>
<td></td>
<td>17-NOV-81</td>
<td>5000.00</td>
<td></td>
<td>10</td>
</tr>
<tr>
<td>7844</td>
<td>TURNER</td>
<td>SALESMAN</td>
<td>7698</td>
<td>08-SEP-81</td>
<td>1500.00</td>
<td>0.00</td>
<td>30</td>
</tr>
<tr>
<td>7876</td>
<td>ADAMS</td>
<td>CLERK</td>
<td>7788</td>
<td>23-MAY-87</td>
<td>1100.00</td>
<td></td>
<td>20</td>
</tr>
<tr>
<td>7900</td>
<td>JAMES</td>
<td>CLERK</td>
<td>7698</td>
<td>03-DEC-81</td>
<td>950.00</td>
<td></td>
<td>30</td>
</tr>
<tr>
<td>7902</td>
<td>FORD</td>
<td>ANALYST</td>
<td>7566</td>
<td>03-DEC-81</td>
<td>3000.00</td>
<td></td>
<td>20</td>
</tr>

<td>7782</td>
<td>23-JAN-82</td>
<td>1300.00</td>
<td></td>
<td>10</td>
</tr>
</tbody>
</table>
```

(14 rows)

You may specify any arbitrary expression in the select list. For example, you can do:

```
SELECT ename, sal, sal * 24 AS yearly_salary, deptno FROM emp;
```

```
<table>
<thead>
<tr>
<th>ename</th>
<th>sal</th>
<th>yearly_salary</th>
<th>deptno</th>
</tr>
</thead>
<tbody>
<tr>
<td>SMITH</td>
<td>800.00</td>
<td>19200.00</td>
<td>20</td>
</tr>
<tr>
<td>ALLEN</td>
<td>1600.00</td>
<td>38400.00</td>
<td>30</td>
</tr>
<tr>
<td>WARD</td>
<td>1250.00</td>
<td>30000.00</td>
<td>30</td>
</tr>
<tr>
<td>JONES</td>
<td>2975.00</td>
<td>71400.00</td>
<td>20</td>
</tr>
<tr>
<td>MARTIN</td>
<td>1250.00</td>
<td>30000.00</td>
<td>30</td>
</tr>
<tr>
<td>BLAKE</td>
<td>2850.00</td>
<td>68400.00</td>
<td>30</td>
</tr>
<tr>
<td>CLARK</td>
<td>2450.00</td>
<td>58800.00</td>
<td>10</td>
</tr>
<tr>
<td>SCOTT</td>
<td>3000.00</td>
<td>72000.00</td>
<td>20</td>
</tr>
<tr>
<td>KING</td>
<td>5000.00</td>
<td>120000.00</td>
<td>10</td>
</tr>
<tr>
<td>TURNER</td>
<td>1500.00</td>
<td>36000.00</td>
<td>30</td>
</tr>
<tr>
<td>ADAMS</td>
<td>1100.00</td>
<td>26400.00</td>
<td>20</td>
</tr>
<tr>
<td>JAMES</td>
<td>950.00</td>
<td>22800.00</td>
<td>30</td>
</tr>
<tr>
<td>FORD</td>
<td>3000.00</td>
<td>72000.00</td>
<td>20</td>
</tr>
<tr>
<td>MILLER</td>
<td>1300.00</td>
<td>31200.00</td>
<td>10</td>
</tr>
</tbody>
</table>
```

(14 rows)

Notice how the `AS` clause is used to re-label the output column. (The `AS` clause is optional.)
A query can be qualified by adding a WHERE clause that specifies which rows are wanted. The WHERE clause contains a Boolean (truth value) expression, and only rows for which the Boolean expression is true are returned. The usual Boolean operators (AND, OR, and NOT) are allowed in the qualification. For example, the following retrieves the employees in department 20 with salaries over $1000.00:

```
SELECT ename, sal, deptno FROM emp WHERE deptno = 20 AND sal > 1000;
```

| ename | sal    | deptno |
|-------|--------+--------|
| JONES | 2975.00| 20     |
| SCOTT | 3000.00| 20     |
| ADAMS | 1100.00| 20     |
| FORD  | 3000.00| 20     |

(4 rows)

You can request that the results of a query be returned in sorted order:

```
SELECT ename, sal, deptno FROM emp ORDER BY ename;
```

| ename | sal    | deptno |
|-------|--------+--------|
| ADAMS | 1100.00| 20     |
| ALLEN | 1600.00| 30     |
| BLAKE | 2850.00| 30     |
| CLARK | 2450.00| 10     |
| FORD  | 3000.00| 20     |
| JAMES | 950.00 | 30     |
| JONES | 2975.00| 20     |
| KING  | 5000.00| 10     |
| MARTIN| 1250.00| 30     |
| MILLER| 1300.00| 10     |
| SCOTT | 3000.00| 20     |
| SMITH | 800.00 | 20     |
| TURNER| 1500.00| 30     |
| WARD  | 1250.00| 30     |

(14 rows)

You can request that duplicate rows be removed from the result of a query:

```
SELECT DISTINCT job FROM emp;
```

<table>
<thead>
<tr>
<th>job</th>
</tr>
</thead>
<tbody>
<tr>
<td>ANALYST</td>
</tr>
<tr>
<td>CLERK</td>
</tr>
<tr>
<td>MANAGER</td>
</tr>
<tr>
<td>PRESIDENT</td>
</tr>
<tr>
<td>SALESMAN</td>
</tr>
</tbody>
</table>

(5 rows)

The following section shows how to obtain rows from more than one table in a single query.
2.5 Joins Between Tables

Thus far, our queries have only accessed one table at a time. Queries can access multiple tables at once, or access the same table in such a way that multiple rows of the table are being processed at the same time. A query that accesses multiple rows of the same or different tables at one time is called a join query. For example, say you wish to list all the employee records together with the name and location of the associated department. To do that, we need to compare the deptno column of each row of the emp table with the deptno column of all rows in the dept table, and select the pairs of rows where these values match. This would be accomplished by the following query:

```
SELECT emp.ename, emp.sal, dept.deptno, dept.dname, dept.loc FROM emp, dept
WHERE emp.deptno = dept.deptno;
```

<table>
<thead>
<tr>
<th>ename</th>
<th>sal</th>
<th>deptno</th>
<th>dname</th>
<th>loc</th>
</tr>
</thead>
<tbody>
<tr>
<td>MILLER</td>
<td>1300.00</td>

<td>SALES</td>
<td>CHICAGO</td>
</tr>
<tr>
<td>JAMES</td>
<td>950.00</td>
<td>30</td>
<td>SALES</td>
<td>CHICAGO</td>
</tr>
</tbody>
</table>

(14 rows)

Observe two things about the result set:

- There is no result row for department 40. This is because there is no matching entry in the emp table for department 40, so the join ignores the unmatched rows in the dept table. Shortly we will see how this can be fixed.

- It is more desirable to list the output columns qualified by table name rather than using * or leaving out the qualification as follows:

```
SELECT ename, sal, dept.deptno, dname, loc FROM emp, dept
WHERE emp.deptno = dept.deptno;
```

Since all the columns had different names (except for deptno which therefore must be qualified), the parser automatically found out which table they belong to, but it is good style to fully qualify column names in join queries:

Join queries of the kind seen thus far can also be written in this alternative form:

```
SELECT emp.ename, emp.sal, dept.deptno, dept.dname, dept.loc FROM emp INNER JOIN dept ON emp.deptno = dept.deptno;
```
This syntax is not as commonly used as the one above, but we show it here to help you understand the following topics.

You will notice that in all the above results for joins no employees were returned that belonged to department 40 and as a consequence, the record for department 40 never appears. Now we will figure out how we can get the department 40 record in the results despite the fact that there are no matching employees. What we want the query to do is to scan the \textit{dept} table and for each row to find the matching \textit{emp} row. If no matching row is found we want some “empty” values to be substituted for the \textit{emp} table’s columns. This kind of query is called an \textit{outer join}. (The joins we have seen so far are \textit{inner joins}.) The command looks like this:

\begin{verbatim}
SELECT emp.ename, emp.sal, dept.deptno, dept.dname, dept.loc FROM dept LEFT OUTER JOIN emp ON emp.deptno = dept.deptno;
\end{verbatim}

\begin{verbatim}
ename | sal    | deptno | dname       | loc
--------+---------+--------+------------+----------
MILLER | 1300.00 | 10     | ACCOUNTING | NEW YORK
CLARK  | 2450.00 | 10     | ACCOUNTING | NEW YORK
KING   | 5000.00 | 10     | ACCOUNTING | NEW YORK
SCOTT  | 3000.00 | 20     | RESEARCH   | DALLAS
JONES  | 2975.00 | 20     | RESEARCH   | DALLAS
SMITH  | 800.00  | 20     | RESEARCH   | DALLAS
ADAMS  | 1100.00 | 20     | RESEARCH   | DALLAS
FORD   | 3000.00 | 20     | RESEARCH   | DALLAS
WARD   | 1250.00 | 30     | SALES      | CHICAGO
TURNER | 1500.00 | 30     | SALES      | CHICAGO
ALLEN  | 1600.00 | 30     | SALES      | CHICAGO
BLAKE  | 2850.00 | 30     | SALES      | CHICAGO
MARTIN | 1250.00 | 30     | SALES      | CHICAGO
JAMES  | 950.00  | 30     | SALES      | CHICAGO
        |        | 40     | OPERATIONS | BOSTON
\end{verbatim}
(15 rows)

This query is called a \textit{left outer join} because the table mentioned on the left of the join operator will have each of its rows in the output at least once, whereas the table on the right will only have those rows output that match some row of the left table. When a left-table row is selected for which there is no right-table match, empty (\texttt{NULL}) values are substituted for the right-table columns.

An alternative syntax for an outer join is to use the outer join operator, “(+)”, in the join condition within the \texttt{WHERE} clause. The outer join operator is placed after the column name of the table for which null values should be substituted for unmatched rows. So for all the rows in the \textit{dept} table that have no matching rows in the \textit{emp} table, Advanced Server returns null for any select list expressions containing columns of \textit{emp}. Hence the above example could be rewritten as:

\begin{verbatim}
SELECT emp.ename, emp.sal, dept.deptno, dept.dname, dept.loc FROM dept, emp
WHERE emp.deptno(+) = dept.deptno;
\end{verbatim}

\begin{verbatim}
ename | sal    | deptno | dname       | loc
--------+---------+--------+------------+----------
MILLER | 1300.00 | 10     | ACCOUNTING | NEW YORK
CLARK  | 2450.00 | 10     | ACCOUNTING | NEW YORK
KING   | 5000.00 | 10     | ACCOUNTING | NEW YORK
\end{verbatim}
(continues on next page)
We can also join a table against itself. This is called a *self join*. As an example, suppose we wish to find the name of each employee along with the name of that employee’s manager. So we need to compare the \texttt{mgr} column of each \texttt{emp} row to the \texttt{empno} column of all other \texttt{emp} rows.

```sql
SELECT e1.ename || ' works for ' || e2.ename AS "Employees and their Managers" FROM emp e1, emp e2 WHERE e1.mgr = e2.empno;
```

### Employees and their Managers

<table>
<thead>
<tr>
<th>Name</th>
<th>Manager Name</th>
<th>Department</th>
<th>Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>FORD</td>
<td>JONES</td>
<td>RESEARCH</td>
<td>DALLAS</td>
</tr>
<tr>
<td>SCOTT</td>
<td>JONES</td>
<td>RESEARCH</td>
<td>DALLAS</td>
</tr>
<tr>
<td>WARD</td>
<td>BLAKE</td>
<td>SALES</td>
<td>CHICAGO</td>
</tr>
<tr>
<td>TURNER</td>
<td>BLAKE</td>
<td>SALES</td>
<td>CHICAGO</td>
</tr>
<tr>
<td>MARTIN</td>
<td>BLAKE</td>
<td>SALES</td>
<td>CHICAGO</td>
</tr>
<tr>

<td>ACCOUNTING</td>
<td>NEW YORK</td>
</tr>
<tr>
<td>CLARK</td>
<td>KING</td>
<td>ACCOUNTING</td>
<td>NEW YORK</td>
</tr>
<tr>
<td>BLAKE</td>
<td>KING</td>
<td>ACCOUNTING</td>
<td>NEW YORK</td>
</tr>
<tr>
<td>JONES</td>
<td>KING</td>
<td>ACCOUNTING</td>
<td>NEW YORK</td>
</tr>
<tr>
<td>SMITH</td>
<td>FORD</td>
<td>RESEARCH</td>
<td>DALLAS</td>
</tr>
<tr>
<td>ADAMS</td>
<td>SCOTT</td>
<td>RESEARCH</td>
<td>DALLAS</td>
</tr>
<tr>
<td>CLARK</td>
<td>KING</td>
<td>ACCOUNTING</td>
<td>NEW YORK</td>
</tr>
</tbody>
</table>

(13 rows)

Here, the \texttt{emp} table has been re-labeled as \texttt{e1} to represent the employee row in the select list and in the join condition, and also as \texttt{e2} to represent the matching employee row acting as manager in the select list and in the join condition. These kinds of aliases can be used in other queries to save some typing, for example:

```sql
SELECT e.ename, e.mgr, d.deptno, d.dname, d.loc FROM emp e, dept d WHERE e.deptno = d.deptno;
```

### Employees and their Managers

<table>
<thead>
<tr>
<th>Name</th>
<th>Manager</th>
<th>Department</th>
<th>Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>MILLER</td>
<td>7782</td>
<td>10</td>
<td>ACCOUNTING</td>

</tr>
</tbody>
</table>
(14 rows)
2.6 Aggregate Functions

Like most other relational database products, Advanced Server supports aggregate functions. An aggregate function computes a single result from multiple input rows. For example, there are aggregates to compute the COUNT, SUM, AVG (average), MAX (maximum), and MIN (minimum) over a set of rows.

As an example, the highest and lowest salaries can be found with the following query:

```
SELECT MAX(sal) highest_salary, MIN(sal) lowest_salary FROM emp;
```

```
<table>
<thead>
<tr>
<th>highest_salary</th>
<th>lowest_salary</th>
</tr>
</thead>
<tbody>
<tr>
<td>5000.00</td>
<td>800.00</td>
</tr>
</tbody>
</table>
```

(1 row)

If we wanted to find the employee with the largest salary, we may be tempted to try:

```
SELECT ename FROM emp WHERE sal = MAX(sal);
```

```
ERROR: aggregates not allowed in WHERE clause
```

This does not work because the aggregate function, MAX, cannot be used in the WHERE clause. This restriction exists because the WHERE clause determines the rows that will go into the aggregation stage so it has to be evaluated before aggregate functions are computed. However, the query can be restated to accomplish the intended result by using a subquery:

```
SELECT ename FROM emp WHERE sal = (SELECT MAX(sal) FROM emp);
```

```
<table>
<thead>
<tr>
<th>ename</th>
</tr>
</thead>
<tbody>
<tr>
<td>KING</td>
</tr>
</tbody>
</table>
```

(1 row)

The subquery is an independent computation that obtains its own result separately from the outer query.

Aggregates are also very useful in combination with the GROUP BY clause. For example, the following query gets the highest salary in each department.

```
SELECT deptno, MAX(sal) FROM emp GROUP BY deptno;
```

```
<table>
<thead>
<tr>
<th>deptno</th>
<th>max</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>5000.00</td>
</tr>
<tr>
<td>20</td>
<td>3000.00</td>
</tr>
<tr>
<td>30</td>
<td>2850.00</td>
</tr>
</tbody>
</table>
```

(3 rows)

This query produces one output row per department. Each aggregate result is computed over the rows matching that department. These grouped rows can be filtered using the HAVING clause.

```
SELECT deptno, MAX(sal) FROM emp GROUP BY deptno HAVING AVG(sal) > 2000;
```

(continues on next page)
This query gives the same results for only those departments that have an average salary greater than 2000.

Finally, the following query takes into account only the highest paid employees who are analysts in each department.

```
SELECT deptno, MAX(sal) FROM emp WHERE job = 'ANALYST' GROUP BY deptno
HAVING AVG(sal) > 2000;
```

| deptno | max   |
|--------+-------|
| 20     | 3000.00 |

(1 row)

There is a subtle distinction between the `WHERE` and `HAVING` clauses. The `WHERE` clause filters out rows before grouping occurs and aggregate functions are applied. The `HAVING` clause applies filters on the results after rows have been grouped and aggregate functions have been computed for each group.

So in the previous example, only employees who are analysts are considered. From this subset, the employees are grouped by department and only those groups where the average salary of analysts in the group is greater than 2000 are in the final result. This is true of only the group for department 20 and the maximum analyst salary in department 20 is 3000.00.
2.7 Updates

The column values of existing rows can be changed using the `UPDATE` command. For example, the following sequence of commands shows the before and after results of giving everyone who is a manager a 10% raise:

```
SELECT ename, sal FROM emp WHERE job = 'MANAGER';

<table>
<thead>
<tr>
<th>ename</th>
<th>sal</th>
</tr>
</thead>
<tbody>
<tr>
<td>JONES</td>
<td>2975.00</td>
</tr>
<tr>
<td>BLAKE</td>
<td>2850.00</td>
</tr>
<tr>
<td>CLARK</td>
<td>2450.00</td>
</tr>
</tbody>
</table>
```

```
UPDATE emp SET sal = sal * 1.1 WHERE job = 'MANAGER';

SELECT ename, sal FROM emp WHERE job = 'MANAGER';

<table>
<thead>
<tr>
<th>ename</th>
<th>sal</th>
</tr>
</thead>
<tbody>
<tr>
<td>JONES</td>
<td>3272.50</td>
</tr>
<tr>
<td>BLAKE</td>
<td>3135.00</td>
</tr>
<tr>
<td>CLARK</td>
<td>2695.00</td>
</tr>
</tbody>
</table>
```
2.8 Deletions

Rows can be removed from a table using the **DELETE** command. For example, the following sequence of commands shows the before and after results of deleting all employees in department 20.

```
SELECT ename, deptno FROM emp;
| ename | deptno |
|-------+--------|
| SMITH | 20     |
| ALLEN | 30     |
| WARD  | 30     |
| JONES | 20     |
| MARTIN| 30     |
| BLAKE | 30     |
| CLARK | 10     |
| SCOTT | 20     |
| KING  | 10     |
| TURNER| 30     |
| ADAMS | 20     |
| JAMES | 30     |
| FORD  | 20     |
| MILLER| 10     |
(14 rows)
```

```
DELETE FROM emp WHERE deptno = 20;
```

```
SELECT ename, deptno FROM emp;
| ename | deptno |
|-------+--------|
| ALLEN | 30     |
| WARD  | 30     |
| MARTIN| 30     |
| BLAKE | 30     |
| CLARK | 10     |
| KING  | 10     |
| TURNER| 30     |
| JAMES | 30     |
| MILLER| 10     |
(9 rows)
```

Be extremely careful of giving a **DELETE** command without a **WHERE** clause such as the following:

```
DELETE FROM tablename;
```

This statement will remove all rows from the given table, leaving it completely empty. The system will not request confirmation before doing this.
2.9 The SQL Language

Advanced Server supports SQL language that is compatible with Oracle syntax as well as syntax and commands for extended functionality (functionality that does not provide database compatibility for Oracle or support Oracle-styled applications).

The *Database Compatibility for Oracle Developer’s SQL Guide* provides detailed information about:

- Compatible SQL syntax and language elements
- Data types
- Supported SQL command syntax

To review a copy of the guide, visit the Advanced Server website at:

https://www.enterprisedb.com/edb-docs
The previous section discussed the basics of using SQL to store and access your data in Advanced Server. This section discusses more advanced SQL features that may simplify management and prevent loss or corruption of your data.

### 3.1 Views

Consider the following `SELECT` command.

```sql
SELECT ename, sal, sal * 24 AS yearly_salary, deptno FROM emp;
```

<table>
<thead>
<tr>
<th>ename</th>
<th>sal</th>
<th>yearly_salary</th>
<th>deptno</th>
</tr>
</thead>
<tbody>
<tr>
<td>SMITH</td>
<td>800.00</td>
<td>19200.00</td>
<td>20</td>
</tr>
<tr>
<td>ALLEN</td>
<td>1600.00</td>
<td>38400.00</td>
<td>30</td>
</tr>
<tr>
<td>WARD</td>
<td>1250.00</td>
<td>30000.00</td>
<td>30</td>
</tr>
<tr>
<td>JONES</td>
<td>2975.00</td>
<td>71400.00</td>
<td>20</td>
</tr>
<tr>
<td>MARTIN</td>
<td>1250.00</td>
<td>30000.00</td>
<td>30</td>
</tr>
<tr>
<td>BLAKE</td>
<td>2850.00</td>
<td>68400.00</td>
<td>30</td>
</tr>
<tr>
<td>CLARK</td>
<td>2450.00</td>
<td>58800.00</td>
<td>10</td>
</tr>
<tr>
<td>SCOTT</td>
<td>3000.00</td>
<td>72000.00</td>
<td>20</td>
</tr>
<tr>
<td>KING</td>
<td>5000.00</td>
<td>120000.00</td>
<td>10</td>
</tr>
<tr>
<td>TURNER</td>
<td>1500.00</td>
<td>36000.00</td>
<td>30</td>
</tr>
<tr>
<td>ADAMS</td>
<td>1100.00</td>
<td>26400.00</td>
<td>20</td>
</tr>
<tr>
<td>JAMES</td>
<td>950.00</td>
<td>22800.00</td>
<td>30</td>
</tr>
<tr>
<td>FORD</td>
<td>3000.00</td>
<td>72000.00</td>
<td>20</td>
</tr>
<tr>
<td>MILLER</td>
<td>1300.00</td>
<td>31200.00</td>
<td>10</td>
</tr>
</tbody>
</table>
```

(14 rows)
If this is a query that is used repeatedly, a shorthand method of reusing this query without re-typing the entire SELECT command each time is to create a view as shown below.

```
CREATE VIEW employee_pay AS SELECT ename, sal, sal * 24 AS yearly_salary, deptno FROM emp;
```

The view name, `employee_pay`, can now be used like an ordinary table name to perform the query.

```
SELECT * FROM employee_pay;
```

<table>
<thead>
<tr>
<th>ename</th>
<th>sal</th>
<th>yearly_salary</th>
<th>deptno</th>
</tr>
</thead>
<tbody>
<tr>
<td>SMITH</td>
<td>800.00</td>
<td>19200.00</td>
<td>20</td>
</tr>
<tr>
<td>ALLEN</td>
<td>1600.00</td>
<td>38400.00</td>
<td>30</td>
</tr>
<tr>
<td>WARD</td>
<td>1250.00</td>
<td>30000.00</td>
<td>30</td>
</tr>
<tr>
<td>JONES</td>
<td>2975.00</td>
<td>71400.00</td>
<td>20</td>
</tr>
<tr>
<td>MARTIN</td>
<td>1250.00</td>
<td>30000.00</td>
<td>30</td>
</tr>
<tr>
<td>BLAKE</td>
<td>2850.00</td>
<td>68400.00</td>
<td>30</td>
</tr>
<tr>
<td>CLARK</td>
<td>2450.00</td>
<td>58800.00</td>
<td>10</td>
</tr>
<tr>
<td>SCOTT</td>
<td>3000.00</td>
<td>72000.00</td>
<td>20</td>
</tr>
<tr>
<td>KING</td>
<td>5000.00</td>
<td>120000.00</td>
<td>10</td>
</tr>
<tr>
<td>TURNER</td>
<td>1500.00</td>
<td>36000.00</td>
<td>30</td>
</tr>
<tr>
<td>ADAMS</td>
<td>1100.00</td>
<td>26400.00</td>
<td>20</td>
</tr>
<tr>
<td>JAMES</td>
<td>950.00</td>
<td>22800.00</td>
<td>30</td>
</tr>
<tr>
<td>FORD</td>
<td>3000.00</td>
<td>72000.00</td>
<td>20</td>
</tr>
<tr>
<td>MILLER</td>
<td>1300.00</td>
<td>31200.00</td>
<td>10</td>
</tr>
</tbody>
</table>
```

(14 rows)

Making liberal use of views is a key aspect of good SQL database design. Views provide a consistent interface that encapsulate details of the structure of your tables which may change as your application evolves.

Views can be used in almost any place a real table can be used. Building views upon other views is not uncommon.
3.2 Foreign Keys

Suppose you want to make sure all employees belong to a valid department. This is called maintaining the **referential integrity** of your data. In simplistic database systems this would be implemented (if at all) by first looking at the `dept` table to check if a matching record exists, and then inserting or rejecting the new employee record. This approach has a number of problems and is very inconvenient. Advanced Server can make it easier for you.

A modified version of the `emp` table presented in *Creating a New Table* is shown in this section with the addition of a foreign key constraint. The modified `emp` table looks like the following:

```sql
CREATE TABLE emp (  
  empno NUMBER(4) NOT NULL CONSTRAINT emp_pk PRIMARY KEY,  
  ename VARCHAR2(10),  
  job VARCHAR2(9),  
  mgr NUMBER(4),  
  hiredate DATE,  
  sal NUMBER(7,2),  
  comm NUMBER(7,2),  
  deptno NUMBER(2) CONSTRAINT emp_ref_dept_fk  
    REFERENCES dept(deptno)  
);   
```

If an attempt is made to issue the following `INSERT` command in the sample `emp` table, the foreign key constraint, `emp_ref_dept_fk`, ensures that department 50 exists in the `dept` table. Since it does not, the command is rejected.

```sql
INSERT INTO emp VALUES (8000,'JONES','CLERK',7902,'17-AUG-07',1200,NULL,50);
ERROR: insert or update on table "emp" violates foreign key constraint "emp_ref_dept_fk"
DETAIL: Key (deptno)=(50) is not present in table "dept".
```

The behavior of foreign keys can be finely tuned to your application. Making correct use of foreign keys will definitely improve the quality of your database applications, so you are strongly encouraged to learn more about them.
3.3 The ROWNUM Pseudo-Column

ROUNUM is a pseudo-column that is assigned an incremental, unique integer value for each row based on the order the rows were retrieved from a query. Therefore, the first row retrieved will have ROWNUM of 1; the second row will have ROWNUM of 2 and so on.

This feature can be used to limit the number of rows retrieved by a query. This is demonstrated in the following example:

```sql
SELECT empno, ename, job FROM emp WHERE ROWNUM < 5;
```

```
empno | ename | job  
-------+-------+--------
7369  | SMITH | CLERK  
7499  | ALLEN | SALESMAN  
7521  | WARD  | SALESMAN  
7566  | JONES | MANAGER  
(4 rows)
```

The ROWNUM value is assigned to each row before any sorting of the result set takes place. Thus, the result set is returned in the order given by the ORDER BY clause, but the ROWNUM values may not necessarily be in ascending order as shown in the following example:

```sql
SELECT ROWNUM, empno, ename, job FROM emp WHERE ROWNUM < 5 ORDER BY ename;
```

```
rownum | empno | ename | job  
--------+-------+-------+--------
2       | 7499  | ALLEN | SALESMAN  
4       | 7566  | JONES | MANAGER  
1       | 7369  | SMITH | CLERK  
3       | 7521  | WARD  | SALESMAN  
(4 rows)
```

The following example shows how a sequence number can be added to every row in the jobhist table. First a new column named, seqno, is added to the table and then seqno is set to ROWNUM in the UPDATE command.

```sql
ALTER TABLE jobhist ADD seqno NUMBER(3);  
UPDATE jobhist SET seqno = ROWNUM;
```

The following SELECT command shows the new seqno values.

```sql
SELECT seqno, empno, TO_CHAR(startdate,'DD-MON-YY') AS start, job FROM jobhist;
```

```
seqno | empno | start   | job  
-------+-------+---------+--------
1      | 7369  | 17-DEC-80 | CLERK  
2      | 7499  | 20-FEB-81 | SALESMAN  
3      | 7521  | 22-FEB-81 | SALESMAN  
4      | 7566  | 02-APR-81 | MANAGER  
```

3.4 Synonyms

A synonym is an identifier that can be used to reference another database object in a SQL statement. A synonym is useful in cases where a database object would normally require full qualification by schema name to be properly referenced in a SQL statement. A synonym defined for that object simplifies the reference to a single, unqualified name.

Advanced Server supports synonyms for:

- tables
- views
- materialized views
- sequences
- procedures
- functions
- types
- objects that are accessible through a database link
- other synonyms

Neither the referenced schema or referenced object must exist at the time that you create the synonym; a synonym may refer to a non-existent object or schema. A synonym will become invalid if you drop the referenced object or schema. You must explicitly drop a synonym to remove it.

As with any other schema object, Advanced Server uses the search path to resolve unqualified synonym names. If you have two synonyms with the same name, an unqualified reference to a synonym will resolve to the first synonym with the given name in the search path. If public is in your search path, you can refer to a synonym in that schema without qualifying that name.

When Advanced Server executes an SQL command, the privileges of the current user are checked against the synonym’s underlying database object; if the user does not have the proper permissions for that object, the SQL command will fail.

Creating a Synonym

Use the CREATE SYNONYM command to create a synonym. The syntax is:

```
CREATE [OR REPLACE] [PUBLIC] SYNONYM [<schema>.]<syn_name>
FOR <object_schema>.<object_name>[<@dblink_name>];
```

Parameters:

**syn_name**

- **syn_name** is the name of the synonym. A synonym name must be unique within a schema.

**schema**

- **schema** specifies the name of the schema that the synonym resides in. If you do not specify a schema name, the synonym is created in the first existing schema in your search path.
object_name

object_name specifies the name of the object.

object_schema

object_schema specifies the name of the schema that the object resides in.

dblink_name

dblink_name specifies the name of the database link through which a target object may be accessed.

Include the REPLACE clause to replace an existing synonym definition with a new synonym definition.

Include the PUBLIC clause to create the synonym in the public schema. Compatible with Oracle databases, the CREATE PUBLIC SYNONYM command creates a synonym that resides in the public schema:

```
CREATE [OR REPLACE] PUBLIC SYNONYM <syn_name> FOR <object_schema>.<object_name>;
```

This just a shorthand way to write:

```
CREATE [OR REPLACE] SYNONYM public.<syn_name> FOR <object_schema>.<object_name>;
```

The following example creates a synonym named personnel that refers to the enterprisedb.emp table.

```
CREATE SYNONYM personnel FOR enterprisedb.emp;
```

Unless the synonym is schema qualified in the CREATE SYNONYM command, it will be created in the first existing schema in your search path. You can view your search path by executing the following command:

```
SHOW SEARCH_PATH;
```

```
search_path
--------------------
development,accounting
(1 row)
```

In our example, if a schema named development does not exist, the synonym will be created in the schema named accounting.

Now, the emp table in the enterprisedb schema can be referenced in any SQL statement (DDL or DML), by using the synonym, personnel:

```
INSERT INTO personnel VALUES (8142,'ANDERSON','CLERK',7902,'17-DEC-06',1300,NULL,20);
SELECT * FROM personnel;
```

(continues on next page)
Deleting a Synonym

To delete a synonym, use the command, `DROP SYNONYM`. The syntax is:

```
DROP [PUBLIC] SYNONYM [<schema>.] <syn_name>
```

**Parameters:**

- **syn_name**
  - `syn_name` is the name of the synonym. A synonym name must be unique within a schema.

- **schema**
  - `schema` specifies the name of the schema in which the synonym resides.

Like any other object that can be schema-qualified, you may have two synonyms with the same name in your search path. To disambiguate the name of the synonym that you are dropping, include a schema name. Unless a synonym is schema qualified in the `DROP SYNONYM` command, Advanced Server deletes the first instance of the synonym it finds in your search path.

You can optionally include the `PUBLIC` clause to drop a synonym that resides in the `public` schema. Compatible with Oracle databases, the `DROP PUBLIC SYNONYM` command drops a synonym that resides in the `public` schema:

```
DROP PUBLIC SYNONYM <syn_name>;
```

The following example drops the synonym, `personnel`:

```
DROP SYNONYM personnel;
```
3.5 Hierarchical Queries

A **hierarchical query** is a type of query that returns the rows of the result set in a hierarchical order based upon data forming a parent-child relationship. A hierarchy is typically represented by an inverted tree structure. The tree is comprised of interconnected **nodes**. Each node may be connected to none, one, or multiple **child** nodes. Each node is connected to one **parent** node except for the top node which has no parent. This node is the **root** node. Each tree has exactly one root node. Nodes that don’t have any children are called **leaf** nodes. A tree always has at least one leaf node - e.g., the trivial case where the tree is comprised of a single node. In this case it is both the root and the leaf.

In a hierarchical query the rows of the result set represent the nodes of one or more trees.

**Note:** It is possible that a single, given row may appear in more than one tree and thus appear more than once in the result set.

The hierarchical relationship in a query is described by the **CONNECT BY** clause which forms the basis of the order in which rows are returned in the result set. The context of where the **CONNECT BY** clause and its associated optional clauses appear in the **SELECT** command is shown below.

```sql
SELECT <select_list> FROM <table_expression> [ WHERE ...]
   [ START WITH <start_expression> ]
   CONNECT BY { PRIOR <parent_expr> = <child_expr> | <child_expr> = PRIOR <parent_expr> }
   [ ORDER SIBLINGS BY <column1> [ ASC | DESC ] [, <column2> [ ASC | DESC ] ] ...]
   [ GROUP BY ...]
   [ HAVING ...]
   [ <other> ...]
```

**select_list** is one or more expressions that comprise the fields of the result set. **table_expression** is one or more tables or views from which the rows of the result set originate. **other** is any additional legal **SELECT** command clauses. The clauses pertinent to hierarchical queries, **START WITH**, **CONNECT BY**, and **ORDER SIBLINGS BY** are described in the following sections.

**Note:** At this time, Advanced Server does not support the use of **AND** (or other operators) in the **CONNECT BY** clause.

### 3.5.1 Defining the Parent/Child Relationship

For any given row, its parent and its children are determined by the **CONNECT BY** clause. The **CONNECT BY** clause must consist of two expressions compared with the equals (=) operator. In addition, one of these two expressions must be preceded by the keyword, **PRIOR**.

For any given row, to determine its children:

1. Evaluate **parent_expr** on the given row
2. Evaluate `child_expr` on any other row resulting from the evaluation of `table_expression`

3. If `parent_expr = child_expr`, then this row is a child node of the given parent row

4. Repeat the process for all remaining rows in `table_expression`. All rows that satisfy the equation in step 3 are the children nodes of the given parent row.

**Note:** The evaluation process to determine if a row is a child node occurs on every row returned by `table_expression` before the `WHERE` clause is applied to `table_expression`.

By iteratively repeating this process treating each child node found in the prior steps as a parent, an inverted tree of nodes is constructed. The process is complete when the final set of child nodes has no children of their own - these are the leaf nodes.

A `SELECT` command that includes a `CONNECT BY` clause typically includes the `START WITH` clause. The `START WITH` clause determines the rows that are to be the root nodes - i.e., the rows that are the initial parent nodes upon which the algorithm described previously is to be applied. This is further explained in the following section.

### 3.5.2 Selecting the Root Nodes

The `START WITH` clause is used to determine the row(s) selected by `table_expression` that are to be used as the root nodes. All rows selected by `table_expression` where `start_expression` evaluates to true become a root node of a tree. Thus, the number of potential trees in the result set is equal to the number of root nodes. As a consequence, if the `START WITH` clause is omitted, then every row returned by `table_expression` is a root of its own tree.

### 3.5.3 Organization Tree in the Sample Application

Consider the `emp` table of the sample application. The rows of the `emp` table form a hierarchy based upon the `mgr` column which contains the employee number of the employee’s manager. Each employee has at most, one manager. KING is the president of the company so he has no manager, therefore KING’s `mgr` column is null. Also, it is possible for an employee to act as a manager for more than one employee. This relationship forms a typical, tree-structured, hierarchical organization chart as illustrated below.
To form a hierarchical query based upon this relationship, the SELECT command includes the clause, CONNECT BY PRIOR empno = mgr. For example, given the company president, KING, with employee number 7839, any employee whose mgr column is 7839 reports directly to KING which is true for JONES, BLAKE, and CLARK (these are the child nodes of KING). Similarly, for employee, JONES, any other employee with mgr column equal to 7566 is a child node of JONES - these are SCOTT and FORD in this example.

The top of the organization chart is KING so there is one root node in this tree. The START WITH mgr IS NULL clause selects only KING as the initial root node.

The complete SELECT command is shown below.

```
SELECT ename, empno, mgr
FROM emp
START WITH mgr IS NULL
CONNECT BY PRIOR empno = mgr;
```

The rows in the query output traverse each branch from the root to leaf moving in a top-to-bottom, left-to-right order. Below is the output from this query.

```
| ename  | empno | mgr  |
|--------|-------+------|
| KING   | 7839  |      |
| JONES  | 7566  | 7839 |
| SCOTT  | 7788  | 7566 |
| ADAMS  | 7876  | 7788 |
| FORD   | 7902  | 7566 |
| SMITH  | 7369  | 7902 |
| BLAKE  | 7698  | 7839 |
| ALLEN  | 7499  | 7698 |
```

(continues on next page)
3.5.4 Node Level

LEVEL is a pseudo-column that can be used wherever a column can appear in the SELECT command. For each row in the result set, LEVEL returns a non-zero integer value designating the depth in the hierarchy of the node represented by this row. The LEVEL for root nodes is 1. The LEVEL for direct children of root nodes is 2, and so on.

The following query is a modification of the previous query with the addition of the LEVEL pseudo-column. In addition, using the LEVEL value, the employee names are indented to further emphasize the depth in the hierarchy of each row.

```
SELECT LEVEL, LPAD (' ', 2 * (LEVEL - 1)) || ename "employee", empno, mgr
FROM emp START WITH mgr IS NULL
CONNECT BY PRIOR empno = mgr;
```

The output from this query follows.

<table>
<thead>
<tr>
<th>level</th>
<th>employee</th>
<th>empno</th>
<th>mgr</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>KING</td>
<td>7839</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>JONES</td>
<td>7566</td>
<td>7839</td>
</tr>
<tr>
<td>3</td>
<td>SCOTT</td>
<td>7788</td>
<td>7566</td>
</tr>
<tr>
<td>4</td>
<td>ADAMS</td>
<td>7876</td>
<td>7788</td>
</tr>
<tr>
<td>3</td>
<td>FORD</td>
<td>7902</td>
<td>7566</td>
</tr>
<tr>
<td>4</td>
<td>SMITH</td>
<td>7369</td>
<td>7902</td>
</tr>
<tr>
<td>2</td>
<td>BLAKE</td>
<td>7698</td>
<td>7839</td>
</tr>
<tr>
<td>3</td>
<td>ALLEN</td>
<td>7499</td>
<td>7698</td>
</tr>
<tr>
<td>3</td>
<td>WARD</td>
<td>7521</td>
<td>7698</td>
</tr>
<tr>
<td>3</td>
<td>MARTIN</td>
<td>7654</td>
<td>7698</td>
</tr>
<tr>
<td>3</td>
<td>TURNER</td>
<td>7844</td>
<td>7698</td>
</tr>
<tr>
<td>3</td>
<td>JAMES</td>
<td>7900</td>
<td>7698</td>
</tr>
<tr>
<td>2</td>
<td>CLARK</td>
<td>7782</td>
<td>7839</td>
</tr>
<tr>
<td>3</td>
<td>MILLER</td>
<td>7934</td>
<td>7782</td>
</tr>
</tbody>
</table>

Nodes that share a common parent and are at the same level are called siblings. For example in the above output, employees ALLEN, WARD, MARTIN, TURNER, and JAMES are siblings since they are all at level three with parent, BLAKE. JONES, BLAKE, and CLARK are siblings since they are at level two and KING is their common parent.
3.5.5 Ordering the Siblings

The result set can be ordered so the siblings appear in ascending or descending order by selected column value(s) using the ORDER SIBLINGS BY clause. This is a special case of the ORDER BY clause that can be used only with hierarchical queries.

The previous query is further modified with the addition of ORDER SIBLINGS BY ename ASC.

```
SELECT LEVEL, LPAD (' ', 2 * (LEVEL - 1)) || ename "employee", empno, mgr
FROM emp START WITH mgr IS NULL
CONNECT BY PRIOR empno = mgr
ORDER SIBLINGS BY ename ASC;
```

The output from the prior query is now modified so the siblings appear in ascending order by name. Siblings BLAKE, CLARK, and JONES are now alphabetically arranged under KING. Siblings ALLEN, JAMES, MARTIN, TURNER, and WARD are alphabetically arranged under BLAKE, and so on.

```
level | employee | empno | mgr
-------+-----------+-------+------
1     | KING      | 7839  |
2     | BLAKE     | 7698  | 7839 |
3     | ALLEN     | 7499  | 7698 |
3     | JAMES     | 7900  | 7698 |
3     | MARTIN    | 7654  | 7698 |
3     | TURNER    | 7844  | 7698 |
3     | WARD      | 7521  | 7698 |
2     | CLARK     | 7782  | 7839 |
3     | MILLER    | 7934  | 7782 |
2     | JONES     | 7566  | 7839 |
3     | FORD      | 7902  | 7566 |
4     | SMITH     | 7369  | 7902 |
3     | SCOTT     | 7788  | 7566 |
4     | ADAMS     | 7876  | 7788 |
(14 rows)
```

This final example adds the WHERE clause and starts with three root nodes. After the node tree is constructed, the WHERE clause filters out rows in the tree to form the result set.

```
SELECT LEVEL, LPAD (' ', 2 * (LEVEL - 1)) || ename "employee", empno, mgr
FROM emp WHERE mgr IN (7839, 7782, 7902, 7788)
START WITH ename IN ('BLAKE','CLARK','JONES')
CONNECT BY PRIOR empno = mgr
ORDER SIBLINGS BY ename ASC;
```

The output from the query shows three root nodes (level one) - BLAKE, CLARK, and JONES. In addition, rows that do not satisfy the WHERE clause have been eliminated from the output.

```
level | employee | empno | mgr
-------+-----------+-------+------
1     | BLAKE     | 7698  | 7839 |
1     | CLARK     | 7782  | 7839 |
2     | MILLER    | 7934  | 7782 |
(continues on next page)
```
3.5.6 Retrieving the Root Node with CONNECT_BY_ROOT

CONNECT_BY_ROOT is a unary operator that can be used to qualify a column in order to return the column’s value of the row considered to be the root node in relation to the current row.

**Note:** A unary operator operates on a single operand, which in the case of CONNECT_BY_ROOT, is the column name following the CONNECT_BY_ROOT keyword.

In the context of the SELECT list, the CONNECT_BY_ROOT operator is shown by the following.

```
SELECT [... ,] CONNECT_BY_ROOT <column> [, ...] 
FROM <table_expression> ...
```

The following are some points to note about the CONNECT_BY_ROOT operator.

- The CONNECT_BY_ROOT operator can be used in the SELECT list, the WHERE clause, the GROUP BY clause, the HAVING clause, the ORDER BY clause, and the ORDER SIBLINGS BY clause as long as the SELECT command is for a hierarchical query.
- The CONNECT_BY_ROOT operator cannot be used in the CONNECT BY clause or the START WITH clause of the hierarchical query.
- It is possible to apply CONNECT_BY_ROOT to an expression involving a column, but to do so, the expression must be enclosed within parentheses.

The following query shows the use of the CONNECT_BY_ROOT operator to return the employee number and employee name of the root node for each employee listed in the result set based on trees starting with employees BLAKE, CLARK, and JONES.

```sql
SELECT LEVEL, LPAD (' ', 2 * (LEVEL - 1)) || ename "employee", empno, mgr,
       CONNECT_BY_ROOT empno "mgr empno",
       CONNECT_BY_ROOT ename "mgr ename"
FROM emp
START WITH ename IN ('BLAKE','CLARK','JONES')
CONNECT BY PRIOR empno = mgr
ORDER SIBLINGS BY ename ASC;
```

Note that the output from the query shows that all of the root nodes in columns mgr empno and mgr ename are one of the employees, BLAKE, CLARK, or JONES, listed in the START WITH clause.

```
<table>
<thead>
<tr>
<th>level</th>
<th>employee</th>
<th>empno</th>
<th>mgr</th>
<th>mgr empno</th>
<th>mgr ename</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>BLAKE</td>
<td>7698</td>
<td>7839</td>
<td>7698</td>
<td>BLAKE</td>
</tr>
</tbody>
</table>
```

(continues on next page)
The following is a similar query, but producing only one tree starting with the single, top-level employee where the **mgr** column is null.

```
SELECT LEVEL, LPAD (' ', 2 * (LEVEL - 1)) || ename "employee", empno, mgr,
       CONNECT_BY_ROOT empno "mgr empno",
       CONNECT_BY_ROOT ename "mgr ename"
FROM emp START WITH mgr IS NULL
CONNECT BY PRIOR empno = mgr
ORDER SIBLINGS BY ename ASC;
```

In the following output, all of the root nodes in columns **mgr empno** and **mgr ename** indicate **KING** as the root for this particular query.

<table>
<thead>
<tr>
<th>level</th>
<th>employee</th>
<th>empno</th>
<th>mgr</th>
<th>mgr empno</th>
<th>mgr ename</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>KING</td>
<td>7839</td>
<td></td>
<td>7839</td>
<td>KING</td>
</tr>
<tr>
<td>2</td>
<td>BLAKE</td>
<td>7698</td>
<td>7839</td>
<td>7839</td>
<td>KING</td>
</tr>
<tr>
<td>3</td>
<td>ALLEN</td>
<td>7499</td>
<td>7698</td>
<td>7839</td>
<td>KING</td>
</tr>
<tr>
<td>3</td>
<td>JAMES</td>
<td>7900</td>
<td>7698</td>
<td>7839</td>
<td>KING</td>
</tr>
<tr>
<td>3</td>
<td>MARTIN</td>
<td>7654</td>
<td>7698</td>
<td>7839</td>
<td>KING</td>
</tr>
<tr>
<td>3</td>
<td>TURNER</td>
<td>7844</td>
<td>7698</td>
<td>7839</td>
<td>KING</td>
</tr>
<tr>
<td>3</td>
<td>WARD</td>
<td>7521</td>
<td>7698</td>
<td>7839</td>
<td>KING</td>
</tr>
<tr>
<td>2</td>
<td>CLARK</td>
<td>7782</td>
<td>7839</td>
<td>7839</td>
<td>KING</td>
</tr>
<tr>
<td>2</td>
<td>MILLER</td>
<td>7934</td>
<td>7782</td>
<td>7839</td>
<td>KING</td>
</tr>
<tr>
<td>1</td>
<td>JONES</td>
<td>7566</td>
<td>7839</td>
<td>7839</td>
<td>KING</td>
</tr>
<tr>
<td>2</td>
<td>FORD</td>
<td>7902</td>
<td>7566</td>
<td>7839</td>
<td>KING</td>
</tr>
<tr>
<td>3</td>
<td>SMITH</td>
<td>7369</td>
<td>7902</td>
<td>7839</td>
<td>KING</td>
</tr>
<tr>
<td>2</td>
<td>SCOTT</td>
<td>7788</td>
<td>7566</td>
<td>7839</td>
<td>KING</td>
</tr>
<tr>
<td>3</td>
<td>ADAMS</td>
<td>7876</td>
<td>7788</td>
<td>7839</td>
<td>KING</td>
</tr>
</tbody>
</table>
```

By contrast, the following example omits the **START WITH** clause thereby resulting in fourteen trees.

```
SELECT LEVEL, LPAD (' ', 2 * (LEVEL - 1)) || ename "employee", empno, mgr,
       CONNECT_BY_ROOT empno "mgr empno",
       CONNECT_BY_ROOT ename "mgr ename"
FROM emp
```

(continues on next page)
The following is the output from the query. Each node appears at least once as a root node under the `mgr` and `empno` columns since even the leaf nodes form the top of their own trees.

```
level | employee | empno | mgr | mgr empno | mgr ename
-------+-------------+-------+------+-----------+-----------
1 | ADAMS | 7876 | 7788 | 7876 | ADAMS
1 | ALLEN | 7499 | 7698 | 7499 | ALLEN
1 | BLAKE | 7698 | 7839 | 7698 | BLAKE
2 | ALLEN | 7499 | 7698 | 7698 | BLAKE
2 | JAMES | 7900 | 7698 | 7698 | BLAKE
2 | MARTIN | 7654 | 7698 | 7698 | BLAKE
2 | TURNER | 7844 | 7698 | 7698 | BLAKE
2 | WARD | 7521 | 7698 | 7698 | BLAKE
1 | CLARK | 7782 | 7839 | 7782 | CLARK
2 | MILLER | 7934 | 7782 | 7782 | CLARK
1 | FORD | 7902 | 7566 | 7902 | FORD
2 | SMITH | 7369 | 7902 | 7902 | FORD
1 | JAMES | 7900 | 7698 | 7900 | JAMES
1 | JONES | 7566 | 7839 | 7566 | JONES
2 | FORD | 7902 | 7566 | 7566 | JONES
3 | SMITH | 7369 | 7902 | 7566 | JONES
2 | SCOTT | 7788 | 7566 | 7566 | JONES
3 | ADAMS | 7876 | 7788 | 7566 | JONES
1 | KING | 7839 | | 7839 | KING
2 | BLAKE | 7698 | 7839 | 7839 | KING
3 | ALLEN | 7499 | 7698 | 7839 | KING
3 | JAMES | 7900 | 7698 | 7839 | KING
3 | MARTIN | 7654 | 7698 | 7839 | KING
3 | TURNER | 7844 | 7698 | 7839 | KING
3 | WARD | 7521 | 7698 | 7839 | KING
2 | CLARK | 7782 | 7839 | 7839 | KING
3 | MILLER | 7934 | 7782 | 7839 | KING
2 | JONES | 7566 | 7839 | 7839 | KING
3 | FORD | 7902 | 7566 | 7839 | KING
4 | SMITH | 7369 | 7902 | 7839 | KING
3 | SCOTT | 7788 | 7566 | 7839 | KING
4 | ADAMS | 7876 | 7788 | 7839 | KING
1 | MARTIN | 7654 | 7698 | 7654 | MARTIN
1 | MILLER | 7934 | 7782 | 7934 | MILLER
1 | SCOTT | 7788 | 7566 | 7788 | SCOTT
2 | ADAMS | 7876 | 7788 | 7788 | SCOTT
1 | SMITH | 7369 | 7902 | 7369 | SMITH
1 | TURNER | 7844 | 7698 | 7844 | TURNER
1 | WARD | 7521 | 7698 | 7521 | WARD
```

(39 rows)

The following illustrates the unary operator effect of `CONNECT_BY_ROOT`. As shown in this example, when applied to an expression that is not enclosed in parentheses, the `CONNECT_BY_ROOT` operator affects only the term, `ename`, immediately following it. The subsequent concatenation of `|| ' manages ' ||`
**ename** is not part of the CONNECT_BY_ROOT operation, hence the second occurrence of ename results in the value of the currently processed row while the first occurrence of ename results in the value from the root node.

```sql
SELECT LEVEL, LPAD (' ', 2 * (LEVEL - 1)) || ename "employee", empno, mgr,
CONNECT_BY_ROOT ename || ' manages ' || ename "top mgr/employee"
FROM emp
START WITH ename IN ('BLAKE','CLARK','JONES')
CONNECT BY PRIOR empno = mgr
ORDER SIBLINGS BY ename ASC;
```

The following is the output from the query. Note the values produced under the top mgr/employee column.

<table>
<thead>
<tr>
<th>level</th>
<th>employee</th>
<th>empno</th>
<th>mgr</th>
<th>top mgr/employee</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>BLAKE</td>
<td>7698</td>
<td>7839</td>
<td>BLAKE manages BLAKE</td>
</tr>
<tr>
<td>2</td>
<td>ALLEN</td>
<td>7499</td>
<td>7698</td>
<td>BLAKE manages ALLEN</td>
</tr>
<tr>
<td>2</td>
<td>JAMES</td>
<td>7900</td>
<td>7698</td>
<td>BLAKE manages JAMES</td>
</tr>
<tr>
<td>2</td>
<td>MARTIN</td>
<td>7654</td>
<td>7698</td>
<td>BLAKE manages MARTIN</td>
</tr>
<tr>
<td>2</td>
<td>TURNER</td>
<td>7844</td>
<td>7698</td>
<td>BLAKE manages TURNER</td>
</tr>
<tr>
<td>2</td>
<td>WARD</td>
<td>7521</td>
<td>7698</td>
<td>BLAKE manages WARD</td>
</tr>
<tr>
<td>1</td>
<td>CLARK</td>

<td>7876</td>
<td>7788</td>
<td>JONES manages ADAMS</td>
</tr>
</tbody>
</table>

(13 rows)

The following example uses the CONNECT_BY_ROOT operator on an expression enclosed in parentheses.

```sql
SELECT LEVEL, LPAD (' ', 2 * (LEVEL - 1)) || ename "employee", empno, mgr,
CONNECT_BY_ROOT ('Manager ' || ename || ' is emp # ' || empno)
"top mgr/empno"
FROM emp
START WITH ename IN ('BLAKE','CLARK','JONES')
CONNECT BY PRIOR empno = mgr
ORDER SIBLINGS BY ename ASC;
```

The following is the output of the query. Note that the values of both ename and empno are affected by the CONNECT_BY_ROOT operator and as a result, return the values from the root node as shown under the top mgr/empno column.

<table>
<thead>
<tr>
<th>level</th>
<th>employee</th>
<th>empno</th>
<th>mgr</th>
<th>top mgr/empno</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>BLAKE</td>
<td>7698</td>
<td>7839</td>
<td>Manager BLAKE is emp # 7698</td>

<td>7654</td>
<td>7698</td>
<td>Manager BLAKE is emp # 7698</td>
</tr>
<tr>
<td>2</td>
<td>TURNER</td>
<td>7844</td>
<td>7698</td>
<td>Manager BLAKE is emp # 7698</td>
</tr>
</tbody>
</table>

(continues on next page)
3.5.7 Retrieving a Path with SYS_CONNECT_BY_PATH

SYS_CONNECT_BY_PATH is a function that works within a hierarchical query to retrieve the column values of a specified column that occur between the current node and the root node. The signature of the function is:

SYS_CONNECT_BY_PATH (<column>, <delimiter>)

The function takes two arguments:

- **column** is the name of a column that resides within a table specified in the hierarchical query that is calling the function.
- **delimiter** is the varchar value that separates each entry in the specified column.

The following example returns a list of employee names, and their managers; if the manager has a manager, that name is appended to the result:

```sql
edb=# SELECT level, ename, SYS_CONNECT_BY_PATH(ename, '/') managers
     FROM emp
     CONNECT BY PRIOR empno = mgr
     START WITH mgr IS NULL
     ORDER BY level, ename, managers;
```

<table>
<thead>
<tr>
<th>level</th>
<th>ename</th>
<th>managers</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>KING</td>
<td>/KING</td>
</tr>
<tr>
<td>2</td>
<td>BLAKE</td>
<td>/KING/BLAKE</td>
</tr>
<tr>
<td>2</td>
<td>CLARK</td>
<td>/KING/CLARK</td>
</tr>
<tr>
<td>2</td>
<td>JONES</td>
<td>/KING/JONES</td>
</tr>
<tr>
<td>3</td>
<td>ALLEN</td>
<td>/KING/BLAKE/ALLEN</td>
</tr>
<tr>
<td>3</td>
<td>FORD</td>
<td>/KING/JONES/FORD</td>
</tr>
<tr>
<td>3</td>
<td>JAMES</td>
<td>/KING/BLAKE/JAMES</td>
</tr>
<tr>
<td>3</td>
<td>MARTIN</td>
<td>/KING/BLAKE/MARTIN</td>
</tr>
<tr>
<td>3</td>
<td>MILLER</td>
<td>/KING/CLARK/MILLER</td>
</tr>
<tr>
<td>3</td>
<td>SCOTT</td>
<td>/KING/JONES/SCOTT</td>
</tr>
<tr>
<td>3</td>
<td>TURNER</td>
<td>/KING/BLAKE/TURNER</td>
</tr>
<tr>
<td>3</td>
<td>WARD</td>
<td>/KING/BLAKE/WARD</td>
</tr>
<tr>
<td>4</td>
<td>ADAMS</td>
<td>/KING/JONES/SCOTT/ADAMS</td>
</tr>
<tr>
<td>4</td>
<td>SMITH</td>
<td>/KING/JONES/FORD/SMITH</td>
</tr>
</tbody>
</table>

(14 rows)
Within the result set:

- The `level` column displays the number of levels that the query returned.
- The `ename` column displays the employee name.
- The `managers` column contains the hierarchical list of managers.

The Advanced Server implementation of `SYS_CONNECT_BY_PATH` does not support use of:

- `SYS_CONNECT_BY_PATH` inside `CONNECT_BY_PATH`
- `SYS_CONNECT_BY_PATH` inside `SYS_CONNECT_BY_PATH`
3.6 Multidimensional Analysis

Multidimensional analysis refers to the process commonly used in data warehousing applications of examining data using various combinations of dimensions. Dimensions are categories used to classify data such as time, geography, a company’s departments, product lines, and so forth. The results associated with a particular set of dimensions are called facts. Facts are typically figures associated with product sales, profits, volumes, counts, etc.

In order to obtain these facts according to a set of dimensions in a relational database system, SQL aggregation is typically used. SQL aggregation basically means data is grouped according to certain criteria (dimensions) and the result set consists of aggregates of facts such as counts, sums, and averages of the data in each group.

The GROUP BY clause of the SQL SELECT command supports the following extensions that simplify the process of producing aggregate results.

- ROLLUP extension
- CUBE extension
- GROUPING SETS extension

In addition, the GROUPING function and the GROUPING_ID function can be used in the SELECT list or the HAVING clause to aid with the interpretation of the results when these extensions are used.

Note: The sample dept and emp tables are used extensively in this discussion to provide usage examples. The following changes were applied to these tables to provide more informative results.

```
UPDATE dept SET loc = 'BOSTON' WHERE deptno = 20;
INSERT INTO emp (empno,ename,job,deptno) VALUES (9001,'SMITH','CLERK',40);
INSERT INTO emp (empno,ename,job,deptno) VALUES (9002,'JONES','ANALYST',40);
INSERT INTO emp (empno,ename,job,deptno) VALUES (9003,'ROGERS','MANAGER',40);
```

The following rows from a join of the emp and dept tables are used:

```
SELECT loc, dname, job, empno FROM emp e, dept d
WHERE e.deptno = d.deptno
ORDER BY 1, 2, 3, 4;
```

<table>
<thead>
<tr>
<th>loc</th>
<th>dname</th>
<th>job</th>
<th>empno</th>
</tr>
</thead>
<tbody>
<tr>
<td>BOSTON</td>
<td>OPERATIONS</td>
<td>ANALYST</td>
<td>9002</td>
</tr>
<tr>
<td>BOSTON</td>
<td>OPERATIONS</td>
<td>CLERK</td>
<td>9001</td>
</tr>
<tr>
<td>BOSTON</td>
<td>OPERATIONS</td>
<td>MANAGER</td>
<td>9003</td>
</tr>
<tr>
<td>BOSTON</td>

<td>SALES</td>
<td>CLERK</td>
<td>7900</td>
</tr>
<tr>
<td>CHICAGO</td>
<td>SALES</td>
<td>MANAGER</td>
<td>7698</td>
</tr>
</tbody>
</table>
```

(continues on next page)
The `loc`, `dname`, and `job` columns are used for the dimensions of the SQL aggregations used in the examples. The resulting facts of the aggregations are the number of employees obtained by using the `COUNT(*)` function.

A basic query grouping the `loc`, `dname`, and `job` columns is given by the following.

```sql
SELECT loc, dname, job, COUNT(*) AS "employees" FROM emp e, dept d WHERE e.deptno = d.deptno GROUP BY loc, dname, job ORDER BY 1, 2, 3;
```

The rows of this result set using the basic `GROUP BY` clause without extensions are referred to as the base aggregate rows.

<table>
<thead>
<tr>
<th>loc</th>
<th>dname</th>
<th>job</th>
<th>employees</th>
</tr>
</thead>
<tbody>
<tr>
<td>BOSTON</td>
<td>OPERATIONS</td>
<td>ANALYST</td>

<td>ACCOUNTING</td>
<td>PRESIDENT</td>
<td>1</td>
</tr>
</tbody>
</table>

(12 rows)

The `ROLLUP` and `CUBE` extensions add to the base aggregate rows by providing additional levels of subtotals to the result set.

The `GROUPING SETS` extension provides the ability to combine different types of groupings into a single result set.

The `GROUPING` and `GROUPING_ID` functions aid in the interpretation of the result set.

The additions provided by these extensions are discussed in more detail in the subsequent sections.
3.6.1 ROLLUP Extension

The ROLLUP extension produces a hierarchical set of groups with subtotals for each hierarchical group as well as a grand total. The order of the hierarchy is determined by the order of the expressions given in the ROLLUP expression list. The top of the hierarchy is the leftmost item in the list. Each successive item proceeding to the right moves down the hierarchy with the rightmost item being the lowest level.

The syntax for a single ROLLUP is as follows:

```
ROLLUP ( { <expr_1> | ( <expr_1a> [, <expr_1b> ] ...) } [, <expr_2> | ( <expr_2a> [, <expr_2b> ] ...) ] ...)
```

Each expr is an expression that determines the grouping of the result set. If enclosed within parenthesis as ( expr_1a, expr_1b, ...) then the combination of values returned by expr_1a and expr_1b defines a single grouping level of the hierarchy.

The base level of aggregates returned in the result set is for each unique combination of values returned by the expression list.

In addition, a subtotal is returned for the first item in the list (expr_1 or the combination of ( expr_1a, expr_1b, ...), whichever is specified) for each unique value. A subtotal is returned for the second item in the list (expr_2 or the combination of ( expr_2a, expr_2b, ...), whichever is specified) for each unique value, within each grouping of the first item and so on. Finally a grand total is returned for the entire result set.

For the subtotal rows, null is returned for the items across which the subtotal is taken.

The ROLLUP extension specified within the context of the GROUP BY clause is shown by the following:

```
SELECT <select_list> FROM ...
GROUP BY [... ,] ROLLUP ( <expression_list> ) [, ...]
```

The items specified in select_list must also appear in the ROLLUP expression_list; or they must be aggregate functions such as COUNT, SUM, AVG, MIN, or MAX; or they must be constants or functions whose return values are independent of the individual rows in the group (for example, the SYSDATE function).

The GROUP BY clause may specify multiple ROLLUP extensions as well as multiple occurrences of other GROUP BY extensions and individual expressions.

The ORDER BY clause should be used if you want the output to display in a hierarchical or other meaningful structure. There is no guarantee on the order of the result set if no ORDER BY clause is specified.

The number of grouping levels or totals is $n + 1$ where $n$ represents the number of items in the ROLLUP expression list. A parenthesized list counts as one item.

The following query produces a rollup based on a hierarchy of columns loc, dname, then job.

```
SELECT loc, dname, job, COUNT(*) AS "employees" FROM emp e, dept d
WHERE e.deptno = d.deptno
GROUP BY ROLLUP (loc, dname, job)
ORDER BY 1, 2, 3;
```
The following is the result of the query. There is a count of the number of employees for each unique combination of `loc`, `dname`, and `job`, as well as subtotals for each unique combination of `loc` and `dname`, for each unique value of `loc`, and a grand total displayed on the last line.

<table>
<thead>
<tr>
<th>loc</th>
<th>dname</th>
<th>job</th>
<th>employees</th>
</tr>
</thead>
<tbody>

<td></td>
<td></td>
<td>3</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>17</td>
</tr>
</tbody>
</table>

(20 rows)

The following query shows the effect of combining items in the `ROLLUP` list within parenthesis.

```sql
SELECT loc, dname, job, COUNT(*) AS "employees" FROM emp e, dept d
WHERE e.deptno = d.deptno
GROUP BY ROLLUP (loc, (dname, job))
ORDER BY 1, 2, 3;
```

In the output, note that there are no subtotals for `loc` and `dname` combinations as in the prior example.

<table>
<thead>
<tr>
<th>loc</th>
<th>dname</th>
<th>job</th>
<th>employees</th>
</tr>
</thead>
<tbody>
<tr>
<td>BOSTON</td>
<td>OPERATIONS</td>
<td>ANALYST</td>
<td>1</td>
</tr>
<tr>
<td>BOSTON</td>
<td>OPERATIONS</td>
<td>CLERK</td>
<td>1</td>
</tr>
<tr>
<td>BOSTON</td>
<td>OPERATIONS</td>
<td>MANAGER</td>
<td>1</td>
</tr>
<tr>
<td>BOSTON</td>
<td>RESEARCH</td>
<td>ANALYST</td>
<td>2</td>
</tr>
<tr>
<td>BOSTON</td>
<td>RESEARCH</td>
<td>CLERK</td>
<td>2</td>
</tr>
<tr>
<td>BOSTON</td>
<td>RESEARCH</td>
<td>MANAGER</td>
<td>1</td>
</tr>
<tr>
<td>BOSTON</td>
<td></td>
<td></td>
<td>8</td>
</tr>
<tr>
<td>CHICAGO</td>
<td>SALES</td>
<td>CLERK</td>
<td>1</td>
</tr>
<tr>
<td>CHICAGO</td>
<td>SALES</td>
<td>MANAGER</td>
<td>1</td>
</tr>
<tr>
<td>CHICAGO</td>
<td>SALES</td>
<td>SALESMAN</td>
<td>4</td>
</tr>
<tr>
<td>CHICAGO</td>
<td></td>
<td></td>
<td>6</td>
</tr>
<tr>
<td>NEW YORK</td>
<td>ACCOUNTING</td>
<td>CLERK</td>
<td>1</td>
</tr>
<tr>
<td>NEW YORK</td>
<td>ACCOUNTING</td>
<td>MANAGER</td>
<td>1</td>
</tr>
<tr>
<td>NEW YORK</td>
<td>ACCOUNTING</td>
<td>PRESIDENT</td>
<td>1</td>
</tr>
</tbody>
</table>

(continues on next page)
If the first two columns in the ROLLUP list are enclosed in parenthesis, the subtotal levels differ as well.

```
SELECT loc, dname, job, COUNT(*) AS "employees" FROM emp e, dept d
WHERE e.deptno = d.deptno
GROUP BY ROLLUP ((loc, dname), job)
ORDER BY 1, 2, 3;
```

Now there is a subtotal for each unique `loc` and `dname` combination, but none for unique values of `loc`.

```
<table>
<thead>
<tr>
<th>loc</th>
<th>dname</th>
<th>job</th>
<th>employees</th>
</tr>
</thead>

<td>PRESIDENT</td>
<td>1</td>
</tr>
<tr>
<td>NEW YORK</td>
<td>ACCOUNTING</td>
<td></td>
<td>3</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>17</td>
</tr>
</tbody>
</table>
```

3.6.2 CUBE Extension

The CUBE extension is similar to the ROLLUP extension. However, unlike ROLLUP, which produces groupings and results in a hierarchy based on a left to right listing of items in the ROLLUP expression list, a CUBE produces groupings and subtotals based on every permutation of all items in the CUBE expression list. Thus, the result set contains more rows than a ROLLUP performed on the same expression list.

The syntax for a single CUBE is as follows:

```
CUBE ( { <expr_1> | ( <expr_1a> [, <expr_1b> ] ...) } [
            [, <expr_2> | ( <expr_2a> [, <expr_2b> ] ...) ] ...] )
```

Each `expr` is an expression that determines the grouping of the result set. If enclosed within parenthesis as `( expr_1a, expr_1b, ... )` then the combination of values returned by `expr_1a` and `expr_1b` defines a single group.

3.6. Multidimensional Analysis
The base level of aggregates returned in the result set is for each unique combination of values returned by
the expression list.

In addition, a subtotal is returned for the first item in the list (expr_1 or the combination of ( expr_1a,
expr_1b, ...), whichever is specified) for each unique value. A subtotal is returned for the second item
in the list (expr_2 or the combination of ( expr_2a, expr_2b, ...), whichever is specified) for
each unique value. A subtotal is also returned for each unique combination of the first item and the second
item. Similarly, if there is a third item, a subtotal is returned for each unique value of the third item, each
unique value of the third item and first item combination, each unique value of the third item and second
item combination, and each unique value of the third item, second item, and first item combination. Finally
a grand total is returned for the entire result set.

For the subtotal rows, null is returned for the items across which the subtotal is taken.

The CUBE extension specified within the context of the GROUP BY clause is shown by the following:

```
SELECT <select_list> FROM ...
GROUP BY [... ,] CUBE ( <expression_list> ) [, ...]
```

The items specified in select_list must also appear in the CUBE expression_list; or they must be
aggregate functions such as COUNT, SUM, AVG, MIN, or MAX; or they must be constants or func-
tions whose return values are independent of the individual rows in the group (for example, the SYSDATE
function).

The GROUP BY clause may specify multiple CUBE extensions as well as multiple occurrences of other
GROUP BY extensions and individual expressions.

The ORDER BY clause should be used if you want the output to display in a meaningful structure. There is
no guarantee on the order of the result set if no ORDER BY clause is specified.

The number of grouping levels or totals is 2 raised to the power of \( n \) where \( n \) represents the number of items
in the CUBE expression list. A parenthesized list counts as one item.

The following query produces a cube based on permutations of columns loc, dname, and job.

```
SELECT loc, dname, job, COUNT(*) AS "employees" FROM emp e, dept d
WHERE e.deptno = d.deptno
GROUP BY CUBE (loc, dname, job)
ORDER BY 1, 2, 3;
```

The following is the result of the query. There is a count of the number of employees for each combination
of loc, dname, and job, as well as subtotals for each combination of loc and dname, for each combi-
nation of loc and job, for each combination of dname and job, for each unique value of loc, for each
unique value of dname, for each unique value of job, and a grand total displayed on the last line.

(50 rows)

The following query shows the effect of combining items in the CUBE list within parenthesis.

```sql
SELECT loc, dname, job, COUNT(*) AS "employees" FROM emp e, dept d
WHERE e.deptno = d.deptno
GROUP BY CUBE (loc, (dname, job))
ORDER BY 1, 2, 3;
```
In the output note that there are no subtotals for permutations involving `loc` and `dname` combinations, `loc` and `job` combinations, or for `dname` by itself, or for `job` by itself.

The following query shows another variation whereby the first expression is specified outside of the `CUBE` extension.

```
SELECT loc, dname, job, COUNT(*) AS "employees" FROM emp e, dept d
WHERE e.deptno = d.deptno
GROUP BY loc, CUBE (dname, job)
ORDER BY 1, 2, 3;
```

In this output, the permutations are performed for `dname` and `job` within each grouping of `loc`.

3.6. Multidimensional Analysis
3.6.3 GROUPING SETS Extension

The use of the GROUPING SETS extension within the GROUP BY clause provides a means to produce one result set that is actually the concatenation of multiple results sets based upon different groupings. In other words, a UNION ALL operation is performed combining the result sets of multiple groupings into one result set.

Note that a UNION ALL operation, and therefore the GROUPING SETS extension, do not eliminate duplicate rows from the result sets that are being combined together.

The syntax for a single GROUPING SETS extension is as follows:

```sql
GROUPING SETS (
    { <expr_1> | ( <expr_1a> [, <expr_1b> ] ...) | 
    ROLLUP ( <expr_list> ) | CUBE ( <expr_list> ) 
} [, ...] )
```

A GROUPING SETS extension can contain any combination of one or more comma-separated expressions, lists of expressions enclosed within parenthesis, ROLLUP extensions, and CUBE extensions.

The GROUPING SETS extension is specified within the context of the GROUP BY clause as shown by the following:

```sql
SELECT <select_list> FROM ... 
GROUP BY [...] GROUPING SETS ( <expression_list> ) [, ...]
```
The items specified in select_list must also appear in the GROUPING SETS expression_list; or they must be aggregate functions such as COUNT, SUM, AVG, MIN, or MAX; or they must be constants or functions whose return values are independent of the individual rows in the group (for example, the SYSDATE function).

The GROUP BY clause may specify multiple GROUPING SETS extensions as well as multiple occurrences of other GROUP BY extensions and individual expressions.

The ORDER BY clause should be used if you want the output to display in a meaningful structure. There is no guarantee on the order of the result set if no ORDER BY clause is specified.

The following query produces a union of groups given by columns loc, dname, and job.

```
SELECT loc, dname, job, COUNT(*) AS "employees" FROM emp e, dept d
WHERE e.deptno = d.deptno
GROUP BY GROUPING SETS (loc, dname, job)
ORDER BY 1, 2, 3;
```

The result is as follows:

<table>
<thead>
<tr>
<th>loc</th>
<th>dname</th>
<th>job</th>
<th>employees</th>
</tr>
</thead>
<tbody>
<tr>
<td>BOSTON</td>
<td></td>
<td></td>
<td>8</td>
</tr>
<tr>
<td>CHICAGO</td>
<td></td>
<td></td>
<td>6</td>
</tr>
<tr>
<td>NEW YORK</td>
<td>ACCOUNTING</td>
<td></td>
<td>3</td>
</tr>
<tr>
<td></td>
<td>OPERATIONS</td>
<td></td>
<td>3</td>
</tr>
<tr>
<td></td>
<td>RESEARCH</td>
<td></td>
<td>5</td>
</tr>
<tr>
<td></td>
<td>SALES</td>
<td></td>
<td>6</td>
</tr>
<tr>
<td></td>
<td></td>
<td>ANALYST</td>
<td>3</td>
</tr>
<tr>
<td></td>
<td></td>
<td>CLERK</td>
<td>5</td>
</tr>
<tr>
<td></td>
<td></td>
<td>MANAGER</td>
<td>4</td>
</tr>
<tr>
<td></td>
<td></td>
<td>PRESIDENT</td>
<td>1</td>
</tr>
<tr>
<td></td>
<td></td>
<td>SALESMAN</td>
<td>4</td>
</tr>
</tbody>
</table>

This is equivalent to the following query, which employs the use of the UNION ALL operator.

```
SELECT loc AS "loc", NULL AS "dname", NULL AS "job", COUNT(*) AS "employees"
FROM emp e, dept d
WHERE e.deptno = d.deptno
GROUP BY loc
UNION ALL
SELECT NULL, dname, NULL, COUNT(*) AS "employees" FROM emp e, dept d
GROUP BY dname
UNION ALL
SELECT NULL, NULL, job, COUNT(*) AS "employees" FROM emp e, dept d
GROUP BY job
ORDER BY 1, 2, 3;
```

The output from the UNION ALL query is the same as the GROUPING SETS output.
The following example shows how various types of `GROUP BY` extensions can be used together within a `GROUPING SETS` expression list.

```sql
SELECT loc, dname, job, COUNT(*) AS "employees" FROM emp e, dept d
WHERE e.deptno = d.deptno
GROUP BY GROUPING SETS (loc, ROLLUP (dname, job), CUBE (job, loc))
ORDER BY 1, 2, 3;
```

The following is the output from this query.

<table>
<thead>
<tr>
<th>loc</th>
<th>dname</th>
<th>job</th>
<th>employees</th>
</tr>
</thead>
<tbody>
<tr>
<td>BOSTON</td>
<td>ACCOUNTING</td>

</tbody>
</table>

(continues on next page)
The output is basically a concatenation of the result sets that would be produced individually from GROUP BY loc, GROUP BY ROLLUP (dname, job), and GROUP BY CUBE (job, loc). These individual queries are shown by the following.

```sql
SELECT loc, NULL AS "dname", NULL AS "job", COUNT(*) AS "employees"
FROM emp e, dept d
WHERE e.deptno = d.deptno
GROUP BY loc
ORDER BY 1;
```

The following is the result set from the GROUP BY loc clause.

```
loc | dname | job | employees
-----+-------+-----+-----------
BOSTON | | | 8
CHICAGO | | | 6
NEW YORK | | | 3
(3 rows)
```

The following query uses the GROUP BY ROLLUP (dname, job) clause.

```sql
SELECT NULL AS "loc", dname, job, COUNT(*) AS "employees" FROM emp e, dept d
WHERE e.deptno = d.deptno
GROUP BY ROLLUP (dname, job)
ORDER BY 2, 3;
```

The following is the result set from the GROUP BY ROLLUP (dname, job) clause.

```
loc | dname | job | employees
-----+-------+-----+-----------
ACCOUNTING | CLERK | | 1
ACCOUNTING | MANAGER | | 1
ACCOUNTING | PRESIDENT | | 1
ACCOUNTING | | | 3
OPERATIONS | ANALYST | | 1
(continues on next page)
```
The following query uses the `GROUP BY CUBE (job, loc)` clause.

```sql
SELECT loc, NULL AS "dname", job, COUNT(*) AS "employees" FROM emp e, dept d
WHERE e.deptno = d.deptno
GROUP BY CUBE (job, loc)
ORDER BY 1, 3;
```

The following is the result set from the `GROUP BY CUBE (job, loc)` clause.

<table>
<thead>
<tr>
<th>loc</th>
<th>dname</th>
<th>job</th>
<th>employees</th>
</tr>
</thead>
<tbody>
<tr>
<td>BOSTON</td>
<td></td>
<td>ANALYST</td>
<td>3</td>
</tr>
<tr>

<td>1</td>
</tr>
<tr>
<td></td>
<td>SALESMAN</td>
<td></td>
<td>4</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>17</td>
</tr>
</tbody>
</table>

(18 rows)

If the previous three queries are combined with the `UNION ALL` operator, a concatenation of the three results sets is produced.

```sql
SELECT loc AS "loc", NULL AS "dname", NULL AS "job", COUNT(*) AS "employees"
FROM emp e, dept d
WHERE e.deptno = d.deptno
```

(continues on next page)
GROUP BY loc
  UNION ALL
SELECT NULL, dname, job, count(*) AS "employees" FROM emp e, dept d
WHERE e.deptno = d.deptno
GROUP BY ROLLUP (dname, job)
  UNION ALL
SELECT loc, NULL, job, count(*) AS "employees" FROM emp e, dept d
WHERE e.deptno = d.deptno
GROUP BY CUBE (job, loc)
ORDER BY 1, 2, 3;

The following is the output, which is the same as when the GROUP BY GROUPING SETS (loc, ROLLUP (dname, job), CUBE (job, loc)) clause is used.

<table>
<thead>
<tr>
<th>loc</th>
<th>dname</th>
<th>job</th>
<th>employees</th>

</tbody>
</table>
3.6.4 GROUPING Function

When using the ROLLUP, CUBE, or GROUPING SETS extensions to the GROUP BY clause, it may sometimes be difficult to differentiate between the various levels of subtotals generated by the extensions as well as the base aggregate rows in the result set. The GROUPING function provides a means of making this distinction.

The general syntax for use of the GROUPING function is shown by the following.

```sql
SELECT [ <expr> ..., ] GROUPING( <col_expr> ) [, <expr> ] ...
FROM ...
GROUP BY [...,]
{ ROLLUP | CUBE | GROUPING SETS }{ [,...] <col_expr>
[,...] } [...]
```

The GROUPING function takes a single parameter that must be an expression of a dimension column specified in the expression list of a ROLLUP, CUBE, or GROUPING SETS extension of the GROUP BY clause.

The return value of the GROUPING function is either a 0 or 1. In the result set of a query, if the column expression specified in the GROUPING function is null because the row represents a subtotal over multiple values of that column then the GROUPING function returns a value of 1. If the row returns results based on a particular value of the column specified in the GROUPING function, then the GROUPING function returns a value of 0. In the latter case, the column can be null as well as non-null, but in any case, it is for a particular value of that column, not a subtotal across multiple values.

The following query shows how the return values of the GROUPING function correspond to the subtotal lines.

```sql
SELECT loc, dname, job, COUNT(*) AS "employees",
   GROUPING(loc) AS "gf_loc",
   GROUPING(dname) AS "gf_dname",
   GROUPING(job) AS "gf_job"
FROM emp e, dept d
WHERE e.deptno = d.deptno
GROUP BY ROLLUP (loc, dname, job)
ORDER BY 1, 2, 3;
```

In the three right-most columns displaying the output of the GROUPING functions, a value of 1 appears on a subtotal line wherever a subtotal is taken across values of the corresponding columns.

<table>
<thead>
<tr>
<th>loc</th>
<th>dname</th>
<th>job</th>
<th>employees</th>
<th>gf_loc</th>
<th>gf_dname</th>
<th>gf_job</th>
</tr>
</thead>
<tbody>
<tr>
<td>BOSTON</td>
<td>OPERATIONS</td>
<td>ANALYST</td>
<td>1</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>BOSTON</td>
<td>OPERATIONS</td>
<td>CLERK</td>
<td>1</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

(continues on next page)
These indicators can be used as screening criteria for particular subtotals. For example, using the previous query, you can display only those subtotals for `loc` and `dname` combinations by using the `GROUPING` function in a `HAVING` clause.

```
SELECT loc, dname, job, COUNT(*) AS "employees",
       GROUPING(loc) AS "gf_loc",
       GROUPING(dname) AS "gf_dname",
       GROUPING(job) AS "gf_job"
FROM emp e, dept d
WHERE e.deptno = d.deptno
GROUP BY ROLLUP (loc, dname, job)
HAVING GROUPING(loc) = 0
       AND GROUPING(dname) = 0
       AND GROUPING(job) = 1
ORDER BY 1, 2;
```

This query produces the following result:

```
loc   | dname    | job | employees | gf_loc | gf_dname | gf_job
----------|------------+-----+-----------+--------+----------+--------
BOSTON | OPERATIONS | | 3 | 0 | 0 | 1
BOSTON | RESEARCH  | | 5 | 0 | 0 | 1
CHICAGO| SALES     | | 6 | 0 | 0 | 1
NEW YORK| ACCOUNTING| | 3 | 0 | 0 | 1
(4 rows)
```

The `GROUPING` function can be used to distinguish a subtotal row from a base aggregate row or from certain subtotal rows where one of the items in the expression list returns null as a result of the column on which the expression is based being null for one or more rows in the table, as opposed to representing a subtotal over the column.

To illustrate this point, the following row is added to the `emp` table. This provides a row with a null value
for the `job` column.

```sql
INSERT INTO emp (empno,ename,deptno) VALUES (9004,'PETERS',40);
```

The following query is issued using a reduced number of rows for clarity.

```sql
SELECT loc, job, COUNT(*) AS "employees",
       GROUPING(loc) AS "gf_loc",
       GROUPING(job) AS "gf_job"
FROM emp e, dept d
WHERE e.deptno = d.deptno AND loc = 'BOSTON'
GROUP BY CUBE (loc, job)
ORDER BY 1, 2;
```

Note that the output contains two rows containing `BOSTON` in the `loc` column and spaces in the `job` column (fourth and fifth entries in the table).

<table>
<thead>
<tr>
<th>loc</th>
<th>job</th>
<th>employees</th>
<th>gf_loc</th>
<th>gf_job</th>
</tr>
</thead>
<tbody>
<tr>
<td>BOSTON</td>
<td>ANALYST</td>
<td>3</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>BOSTON</td>
<td>CLERK</td>
<td>3</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>BOSTON</td>
<td>MANAGER</td>
<td>2</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>BOSTON</td>
<td></td>
<td>1</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>
| BOSTON|        | 9         | 0      | 1      | 0
| ANALYST|        | 3         | 1      | 0      |
| CLERK  |        | 3         | 1      | 0      |
| MANAGER|        | 2         | 1      | 0      |
|        |        | 1         | 1      | 0      |
|        |        | 9         | 1      | 1      |

(10 rows)

The fifth row where the `GROUPING` function on the `job` column (`gf_job`) returns 1 indicates this is a subtotal over all jobs. Note that the row contains a subtotal value of 9 in the `employees` column.

The fourth row where the `GROUPING` function on the `job` column as well as on the `loc` column returns 0 indicates this is a base aggregate of all rows where `loc` is `BOSTON` and `job` is null, which is the row inserted for this example. The `employees` column contains 1, which is the count of the single such row inserted.

Also note that in the ninth row (next to last) the `GROUPING` function on the `job` column returns 0 while the `GROUPING` function on the `loc` column returns 1 indicating this is a subtotal over all locations where the `job` column is null, which again, is a count of the single row inserted for this example.

3.6. Multidimensional Analysis
3.6.5 GROUPING_ID Function

The GROUPING_ID function provides a simplification of the GROUPING function in order to determine the subtotal level of a row in the result set from a ROLLBACK, CUBE, or GROUPING SETS extension.

The GROUPING function takes only one column expression and returns an indication of whether or not a row is a subtotal over all values of the given column. Thus, multiple GROUPING functions may be required to interpret the level of subtotals for queries with multiple grouping columns.

The GROUPING_ID function accepts one or more column expressions that have been used in the ROLLBACK, CUBE, or GROUPING SETS extensions and returns a single integer that can be used to determine over which of these columns a subtotal has been aggregated.

The general syntax for use of the GROUPING_ID function is shown by the following.

```
SELECT [ <expr> ...],
    GROUPING_ID( <col_expr_1> [, <col_expr_2> ] ... )
[, <expr> ] ...
FROM ...
GROUP BY [,...]
{ ROLLUP | CUBE | GROUPING SETS } [ [,...] <col_expr_1>
[, <col_expr_2> ] [ [,...] ] [,...]
```

The GROUPING_ID function takes one or more parameters that must be expressions of dimension columns specified in the expression list of a ROLLUP, CUBE, or GROUPING SETS extension of the GROUP BY clause.

The GROUPING_ID function returns an integer value. This value corresponds to the base-10 interpretation of a bit vector consisting of the concatenated 1’s and 0’s that would be returned by a series of GROUPING functions specified in the same left-to-right order as the ordering of the parameters specified in the GROUPING_ID function.

The following query shows how the returned values of the GROUPING_ID function represented in column gid correspond to the values returned by two GROUPING functions on columns loc and dname.

```
SELECT loc, dname, COUNT(*) AS "employees",
    GROUPING(loc) AS "gf_loc", GROUPING(dname) AS "gf_dname",
    GROUPING_ID(loc, dname) AS "gid"
FROM emp e, dept d
WHERE e.deptno = d.deptno
GROUP BY CUBE (loc, dname)
ORDER BY 6, 1, 2;
```

In the following output, note the relationship between a bit vector consisting of the gf_loc value and gf_dname value compared to the integer given in gid.

<table>
<thead>
<tr>
<th>loc</th>
<th>dname</th>
<th>employees</th>
<th>gf_loc</th>
<th>gf_dname</th>
<th>gid</th>
</tr>
</thead>
<tbody>
<tr>
<td>BOSTON</td>
<td>OPERATIONS</td>
<td>3</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>BOSTON</td>
<td>RESEARCH</td>
<td>5</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>CHICAGO</td>
<td>SALES</td>
<td>6</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>NEW YORK</td>
<td>ACCOUNTING</td>
<td>3</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

(continues on next page)
The following table provides specific examples of the GROUPING_ID function calculations based on the GROUPING function return values for four rows of the output.

<table>
<thead>
<tr>
<th>loc</th>
<th>dname</th>
<th>Bit Vector</th>
<th>GROUPING_ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>BOSTON</td>
<td>OPERATIONS</td>
<td>0 * 2^1 + 0 * 2^0</td>
<td>0</td>
</tr>
<tr>
<td>BOSTON</td>
<td>null</td>
<td>0 * 2^1 + 1 * 2^0</td>
<td>1</td>
</tr>
<tr>
<td>null</td>
<td>ACCOUNTING</td>
<td>1 * 2^1 + 0 * 2^0</td>
<td>2</td>
</tr>
<tr>
<td>null</td>
<td>null</td>
<td>1 * 2^1 + 1 * 2^0</td>
<td>3</td>
</tr>
</tbody>
</table>

The following table summarizes how the GROUPING_ID function return values correspond to the grouping columns over which aggregation occurs.

<table>
<thead>
<tr>
<th>Aggregation by Column</th>
<th>Bit Vector</th>
<th>GROUPING_ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>loc, dname</td>
<td>0 0</td>
<td>0</td>
</tr>
<tr>
<td>loc</td>
<td>0 1</td>
<td>1</td>
</tr>
<tr>
<td>dname</td>
<td>1 0</td>
<td>2</td>
</tr>
<tr>
<td>Grand Total</td>
<td>1 1</td>
<td>3</td>
</tr>
</tbody>
</table>

So to display only those subtotals by dname, the following simplified query can be used with a HAVING clause based on the GROUPING_ID function.

```sql
SELECT loc, dname, COUNT(*) AS "employees",
       GROUPING(loc) AS "gf_loc",
       GROUPING(dname) AS "gf_dname",
       GROUPING_ID(loc, dname) AS "gid"
FROM emp e, dept d
WHERE e.deptno = d.deptno
GROUP BY CUBE (loc, dname)
HAVING GROUPING_ID(loc, dname) = 2
ORDER BY 6, 1, 2;
```

The following is the result of the query.
<table>
<thead>
<tr>
<th>loc</th>
<th>dname</th>
<th>employees</th>
<th>gf_loc</th>
<th>gf_dname</th>
<th>gid</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACCOUNTING</td>
<td>3</td>
<td>1</td>
<td>0</td>
<td>2</td>
<td></td>
</tr>
<tr>
<td>OPERATIONS</td>
<td>3</td>
<td>1</td>
<td>0</td>
<td>2</td>
<td></td>
</tr>
<tr>
<td>RESEARCH</td>
<td>5</td>
<td>1</td>
<td>0</td>
<td>2</td>
<td></td>
</tr>
<tr>
<td>SALES</td>
<td>6</td>
<td>1</td>
<td>0</td>
<td>2</td>
<td></td>
</tr>
</tbody>
</table>

(4 rows)
Advanced Server allows a database superuser to create named *profiles*. Each profile defines rules for password management that augment *password* and *md5* authentication. The rules in a profile can:

- count failed login attempts
- lock an account due to excessive failed login attempts
- mark a password for expiration
- define a grace period after a password expiration
- define rules for password complexity
- define rules that limit password re-use

A profile is a named set of password attributes that allow you to easily manage a group of roles that share comparable authentication requirements. If the password requirements change, you can modify the profile to have the new requirements applied to each user that is associated with that profile.

After creating the profile, you can associate the profile with one or more users. When a user connects to the server, the server enforces the profile that is associated with their login role. Profiles are shared by all databases within a cluster, but each cluster may have multiple profiles. A single user with access to multiple databases will use the same profile when connecting to each database within the cluster.

Advanced Server creates a profile named *default* that is associated with a new role when the role is created unless an alternate profile is specified. If you upgrade to Advanced Server from a previous server version, existing roles will automatically be assigned to the *default* profile. You cannot delete the *default* profile.

The *default* profile specifies the following attributes:
<table>
<thead>
<tr>
<th>Attribute</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>FAILED_LOGIN_ATTEMPTS</td>
<td>UNLIMITED</td>
</tr>
<tr>
<td>PASSWORD_LOCK_TIME</td>
<td>UNLIMITED</td>
</tr>
<tr>
<td>PASSWORD_LIFE_TIME</td>
<td>UNLIMITED</td>
</tr>
<tr>
<td>PASSWORD_GRACE_TIME</td>
<td>UNLIMITED</td>
</tr>
<tr>
<td>PASSWORD_REUSE_TIME</td>
<td>UNLIMITED</td>
</tr>
<tr>
<td>PASSWORD_REUSE_MAX</td>
<td>UNLIMITED</td>
</tr>
<tr>
<td>PASSWORD_VERIFY_FUNCTION</td>
<td>NULL</td>
</tr>
<tr>
<td>PASSWORD_ALLOW_HASHED</td>
<td>TRUE</td>
</tr>
</tbody>
</table>

A database superuser can use the ALTER PROFILE command to modify the values specified by the default profile. For more information about modifying a profile, see *Altering a Profile*. 
4.1 Creating a New Profile

Use the CREATE PROFILE command to create a new profile. The syntax is:

```sql
CREATE PROFILE <profile_name>
  [LIMIT {<parameter value>} ... ];
```

Include the LIMIT clause and one or more space-delimited parameter/value pairs to specify the rules enforced by Advanced Server.

Parameters:

- **profile_name** specifies the name of the profile.
- **parameter** specifies the attribute limited by the profile.
- **value** specifies the parameter limit.

Advanced Server supports the value shown below for each parameter:

- **FAILED_LOGIN_ATTEMPTS** specifies the number of failed login attempts that a user may make before the server locks the user out of their account for the length of time specified by PASSWORD_LOCK_TIME. Supported values are:
  - An INTEGER value greater than 0.
  - **DEFAULT** - the value of FAILED_LOGIN_ATTEMPTS specified in the DEFAULT profile.
  - **UNLIMITED** – the connecting user may make an unlimited number of failed login attempts.

- **PASSWORD_LOCK_TIME** specifies the length of time that must pass before the server unlocks an account that has been locked because of FAILED_LOGIN_ATTEMPTS. Supported values are:
  - A NUMERIC value greater than or equal to 0. To specify a fractional portion of a day, specify a decimal value. For example, use the value 4.5 to specify 4 days, 12 hours.
  - **DEFAULT** - the value of PASSWORD_LOCK_TIME specified in the DEFAULT profile.
  - **UNLIMITED** – the account is locked until it is manually unlocked by a database superuser.

- **PASSWORD_LIFE_TIME** specifies the number of days that the current password may be used before the user is prompted to provide a new password. Include the PASSWORD_GRACE_TIME clause when using the PASSWORD_LIFE_TIME clause to specify the number of days that will pass after the password expires before connections by the role are rejected. If PASSWORD_GRACE_TIME is not specified, the password will expire on the day specified by the default value of PASSWORD_GRACE_TIME, and the user will not be allowed to execute any command until a new password is provided. Supported values are:
  - A NUMERIC value greater than or equal to 0. To specify a fractional portion of a day, specify a decimal value. For example, use the value 4.5 to specify 4 days, 12 hours.
  - **DEFAULT** - the value of PASSWORD_LIFE_TIME specified in the DEFAULT profile.
• **UNLIMITED** – The password does not have an expiration date.

**PASSWORD_GRACE_TIME** specifies the length of the grace period after a password expires until the user is forced to change their password. When the grace period expires, a user will be allowed to connect, but will not be allowed to execute any command until they update their expired password. Supported values are:

• A **NUMERIC** value greater than or equal to 0. To specify a fractional portion of a day, specify a decimal value. For example, use the value 4.5 to specify 4 days, 12 hours.

• **DEFAULT** - the value of **PASSWORD_GRACE_TIME** specified in the **DEFAULT** profile.

• **UNLIMITED** – The grace period is infinite.

**PASSWORD_REUSE_TIME** specifies the number of days a user must wait before re-using a password. The **PASSWORD_REUSE_TIME** and **PASSWORD_REUSE_MAX** parameters are intended to be used together. If you specify a finite value for one of these parameters while the other is **UNLIMITED**, old passwords can never be reused. If both parameters are set to **UNLIMITED** there are no restrictions on password reuse. Supported values are:

• A **NUMERIC** value greater than or equal to 0. To specify a fractional portion of a day, specify a decimal value. For example, use the value 4.5 to specify 4 days, 12 hours.

• **DEFAULT** - the value of **PASSWORD_REUSE_TIME** specified in the **DEFAULT** profile.

• **UNLIMITED** – The password can be re-used without restrictions.

**PASSWORD_REUSE_MAX** specifies the number of password changes that must occur before a password can be reused. The **PASSWORD_REUSE_TIME** and **PASSWORD_REUSE_MAX** parameters are intended to be used together. If you specify a finite value for one of these parameters while the other is **UNLIMITED**, old passwords can never be reused. If both parameters are set to **UNLIMITED** there are no restrictions on password reuse. Supported values are:

• An **INTEGER** value greater than or equal to 0.

• **DEFAULT** - the value of **PASSWORD_REUSE_MAX** specified in the **DEFAULT** profile.

• **UNLIMITED** – The password can be re-used without restrictions.

**PASSWORD_VERIFY_FUNCTION** specifies password complexity. Supported values are:

• The name of a PL/SQL function.

• **DEFAULT** - the value of **PASSWORD_VERIFY_FUNCTION** specified in the **DEFAULT** profile.

• **NULL**

**PASSWORD_ALLOW_HASHED** specifies whether an encrypted password to be allowed for use or not. If you specify the value as **TRUE**, the system allows a user to change the password by specifying a hash computed encrypted password on the client side. However, if you specify the value as **FALSE**, then a password must be specified in a plain-text form in order to be validated effectively, else an error will be thrown if a server receives an encrypted password. Supported values are:

• A **BOOLEAN** value **TRUE/ON/YES/1** or **FALSE/OFF/NO/0**.
• DEFAULT - the value of PASSWORD_ALLOW_HASHED specified in the DEFAULT profile.

Note: The PASSWORD_ALLOW_HASHED is not an Oracle-compatible parameter.

Notes

Use DROP PROFILE command to remove the profile.

Examples

The following command creates a profile named acctg. The profile specifies that if a user has not authenticated with the correct password in five attempts, the account will be locked for one day:

```
CREATE PROFILE acctg LIMIT
   FAILED_LOGIN_ATTEMPTS 5
   PASSWORD_LOCK_TIME 1;
```

The following command creates a profile named sales. The profile specifies that a user must change their password every 90 days:

```
CREATE PROFILE sales LIMIT
   PASSWORD_LIFE_TIME 90
   PASSWORD_GRACE_TIME 3;
```

If the user has not changed their password before the 90 days specified in the profile has passed, they will be issued a warning at login. After a grace period of 3 days, their account will not be allowed to invoke any commands until they change their password.

The following command creates a profile named accts. The profile specifies that a user cannot re-use a password within 180 days of the last use of the password, and must change their password at least 5 times before re-using the password:

```
CREATE PROFILE accts LIMIT
   PASSWORD_REUSE_TIME 180
   PASSWORD_REUSE_MAX 5;
```

The following command creates a profile named resources; the profile calls a user-defined function named password_rules that will verify that the password provided meets their standards for complexity:

```
CREATE PROFILE resources LIMIT
   PASSWORD_VERIFY_FUNCTION password_rules;
```
4.1.1 Creating a Password Function

When specifying `PASSWORD_VERIFY_FUNCTION`, you can provide a customized function that specifies the security rules that will be applied when your users change their password. For example, you can specify rules that stipulate that the new password must be at least \( n \) characters long, and may not contain a specific value.

The password function has the following signature:

\[
\text{<function_name>} (<user_name> VARCHAR2, 
\text{<new_password> VARCHAR2,} 
\text{<old_password> VARCHAR2}) \text{ RETURN boolean}
\]

Where:

- `user_name` is the name of the user.
- `new_password` is the new password.
- `old_password` is the user’s previous password. If you reference this parameter within your function:

  When a database superuser changes their password, the third parameter will always be `NULL`.

  When a user with the `CREATEROLE` attribute changes their password, the parameter will pass the previous password if the statement includes the `REPLACE` clause. Note that the `REPLACE` clause is optional syntax for a user with the `CREATEROLE` privilege.

  When a user that is not a database superuser and does not have the `CREATEROLE` attribute changes their password, the third parameter will contain the previous password for the role.

The function returns a Boolean value. If the function returns true and does not raise an exception, the password is accepted; if the function returns false or raises an exception, the password is rejected. If the function raises an exception, the specified error message is displayed to the user. If the function does not raise an exception, but returns false, the following error message is displayed:

`ERROR: password verification for the specified password failed`

The function must be owned by a database superuser, and reside in the `sys` schema.

Example:

The following example creates a profile and a custom function; then, the function is associated with the profile. The following `CREATE PROFILE` command creates a profile named `acctg_pwd_profile`:

```
CREATE PROFILE acctg_pwd_profile;
```

The following commands create a (schema-qualified) function named `verify_password`:

```
CREATE OR REPLACE FUNCTION sys.verify_password(user_name varchar2, new_password varchar2, old_password varchar2)
```

(continues on next page)
RETURN boolean IMMUTABLE IS BEGIN IF (length(new_password) < 5) THEN raise_application_error(-20001, 'too short'); END IF; IF substring(new_password FROM old_password) IS NOT NULL THEN raise_application_error(-20002, 'includes old password'); END IF; RETURN true; END;

The function first ensures that the password is at least 5 characters long, and then compares the new password to the old password. If the new password contains fewer than 5 characters, or contains the old password, the function raises an error.

The following statement sets the ownership of the verify_password function to the enterprisedb database superuser:

```
ALTER FUNCTION verify_password(varchar2, varchar2, varchar2) OWNER TO enterprisedb;
```

Then, the verify_password function is associated with the profile:

```
ALTER PROFILE acctg_pwd_profile LIMIT PASSWORD_VERIFY_FUNCTION verify_password;
```

The following statements confirm that the function is working by first creating a test user (alice), and then attempting to associate invalid and valid passwords with her role:

```
CREATE ROLE alice WITH LOGIN PASSWORD 'temp_password' PROFILE acctg_pwd_profile;
```

Then, when alice connects to the database and attempts to change her password, she must adhere to the rules established by the profile function. A non-superuser without CREATEROLE must include the REPLACE clause when changing a password:

```
edb=> ALTER ROLE alice PASSWORD 'hey';
ERROR: missing REPLACE clause
```

The new password must be at least 5 characters long:

```
edb=> ALTER USER alice PASSWORD 'hey' REPLACE 'temp_password';
ERROR: EDB-20001: too short
CONTEXT: edb-spl function verify_password(character varying,character varying,character varying) line 5 at procedure/function invocation statement
```
If the new password is acceptable, the command completes without error:

```
edb=> ALTER USER alice PASSWORD 'hello' REPLACE 'temp_password';
```

If `alice` decides to change her password, the new password must not contain the old password:

```
edb=> ALTER USER alice PASSWORD 'helloworld' REPLACE 'hello';
ERROR: EDB-20002: includes old password
CONTEXT: edb-spl function verify_password(character varying,character varying,character varying) line 10 at procedure/function invocation statement
```

To remove the verify function, set `password_verify_function` to `NULL`:

```
ALTER PROFILE acctg_pwd_profile LIMIT password_verify_function NULL;
```

Then, all password constraints will be lifted:

```
edb=# ALTER ROLE alice PASSWORD 'hey';
```

---

4.1. Creating a New Profile
4.2 Altering a Profile

Use the `ALTER PROFILE` command to modify a user-defined profile; Advanced Server supports two forms of the command:

```
ALTER PROFILE <profile_name> RENAME TO <new_name>;
ALTER PROFILE <profile_name>
    LIMIT {<parameter value>}[...];
```

Include the `LIMIT` clause and one or more space-delimited `parameter/value` pairs to specify the rules enforced by Advanced Server, or use `ALTER PROFILE...RENAME TO` to change the name of a profile.

**Parameters:**
- `profile_name` specifies the name of the profile.
- `new_name` specifies the new name of the profile.
- `parameter` specifies the attribute limited by the profile.
- `value` specifies the parameter limit.

See the table in *Creating a New Profile*, for a complete list of accepted parameter/value pairs.

**Examples**

The following example modifies a profile named `acctg_profile`:

```
ALTER PROFILE acctg_profile
    LIMIT FAILED_LOGIN_ATTEMPTS 3 PASSWORD_LOCK_TIME 1;
```

`acctg_profile` will count failed connection attempts when a login role attempts to connect to the server. The profile specifies that if a user has not authenticated with the correct password in three attempts, the account will be locked for one day.

The following example changes the name of `acctg_profile` to `payables_profile`:

```
ALTER PROFILE acctg_profile RENAME TO payables_profile;
```
4.3 Dropping a Profile

Use the DROP PROFILE command to drop a profile. The syntax is:

```
DROP PROFILE [IF EXISTS] <profile_name> [CASCADE|RESTRICT];
```

Include the IF EXISTS clause to instruct the server to not throw an error if the specified profile does not exist. The server will issue a notice if the profile does not exist.

Include the optional CASCADE clause to reassign any users that are currently associated with the profile to the default profile, and then drop the profile. Include the optional RESTRICT clause to instruct the server to not drop any profile that is associated with a role. This is the default behavior.

**Parameters**

`profile_name`

The name of the profile being dropped.

**Examples**

The following example drops a profile named `acctg_profile`:

```
DROP PROFILE acctg_profile CASCADE;
```

The command first re-associates any roles associated with the `acctg_profile` profile with the default profile, and then drops the `acctg_profile` profile.

The following example drops a profile named `acctg_profile`:

```
DROP PROFILE acctg_profile RESTRICT;
```

The RESTRICT clause in the command instructs the server to not drop `acctg_profile` if there are any roles associated with the profile.
4.4 Associating a Profile with an Existing Role

After creating a profile, you can use the `ALTER USER... PROFILE` or `ALTER ROLE... PROFILE` command to associate the profile with a role. The command syntax related to profile management functionality is:

```
ALTER USER|ROLE <name> [\[WITH\] option[...]]
```

where `option` can be the following compatible clauses:

```
| PROFILE <profile_name>
| ACCOUNT {LOCK|UNLOCK}
| PASSWORD EXPIRE [AT '<timestamp>'
```

or `option` can be the following non-compatible clauses:

```
| PASSWORD SET AT '<timestamp>'
| LOCK TIME '<timestamp>'
| STORE PRIOR PASSWORD {'<password>' '<timestamp>}' [, ...]
```

For information about the administrative clauses of the `ALTER USER` or `ALTER ROLE` command that are supported by Advanced Server, please see the PostgreSQL core documentation available at:

https://www.postgresql.org/docs/current/static/sql-commands.html

Only a database superuser can use the `ALTER USER|ROLE` clauses that enforce profile management. The clauses enforce the following behaviors:

- Include the `PROFILE` clause and a `profile_name` to associate a pre-defined profile with a role, or to change which pre-defined profile is associated with a user.
- Include the `ACCOUNT` clause and the `LOCK` or `UNLOCK` keyword to specify that the user account should be placed in a locked or unlocked state.
- Include the `LOCK TIME` 'timestamp' clause and a date/time value to lock the role at the specified time, and unlock the role at the time indicated by the `PASSWORD_LOCK_TIME` parameter of the profile assigned to this role. If `LOCK TIME` is used with the `ACCOUNT LOCK` clause, the role can only be unlocked by a database superuser with the `ACCOUNT UNLOCK` clause.
- Include the `PASSWORD EXPIRE` clause with the `AT 'timestamp'` keywords to specify a date/time when the password associated with the role will expire. If you omit the `AT 'timestamp'` keywords, the password will expire immediately.
- Include the `PASSWORD SET AT 'timestamp'` keywords to set the password modification date to the time specified.
- Include the `STORE PRIOR PASSWORD` {'password' 'timestamp'} [, ...] clause to modify the password history, adding the new password and the time the password was set.

Each login role may only have one profile. To discover the profile that is currently associated with a login role, query the `profile` column of the `DBA_USERS` view.
Parameters

name

The name of the role with which the specified profile will be associated.

password

The password associated with the role.

profile_name

The name of the profile that will be associated with the role.

timestamp

The date and time at which the clause will be enforced. When specifying a value for `timestamp`, enclose the value in single-quotes.

Examples

The following command uses the `ALTER USER... PROFILE` command to associate a profile named `acctg` with a user named `john`:

```
ALTER USER john PROFILE acctg_profile;
```

The following command uses the `ALTER ROLE... PROFILE` command to associate a profile named `acctg` with a user named `john`:

```
ALTER ROLE john PROFILE acctg_profile;
```
4.5 Unlocking a Locked Account

A database superuser can use clauses of the ALTER USER|ROLE... command to lock or unlock a role. The syntax is:

```
ALTER USER|ROLE <name>
  ACCOUNT {LOCK|UNLOCK}
  LOCK TIME '<<timestamp>>'
```

Include the ACCOUNT LOCK clause to lock a role immediately; when locked, a role’s LOGIN functionality is disabled. When you specify the ACCOUNT LOCK clause without the LOCK TIME clause, the state of the role will not change until a superuser uses the ACCOUNT UNLOCK clause to unlock the role.

Use the ACCOUNT UNLOCK clause to unlock a role.

Use the LOCK TIME 'timestamp' clause to instruct the server to lock the account at the time specified by the given timestamp for the length of time specified by the PASSWORD_LOCK_TIME parameter of the profile associated with this role.

Combine the LOCK TIME 'timestamp' clause and the ACCOUNT LOCK clause to lock an account at a specified time until the account is unlocked by a superuser invoking the ACCOUNT UNLOCK clause.

**Parameters**

- **name**
  
  The name of the role that is being locked or unlocked.

- **timestamp**
  
  The date and time at which the role will be locked. When specifying a value for timestamp, enclose the value in single-quotes.

**Note:** This command (available only in Advanced Server) is implemented to support Oracle-styled profile management.

**Examples**

The following example uses the ACCOUNT LOCK clause to lock the role named john. The account will remain locked until the account is unlocked with the ACCOUNT UNLOCK clause:

```
ALTER ROLE john ACCOUNT LOCK;
```

The following example uses the ACCOUNT UNLOCK clause to unlock the role named john:

```
ALTER USER john ACCOUNT UNLOCK;
```

The following example uses the LOCK TIME 'timestamp' clause to lock the role named john on September 4, 2015:

```
ALTER ROLE john LOCK TIME 'September 4 12:00:00 2015';
```
The role will remain locked for the length of time specified by the `PASSWORD_LOCK_TIME` parameter.

The following example combines the `LOCK TIME 'timestamp'` clause and the `ACCOUNT LOCK` clause to lock the role named `john` on September 4, 2015:

```
ALTER ROLE john LOCK TIME 'September 4 12:00:00 2015' ACCOUNT LOCK;
```

The role will remain locked until a database superuser uses the `ACCOUNT UNLOCK` command to unlock the role.
4.6 Creating a New Role Associated with a Profile

A database superuser can use clauses of the `CREATE USER|ROLE` command to assign a named profile to a role when creating the role, or to specify profile management details for a role. The command syntax related to profile management functionality is:

```
CREATE USER|ROLE <name> [[WITH] <option> [...]]
```

where `option` can be the following compatible clauses:

```
| PROFILE <profile_name>
| ACCOUNT {LOCK|UNLOCK}
| PASSWORD EXPIRE [AT '<timestamp>']
```

or `option` can be the following non-compatible clauses:

```
| LOCK TIME '<timestamp>'
```

For information about the administrative clauses of the `CREATE USER` or `CREATE ROLE` command that are supported by Advanced Server, see the PostgreSQL core documentation available at:

https://www.postgresql.org/docs/current/static/sql-commands.html

`CREATE ROLE|USER... PROFILE` adds a new role with an associated profile to an Advanced Server database cluster.

Roles created with the `CREATE USER` command are (by default) login roles. Roles created with the `CREATE ROLE` command are (by default) not login roles. To create a login account with the `CREATE ROLE` command, you must include the `LOGIN` keyword.

Only a database superuser can use the `CREATE USER|ROLE` clauses that enforce profile management; these clauses enforce the following behaviors:

- Include the `PROFILE` clause and a `profile_name` to associate a pre-defined profile with a role, or to change which pre-defined profile is associated with a user.
- Include the `ACCOUNT` clause and the `LOCK` or `UNLOCK` keyword to specify that the user account should be placed in a locked or unlocked state.
- Include the `LOCK TIME 'timestamp'` clause and a date/time value to lock the role at the specified time, and unlock the role at the time indicated by the `PASSWORD_LOCK_TIME` parameter of the profile assigned to this role. If `LOCK TIME` is used with the `ACCOUNT LOCK` clause, the role can only be unlocked by a database superuser with the `ACCOUNT UNLOCK` clause.
- Include the `PASSWORD EXPIRE` clause with the optional `AT 'timestamp'` keywords to specify a date/time when the password associated with the role will expire. If you omit the `AT 'timestamp'` keywords, the password will expire immediately.

Each login role may only have one profile. To discover the profile that is currently associated with a login role, query the `profile` column of the `DBA_USERS` view.

Parameters
name

The name of the role.

profile_name

The name of the profile associated with the role.

timestamp

The date and time at which the clause will be enforced. When specifying a value for timestamp, enclose the value in single-quotes.

Examples

The following example uses CREATE USER to create a login role named john who is associated with the acctg_profile profile:

```
CREATE USER john PROFILE acctg_profile IDENTIFIED BY "1safepwd";
```

john can log in to the server, using the password 1safepwd.

The following example uses CREATE ROLE to create a login role named john who is associated with the acctg_profile profile:

```
CREATE ROLE john PROFILE acctg_profile LOGIN PASSWORD "1safepwd";
```

john can log in to the server, using the password 1safepwd.
4.7 Backing up Profile Management Functions

A profile may include a `PASSWORD_VERIFY_FUNCTION` clause that refers to a user-defined function that specifies the behavior enforced by Advanced Server. Profiles are global objects; they are shared by all of the databases within a cluster. While profiles are global objects, user-defined functions are database objects.

Invoking `pg_dumpall` with the `-g` or `-r` option will create a script that recreates the definition of any existing profiles, but that does not recreate the user-defined functions that are referred to by the `PASSWORD_VERIFY_FUNCTION` clause. You should use the `pg_dump` utility to explicitly dump (and later restore) the database in which those functions reside.

The script created by `pg_dump` will contain a command that includes the clause and function name:

```
ALTER PROFILE... LIMIT PASSWORD_VERIFY_FUNCTION <function_name>
```

to associate the restored function with the profile with which it was previously associated.

If the `PASSWORD_VERIFY_FUNCTION` clause is set to `DEFAULT` or `NULL`, the behavior will be replicated by the script generated by the `pg_dumpall -g` or `pg_dumpall -r` command.
When you invoke a `DELETE`, `INSERT`, `SELECT` or `UPDATE` command, the server generates a set of execution plans; after analyzing those execution plans, the server selects a plan that will (generally) return the result set in the least amount of time. The server’s choice of plan is dependent upon several factors:

- The estimated execution cost of data handling operations.
- Parameter values assigned to parameters in the `Query Tuning` section of the `postgresql.conf` file.
- Column statistics that have been gathered by the `ANALYZE` command.

As a rule, the query planner will select the least expensive plan. You can use an `optimizer hint` to influence the server as it selects a query plan. An optimizer hint is a directive (or multiple directives) embedded in a comment-like syntax that immediately follows a `DELETE`, `INSERT`, `SELECT` or `UPDATE` command. Keywords in the comment instruct the server to employ or avoid a specific plan when producing the result set.

**Synopsis**

```plaintext
{ DELETE | INSERT | SELECT | UPDATE } /*+ { <hint> [ <comment> ] } [...] */
<statement_body>
```

```plaintext
{ DELETE | INSERT | SELECT | UPDATE } --+ { <hint> [ <comment> ] } [...] 
<statement_body>
```

Optimizer hints may be included in either of the forms shown above. Note that in both forms, a plus sign (+) must immediately follow the `/*` or `--` opening comment symbols, with no intervening space, or the server will not interpret the following tokens as hints.

If you are using the first form, the hint and optional comment may span multiple lines. The second form requires all hints and comments to occupy a single line; the remainder of the statement must start on a new line.
Description

Please Note:

- The database server will always try to use the specified hints if at all possible.

- If a planner method parameter is set so as to disable a certain plan type, then this plan will not be used even if it is specified in a hint, unless there are no other possible options for the planner. Examples of planner method parameters are `enable_indexscan`, `enable_seqscan`, `enable_hashjoin`, `enable_mergejoin`, and `enable_nestloop`. These are all Boolean parameters.

- Remember that the hint is embedded within a comment. As a consequence, if the hint is misspelled or if any parameter to a hint such as view, table, or column name is misspelled, or non-existent in the SQL command, there will be no indication that any sort of error has occurred. No syntax error will be given and the entire hint is simply ignored.

- If an alias is used for a table or view name in the SQL command, then the alias name, not the original object name, must be used in the hint. For example, in the command, `SELECT /*+ FULL(acct) */ * FROM accounts acct . . . , acct, the alias for accounts, must be specified in the FULL hint, not the table name, accounts.

Use the `EXPLAIN` command to ensure that the hint is correctly formed and the planner is using the hint. See the Advanced Server documentation set for information on the `EXPLAIN` command.

In general, optimizer hints should not be used in production applications (where table data changes throughout the life of the application). By ensuring that dynamic columns are `ANALYZED` frequently, the column statistics will be updated to reflect value changes, and the planner will use such information to produce the least cost plan for any given command execution. Use of optimizer hints defeats the purpose of this process and will result in the same plan regardless of how the table data changes.

Parameters

`hint`

An optimizer hint directive.

`comment`

A string with additional information. Note that there are restrictions as to what characters may be included in the comment. Generally, `comment` may only consist of alphabetic, numeric, the underscore, dollar sign, number sign and space characters. These must also conform to the syntax of an identifier. Any subsequent hint will be ignored if the comment is not in this form.

`statement_body`

The remainder of the `DELETE`, `INSERT`, `SELECT`, or `UPDATE` command.

The following sections describe the optimizer hint directives in more detail.
5.1 Default Optimization Modes

There are a number of optimization modes that can be chosen as the default setting for an Advanced Server database cluster. This setting can also be changed on a per session basis by using the `ALTER SESSION` command as well as in individual `DELETE, SELECT, and UPDATE` commands within an optimizer hint. The configuration parameter that controls these default modes is named `OPTIMIZER_MODE`.

The following table shows the possible values.

<table>
<thead>
<tr>
<th>Hint</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALL_ROWS</td>
<td>Optimizes for retrieval of all rows of the result set.</td>
</tr>
<tr>
<td>CHOOSE</td>
<td>Does no default optimization based on assumed number of rows to be retrieved from the result set. This is the default.</td>
</tr>
<tr>
<td>FIRST_ROWS</td>
<td>Optimizes for retrieval of only the first row of the result set.</td>
</tr>
<tr>
<td>FIRST_ROWS_10</td>
<td>Optimizes for retrieval of the first 10 rows of the result set.</td>
</tr>
<tr>
<td>FIRST_ROWS_100</td>
<td>Optimizes for retrieval of the first 100 rows of the result set.</td>
</tr>
<tr>
<td>FIRST_ROWS_1000</td>
<td>Optimizes for retrieval of the first 1000 rows of the result set.</td>
</tr>
<tr>
<td>FIRST_ROWS(n)</td>
<td>Optimizes for retrieval of the first (n) rows of the result set. This form may not be used as the object of the <code>ALTER SESSION SET OPTIMIZER_MODE</code> command. It may only be used in the form of a hint in a SQL command.</td>
</tr>
</tbody>
</table>

These optimization modes are based upon the assumption that the client submitting the SQL command is interested in viewing only the first “\(n\)” rows of the result set and will then abandon the remainder of the result set. Resources allocated to the query are adjusted as such.

**Examples**

Alter the current session to optimize for retrieval of the first 10 rows of the result set.

```
ALTER SESSION SET OPTIMIZER_MODE = FIRST_ROWS_10;
```

The current value of the `OPTIMIZER_MODE` parameter can be shown by using the `SHOW` command. Note that this command is a utility dependent command. In PSQL, the `SHOW` command is used as follows:

```
SHOW OPTIMIZER_MODE;
```

```
optimizer_mode
--------------
first_rows_10
(1 row)
```

The `SHOW` command, compatible with Oracle databases, has the following syntax:

```
SHOW PARAMETER OPTIMIZER_MODE;
```

```
NAME
-----------------------------
VALUE
```

(continues on next page)
The following example shows an optimization mode used in a SELECT command as a hint:

```
SELECT /*+ FIRST_ROWS(7) */ * FROM emp;
```

5.2 Access Method Hints

The following hints influence how the optimizer accesses relations to create the result set.

<table>
<thead>
<tr>
<th>Hint</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FULL(table)</td>
<td>Perform a full sequential scan on table.</td>
</tr>
<tr>
<td>INDEX(table [ index ] [ ...])</td>
<td>Use index on table to access the relation.</td>
</tr>
<tr>
<td>NO_INDEX(table [ index ] [ ...])</td>
<td>Do not use index on table to access the relation.</td>
</tr>
</tbody>
</table>

In addition, the ALL_ROWS, FIRST_ROWS, and FIRST_ROWS(n) hints can be used.

Examples

The sample application does not have sufficient data to illustrate the effects of optimizer hints so the remainder of the examples in this section will use a banking database created by the pgbench application located in the Advanced Server bin subdirectory.

The following steps create a database named bank, populated by the tables, pgbench_accounts, pgbench_branches, pgbench_tellers, and pgbench_history. The -s 20 option specifies a scaling factor of twenty, which results in the creation of twenty branches, each with 100,000 accounts, resulting in a total of 2,000,000 rows in the pgbench_accounts table and twenty rows in the
pgbench_branches table. Ten tellers are assigned to each branch resulting in a total of 200 rows in the pgbench_tellers table.

The following initializes the pgbench application in the bank database.

```sql
createdb -U enterprisedb bank
CREATE DATABASE
pgbench -i -s 20 -U enterprisedb bank
NOTICE: table "pgbench_history" does not exist, skipping
NOTICE: table "pgbench_tellers" does not exist, skipping
NOTICE: table "pgbench_accounts" does not exist, skipping
NOTICE: table "pgbench_branches" does not exist, skipping
creating tables...
100000 of 2000000 tuples (5%) done (elapsed 0.11 s, remaining 2.10 s)

5.2. Access Method Hints
The EXPLAIN command shows the plan selected by the query planner. In the following example, aid is the primary key column, so an indexed search is used on index, `pgbench_accounts_pkey`.

```
EXPLAIN SELECT * FROM pgbench_accounts WHERE aid = 100;

QUERY PLAN
---------------------------------------------------------------------
Index Scan using pgbench_accounts_pkey on pgbench_accounts (cost=0.43..8.45 rows=1 width=97)
  Index Cond: (aid = 100)
(2 rows)
```

The FULL hint is used to force a full sequential scan instead of using the index as shown below:

```
EXPLAIN SELECT /*+ FULL(pgbench_accounts) */ * FROM pgbench_accounts WHERE aid = 100;

QUERY PLAN
---------------------------------------------------------------------
Seq Scan on pgbench_accounts (cost=0.00..58781.69 rows=1 width=97)
  Filter: (aid = 100)
(2 rows)
```

The NO_INDEX hint forces a parallel sequential scan instead of use of the index as shown below:

```
EXPLAIN SELECT /*+ NO_INDEX(pgbench_accounts pgbench_accounts_pkey) */ * FROM pgbench_accounts WHERE aid = 100;

QUERY PLAN
---------------------------------------------------------------------
Gather (cost=1000.00..45094.80 rows=1 width=97)
  Workers Planned: 2
  -> Parallel Seq Scan on pgbench_accounts (cost=0.00..44094.70 rows=1 width=97)
    Filter: (aid = 100)
(4 rows)
```

In addition to using the EXPLAIN command as shown in the prior examples, more detailed information regarding whether or not a hint was used by the planner can be obtained by setting the trace_hints configuration parameter as follows:

```
SET trace_hints TO on;
```

The SELECT command with the NO_INDEX hint is repeated below to illustrate the additional information produced when the trace_hints configuration parameters is set.

```
EXPLAIN SELECT /*+ NO_INDEX(pgbench_accounts pgbench_accounts_pkey) */ * FROM pgbench_accounts WHERE aid = 100;

INFO: [HINTS] Index Scan of [pgbench_accounts].[pgbench_accounts_pkey]
```

(continues on next page)
rejected due to NO_INDEX hint.

QUERY PLAN

Gather (cost=1000.00..45094.80 rows=1 width=97)
Workers Planned: 2
  -> Parallel Seq Scan on pgbench_accounts (cost=0.00..44094.70 rows=1
  width=97)
      Filter: (aid = 100)
(4 rows)

Note that if a hint is ignored, the INFO: [HINTS] line will not appear. This may be an indication that there was a syntax error or some other misspelling in the hint as shown in the following example where the index name is misspelled.

EXPLAIN SELECT /*+ NO_INDEX(pgbench_accounts pgbench_accounts_xxx) */ * FROM pgbench_accounts WHERE aid = 100;

QUERY PLAN

------------------
Index Scan using pgbench_accounts_pkey on pgbench_accounts (cost=0.43..8.45 rows=1 width=97)
  Index Cond: (aid = 100)
(2 rows)
5.3 Specifying a Join Order

Include the ORDERED directive to instruct the query optimizer to join tables in the order in which they are listed in the FROM clause. If you do not include the ORDERED keyword, the query optimizer will choose the order in which to join the tables.

For example, the following command allows the optimizer to choose the order in which to join the tables listed in the FROM clause:

```sql
SELECT e.ename, d.dname, h.startdate
FROM emp e, dept d, jobhist h
WHERE d.deptno = e.deptno
AND h.empno = e.empno;
```

The following command instructs the optimizer to join the tables in the ordered specified:

```sql
SELECT /*+ ORDERED */ e.ename, d.dname, h.startdate
FROM emp e, dept d, jobhist h
WHERE d.deptno = e.deptno
AND h.empno = e.empno;
```

In the ORDERED version of the command, Advanced Server will first join `emp e` with `dept d` before joining the results with `jobhist h`. Without the ORDERED directive, the join order is selected by the query optimizer.

**Note:** The ORDERED directive does not work for Oracle-style outer joins (those joins that contain a ‘+’ sign).

5.4 Joining Relations Hints

When two tables are to be joined, there are three possible plans that may be used to perform the join.

- **Nested Loop Join** – A table is scanned once for every row in the other joined table.
- **Merge Sort Join** – Each table is sorted on the join attributes before the join starts. The two tables are then scanned in parallel and the matching rows are combined to form the join rows.
- **Hash Join** – A table is scanned and its join attributes are loaded into a hash table using its join attributes as hash keys. The other joined table is then scanned and its join attributes are used as hash keys to locate the matching rows from the first table.

The following table lists the optimizer hints that can be used to influence the planner to use one type of join plan over another.
### Example

In the following example, the **USE_HASH** hint is used for a join on the `pgbench_branches` and `pgbench_accounts` tables. The query plan shows that a hash join is used by creating a hash table from the join attribute of the `pgbench_branches` table.

```sql
EXPLAIN SELECT /*+ USE_HASH(b) */ b.bid, a.aid, abalance FROM pgbench_branches b, pgbench_accounts a WHERE b.bid = a.bid;
```

**QUERY PLAN**

```
Hash Join (cost=21.45..81463.06 rows=2014215 width=12)
  Hash Cond: (a.bid = b.bid)
    -> Seq Scan on pgbench_accounts a (cost=0.00..53746.15 rows=2014215 width=12)
    -> Hash (cost=21.20..21.20 rows=20 width=4)
      -> Seq Scan on pgbench_branches b (cost=0.00..21.20 rows=20 width=4)
(5 rows)
```

Next, the **NO_USE_HASH(a b)** hint forces the planner to use an approach other than hash tables. The result is a merge join.

```sql
EXPLAIN SELECT /*+ NO_USE_HASH(a b) */ b.bid, a.aid, abalance FROM pgbench_branches b, pgbench_accounts a WHERE b.bid = a.bid;
```

**QUERY PLAN**

```
Merge Join (cost=333526.08..368774.94 rows=2014215 width=12)
  Merge Cond: (b.bid = a.bid)
    -> Sort (cost=21.63..21.68 rows=20 width=4)
      Sort Key: b.bid
    -> Seq Scan on pgbench_branches b (cost=0.00..21.20 rows=20 width=4)
    -> Materialize (cost=333504.45..343575.53 rows=2014215 width=12)
      -> Sort (cost=333504.45..338539.99 rows=2014215 width=12)
        Sort Key: a.bid
      -> Seq Scan on pgbench_accounts a (cost=0.00..53746.15 rows=2014215 width=12)
(9 rows)
```
Finally, the `USE_MERGE` hint forces the planner to use a merge join.

```sql
EXPLAIN SELECT /*+ USE_MERGE(a) */ b.bid, a.aid, abalance FROM pgbench_branches b, pgbench_accounts a WHERE b.bid = a.bid;
```

**QUERY PLAN**

```
-----------------------------------------------------------------------------
------------------
Merge Join (cost=333526.08..368774.94 rows=2014215 width=12)
  Merge Cond: (b.bid = a.bid)
  -> Sort (cost=21.63..21.68 rows=20 width=4)
    Sort Key: b.bid
    -> Seq Scan on pgbench_branches b (cost=0.00..21.20 rows=20 width=4)
  -> Materialize (cost=333504.45..343575.53 rows=2014215 width=12)
    -> Sort (cost=333504.45..338539.99 rows=2014215 width=12)
      Sort Key: a.bid
      -> Seq Scan on pgbench_accounts a (cost=0.00..53746.15 rows=2014215 width=12)
(9 rows)
```

In this three-table join example, the planner first performs a hash join on the `pgbench_branches` and `pgbench_history` tables, then finally performs a hash join of the result with the `pgbench_accounts` table.

```sql
EXPLAIN SELECT h.mtime, h.delta, b.bid, a.aid FROM pgbench_history h, pgbench_branches b, pgbench_accounts a WHERE h.bid = b.bid AND h.aid = a.aid;
```

**QUERY PLAN**

```
-----------------------------------------------------------------------------
-----------
Hash Join (cost=86814.29..123103.29 rows=500000 width=20)
  Hash Cond: (h.aid = a.aid)
  -> Hash Join (cost=21.45..15081.45 rows=500000 width=20)
    Hash Cond: (h.bid = b.bid)
      -> Seq Scan on pgbench_history h (cost=0.00..8185.00 rows=500000 width=20)
      -> Hash (cost=21.20..21.20 rows=20 width=4)
        -> Seq Scan on pgbench_branches b (cost=0.00..21.20 rows=20 width=4)
  -> Hash (cost=53746.15..53746.15 rows=2014215 width=4)
    -> Seq Scan on pgbench_accounts a (cost=0.00..53746.15 rows=2014215 width=4)
(9 rows)
```

This plan is altered by using hints to force a combination of a merge sort join and a hash join.

```sql
EXPLAIN SELECT /*+ USE_MERGE(h b) USE_HASH(a) */ h.mtime, h.delta, b.bid, a.aid FROM pgbench_history h, pgbench_branches b, pgbench_accounts a WHERE h.bid = b.bid AND h.aid = a.aid;
```

**QUERY PLAN**

```
(continues on next page)
```
Hash Join (cost=152583.39..182562.49 rows=500000 width=20)
  Hash Cond: (h.aid = a.aid)
  ->  Merge Join (cost=65790.55..74540.65 rows=500000 width=20)
      Merge Cond: (b.bid = h.bid)
      ->  Sort (cost=21.63..21.68 rows=20 width=4)
          Sort Key: b.bid
          ->  Seq Scan on pgbench_branches b (cost=0.00..21.20 rows=20 width=4)
      ->  Materialize (cost=65768.92..68268.92 rows=500000 width=20)
          ->  Sort (cost=65768.92..67018.92 rows=500000 width=20)
              Sort Key: h.bid
          ->  Seq Scan on pgbench_history h (cost=0.00..8185.00 rows=500000 width=20)
      ->  Hash (cost=53746.15..53746.15 rows=2014215 width=4)
          ->  Seq Scan on pgbench_accounts a (cost=0.00..53746.15 rows=2014215 width=4)
  (13 rows)

5.5 Global Hints

Thus far, hints have been applied directly to tables that are referenced in the SQL command. It is also possible to apply hints to tables that appear in a view when the view is referenced in the SQL command. The hint does not appear in the view, itself, but rather in the SQL command that references the view.

When specifying a hint that is to apply to a table within a view, the view and table names are given in dot notation within the hint argument list.

Synopsis

<hint>({<view>.<table>})

Parameters

hint

Any of the hints in table Access Method Hints, Joining Relations Hints.

view

The name of the view containing table.

table

The table on which the hint is to be applied.

Examples

A view named, tx, is created from the three-table join of pgbench_history, pgbench_branches, and pgbench_accounts shown in the final example of Joining Relations Hints.

5.5. Global Hints
CREATE VIEW tx AS SELECT h.mtime, h.delta, b.bid, a.aid FROM pgbench_history h, pgbench_branches b, pgbench_accounts a WHERE h.bid = b.bid AND h.aid = a.aid;

The query plan produced by selecting from this view is shown below:

```
EXPLAIN SELECT * FROM tx;

QUERY PLAN

Hash Join (cost=86814.29..123103.29 rows=500000 width=20)
  Hash Cond: (h.aid = a.aid)
  -> Hash Join (cost=21.45..15081.45 rows=500000 width=20)
    Hash Cond: (h.bid = b.bid)
    -> Seq Scan on pgbench_history h (cost=0.00..8185.00 rows=500000 width=20)
    -> Hash (cost=21.20..21.20 rows=20 width=4)
      -> Seq Scan on pgbench_branches b (cost=0.00..21.20 rows=20 width=4)
  -> Hash (cost=53746.15..53746.15 rows=2014215 width=4)
    -> Seq Scan on pgbench_accounts a (cost=0.00..53746.15 rows=2014215 width=4)
(9 rows)
```

The same hints that were applied to this join at the end of *Joining Relations Hints* can be applied to the view as follows:

```
EXPLAIN SELECT /*+ USE_MERGE(tx.h tx.b) USE_HASH(tx.a) */ * FROM tx;

QUERY PLAN

Hash Join (cost=152583.39..182562.49 rows=500000 width=20)
  Hash Cond: (h.aid = a.aid)
  -> Merge Join (cost=65790.55..74540.65 rows=500000 width=20)
    Merge Cond: (b.bid = h.bid)
    -> Sort (cost=21.63..21.68 rows=20 width=4)
      Sort Key: b.bid
    -> Seq Scan on pgbench_branches b (cost=0.00..21.20 rows=20 width=4)
      -> Materialize (cost=65768.92..68268.92 rows=500000 width=20)
      -> Sort (cost=65768.92..67018.92 rows=500000 width=20)
        Sort Key: h.bid
        -> Seq Scan on pgbench_history h (cost=0.00..8185.00 rows=500000 width=20)
  -> Hash (cost=53746.15..53746.15 rows=2014215 width=4)
    -> Seq Scan on pgbench_accounts a (cost=0.00..53746.15 rows=2014215 width=4)
(13 rows)
```

In addition to applying hints to tables within stored views, hints can be applied to tables within subqueries as illustrated by the following example. In this query on the sample application *emp* table, employees and
their managers are listed by joining the `emp` table with a subquery of the `emp` table identified by the alias, `b`.

```sql
SELECT a.empno, a.ename, b.empno "mgr empno", b.ename "mgr ename" FROM emp a, (SELECT * FROM emp) b WHERE a.mgr = b.empno;
```

<table>
<thead>
<tr>
<th>empno</th>
<th>ename</th>
<th>mgr empno</th>
<th>mgr ename</th>
</tr>
</thead>
<tbody>
<tr>
<td>7369</td>
<td>SMITH</td>
<td>7902</td>
<td>FORD</td>
</tr>
<tr>
<td>7499</td>
<td>ALLEN</td>
<td>7698</td>
<td>BLAKE</td>
</tr>
<tr>
<td>7521</td>
<td>WARD</td>
<td>7698</td>
<td>BLAKE</td>
</tr>
<tr>
<td>7566</td>
<td>JONES</td>
<td>7839</td>
<td>KING</td>
</tr>
<tr>
<td>7654</td>
<td>MARTIN</td>
<td>7698</td>
<td>BLAKE</td>
</tr>
<tr>
<td>7698</td>
<td>BLAKE</td>
<td>7839</td>
<td>KING</td>
</tr>
<tr>
<td>7782</td>
<td>CLARK</td>
<td>7839</td>
<td>KING</td>
</tr>
<tr>
<td>7788</td>
<td>SCOTT</td>
<td>7566</td>
<td>JONES</td>
</tr>
<tr>
<td>7844</td>
<td>TURNER</td>
<td>7698</td>
<td>BLAKE</td>
</tr>
<tr>
<td>7876</td>
<td>ADAMS</td>
<td>7788</td>
<td>SCOTT</td>
</tr>
<tr>
<td>7900</td>
<td>JAMES</td>
<td>7698</td>
<td>BLAKE</td>
</tr>
<tr>
<td>7902</td>
<td>FORD</td>
<td>7566</td>
<td>JONES</td>
</tr>
<tr>
<td>7934</td>
<td>MILLER</td>
<td>7782</td>
<td>CLARK</td>
</tr>
</tbody>
</table>

(13 rows)

The plan chosen by the query planner is shown below:

```sql
EXPLAIN SELECT a.empno, a.ename, b.empno "mgr empno", b.ename "mgr ename" FROM emp a, (SELECT * FROM emp) b WHERE a.mgr = b.empno;
```

```
<table>
<thead>
<tr>
<th>QUERY PLAN</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hash Join (cost=1.32..2.64 rows=13 width=22)</td>
</tr>
<tr>
<td>Hash Cond: (a.mgr = emp.empno)</td>
</tr>
<tr>
<td>-&gt; Seq Scan on emp a (cost=0.00..1.14 rows=14 width=16)</td>
</tr>
<tr>
<td>-&gt; Hash (cost=1.14..1.14 rows=14 width=11)</td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td>(5 rows)</td>
</tr>
</tbody>
</table>
```

A hint can be applied to the `emp` table within the subquery to perform an index scan on index, `emp_pk`, instead of a table scan. Note the difference in the query plans.

```sql
EXPLAIN SELECT /*+ INDEX(b.emp emp_pk) */ a.empno, a.ename, b.empno "mgr empno", b.ename "mgr ename" FROM emp a, (SELECT * FROM emp) b WHERE a.mgr = b.empno;
```

```
<table>
<thead>
<tr>
<th>QUERY PLAN</th>
</tr>
</thead>
<tbody>
<tr>
<td>Merge Join (cost=4.17..13.11 rows=13 width=22)</td>
</tr>
<tr>
<td>Merge Cond: (a.mgr = emp.empno)</td>
</tr>
<tr>
<td>-&gt; Sort (cost=1.41..1.44 rows=14 width=16)</td>
</tr>
<tr>
<td>Sort Key: a.mgr</td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td>-&gt; Index Scan using emp_pk on emp (cost=0.14..12.35 rows=14 width=11)</td>
</tr>
<tr>
<td>(6 rows)</td>
</tr>
</tbody>
</table>
```

5.5. Global Hints 106
5.6 Using the APPEND Optimizer Hint

By default, Advanced Server will add new data into the first available free-space in a table (vacated by vacuumed records). Include the APPEND directive after an INSERT or SELECT command to instruct the server to bypass mid-table free space, and affix new rows to the end of the table. This optimizer hint can be particularly useful when bulk loading data.

The syntax is:

```sql
/*+APPEND*/
```

For example, the following command, compatible with Oracle databases, instructs the server to append the data in the INSERT statement to the end of the sales table:

```sql
INSERT /*+APPEND*/ INTO sales VALUES
  (10, 10, '01-Mar-2011', 10, 'OR');
```

Note that Advanced Server supports the APPEND hint when adding multiple rows in a single INSERT statement:

```sql
INSERT /*+APPEND*/ INTO sales VALUES
  (20, 20, '01-Aug-2011', 20, 'NY'),
  (30, 30, '01-Feb-2011', 30, 'FL'),
  (40, 40, '01-Nov-2011', 40, 'TX');
```

The APPEND hint can also be included in the SELECT clause of an INSERT INTO statement:

```sql
INSERT INTO sales_history SELECT /*+APPEND*/ FROM sales;
```
5.7 Parallelism Hints

The PARALLEL optimizer hint is used to force parallel scanning.
The NO_PARALLEL optimizer hint prevents usage of a parallel scan.

Synopsis

```
PARALLEL (<table> [ <parallel_degree> | DEFAULT ])
NO_PARALLEL (<table>)
```

Description

Parallel scanning is the usage of multiple background workers to simultaneously perform a scan of a table (that is, in parallel) for a given query. This process provides performance improvement over other methods such as the sequential scan.

Parameters

table

The table to which the parallel hint is to be applied.

parallel_degree | DEFAULT

parallel_degree is a positive integer that specifies the desired number of workers to use for a parallel scan. If specified, the lesser of parallel_degree and configuration parameter max_parallel_workers_per_gather is used as the planned number of workers. For information on the max_parallel_workers_per_gather parameter, see Asynchronous Behavior located under Resource Consumption in the PostgreSQL core documentation available at:

https://www.postgresql.org/docs/current/static/runtime-config-resource.html

If DEFAULT is specified, then the maximum possible parallel degree is used.

If both parallel_degree and DEFAULT are omitted, then the query optimizer determines the parallel degree. In this case, if table has been set with the parallel_workers storage parameter, then this value is used as the parallel degree, otherwise the optimizer uses the maximum possible parallel degree as if DEFAULT was specified. For information on the parallel_workers storage parameter, see the Storage Parameters located under CREATE TABLE in the PostgreSQL core documentation available at:

https://www.postgresql.org/docs/current/static/sql-createtable.html

Regardless of the circumstance, the parallel degree never exceeds the setting of configuration parameter max_parallel_workers_per_gather.

Examples

The following configuration parameter settings are in effect:
The following example shows the default scan on table `pgbench_accounts`. Note that a sequential scan is shown in the query plan.

```sql
SET trace_hints TO on;
EXPLAIN SELECT * FROM pgbench_accounts;
```

```
QUERY PLAN
---------------------------------------------------------------------------
| Seq Scan on pgbench_accounts (cost=0.00..53746.15 rows=2014215 width=97) |
(1 row)
```

The following example uses the `PARALLEL` hint. In the query plan, the Gather node, which launches the background workers, indicates that two workers are planned to be used.

```sql
EXPLAIN SELECT /*+ PARALLEL(pgbench_accounts) */ * FROM pgbench_accounts;
```

```
INFO: [HINTS] SeqScan of [pgbench_accounts] rejected due to PARALLEL hint.
INFO: [HINTS] PARALLEL on [pgbench_accounts] accepted.
INFO: [HINTS] Index Scan of [pgbench_accounts].[pgbench_accounts_pkey] rejected due to PARALLEL hint.
QUERY PLAN
---------------------------------------------------------------------------
| Gather (cost=1000.00..244418.06 rows=2014215 width=97) |
| Workers Planned: 2 |
  | -> Parallel Seq Scan on pgbench_accounts (cost=0.00..41996.56 rows=839256 width=97) |
(3 rows)
```

Now, the `max_parallel_workers_per_gather` setting is increased:

```sql
SHOW max_worker_processes;
max_worker_processes
----------------------
8 (1 row)
SHOW max_parallel_workers_per_gather;
max_parallel_workers_per_gather
---------------------------------
2 (1 row)
```

The following example shows the default scan on table `pgbench_accounts`. Note that a sequential scan is shown in the query plan.

```
SET trace_hints TO on;
EXPLAIN SELECT * FROM pgbench_accounts;
```

```
QUERY PLAN
---------------------------------------------------------------------------
| Seq Scan on pgbench_accounts (cost=0.00..53746.15 rows=2014215 width=97) |
(1 row)
```

The following example uses the `PARALLEL` hint. In the query plan, the Gather node, which launches the background workers, indicates that two workers are planned to be used.

```sql
EXPLAIN SELECT /*+ PARALLEL(pgbench_accounts) */ * FROM pgbench_accounts;
```

```
INFO: [HINTS] SeqScan of [pgbench_accounts] rejected due to PARALLEL hint.
INFO: [HINTS] PARALLEL on [pgbench_accounts] accepted.
INFO: [HINTS] Index Scan of [pgbench_accounts].[pgbench_accounts_pkey] rejected due to PARALLEL hint.
QUERY PLAN
---------------------------------------------------------------------------
| Gather (cost=1000.00..244418.06 rows=2014215 width=97) |
| Workers Planned: 2 |
  | -> Parallel Seq Scan on pgbench_accounts (cost=0.00..41996.56 rows=839256 width=97) |
(3 rows)
```

Note: If `trace_hints` is set to `on`, the `INFO: [HINTS]` lines appear stating that `PARALLEL` has been accepted for `pgbench_accounts` as well as other hint information. For the remaining examples, these lines will not be displayed as they generally show the same output (that is, `trace_hints` has been reset to `off`).

Now, the `max_parallel_workers_per_gather` setting is increased:

```sql
SHOW max_worker_processes;
max_worker_processes
----------------------
8 (1 row)
SHOW max_parallel_workers_per_gather;
max_parallel_workers_per_gather
---------------------------------
2 (1 row)
```
SET max_parallel_workers_per_gather TO 6;
SHOW max_parallel_workers_per_gather;
max_parallel_workers_per_gather
---------------------------------
6
(1 row)

The same query on pgbench_accounts is issued again with no parallel degree specification in the PARALLEL hint. Note that the number of planned workers has increased to 4 as determined by the optimizer.

EXPLAIN SELECT /*+ PARALLEL(pgbench_accounts) */ * FROM pgbench_accounts;

QUERY PLAN
-------------------------------------------------------------------------------
---------------------
Gather (cost=1000.00..241061.04 rows=2014215 width=97)
  Workers Planned: 4
    -> Parallel Seq Scan on pgbench_accounts (cost=0.00..38639.54 rows=503554 width=97)
(3 rows)

Now, a value of 6 is specified for the parallel degree parameter of the PARALLEL hint. The planned number of workers is now returned as this specified value:

EXPLAIN SELECT /*+ PARALLEL(pgbench_accounts 6) */ * FROM pgbench_accounts;

QUERY PLAN
-------------------------------------------------------------------------------
---------------------
Gather (cost=1000.00..239382.52 rows=2014215 width=97)
  Workers Planned: 6
    -> Parallel Seq Scan on pgbench_accounts (cost=0.00..36961.03 rows=335702 width=97)
(3 rows)

The same query is now issued with the DEFAULT setting for the parallel degree. The results indicate that the maximum allowable number of workers is planned.

EXPLAIN SELECT /*+ PARALLEL(pgbench_accounts DEFAULT) */ * FROM pgbench_accounts;

QUERY PLAN
-------------------------------------------------------------------------------
---------------------
Gather (cost=1000.00..239382.52 rows=2014215 width=97)
  Workers Planned: 6
    -> Parallel Seq Scan on pgbench_accounts (cost=0.00..36961.03 rows=335702 width=97)
(3 rows)

5.7. ParallelismHints
Table `pgbench_accounts` is now altered so that the `parallel_workers` storage parameter is set to 3.

**Note:** This format of the `ALTER TABLE` command to set the `parallel_workers` parameter is not compatible with Oracle databases.

The `parallel_workers` setting is shown by the PSQL `\d+` command.

```
ALTER TABLE pgbench_accounts SET (parallel_workers=3);
\+ pgbench_accounts
<table>
<thead>
<tr>
<th>Column</th>
<th>Type</th>
<th>Modifiers</th>
<th>Storage</th>
<th>Stats target</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>aid</td>
<td>integer</td>
<td>not null</td>
<td>plain</td>
<td></td>
<td></td>
</tr>
<tr>
<td>bid</td>
<td>integer</td>
<td></td>
<td>plain</td>
<td></td>
<td></td>
</tr>
<tr>
<td>abalance</td>
<td>integer</td>
<td></td>
<td>plain</td>
<td></td>
<td></td>
</tr>
<tr>
<td>filler</td>
<td>character(84)</td>
<td></td>
<td>extended</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Indexes:
- "pgbench_accounts_pkey" PRIMARY KEY, btree (aid)

Options: fillfactor=100, parallel_workers=3
```

Now, when the `PARALLEL` hint is given with no parallel degree, the resulting number of planned workers is the value from the `parallel_workers` parameter:

```
EXPLAIN SELECT /*+ PARALLEL(pgbench_accounts) */ * FROM pgbench_accounts;
```

```
QUERY PLAN
-------------------------------------------------------------------------------
Gather (cost=1000.00..242522.97 rows=2014215 width=97)
 Workers Planned: 3
 -> Parallel Seq Scan on pgbench_accounts (cost=0.00..40101.47 rows=649747 width=97)
(3 rows)
```

Specifying a parallel degree value or `DEFAULT` in the `PARALLEL` hint overrides the `parallel_workers` setting.

The following example shows the `NO_PARALLEL` hint. Note that with `trace_hints` set to `on`, the `INFO: [HINTS]` message states that the parallel scan was rejected due to the `NO_PARALLEL` hint.

```
EXPLAIN SELECT /*+ NO_PARALLEL(pgbench_accounts) */ * FROM pgbench_accounts;
INFO: [HINTS] Parallel SeqScan of [pgbench_accounts] rejected due to NO_PARALLEL hint.
```

```
QUERY PLAN
---------------------------------------------------------------------------
Seq Scan on pgbench_accounts (cost=0.00..53746.15 rows=2014215 width=97)
(1 row)
```

5.7. Parallelism Hints
## 5.8 Conflicting Hints

If a command includes two or more conflicting hints, the server will ignore the contradictory hints. The following table lists hints that are contradictory to each other.

<table>
<thead>
<tr>
<th>Hint</th>
<th>Conflicting Hint</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALL_ROWS</td>
<td>FIRST_ROWS - all formats</td>
</tr>
</tbody>
</table>
| FULL(table)          | INDEX(table [ index ])
|                      | PARALLEL(table [ degree ])
| INDEX(table)         | FULL(table)
|                      | NO_INDEX(table)
|                      | PARALLEL(table [ degree ])
| INDEX(table index)   | FULL(table)
|                      | NO_INDEX(table index)
|                      | PARALLEL(table [ degree ])
| PARALLEL(table [ degree ]) | FULL(table)
|                      | INDEX(table)
|                      | NO_PARALLEL(table)
| USE_HASH(table)      | NO_USE_HASH(table)
| USE_MERGE(table)     | NO_USE_MERGE(table)
| USE_NL(table)        | NO_USE_NL(table)
dblink_ora provides an OCI-based database link that allows you to SELECT, INSERT, UPDATE or DELETE data stored on an Oracle system from within Advanced Server.

**Connecting to an Oracle Database**

To enable Oracle connectivity, download Oracle’s freely available OCI drivers from their website, presently at:

For Linux, if the Oracle instant client that you’ve downloaded does not include the `libclntsh.so` library, you must create a symbolic link named `libclntsh.so` that points to the downloaded version. Navigate to the instant client directory and execute the following command:

```bash
ln -s libclntsh.so.<version> libclntsh.so
```

Where `version` is the version number of the `libclntsh.so` library. For example:

```bash
ln -s libclntsh.so.12.1 libclntsh.so
```

Before creating a link to an Oracle server, you must tell Advanced Server where to find the OCI driver.

Set the `LD_LIBRARY_PATH` environment variable on Linux (or `PATH` on Windows) to the `lib` directory of the Oracle client installation directory.

For Windows only, you can instead set the value of the `oracle_home` configuration parameter in the `postgresql.conf` file. The value specified in the `oracle_home` configuration parameter will override the Windows `PATH` environment variable.

The `LD_LIBRARY_PATH` environment variable on Linux (`PATH` environment variable or `oracle_home` configuration parameter on Windows) must be set properly each time you start Advanced Server.
When using a Linux service script to start Advanced Server, be sure LD_LIBRARY_PATH has been set within the service script so it is in effect when the script invokes the pg_ctl utility to start Advanced Server.

For Windows only: To set the oracle_home configuration parameter in the postgresql.conf file, edit the file, adding the following line:

```plaintext
oracle_home = 'lib_directory'
```

Substitute the name of the Windows directory that contains oci.dll for lib_directory.

After setting the oracle_home configuration parameter, you must restart the server for the changes to take effect. Restart the server from the Windows Services console.

### 6.1 dblink_ora Functions and Procedures

dblink_ora supports the following functions and procedures.

#### 6.1.1 dblink_ora_connect()

The dblink_ora_connect() function establishes a connection to an Oracle database with user-specified connection information. The function comes in two forms; the signature of the first form is:

```plaintext
dblink_ora_connect(<conn_name>, <server_name>, <service_name>, <user_name>,
                    <password>, <port>, <asDBA>)
```

Where:
- `conn_name` specifies the name of the link.
- `server_name` specifies the name of the host.
- `service_name` specifies the name of the service.
- `user_name` specifies the name used to connect to the server.
- `password` specifies the password associated with the user name.
- `port` specifies the port number.
- `asDBA` is True if you wish to request SYSDBA privileges on the Oracle server. This parameter is optional; if omitted, the default value is FALSE.

The first form of dblink_ora_connect() returns a TEXT value.

The signature of the second form of the dblink_ora_connect() function is:

```plaintext
dblink_ora_connect(<foreign_server_name>, <asDBA>)
```

Where:
foreign_server_name specifies the name of a foreign server.

asDBA is True if you wish to request SYSDBA privileges on the Oracle server. This parameter is optional; if omitted, the default value is FALSE.

The second form of the dblink_ora_connect() function allows you to use the connection properties of a pre-defined foreign server when establishing a connection to the server.

Before invoking the second form of the dblink_ora_connect() function, use the CREATE SERVER command to store the connection properties for the link to a system table. When you call the dblink_ora_connect() function, substitute the server name specified in the CREATE SERVER command for the name of the link.

The second form of dblink_ora_connect() returns a TEXT value.

### 6.1.2 dblink_ora_status()

The dblink_ora_status() function returns the database connection status. The signature is:

```

dblink_ora_status(<conn_name>)
```

Where:

- `conn_name` specifies the name of the link.

If the specified connection is active, the function returns a TEXT value of OK.

### 6.1.3 dblink_ora_disconnect()

The dblink_ora_disconnect() function closes a database connection. The signature is:

```

dblink_ora_disconnect(<conn_name>)
```

Where:

- `conn_name` specifies the name of the link.

The function returns a TEXT value.

### 6.1.4 dblink_ora_record()

The dblink_ora_record() function retrieves information from a database. The signature is:

```

dblink_ora_record(<conn_name>, <query_text>)
```

Where:

- `conn_name` specifies the name of the link.
- `query_text` specifies the text of the SQL SELECT statement that will be invoked on the Oracle server.
The function returns a SETOF record.

6.1.5 dblink_ora_call()

The dblink_ora_call() function executes a non-SELECT statement on an Oracle database and returns a result set. The signature is:

\[
\text{dblink_ora_call(<conn\_name>, <command>, <iterations>)}
\]

Where:

- **conn_name** specifies the name of the link.
- **command** specifies the text of the SQL statement that will be invoked on the Oracle server.
- **iterations** specifies the number of times the statement is executed.

The function returns a SETOF record.

6.1.6 dblink_ora_exec()

The dblink_ora_exec() procedure executes a DML or DDL statement in the remote database. The signature is:

\[
\text{dblink_ora_exec(<conn\_name>, <command>)}
\]

Where:

- **conn_name** specifies the name of the link.
- **command** specifies the text of the INSERT, UPDATE, or DELETE SQL statement that will be invoked on the Oracle server.

The function returns a VOID.

6.1.7 dblink_ora_copy()

The dblink_ora_copy() function copies an Oracle table to an EDB table. The dblink_ora_copy() function returns a BIGINT value that represents the number of rows copied. The signature is:

\[
\text{dblink_ora_copy(<conn\_name>, <command>, <schema\_name>, <table\_name>, <truncate>, <count>)}
\]

Where:

- **conn_name** specifies the name of the link.
- **command** specifies the text of the SQL SELECT statement that will be invoked on the Oracle server.
- **schema_name** specifies the name of the target schema.
table_name specifies the name of the target table.

truncate specifies if the server should TRUNCATE the table prior to copying; specify TRUE to indicate that the server should TRUNCATE the table. truncate is optional; if omitted, the value is FALSE.

count instructs the server to report status information every n record, where n is the number specified. During the execution of the function, Advanced Server raises a notice of severity INFO with each iteration of the count. For example, if FeedbackCount is 10, dblink_ora_copy() raises a notice every 10 records. count is optional; if omitted, the value is 0.

6.2 Calling dblink_ora Functions

The following command establishes a connection using the dblink_ora_connect() function:

```
SELECT dblink_ora_connect('acctg', 'localhost', 'xe', 'hr', 'pwd', 1521);
```

The example connects to a service named xe running on port 1521 (on the localhost) with a user name of hr and a password of pwd. You can use the connection name acctg to refer to this connection when calling other dblink_ora functions.

The following command uses the dblink_ora_copy() function over a connection namededb_conn to copy the empid and deptno columns from a table (on an Oracle server) named ora_acctg to a table located in the public schema on an instance of Advanced Server named as_acctg. The TRUNCATE option is enforced, and a feedback count of 3 is specified:

```
edb=# SELECT dblink_ora_copy('edb_conn','select empid, deptno FROM ora_acctg', 'public', 'as_acctg', true, 3);

INFO: Row: 0
INFO: Row: 3
INFO: Row: 6
INFO: Row: 9
INFO: Row: 12

  dblink_ora_copy
-----------------
   12
(1 row)
```

The following SELECT statement uses dblink_ora_record() function and the acctg connection to retrieve information from the Oracle server:

```
SELECT * FROM dblink_ora_record( 'acctg', 'SELECT first_name from employees') AS t1(id VARCHAR);
```

The command retrieves a list that includes all of the entries in the first_name column of the employees table.

6.2. Calling dblink_ora Functions
The Open Client Library provides application interoperability with the Oracle Call Interface – an application that was formerly “locked in” can now work with either an EDB Postgres Advanced Server or an Oracle database with minimal to no changes to the application code. The EDB implementation of the Open Client Library is written in C.

The following diagram compares the Open Client Library and Oracle Call Interface application stacks.
For detailed usage information about the Open Client Library and the supported functions, see the *EDB Postgres Advanced Server OCL Connector Guide*, available at:

https://www.enterprisedb.com/edb-docs

**Note:** EDB does not support use of the Open Client Library with Oracle Real Application Clusters (RAC) and Oracle Exadata; the aforementioned Oracle products have not been evaluated nor certified with this EDB product.
Oracle Catalog Views

The Oracle Catalog Views provide information about database objects in a manner compatible with the Oracle data dictionary views. Information about the supported views is now available in the *Database Compatibility for Oracle Developer’s Catalog Views Guide*, available at:

https://www.enterprisedb.com/edb-docs
Compatible tools and utility programs can allow a developer to work with Advanced Server in a familiar environment. The tools supported by Advanced Server include:

- EDB*Plus
- EDB*Loader
- EDB*Wrap
- The Dynamic Runtime Instrumentation Tools Architecture (DRITA)

For detailed information about the functionality supported by Advanced Server, see the *Database Compatibility for Oracle Developer’s Tools and Utilities Guide*, available at:

https://www.enterprisedb.com/edb-docs
EDB has enhanced ECPG (the PostgreSQL pre-compiler) to create ECPGPlus. ECPGPlus allows you to include embedded SQL commands in C applications; when you use ECPGPlus to compile an application that contains embedded SQL commands, the SQL code is syntax-checked and translated into C.

ECPGPlus supports Pro*C compatible syntax in C programs when connected to an Advanced Server database. ECPGPlus supports:

- Pro*C compatible anonymous blocks.
- A CALL statement compatible with Oracle databases.

As part of ECPGPlus’ Pro*C compatibility, you do not need to include the BEGIN DECLARE SECTION and END DECLARE SECTION directives.

For more information about using ECPGPlus, see the *EDB Postgres Advanced Server ECPG Connector Guide* available from the EDB website at:

https://www.enterprisedb.com/edb-docs
The system catalog tables contain definitions of database objects that are available to Advanced Server; the layout of the system tables is subject to change. If you are writing an application that depends on information stored in the system tables, it would be prudent to use an existing catalog view, or create a catalog view to isolate the application from changes to the system table.

For detailed information about the system catalog tables, see the *Database Compatibility for Oracle Developer’s Catalog Views Guide*, available at:

https://www.enterprisedb.com/edb-docs
Conclusion

- EnterpriseDB and Postgres Enterprise Manager are registered trademarks of EnterpriseDB Corporation. EDB and EDB Postgres are trademarks of EnterpriseDB Corporation. Oracle is a registered trademark of Oracle, Inc. Other trademarks may be trademarks of their respective owners.

- EDB designs, establishes coding best practices, reviews, and verifies input validation for the logon UI for EDB Postgres products where present. EDB follows the same approach for additional input components, however the nature of the product may require that it accepts freeform SQL, WMI or other strings to be entered and submitted by trusted users for which limited validation is possible. In such cases it is not possible to prevent users from entering incorrect or otherwise dangerous inputs.

- EDB reserves the right to add features to products that accept freeform SQL, WMI or other potentially dangerous inputs from authenticated, trusted users in the future, but will ensure all such features are designed and tested to ensure they provide the minimum possible risk, and where possible, require superuser or equivalent privileges.

- EDB does not warrant that we can or will anticipate all potential threats and therefore our process cannot fully guarantee that all potential vulnerabilities have been addressed or considered.
