Advanced Server’s stored procedural language (SPL) is a highly productive, procedural programming language for writing custom procedures, functions, triggers, and packages for Advanced Server that provides:

- full procedural programming functionality to complement the SQL language
- a single, common language to create stored procedures, functions, triggers, and packages for the Advanced Server database
- a seamless development and testing environment
- the use of reusable code
- ease of use

This guide describes the basic elements of an SPL program, before providing an overview of the organization of an SPL program and how it is used to create a procedure or a function. Guides about the other compatibility features (such as triggers or built-in functions) that might be used in conjunction with the SPL language are available at the EDB website.

### 1.1 Character Set

SPL programs are written using the following set of characters:

- Uppercase letters A thru Z and lowercase letters a thru z
- Digits 0 thru 9
- Symbols ( ) + − * / < > = ! ~ ^ ; : . ' @ % , " # $ & _ | { } ? [ ]
- White space characters tabs, spaces, and carriage returns
Identifiers, expressions, statements, control structures, etc. that comprise the SPL language are written using these characters.

**Note:** The data that can be manipulated by an SPL program is determined by the character set supported by the database encoding.

### 1.2 Case Sensitivity

Keywords and user-defined identifiers that are used in an SPL program are case insensitive. So for example, the statement `DBMS_OUTPUT.PUT_LINE('Hello World');` is interpreted to mean the same thing as `dbms_output.put_line('Hello World');` or `Dbms_Output.Put_Line('Hello World');` or `DBMS_output.Put_line('Hello World');`.

Character and string constants, however, are case sensitive as well as any data retrieved from the Advanced Server database or data obtained from other external sources. The statement `DBMS_OUTPUT.PUT_LINE('Hello World!');` produces the following output:

```
Hello World!
```

However the statement `DBMS_OUTPUT.PUT_LINE('HELLO WORLD!');` produces the output:

```
HELLO WORLD!
```

### 1.3 Identifiers

Identifiers are user-defined names that are used to identify various elements of an SPL program including variables, cursors, labels, programs, and parameters. The syntax rules for valid identifiers are the same as for identifiers in the SQL language.

An identifier must not be the same as an SPL keyword or a keyword of the SQL language. The following are some examples of valid identifiers:

```
 x
 last___name
 a_S_Sign
 Many$$$$$$signs_____
 THIS_IS_AN_EXTREMELY_LONG_NAME
 A1
```
1.4 Qualifiers

A qualifier is a name that specifies the owner or context of an entity that is the object of the qualification. A qualified object is specified as the qualifier name followed by a dot with no intervening white space, followed by the name of the object being qualified with no intervening white space. This syntax is called dot notation.

The following is the syntax of a qualified object.

```
<qualifier.> [ <qualifier.> ]... <object>
```

qualifier is the name of the owner of the object. object is the name of the entity belonging to qualifier. It is possible to have a chain of qualifications where the preceding qualifier owns the entity identified by the subsequent qualifier(s) and object.

Almost any identifier can be qualified. What an identifier is qualified by depends upon what the identifier represents and the context of its usage.

Some examples of qualification follow:

- Procedure and function names qualified by the schema to which they belong - e.g., `schema_name.procedure_name(...)`
- Trigger names qualified by the schema to which they belong - e.g., `schema_name.trigger_name`
- Column names qualified by the table to which they belong - e.g., `emp.empno`
- Table names qualified by the schema to which they belong - e.g., `public.emp`
- Column names qualified by table and schema - e.g., `public.emp.empno`

As a general rule, wherever a name appears in the syntax of an SPL statement, its qualified name can be used as well. Typically a qualified name would only be used if there is some ambiguity associated with the name. For example, if two procedures with the same name belonging to two different schemas are invoked from within a program or if the same name is used for a table column and SPL variable within the same program.

You should avoid using qualified names if at all possible. In this chapter, the following conventions are adopted to avoid naming conflicts:

- All variables declared in the declaration section of an SPL program are prefixed by `v_`. E.g., `v_empno`
- All formal parameters declared in a procedure or function definition are prefixed by `p_`. E.g., `p_empno`
- Column names and table names do not have any special prefix conventions. E.g., column `empno` in table `emp`
1.5 Constants

Constants or literals are fixed values that can be used in SPL programs to represent values of various types - e.g., numbers, strings, dates, etc. Constants come in the following types:

- Numeric (Integer and Real)
- Character and String
- Date/time

1.6 User-Defined PL/SQL Subtypes

Advanced Server supports user-defined PL/SQL subtypes and (subtype) aliases. A subtype is a data type with an optional set of constraints that restrict the values that can be stored in a column of that type. The rules that apply to the type on which the subtype is based are still enforced, but you can use additional constraints to place limits on the precision or scale of values stored in the type.

You can define a subtype in the declaration of a PL function, procedure, anonymous block or package. The syntax is:

```
SUBTYPE <subtype_name> IS <type_name>[(<constraint>)] [NOT NULL]
```

Where constraint is:

```
{<precision> [, <scale>] | <length>}
```

Where:

- **subtype_name**
  - specifies the name of the subtype.
- **type_name**
  - specifies the name of the original type on which the subtype is based.
  - **type_name** may be:
    - The name of any of the type supported by Advanced Server.
    - The name of any composite type.
    - A column anchored by a %TYPE operator.
    - The name of another subtype.

Include the **constraint** clause to define restrictions for types that support precision or scale.

- **precision**
  - precision specifies the total number of digits permitted in a value of the subtype.
- **scale**
  - scale specifies the number of fractional digits permitted in a value of the subtype.
length

length specifies the total length permitted in a value of CHARACTER, VARCHAR, or TEXT base types.

Include the NOT NULL clause to specify that NULL values may not be stored in a column of the specified subtype.

Note that a subtype that is based on a column will inherit the column size constraints, but the subtype will not inherit NOT NULL or CHECK constraints.

Unconstrained Subtypes

To create an unconstrained subtype, use the SUBTYPE command to specify the new subtype name and the name of the type on which the subtype is based. For example, the following command creates a subtype named address that has all of the attributes of the type, CHAR:

```
SUBTYPE address IS CHAR;
```

You can also create a subtype (constrained or unconstrained) that is a subtype of another subtype:

```
SUBTYPE cust_address IS address NOT NULL;
```

This command creates a subtype named cust_address that shares all of the attributes of the address subtype. Include the NOT NULL clause to specify that a value of the cust_address may not be NULL.

Constrained Subtypes

Include a length value when creating a subtype that is based on a character type to define the maximum length of the subtype. For example:

```
SUBTYPE acct_name IS VARCHAR (15);
```

This example creates a subtype named acct_name that is based on a VARCHAR data type, but is limited to 15 characters in length.

Include values for precision (to specify the maximum number of digits in a value of the subtype) and optionally, scale (to specify the number of digits to the right of the decimal point) when constraining a numeric base type. For example:

```
SUBTYPE acct_balance IS NUMBER (5, 2);
```

This example creates a subtype named acct_balance that shares all of the attributes of a NUMBER type, but that may not exceed 3 digits to the left of the decimal point and 2 digits to the right of the decimal.

An argument declaration (in a function or procedure header) is a formal argument. The value passed to a function or procedure is an actual argument. When invoking a function or procedure, the caller provides (0 or more) actual arguments. Each actual argument is assigned to a formal argument that holds the value within the body of the function or procedure.

If a formal argument is declared as a constrained subtype:

- Advanced Server does not enforce subtype constraints when assigning an actual argument to a formal argument when invoking a function.
- Advanced Server enforces subtype constraints when assigning an actual argument to a formal argument when invoking a procedure.
Using the %TYPE Operator

You can use %TYPE notation to declare a subtype anchored to a column. For example:

```sql
SUBTYPE emp_type IS emp.empno%TYPE
```

This command creates a subtype named `emp_type` whose base type matches the type of the `empno` column in the `emp` table. A subtype that is based on a column will share the column size constraints; NOT NULL and CHECK constraints are not inherited.

Subtype Conversion

Unconstrained subtypes are aliases for the type on which they are based. Any variable of type subtype (unconstrained) is interchangeable with a variable of the base type without conversion, and vice versa.

A variable of a constrained subtype may be interchanged with a variable of the base type without conversion, but a variable of the base type may only be interchanged with a constrained subtype if it complies with the constraints of the subtype. A variable of a constrained subtype may be implicitly converted to another subtype if it is based on the same subtype, and the constraint values are within the values of the subtype to which it is being converted.
SPL is a procedural, block-structured language. There are four different types of programs that can be created using SPL, namely procedures, functions, triggers, and packages.

In addition, SPL is used to create subprograms. A subprogram refers to a subprocedure or a subfunction, which are nearly identical in appearance to procedures and functions, but differ in that procedures and functions are standalone programs, which are individually stored in the database and can be invoked by other SPL programs or from PSQL. Subprograms can only be invoked from within the standalone program within which they have been created.

2.1 SPL Block Structure

Regardless of whether the program is a procedure, function, subprogram, or trigger, an SPL program has the same block structure. A block consists of up to three sections - an optional declaration section, a mandatory executable section, and an optional exception section. Minimally, a block has an executable section that consists of one or more SPL statements within the keywords, BEGIN and END.

The optional declaration section is used to declare variables, cursors, types, and subprograms that are used by the statements within the executable and exception sections. Declarations appear just prior to the BEGIN keyword of the executable section. Depending upon the context of where the block is used, the declaration section may begin with the keyword DECLARE.

You can include an exception section within the BEGIN – END block. The exception section begins with the keyword, EXCEPTION, and continues until the end of the block in which it appears. If an exception is thrown by a statement within the block, program control goes to the exception section where the thrown exception may or may not be handled depending upon the exception and the contents of the exception section.

The following is the general structure of a block:
[ [ DECLARE ]
  <pragmas>
  <declarations> ]
BEGIN
  <statements>
[ EXCEPTION
    WHEN <exception_condition> THEN
    <statements> [, ...] ]
END;

pragmas are the directives (AUTONOMOUS_TRANSACTION is the currently supported pragma).
declarations are one or more variable, cursor, type, or subprogram declarations that are local to the
block. If subprogram declarations are included, they must be declared after all other variable, cursor, and
type declarations. Each declaration must be terminated by a semicolon. The use of the keyword DECLARE
depends upon the context in which the block appears.

statements are one or more SPL statements. Each statement must be terminated by a semicolon. The
end of the block denoted by the keyword END must also be terminated by a semicolon.

If present, the keyword EXCEPTION marks the beginning of the exception section.
exception_condition is a conditional expression testing for one or more types of exceptions.
If an exception matches one of the exceptions in exception_condition, the statements fol-
lowing the WHEN exception_condition clause are executed. There may be one or more WHEN
exception_condition clauses, each followed by statements.

Note: A BEGIN/END block in itself, is considered a statement; thus, blocks may be nested. The exception
section may also contain nested blocks.

The following is the simplest possible block consisting of the NULL statement within the executable section.
The NULL statement is an executable statement that does nothing.

BEGIN
  NULL;
END;

The following block contains a declaration section as well as the executable section.

DECLARE
  v_numerator   NUMBER(2);
  v_denominator NUMBER(2);
  v_result      NUMBER(5,2);
BEGIN
  v_numerator := 75;
  v_denominator := 14;
  v_result := v_numerator / v_denominator;
  DBMS_OUTPUT.PUT_LINE(v_numerator || ' divided by ' || v_denominator ||
                       ' is ' || v_result);
END;

In this example, three numeric variables are declared of data type NUMBER. Values are assigned to two of
the variables, and one number is divided by the other, storing the results in a third variable which is then displayed. If executed, the output would be:

```
75 divided by 14 is 5.36
```

The following block consists of a declaration, an executable, and an exception:

```sql
DECLARE
   v_numerator    NUMBER(2);
   v_denominator  NUMBER(2);
   v_result       NUMBER(5,2);
BEGIN
   v_numerator := 75;
   v_denominator := 0;
   v_result := v_numerator / v_denominator;
   DBMS_OUTPUT.PUT_LINE(v_numerator || ' divided by ' || v_denominator || ' is ' || v_result);
EXCEPTION
   WHEN OTHERS THEN
      DBMS_OUTPUT.PUT_LINE('An exception occurred');
END;
```

The following output shows that the statement within the exception section is executed as a result of the division by zero.

```
An exception occurred
```

### 2.2 Anonymous Blocks

Blocks are typically written as part of a procedure, function, subprogram, or trigger. Procedure, function, and trigger programs are named and stored in the database for re-use. For quick (one-time) execution (such as testing), you can simply enter the block without providing a name or storing it in the database.

A block of this type is called an anonymous block. An anonymous block is unnamed and is not stored in the database. Once the block has been executed and erased from the application buffer, it cannot be re-executed unless the block code is re-entered into the application.

Typically, the same block of code will be re-executed many times. In order to run a block of code repeatedly without the necessity of re-entering the code each time, with some simple modifications, an anonymous block can be turned into a procedure or function. The following sections discuss how to create a procedure or function that can be stored in the database and invoked repeatedly by another procedure, function, or application program.
2.3 Procedures Overview

Procedures are standalone SPL programs that are invoked or called as an individual SPL program statement. When called, procedures may optionally receive values from the caller in the form of input parameters and optionally return values to the caller in the form of output parameters.

2.3.1 Creating a Procedure

The `CREATE PROCEDURE` command defines and names a standalone procedure that will be stored in the database.

If a schema name is included, then the procedure is created in the specified schema. Otherwise it is created in the current schema. The name of the new procedure must not match any existing procedure with the same input argument types in the same schema. However, procedures of different input argument types may share a name (this is called overloading). (Overloading of procedures is an Advanced Server feature - overloading of stored, standalone procedures is not compatible with Oracle databases.)

To update the definition of an existing procedure, use `CREATE OR REPLACE PROCEDURE`. It is not possible to change the name or argument types of a procedure this way (if you tried, you would actually be creating a new, distinct procedure). When using `OUT` parameters, you cannot change the types of any `OUT` parameters except by dropping the procedure.

```sql
CREATE [OR REPLACE] PROCEDURE <name> [ (<parameters>) ]
  [ IMMUTABLE
  | STABLE
  | VOLATILE
  | DETERMINISTIC
  | [ NOT ] LEAKPROOF
  | CALLED ON NULL INPUT
  | RETURNS NULL ON NULL INPUT
  | STRICT
  | [ EXTERNAL ] SECURITY INVOKER
  | [ EXTERNAL ] SECURITY DEFINER
  | AUTHID DEFINER
  | AUTHID CURRENT_USER
  | PARALLEL { UNSAFE | RESTRICTED | SAFE }
  | COST <execution_cost>
  | ROWS <result_rows>
  | SET <configuration_parameter>
      { TO <value> | = <value> | FROM CURRENT }
  ...
  { IS | AS }
  [ PRAGMA AUTONOMOUS_TRANSACTION; ]
  [ <declarations> ]
  BEGIN
      <statements>
  END [ <name> ];
```

Where:
name

name is the identifier of the procedure.

parameters

parameters is a list of formal parameters.

declarations

declarations are variable, cursor, type, or subprogram declarations. If subprogram declarations are included, they must be declared after all other variable, cursor, and type declarations.

statements

statements are SPL program statements (the BEGIN – END block may contain an EXCEPTION section).

IMMUTABLE

STABLE

VOLATILE

These attributes inform the query optimizer about the behavior of the procedure; you can specify only one choice. VOLATILE is the default behavior.

IMMUTABLE indicates that the procedure cannot modify the database and always reaches the same result when given the same argument values; it does not do database lookups or otherwise use information not directly present in its argument list. If you include this clause, any call of the procedure with all-constant arguments can be immediately replaced with the procedure value.

STABLE indicates that the procedure cannot modify the database, and that within a single table scan, it will consistently return the same result for the same argument values, but that its result could change across SQL statements. This is the appropriate selection for procedures that depend on database lookups, parameter variables (such as the current time zone), etc.

VOLATILE indicates that the procedure value can change even within a single table scan, so no optimizations can be made. Please note that any function that has side-effects must be classified volatile, even if its result is quite predictable, to prevent calls from being optimized away.

DETERMINISTIC

DETERMINISTIC is a synonym for IMMUTABLE. A DETERMINISTIC procedure cannot modify the database and always reaches the same result when given the same argument values; it does not do database lookups or otherwise use information not directly present in its argument list. If you include this clause, any call of the procedure with all-constant arguments can be immediately replaced with the procedure value.

[ NOT ] LEAKPROOF

A LEAKPROOF procedure has no side effects, and reveals no information about the values used to call the procedure.

CALLED ON NULL INPUT

RETURNS NULL ON NULL INPUT
**STRICT**

**CALLED ON NULL INPUT** (the default) indicates that the procedure will be called normally when some of its arguments are **NULL**. It is the author’s responsibility to check for **NULL** values if necessary and respond appropriately.

**RETURNS NULL ON NULL INPUT** or **STRICT** indicates that the procedure always returns **NULL** whenever any of its arguments are **NULL**. If these clauses are specified, the procedure is not executed when there are **NULL** arguments; instead a **NULL** result is assumed automatically.

**[EXTERNAL] SECURITY DEFINER**

**SECURITY DEFINER** specifies that the procedure will execute with the privileges of the user that created it; this is the default. The key word **EXTERNAL** is allowed for SQL conformance, but is optional.

**[EXTERNAL] SECURITY INVOKER**

The **SECURITY INVOKER** clause indicates that the procedure will execute with the privileges of the user that calls it. The key word **EXTERNAL** is allowed for SQL conformance, but is optional.

**AUTHID DEFINER**

**AUTHID CURRENT_USER**

The **AUTHID DEFINER** clause is a synonym for **[EXTERNAL] SECURITY DEFINER**. If the **AUTHID** clause is omitted or if **AUTHID DEFINER** is specified, the rights of the procedure owner are used to determine access privileges to database objects.

The **AUTHID CURRENT_USER** clause is a synonym for **[EXTERNAL] SECURITY INVOKER**. If **AUTHID CURRENT_USER** is specified, the rights of the current user executing the procedure are used to determine access privileges.

**PARALLEL** { **UNSAFE** | **RESTRICTED** | **SAFE** }

The **PARALLEL** clause enables the use of parallel sequential scans (parallel mode). A parallel sequential scan uses multiple workers to scan a relation in parallel during a query in contrast to a serial sequential scan.

When set to **UNSAFE**, the procedure cannot be executed in parallel mode. The presence of such a procedure forces a serial execution plan. This is the default setting if the **PARALLEL** clause is omitted.

When set to **RESTRICTED**, the procedure can be executed in parallel mode, but the execution is restricted to the parallel group leader. If the qualification for any particular relation has anything that is parallel restricted, that relation won’t be chosen for parallelism.

When set to **SAFE**, the procedure can be executed in parallel mode with no restriction.

**COST** execution_cost

**execution_cost** is a positive number giving the estimated execution cost for the procedure, in units of **cpu_operator_cost**. If the procedure returns a set, this is the cost per returned row. Larger values cause the planner to try to avoid evaluating the function more often than necessary.
ROWS result_rows

result_rows is a positive number giving the estimated number of rows that the planner should expect the procedure to return. This is only allowed when the procedure is declared to return a set. The default assumption is 1000 rows.

SET configuration_parameter { TO value | = value | FROM CURRENT }

The SET clause causes the specified configuration parameter to be set to the specified value when the procedure is entered, and then restored to its prior value when the procedure exits. SET FROM CURRENT saves the session’s current value of the parameter as the value to be applied when the procedure is entered.

If a SET clause is attached to a procedure, then the effects of a SET LOCAL command executed inside the procedure for the same variable are restricted to the procedure; the configuration parameter’s prior value is restored at procedure exit. An ordinary SET command (without LOCAL) overrides the SET clause, much as it would do for a previous SET LOCAL command, with the effects of such a command persisting after procedure exit, unless the current transaction is rolled back.

PRAGMA AUTONOMOUS_TRANSACTION

PRAGMA AUTONOMOUS_TRANSACTION is the directive that sets the procedure as an autonomous transaction.

Note: The STRICT, LEAKPROOF, PARALLEL, COST, ROWS and SET keywords provide extended functionality for Advanced Server and are not supported by Oracle.

Note: By default, stored procedures are created as SECURITY DEFINERS, but when written in plpgsql, the stored procedures are created as SECURITY INVOKERS.

Example

The following is an example of a simple procedure that takes no parameters.

CREATE OR REPLACE PROCEDURE simple_procedure
IS
BEGIN
  DBMS_OUTPUT.PUT_LINE('That''s all folks!');
END simple_procedure;

The procedure is stored in the database by entering the procedure code in Advanced Server.

The following example demonstrates using the AUTHID DEFINER and SET clauses in a procedure declaration. The update_salary procedure conveys the privileges of the role that defined the procedure to the role that is calling the procedure (while the procedure executes):

CREATE OR REPLACE PROCEDURE update_salary(id INT, new_salary NUMBER)
SET SEARCH_PATH = 'public' SET WORK_MEM = '1MB'
AUTHID DEFINER IS

(continues on next page)
BEGIN
  UPDATE emp SET salary = new_salary WHERE emp_id = id;
END;

Include the `SET` clause to set the procedure’s search path to `public` and the work memory to `1MB`. Other procedures, functions and objects will not be affected by these settings.

In this example, the `AUTHID DEFINER` clause temporarily grants privileges to a role that might otherwise not be allowed to execute the statements within the procedure. To instruct the server to use the privileges associated with the role invoking the procedure, replace the `AUTHID DEFINER` clause with the `AUTHID CURRENT_USER` clause.

### 2.3.2 Calling a Procedure

A procedure can be invoked from another SPL program by simply specifying the procedure name followed by its parameters, if any, followed by a semicolon.

```
<name> [ ([ <parameters> ]) ] ;
```

**Where:**

- `name` is the identifier of the procedure.
- `parameters` is a list of actual parameters.

**Note:** If there are no actual parameters to be passed, the procedure may be called with an empty parameter list, or the opening and closing parenthesis may be omitted entirely.

**Note:** The syntax for calling a procedure is the same as in the preceding syntax diagram when executing it with the `EXEC` command in PSQL or EDB*Plus. See the *Database Compatibility for Oracle Developers Tools and Utilities Guide* for information about the `EXEC` command.

The following is an example of calling the procedure from an anonymous block:

```
BEGIN
    simple_procedure;
END;

That's all folks!
```

**Note:** Each application has its own unique way to call a procedure. For example, in a Java application, the application programming interface, JDBC, is used.
2.3.3 Deleting a Procedure

A procedure can be deleted from the database using the DROP PROCEDURE command.

```
DROP PROCEDURE [ IF EXISTS ] <name> [ (<parameters>) ]
    [ CASCADE | RESTRICT ];
```

Where `name` is the name of the procedure to be dropped.

**Note:** The specification of the parameter list is required in Advanced Server under certain circumstances such as if this is an overloaded procedure. Oracle requires that the parameter list always be omitted.

**Note:** Usage of `IF EXISTS`, `CASCADE`, or `RESTRICT` is not compatible with Oracle databases. See the DROP PROCEDURE command in the *Database Compatibility for Oracle Developers Reference Guide* for information on these options.

The previously created procedure is dropped in this example:

```
DROP PROCEDURE simple_procedure;
```
2.4 Functions Overview

Functions are standalone SPL programs that are invoked as expressions. When evaluated, a function returns a value that is substituted in the expression in which the function is embedded. Functions may optionally take values from the calling program in the form of input parameters. In addition to the fact that the function, itself, returns a value, a function may optionally return additional values to the caller in the form of output parameters. The use of output parameters in functions, however, is not an encouraged programming practice.

2.4.1 Creating a Function

The CREATE FUNCTION command defines and names a standalone function that will be stored in the database.

If a schema name is included, then the function is created in the specified schema. Otherwise it is created in the current schema. The name of the new function must not match any existing function with the same input argument types in the same schema. However, functions of different input argument types may share a name (this is called overloading). (Overloading of functions is an Advanced Server feature - overloading of stored, standalone functions is not compatible with Oracle databases).

To update the definition of an existing function, use CREATE OR REPLACE FUNCTION. It is not possible to change the name or argument types of a function this way (if you tried, you would actually be creating a new, distinct function). Also, CREATE OR REPLACE FUNCTION will not let you change the return type of an existing function. To do that, you must drop and recreate the function. Also when using OUT parameters, you cannot change the types of any OUT parameters except by dropping the function.

```sql
CREATE [ OR REPLACE ] FUNCTION <name> [ (<parameters>) ]
RETURN <data_type>
[ IMMUTABLE | STABLE | VOLATILE | DETERMINISTIC | [ NOT ] LEAKPROOF | CALLED ON NULL INPUT | RETURNS NULL ON NULL INPUT | STRICT | [ EXTERNAL ] SECURITY INVOKER | [ EXTERNAL ] SECURITY DEFINER | AUTHID DEFINER | AUTHID CURRENT_USER | PARALLEL { UNSAFE | RESTRICTED | SAFE } | COST <execution_cost> | ROWS <result_rows> ]
[ SET <configuration_parameter> ]
{ TO <value> | = <value> | FROM CURRENT }
...]
( IS | AS )
[ PRAGMA AUTONOMOUS_TRANSACTION; ]
[ <declarations> ]
BEGIN
(continues on next page)
Where:

name

name is the identifier of the function.

parameters

parameters is a list of formal parameters.

data_type

data_type is the data type of the value returned by the function’s RETURN statement.

declarations

declarations are variable, cursor, type, or subprogram declarations. If subprogram declarations are included, they must be declared after all other variable, cursor, and type declarations.

statements

statements are SPL program statements (the BEGIN – END block may contain an EXCEPTION section).

IMMUTABLE

STABLE

VOLATILE

These attributes inform the query optimizer about the behavior of the function; you can specify only one choice. VOLATILE is the default behavior.

IMMUTABLE indicates that the function cannot modify the database and always reaches the same result when given the same argument values; it does not do database lookups or otherwise use information not directly present in its argument list. If you include this clause, any call of the function with all-constant arguments can be immediately replaced with the function value.

STABLE indicates that the function cannot modify the database, and that within a single table scan, it will consistently return the same result for the same argument values, but that its result could change across SQL statements. This is the appropriate selection for function that depend on database lookups, parameter variables (such as the current time zone), etc.

VOLATILE indicates that the function value can change even within a single table scan, so no optimizations can be made. Please note that any function that has side-effects must be classified volatile, even if its result is quite predictable, to prevent calls from being optimized away.

DETERMINISTIC

DETERMINISTIC is a synonym for IMMUTABLE. A DETERMINISTIC function cannot modify the database and always reaches the same result when given the same argument values; it does not do database lookups or otherwise use information not directly present in its
argument list. If you include this clause, any call of the function with all-constant arguments can be immediately replaced with the function value.

[ NOT ] LEAKPROOF

A LEAKPROOF function has no side effects, and reveals no information about the values used to call the function.

CALLED ON NULL INPUT

RETURNS NULL ON NULL INPUT

STRICT

CALLED ON NULL INPUT (the default) indicates that the procedure will be called normally when some of its arguments are NULL. It is the author’s responsibility to check for NULL values if necessary and respond appropriately.

RETURNS NULL ON NULL INPUT or STRICT indicates that the procedure always returns NULL whenever any of its arguments are NULL. If these clauses are specified, the procedure is not executed when there are NULL arguments; instead a NULL result is assumed automatically.

[ EXTERNAL ] SECURITY DEFINER

SECURITY DEFINER specifies that the function will execute with the privileges of the user that created it; this is the default. The key word EXTERNAL is allowed for SQL conformance, but is optional.

[ EXTERNAL ] SECURITY INVOKER

The SECURITY INVOKER clause indicates that the function will execute with the privileges of the user that calls it. The key word EXTERNAL is allowed for SQL conformance, but is optional.

AUTHID DEFINER

AUTHID CURRENT_USER

The AUTHID DEFINER clause is a synonym for [EXTERNAL] SECURITY DEFINER. If the AUTHID clause is omitted or if AUTHID DEFINER is specified, the rights of the function owner are used to determine access privileges to database objects.

The AUTHID CURRENT_USER clause is a synonym for [EXTERNAL] SECURITY INVOKER. If AUTHID CURRENT_USER is specified, the rights of the current user executing the function are used to determine access privileges.

PARALLEL { UNSAFE | RESTRICTED | SAFE }

The PARALLEL clause enables the use of parallel sequential scans (parallel mode). A parallel sequential scan uses multiple workers to scan a relation in parallel during a query in contrast to a serial sequential scan.

When set to UNSAFE, the function cannot be executed in parallel mode. The presence of such a function in a SQL statement forces a serial execution plan. This is the default setting if the PARALLEL clause is omitted.
When set to `RESTRICTED`, the function can be executed in parallel mode, but the execution is restricted to the parallel group leader. If the qualification for any particular relation has anything that is parallel restricted, that relation won’t be chosen for parallelism.

When set to `SAFE`, the function can be executed in parallel mode with no restriction.

```plaintext
COST execution_cost

execution_cost is a positive number giving the estimated execution cost for the function, in units of cpu_operator_cost. If the function returns a set, this is the cost per returned row. Larger values cause the planner to try to avoid evaluating the function more often than necessary.

ROWS result_rows

result_rows is a positive number giving the estimated number of rows that the planner should expect the function to return. This is only allowed when the function is declared to return a set. The default assumption is 1000 rows.

SET configuration_parameter { TO value | = value | FROM CURRENT }

The SET clause causes the specified configuration parameter to be set to the specified value when the function is entered, and then restored to its prior value when the function exits. SET FROM CURRENT saves the session’s current value of the parameter as the value to be applied when the function is entered.

If a SET clause is attached to a function, then the effects of a SET LOCAL command executed inside the function for the same variable are restricted to the function; the configuration parameter’s prior value is restored at function exit. An ordinary SET command (without LOCAL) overrides the SET clause, much as it would do for a previous SET LOCAL command, with the effects of such a command persisting after procedure exit, unless the current transaction is rolled back.

PRAGMA AUTONOMOUS_TRANSACTION

PRAGMA AUTONOMOUS_TRANSACTION is the directive that sets the function as an autonomous transaction.

---

**Note:** The `STRICT`, `LEAKPROOF`, `PARALLEL`, `COST`, `ROWS` and `SET` keywords provide extended functionality for Advanced Server and are not supported by Oracle.

### Examples

The following is an example of a simple function that takes no parameters.

```sql
CREATE OR REPLACE FUNCTION simple_function
    RETURN VARCHAR2
IS
BEGIN
    RETURN 'That''s All Folks!';
END simple_function;
```
The following function takes two input parameters. Parameters are discussed in more detail in subsequent sections.

```sql
CREATE OR REPLACE FUNCTION emp_comp (
    p_sal NUMBER,
    p_comm NUMBER
) RETURN NUMBER
IS
    BEGIN
        RETURN (p_sal + NVL(p_comm, 0)) * 24;
    END emp_comp;
```

The following example demonstrates using the `AUTHID CURRENT_USER` clause and `STRICT` keyword in a function declaration:

```sql
CREATE OR REPLACE FUNCTION dept_salaries(dept_id int) RETURN NUMBER
    STRICT
    AUTHID CURRENT_USER
BEGIN
    RETURN QUERY (SELECT sum(salary) FROM emp WHERE deptno = id);
END;
```

Include the `STRICT` keyword to instruct the server to return `NULL` if any input parameter passed is `NULL`; if a `NULL` value is passed, the function will not execute.

The `dept_salaries` function executes with the privileges of the role that is calling the function. If the current user does not have sufficient privileges to perform the `SELECT` statement querying the `emp` table (to display employee salaries), the function will report an error. To instruct the server to use the privileges associated with the role that defined the function, replace the `AUTHID CURRENT_USER` clause with the `AUTHID DEFINER` clause.

### 2.4.2 Calling a Function

A function can be used anywhere an expression can appear within an SPL statement. A function is invoked by simply specifying its name followed by its parameters enclosed in parenthesis, if any.

```
$name$ [ ([<parameters>])] ]
```

$name$ is the name of the function. `<parameters>` is a list of actual parameters.

**Note:** If there are no actual parameters to be passed, the function may be called with an empty parameter list, or the opening and closing parenthesis may be omitted entirely.

The following shows how the function can be called from another SPL program.

```
BEGIN
    DBMS_OUTPUT.PUT_LINE(simple_function);
END;
```
A function is typically used within a SQL statement as shown in the following.

```sql
SELECT empno "EMPNO", ename "ENAME", sal "SAL", comm "COMM", 
    emp_comp(sal, comm) "YEARLY COMPENSATION" FROM emp;
```

<table>
<thead>
<tr>
<th>EMPNO</th>
<th>ENAME</th>
<th>SAL</th>
<th>COMM</th>
<th>YEARLY COMPENSATION</th>
</tr>
</thead>
<tbody>

<td>1300.00</td>
<td></td>
<td>31200.00</td>
</tr>
</tbody>
</table>

(14 rows)

### 2.4.3 Deleting a Function

A function can be deleted from the database using the `DROP FUNCTION` command.

```sql
DROP FUNCTION [ IF EXISTS ] <name> [ (<parameters>) ]
    [ CASCADE | RESTRICT ];
```

Where `name` is the name of the function to be dropped.

**Note:** The specification of the parameter list is required in Advanced Server under certain circumstances such as if this is an overloaded function. Oracle requires that the parameter list always be omitted.

**Note:** Usage of `IF EXISTS`, `CASCADE`, or `RESTRICT` is not compatible with Oracle databases. See the `DROP FUNCTION` command in the *Database Compatibility for Oracle Developers Reference Guide* for information on these options.

The previously created function is dropped in this example:

```sql
DROP FUNCTION simple_function;

2.4. Functions Overview  21
2.5 Procedure and Function Parameters

An important aspect of using procedures and functions is the capability to pass data from the calling program to the procedure or function and to receive data back from the procedure or function. This is accomplished by using parameters.

Parameters are declared in the procedure or function definition, enclosed within parenthesis following the procedure or function name. Parameters declared in the procedure or function definition are known as formal parameters. When the procedure or function is invoked, the calling program supplies the actual data that is to be used in the called program’s processing as well as the variables that are to receive the results of the called program’s processing. The data and variables supplied by the calling program when the procedure or function is called are referred to as the actual parameters.

The following is the general format of a formal parameter declaration.

`(<name> [ IN | OUT | IN OUT ] <data_type> [ DEFAULT <value> ])`

- `name` is an identifier assigned to the formal parameter. If specified, IN defines the parameter for receiving input data into the procedure or function. An IN parameter can also be initialized to a default value. If specified, OUT defines the parameter for returning data from the procedure or function. If specified, IN OUT allows the parameter to be used for both input and output. If all of IN, OUT, and IN OUT are omitted, then the parameter acts as if it were defined as IN by default. Whether a parameter is IN, OUT, or IN OUT is referred to as the parameter’s mode. 
- `data_type` defines the data type of the parameter.
- `value` is a default value assigned to an IN parameter in the called program if an actual parameter is not specified in the call.

The following is an example of a procedure that takes parameters:

```sql
CREATE OR REPLACE PROCEDURE emp_query (  
    p_deptno IN NUMBER,  
    p_empno IN OUT NUMBER,  
    p_ename IN OUT VARCHAR2,  
    p_job OUT VARCHAR2,  
    p_hiredate OUT DATE,  
    p_sal OUT NUMBER  
)  
IS  
BEGIN  
    SELECT empno, ename, job, hiredate, sal  
    INTO p_empno, p_ename, p_job, p_hiredate, p_sal  
    FROM emp  
    WHERE deptno = p_deptno  
    AND (empno = p_empno  
    OR ename = UPPER(p_ename));  
END;
```

In this example, `p_deptno` is an IN formal parameter, `p_empno` and `p_ename` are IN OUT formal parameters, and `p_job`, `p_hiredate`, and `p_sal` are OUT formal parameters.

Note: In the previous example, no maximum length was specified on the VARCHAR2 parameters and no precision and scale were specified on the NUMBER parameters. It is illegal to specify a length, precision,
scale or other constraints on parameter declarations. These constraints are automatically inherited from the actual parameters that are used when the procedure or function is called.

The `emp_query` procedure can be called by another program, passing it the actual parameters. The following is an example of another SPL program that calls `emp_query`.

```sql
DECLARE
  v_deptno NUMBER(2);
  v_empno NUMBER(4);
  v_ename VARCHAR2(10);
  v_job VARCHAR2(9);
  v_hiredate DATE;
  v_sal NUMBER;
BEGIN
  v_deptno := 30;
  v_empno := 7900;
  v_ename := '';
  emp_query(v_deptno, v_empno, v_ename, v_job, v_hiredate, v_sal);
  DBMS_OUTPUT.PUT_LINE('Department : ' || v_deptno);
  DBMS_OUTPUT.PUT_LINE('Employee No: ' || v_empno);
  DBMS_OUTPUT.PUT_LINE('Name : ' || v_ename);
  DBMS_OUTPUT.PUT_LINE('Job : ' || v_job);
  DBMS_OUTPUT.PUT_LINE('Hire Date : ' || v_hiredate);
  DBMS_OUTPUT.PUT_LINE('Salary : ' || v_sal);
END;
```

In this example, `v_deptno`, `v_empno`, `v_ename`, `v_job`, `v_hiredate`, and `v_sal` are the actual parameters.

The output from the preceding example is shown as follows:

```
Department : 30
Employee No: 7900
Name : JAMES
Job : CLERK
Hire Date : 03-DEC-81
Salary : 950
```

### 2.5.1 Positional vs. Named Parameter Notation

You can use either positional or named parameter notation when passing parameters to a function or procedure. If you specify parameters using positional notation, you must list the parameters in the order that they are declared; if you specify parameters with named notation, the order of the parameters is not significant.

To specify parameters using named notation, list the name of each parameter followed by an arrow (=>) and the parameter value. Named notation is more verbose, but makes your code easier to read and maintain.

A simple example that demonstrates using positional and named parameter notation follows:
CREATE OR REPLACE PROCEDURE emp_info (  
p_deptno IN NUMBER,  
p_empno IN OUT NUMBER,  
p_ename IN OUT VARCHAR2,  
)  
IS  
BEGIN  
dbms_output.put_line('Department Number = ' || p_deptno);  
dbms_output.put_line('Employee Number = ' || p_empno);  
dbms_output.put_line('Employee Name = ' || p_ename);  
END;  

To call the procedure using positional notation, pass the following:

emp_info(30, 7455, 'Clark');

To call the procedure using named notation, pass the following:

emp_info(p_ename =>'Clark', p_empno=>7455, p_deptno=>30);

Using named notation can alleviate the need to re-arrange a procedure's parameter list if the parameter list changes, if the parameters are reordered or if a new optional parameter is added.

In a case where you have a default value for an argument and the argument is not a trailing argument, you must use named notation to call the procedure or function. The following case demonstrates a procedure with two, leading, default arguments.

CREATE OR REPLACE PROCEDURE check_balance (  
p_customerID IN NUMBER DEFAULT NULL,  
p_balance IN NUMBER DEFAULT NULL,  
p_amount IN NUMBER  
)  
IS  
declare  
balance NUMBER;  
BEGIN  
IF (p_balance IS NULL AND p_customerID IS NULL) THEN  
RAISE_APPLICATION_ERROR  
( -20010, 'Must provide balance or customer');  
ELSEIF (p_balance IS NOT NULL AND p_customerID IS NOT NULL) THEN  
RAISE_APPLICATION_ERROR  
( -20020, 'Must provide balance or customer, not both');  
ELSEIF (p_balance IS NULL) THEN  
balance := getCustomerBalance(p_customerID);  
ELSE  
balance := p_balance;  
END IF;  
IF (amount > balance) THEN  
RAISE_APPLICATION_ERROR  
( -20030, 'Balance insufficient');  
END IF;  
END;  

2.5. Procedure and Function Parameters
You can only omit non-trailing argument values (when you call this procedure) by using named notation; when using positional notation, only trailing arguments are allowed to default. You can call this procedure with the following arguments:

```sql
check_balance(p_customerID => 10, p_amount = 500.00)
check_balance(p_balance => 1000.00, p_amount = 500.00)
```

You can use a combination of positional and named notation (mixed notation) to specify parameters. A simple example that demonstrates using mixed parameter notation follows:

```sql
CREATE OR REPLACE PROCEDURE emp_info (  
  p_deptno IN NUMBER,  
  p_empno IN OUT NUMBER,  
  p_ename IN OUT VARCHAR2,  
)  
IS  
BEGIN  
  dbms_output.put_line('Department Number = ' || p_deptno);  
  dbms_output.put_line('Employee Number = ' || p_empno);  
  dbms_output.put_line('Employee Name = ' || p_ename);  
END;
```

You can call the procedure using mixed notation:

```sql
emp_info(30, p_ename =>'Clark', p_empno=>7455);
```

If you do use mixed notation, remember that named arguments cannot precede positional arguments.

### 2.5.2 Parameter Modes

As previously discussed, a parameter has one of three possible modes - IN, OUT, or IN OUT. The following characteristics of a formal parameter are dependent upon its mode:

- Its initial value when the procedure or function is called.
- Whether or not the called procedure or function can modify the formal parameter.
- How the actual parameter value is passed from the calling program to the called program.
- What happens to the formal parameter value when an unhandled exception occurs in the called program.

The following table summarizes the behavior of parameters according to their mode.
As shown by the table, an IN formal parameter is initialized to the actual parameter with which it is called unless it was explicitly initialized with a default value. The IN parameter may be referenced within the called program, however, the called program may not assign a new value to the IN parameter. After control returns to the calling program, the actual parameter always contains the same value as it was set to prior to the call.

The OUT formal parameter is initialized to the actual parameter with which it is called. The called program may reference and assign new values to the formal parameter. If the called program terminates without an exception, the actual parameter takes on the value last set in the formal parameter. If a handled exception occurs, the value of the actual parameter takes on the last value assigned to the formal parameter. If an unhandled exception occurs, the value of the actual parameter remains as it was prior to the call.

Like an IN parameter, an IN OUT formal parameter is initialized to the actual parameter with which it is called. Like an OUT parameter, an IN OUT formal parameter is modifiable by the called program and the last value in the formal parameter is passed to the calling program’s actual parameter if the called program terminates without an exception. If a handled exception occurs, the value of the actual parameter takes on the last value assigned to the formal parameter. If an unhandled exception occurs, the value of the actual parameter remains as it was prior to the call.

### 2.5.3 Using Default Values in Parameters

You can set a default value of a formal parameter by including the DEFAULT clause or using the assignment operator (:=) in the CREATE PROCEDURE or CREATE FUNCTION statement.

The general form of a formal parameter declaration is:

```
(name [ IN|OUT|IN OUT ] <data_type> [{DEFAULT | := } <expr> ])
```

- **name** is an identifier assigned to the parameter.
- **IN|OUT|IN OUT** specifies the parameter mode.
- **data_type** is the data type assigned to the variable.
expr is the default value assigned to the parameter. If you do not include a DEFAULT clause, the caller must provide a value for the parameter.

The default value is evaluated every time the function or procedure is invoked. For example, assigning SYSDATE to a parameter of type DATE causes the parameter to have the time of the current invocation, not the time when the procedure or function was created.

The following simple procedure demonstrates using the assignment operator to set a default value of SYSDATE into the parameter hiredate:

```sql
CREATE OR REPLACE PROCEDURE hire_emp (
p_empno NUMBER,
p_ename VARCHAR2,
p_hiredate DATE := SYSDATE)
IS
BEGIN
    INSERT INTO emp(empno, ename, hiredate)
    VALUES(p_empno, p_ename, p_hiredate);
    DBMS_OUTPUT.PUT_LINE('Hired!');
END hire_emp;
```

If the parameter declaration includes a default value, you can omit the parameter from the actual parameter list when you call the procedure. Calls to the sample procedure (hire_emp) must include two arguments: the employee number (p_empno) and employee name (p_ename). The third parameter (p_hiredate) defaults to the value of SYSDATE:

```sql
hire_emp (7575, Clark)
```

If you do include a value for the actual parameter when you call the procedure, that value takes precedence over the default value:

```sql
hire_emp (7575, Clark, 15-FEB-2010)
```

Adds a new employee with a hiredate of February 15, 2010, regardless of the current value of SYSDATE.

You can write the same procedure by substituting the DEFAULT keyword for the assignment operator:

```sql
CREATE OR REPLACE PROCEDURE hire_emp (
p_empno NUMBER,
p_ename VARCHAR2,
p_hiredate DATE DEFAULT SYSDATE)
IS
BEGIN
    INSERT INTO emp(empno, ename, hiredate)
    VALUES(p_empno, p_ename, p_hiredate);
    DBMS_OUTPUT.PUT_LINE('Hired!');
END hire_emp;
```
2.6 Subprograms – Subprocedures and Subfunctions

The capability and functionality of SPL procedure and function programs can be used in an advantageous manner to build well-structured and maintainable programs by organizing the SPL code into subprocedures and subfunctions.

The same SPL code can be invoked multiple times from different locations within a relatively large SPL program by declaring subprocedures and subfunctions within the SPL program.

Subprocedures and subfunctions have the following characteristics:

- The syntax, structure, and functionality of subprocedures and subfunctions are practically identical to standalone procedures and functions. The major difference is the use of the keyword `PROCEDURE` or `FUNCTION` instead of `CREATE PROCEDURE` or `CREATE FUNCTION` to declare the subprogram.

- Subprocedures and subfunctions provide isolation for the identifiers (that is, variables, cursors, types, and other subprograms) declared within itself. That is, these identifiers cannot be accessed nor altered from the upper, parent level SPL programs or subprograms outside of the subprocedure or subfunction. This ensures that the subprocedure and subfunction results are reliable and predictable.

- The declaration section of subprocedures and subfunctions can include its own subprocedures and subfunctions. Thus, a multi-level hierarchy of subprograms can exist in the standalone program. Within the hierarchy, a subprogram can access the identifiers of upper level parent subprograms and also invoke upper level parent subprograms. However, the same access to identifiers and invocation cannot be done for lower level child subprograms in the hierarchy.

Subprocedures and subfunctions can be declared and invoked from within any of the following types of SPL programs:

- Standalone procedures and functions
- Anonymous blocks
- Triggers
- Packages
- Procedure and function methods of an object type body
- Subprocedures and subfunctions declared within any of the preceding programs

The rules regarding subprocedure and subfunction structure and access are discussed in more detail in the next sections.
2.6.1 Creating a Subprocedure

The `PROCEDURE` clause specified in the declaration section defines and names a subprocedure local to that block.

The term `block` refers to the SPL block structure consisting of an optional declaration section, a mandatory executable section, and an optional exception section. Blocks are the structures for standalone procedures and functions, anonymous blocks, subprograms, triggers, packages, and object type methods.

The phrase `the identifier is local to the block` means that the identifier (that is, a variable, cursor, type, or subprogram) is declared within the declaration section of that block and is therefore accessible by the SPL code within the executable section and optional exception section of that block.

Subprocedures can only be declared after all other variable, cursor, and type declarations included in the declaration section. (That is, subprograms must be the last set of declarations.)

```
PROCEDURE <name> [ (<parameters>) ]
{ IS | AS }
[ PRAGMA AUTONOMOUS_TRANSACTION; ]
[ <declarations> ]
BEGIN
 <statements>
END [ <name> ];
```

Where:

- **name**
  - name is the identifier of the subprocedure.

- **parameters**
  - parameters is a list of formal parameters.

- **PRAGMA AUTONOMOUS_TRANSACTION**
  - `PRAGMA AUTONOMOUS_TRANSACTION` is the directive that sets the subprocedure as an autonomous transaction.

- **declarations**
  - declarations are variable, cursor, type, or subprogram declarations. If subprogram declarations are included, they must be declared after all other variable, cursor, and type declarations.

- **statements**
  - statements are SPL program statements (the `BEGIN` – `END` block may contain an `EXCEPTION` section).

Examples

The following example is a subprocedure within an anonymous block.

```
DECLARE
 PROCEDURE list_emp
 IS
```
v_empno NUMBER(4);
v_ename VARCHAR2(10);
CURSOR emp_cur IS
    SELECT empno, ename FROM emp ORDER BY empno;
BEGIN
    OPEN emp_cur;
    DBMS_OUTPUT.PUT_LINE('Subprocedure list_emp:');
    DBMS_OUTPUT.PUT_LINE('EMPNO ENAME');
    DBMS_OUTPUT.PUT_LINE('----- -------');
    LOOP
        FETCH emp_cur INTO v_empno, v_ename;
        EXIT WHEN emp_cur%NOTFOUND;
        DBMS_OUTPUT.PUT_LINE(v_empno || ' ' || v_ename);
    END LOOP;
    CLOSE emp_cur;
END;
BEGIN
    list_emp;
END;

Invoking this anonymous block produces the following output:

Subprocedure list_emp:
EMPNO   ENAME
------- -------
7369    SMITH
7499    ALLEN
7521    WARD
7566    JONES
7654    MARTIN
7698    BLAKE
7782    CLARK
7788    SCOTT
7839    KING
7844    TURNER
7876    ADAMS
7900    JAMES
7902    FORD
7934    MILLER

The following example is a subprocedure within a trigger.

CREATE OR REPLACE TRIGGER dept_audit_trig
    AFTER INSERT OR UPDATE OR DELETE ON dept
DECLARE
    v_action VARCHAR2(24);
    PROCEDURE display_action (
        p_action IN VARCHAR2
    ) IS
BEGIN

Invoking this trigger produces the following output:

```
INSERT INTO dept VALUES (50, 'HR', 'DENVER');
User enterprisedb added dept on 2016-07-26
```

### 2.6.2 Creating a Subfunction

The `FUNCTION` clause specified in the declaration section defines and names a subfunction local to that block.

The term *block* refers to the SPL block structure consisting of an optional declaration section, a mandatory executable section, and an optional exception section. Blocks are the structures for standalone procedures and functions, anonymous blocks, subprograms, triggers, packages, and object type methods.

The phrase *the identifier is local to the block* means that the identifier (that is, a variable, cursor, type, or subprogram) is declared within the declaration section of that block and is therefore accessible by the SPL code within the executable section and optional exception section of that block.

```
FUNCTION <name> [ (<parameters>) ]
RETURN <data_type>
{ IS | AS }
[ PRAGMA AUTONOMOUS_TRANSACTION; ]
[ <declarations> ]
BEGIN
<statements>
END [ <name> ];
```

Where:

- **name**
  - *name* is the identifier of the subfunction.

- **parameters**
  - *parameters* is a list of formal parameters.
data_type

data_type is the data type of the value returned by the function’s RETURN statement.

PRAGMA AUTONOMOUS_TRANSACTION

PRAGMA AUTONOMOUS_TRANSACTION is the directive that sets the subfunction as an autonomous transaction.

declarations

declarations are variable, cursor, type, or subprogram declarations. If subprogram declarations are included, they must be declared after all other variable, cursor, and type declarations.

statements

statements are SPL program statements (the BEGIN – END block may contain an EXCEPTION section).

Examples

The following example shows the use of a recursive subfunction:

```sql
DECLARE
  FUNCTION factorial (n BINARY_INTEGER) RETURN BINARY_INTEGER IS BEGIN
    IF n = 1 THEN
      RETURN n;
    ELSE
      RETURN n * factorial(n-1);
    END IF;
  END factorial;
BEGIN
  FOR i IN 1..5 LOOP
    DBMS_OUTPUT.PUT_LINE(i || '!' = ' ' || factorial(i));
  END LOOP;
END;
```

The output from the example is the following:

1! = 1
2! = 2
3! = 6
4! = 24
5! = 120
2.6.3 Block Relationships

This section describes the terminology of the relationship between blocks that can be declared in an SPL program. The ability to invoke subprograms and access identifiers declared within a block depends upon this relationship.

The following are the basic terms:

- A **block** is the basic SPL structure consisting of an optional declaration section, a mandatory executable section, and an optional exception section. Blocks implement standalone procedure and function programs, anonymous blocks, triggers, packages, and subprocedures and subfunctions.

- An identifier (variable, cursor, type, or subprogram) **local to a block** means that it is declared within the declaration section of the given block. Such local identifiers are accessible from the executable section and optional exception section of the block.

- The **parent block** contains the declaration of another block (the **child block**).

- **Descendent blocks** are the set of blocks forming the child relationship starting from a given parent block.

- **Ancestor blocks** are the set of blocks forming the parental relationship starting from a given child block.

- The set of descendent (or ancestor) blocks form a **hierarchy**.

- The **level** is an ordinal number of a given block from the highest, ancestor block. For example, given a standalone procedure, the subprograms declared within the declaration section of this procedure are all at the same level, for example call it level 1. Additional subprograms within the declaration section of the subprograms declared in the standalone procedure are at the next level, which is level 2.

- The **sibling blocks** are the set of blocks that have the same parent block (that is, they are all locally declared in the same block). Sibling blocks are also always at the same level relative to each other.

The following schematic of a set of procedure declaration sections provides an example of a set of blocks and their relationships to their surrounding blocks.

The two vertical lines on the left-hand side of the blocks indicate there are two pairs of sibling blocks. **block_1a** and **block_1b** is one pair, and **block_2a** and **block_2b** is the second pair.

The relationship of each block with its ancestors is shown on the right-hand side of the blocks. There are three hierarchical paths formed when progressing up the hierarchy from the lowest level child blocks. The first consists of **block_0**, **block_1a**, **block_2a**, and **block_3**. The second is **block_0**, **block_1a**, and **block_2b**. The third is **block_0**, **block_1b**, and **block_2b**.

```sql
CREATE PROCEDURE block_0
IS

    +---- PROCEDURE block_1a ------- Local to block_0
    | IS
    |    +---- PROCEDURE block_2a ---- Local to block_1a and descendant

(continues on next page)
```
The rules for invoking subprograms based upon block location is described starting with *Invoking Subpro-grams*. The rules for accessing variables based upon block location is described in *Accessing Subprogram Variables*.
2.6.4 Invoking Subprograms

A subprogram is invoked in the same manner as a standalone procedure or function by specifying its name and any actual parameters.

The subprogram may be invoked with none, one, or more qualifiers, which are the names of the parent subprograms or labeled anonymous blocks forming the ancestor hierarchy from where the subprogram has been declared.

The invocation is specified as a dot-separated list of qualifiers ending with the subprogram name and any of its arguments as shown by the following:

```
[[<qualifier_1.>][...]<qualifier_n.>]<subprog> [{<arguments>}]`
```

If specified, qualifier_n is the subprogram in which subprog has been declared in its declaration section. The preceding list of qualifiers must reside in a continuous path up the hierarchy from qualifier_n to qualifier_1. qualifier_1 may be any ancestor subprogram in the path as well as any of the following:

- Standalone procedure name containing the subprogram
- Standalone function name containing subprogram
- Package name containing the subprogram
- Object type name containing the subprogram within an object type method
- An anonymous block label included prior to the DECLARE keyword if a declaration section exists, or prior to the BEGIN keyword if there is no declaration section.

**Note:** qualifier_1 may not be a schema name, otherwise an error is thrown upon invocation of the subprogram. This Advanced Server restriction is not compatible with Oracle databases, which allow use of the schema name as a qualifier.

arguments is the list of actual parameters to be passed to the subprocedure or subfunction.

Upon invocation, the search for the subprogram occurs as follows:

- The invoked subprogram name of its type (that is, subprocedure or subfunction) along with any qualifiers in the specified order, (referred to as the invocation list) is used to find a matching set of blocks residing in the same hierarchical order. The search begins in the block hierarchy where the lowest level is the block from where the subprogram is invoked. The declaration of the subprogram must be in the SPL code prior to the code line where it is invoked when the code is observed from top to bottom. (An exception to this requirement can be accomplished using a forward declaration. See Using Forward Declarations for information on forward declarations.)

- If the invocation list does not match the hierarchy of blocks starting from the block where the subprogram is invoked, a comparison is made by matching the invocation list starting with the parent of the previous starting block. In other words, the comparison progresses up the hierarchy.

- If there are sibling blocks of the ancestors, the invocation list comparison also includes the hierarchy of the sibling blocks, but always comparing in an upward level, never comparing the descendants of
the sibling blocks.

- This comparison process continues up the hierarchies until the first complete match is found in which case the located subprogram is invoked. Note that the formal parameter list of the matched subprogram must comply with the actual parameter list specified for the invoked subprogram, otherwise an error occurs upon invocation of the subprogram.

- If no match is found after searching up to the standalone program, then an error is thrown upon invocation of the subprogram.

Note: The Advanced Server search algorithm for subprogram invocation is not quite compatible with Oracle databases. For Oracle, the search looks for the first match of the first qualifier (that is qualifier_1). When such a match is found, all remaining qualifiers, the subprogram name, subprogram type, and arguments of the invocation must match the hierarchy content where the matching first qualifier is found, otherwise an error is thrown. For Advanced Server, a match is not found unless all qualifiers, the subprogram name, and the subprogram type of the invocation match the hierarchy content. If such an exact match is not initially found, Advanced Server continues the search progressing up the hierarchy.

The location of subprograms relative to the block from where the invocation is made can be accessed as follows:

- Subprograms declared in the local block can be invoked from the executable section or the exception section of the same block.

- Subprograms declared in the parent or other ancestor blocks can be invoked from the child block of the parent or other ancestors.

- Subprograms declared in sibling blocks can be called from a sibling block or from any descendent block of the sibling.

However, the following location of subprograms cannot be accessed relative to the block from where the invocation is made:

- Subprograms declared in blocks that are descendants of the block from where the invocation is attempted.

- Subprograms declared in blocks that are descendants of a sibling block from where the invocation is attempted.

The following examples illustrate the various conditions previously described.

**Invoking Locally Declared Subprograms**

The following example contains a single hierarchy of blocks contained within standalone procedure level_0. Within the executable section of procedure level_1a, the means of invoking the local procedure level_2a are shown, both with and without qualifiers.

Also note that access to the descendant of local procedure level_2a, which is procedure level_3a, is not permitted, with or without qualifiers. These calls are commented out in the example.

```
CREATE OR REPLACE PROCEDURE level_0
IS
```

(continues on next page)
PROCEDURE level_1a
IS
  PROCEDURE level_2a
  IS
    PROCEDURE level_3a
    IS
      BEGIN
        DBMS_OUTPUT.PUT_LINE('........ BLOCK level_3a');
        DBMS_OUTPUT.PUT_LINE('........ END BLOCK level_3a');
      END level_3a;
      BEGIN
        DBMS_OUTPUT.PUT_LINE('...... BLOCK level_2a');
        DBMS_OUTPUT.PUT_LINE('...... END BLOCK level_2a');
      END level_2a;
      BEGIN
        DBMS_OUTPUT.PUT_LINE('.. BLOCK level_1a');
        level_2a; -- Local block called
        level_1a.level_2a; -- Qualified local block called
        level_0.level_1a.level_2a; -- Double qualified local block called
      END level_1a;
      BEGIN
        DBMS_OUTPUT.PUT_LINE('BLOCK level_0');
        level_1a;
        DBMS_OUTPUT.PUT_LINE('END BLOCK level_0');
      END level_0;

When the standalone procedure is invoked, the output is the following, which indicates that procedure level_2a is successfully invoked from the calls in the executable section of procedure level_1a.

BEGIN
  level_0;
END;

BLOCK level_0
.. BLOCK level_1a
.... BLOCK level_2a
.... END BLOCK level_2a
.... BLOCK level_2a
.... END BLOCK level_2a
.... BLOCK level_2a
.... END BLOCK level_2a
.. END BLOCK level_1a
END BLOCK level_0

If you were to attempt to run procedure level_0 with any of the calls to the descendent block uncom-
mented, then an error occurs.

**Invoking Subprograms Declared in Ancestor Blocks**

The following example shows how subprograms can be invoked that are declared in parent and other ancestor blocks relative to the block where the invocation is made.

In this example, the executable section of procedure `level_3a` invokes procedure `level_2a`, which is its parent block. (Note that `v_cnt` is used to avoid an infinite loop.)

```sql
CREATE OR REPLACE PROCEDURE level_0
IS
  v_cnt NUMBER(2) := 0;
PROCEDURE level_1a
IS
  PROCEDURE level_2a
  IS
    PROCEDURE level_3a
    IS
      BEGIN
        DBMS_OUTPUT.PUT_LINE('........ BLOCK level_3a');
        v_cnt := v_cnt + 1;
        IF v_cnt < 2 THEN
          level_2a; -- Parent block called
        END IF;
        DBMS_OUTPUT.PUT_LINE('........ END BLOCK level_3a');
      END level_3a;
      BEGIN
        DBMS_OUTPUT.PUT_LINE('...... BLOCK level_2a');
        level_3a; -- Local block called
        DBMS_OUTPUT.PUT_LINE('...... END BLOCK level_2a');
      END level_2a;
  BEGIN
    DBMS_OUTPUT.PUT_LINE('.. BLOCK level_1a');
    level_2a; -- Local block called
    DBMS_OUTPUT.PUT_LINE('.. END BLOCK level_1a');
  END level_1a;
BEGIN
  DBMS_OUTPUT.PUT_LINE('BLOCK level_0');
  level_1a;
  DBMS_OUTPUT.PUT_LINE('END BLOCK level_0');
END level_0;
```

The following is the resulting output:

```
BEGIN
  level_0;
END;

BLOCK level_0
.. BLOCK level_1a
........ BLOCK level_2a
......... BLOCK level_3a
....... BLOCK level_2a
(continues on next page)
```

2.6. Subprograms – Subprocedures and Subfunctions
In a similar example, the executable section of procedure `level_3a` invokes procedure `level_1a`, which is further up the ancestor hierarchy. (Note that `v_cnt` is used to avoid an infinite loop.)

```sql
CREATE OR REPLACE PROCEDURE level_0
IS
  v_cnt NUMBER(2) := 0;
  PROCEDURE level_1a
  IS
    PROCEDURE level_2a
    IS
      PROCEDURE level_3a
      IS
        BEGIN
          DBMS_OUTPUT.PUT_LINE('........ BLOCK level_3a');
          v_cnt := v_cnt + 1;
          IF v_cnt < 2 THEN
            level_1a; -- Ancestor block called
          END IF;
          DBMS_OUTPUT.PUT_LINE('........ END BLOCK level_3a');
        END level_3a;
      BEGIN
        DBMS_OUTPUT.PUT_LINE('...... BLOCK level_2a');
        level_3a; -- Local block called
        DBMS_OUTPUT.PUT_LINE('...... END BLOCK level_2a');
      END level_2a;
    BEGIN
      DBMS_OUTPUT.PUT_LINE('.. BLOCK level_1a');
      level_2a; -- Local block called
      DBMS_OUTPUT.PUT_LINE('.. END BLOCK level_1a');
    END level_1a;
  BEGIN
    DBMS_OUTPUT.PUT_LINE('BLOCK level_0');
    level_1a;
    DBMS_OUTPUT.PUT_LINE('END BLOCK level_0');
  END level_0;
END level_0;
```

The following is the resulting output:

```
BEGIN
  level_0;
END;
```

(continues on next page)
Invoking Subprograms Declared in Sibling Blocks

The following examples show how subprograms can be invoked that are declared in a sibling block relative to the local, parent, or other ancestor blocks from where the invocation of the subprogram is made.

In this example, the executable section of procedure `level_1b` invokes procedure `level_1a`, which is its sibling block. Both are local to standalone procedure `level_0`.

Note that invocation of `level_2a` or equivalently, `level_1a.level_2a` from within procedure `level_1b` is commented out as this call would result in an error. Invoking a descendent subprogram (level_2a) of sibling block (level_1a) is not permitted.
BEGIN
  DBMS_OUTPUT.PUT_LINE('BLOCK level_0');
  level_1b;
  DBMS_OUTPUT.PUT_LINE('END BLOCK level_0');
END level_0;

The following is the resulting output:

BEGIN
  level_0;
END;

BLOCK level_0
.. BLOCK level_1b
.. BLOCK level_1a
.. END BLOCK level_1a
.. END BLOCK level_1b
END BLOCK level_0

In the following example, procedure level_1a, which is the sibling of procedure level_1b, which is an ancestor of procedure level_3b is successfully invoked.

CREATE OR REPLACE PROCEDURE level_0
IS
  PROCEDURE level_1a
  IS
    BEGIN
      DBMS_OUTPUT.PUT_LINE('.. BLOCK level_1a');
      DBMS_OUTPUT.PUT_LINE('.. END BLOCK level_1a');
    END level_1a;
  PROCEDURE level_1b
  IS
    PROCEDURE level_2b
    IS
      PROCEDURE level_3b
      IS
        BEGIN
          DBMS_OUTPUT.PUT_LINE('....... BLOCK level_3b');
          level_1a; -- Ancestor's sibling block
called
          level_0.level_1a; -- Qualified ancestor's sibling block
          DBMS_OUTPUT.PUT_LINE('....... END BLOCK level_3b');
          END level_3b;
    BEGIN
      DBMS_OUTPUT.PUT_LINE('...... BLOCK level_2b);
      level_3b; -- Local block called
      DBMS_OUTPUT.PUT_LINE('...... END BLOCK level_2b');
    END level_2b;
    BEGIN
      DBMS_OUTPUT.PUT_LINE('.. BLOCK level_1b');
      (continues on next page)
level_2b; -- Local block called
DBMS_OUTPUT.PUT_LINE('.. END BLOCK level_1b');
END level_1b;
BEGIN
  DBMS_OUTPUT.PUT_LINE('BLOCK level_0');
  level_1b;
  DBMS_OUTPUT.PUT_LINE('END BLOCK level_0');
END level_0;

The following is the resulting output:

BEGIN
  level_0;
END;

BLOCK level_0
  .. BLOCK level_1b
  ...... BLOCK level_2b
  .......... BLOCK level_3b
  .. BLOCK level_1a
  .. END BLOCK level_1a
  .. BLOCK level_1a
  .. END BLOCK level_1a
  .......... END BLOCK level_3b
  ...... END BLOCK level_2b
  .. END BLOCK level_1b
END BLOCK level_0

2.6.5 Using Forward Declarations

As discussed so far, when a subprogram is to be invoked, it must have been declared somewhere in the hierarchy of blocks within the standalone program, but prior to where it is invoked. In other words, when scanning the SPL code from beginning to end, the subprogram declaration must be found before its invocation.

However, there is a method of constructing the SPL code so that the full declaration of the subprogram (that is, its optional declaration section, its mandatory executable section, and optional exception section) appears in the SPL code after the point in the code where it is invoked.

This is accomplished by inserting a forward declaration in the SPL code prior to its invocation. The forward declaration is the specification of a subprocedure or subfunction name, formal parameters, and return type if it is a subfunction.

The full subprogram specification consisting of the optional declaration section, the executable section, and the optional exception section must be specified in the same declaration section as the forward declaration, but may appear following other subprogram declarations that invoke this subprogram with the forward declaration.

Typical usage of a forward declaration is when two subprograms invoke each other as shown by the following:
DECLARE
    FUNCTION add_one (p_add IN NUMBER)
    RETURN NUMBER;
FUNCTION test_max (p_test IN NUMBER)
RETURN NUMBER
IS
BEGIN
    IF p_test < 5 THEN
        RETURN add_one(p_test);
    END IF;
    DBMS_OUTPUT.PUT('Final value is ');
    RETURN p_test;
END;
FUNCTION add_one (p_add IN NUMBER)
RETURN NUMBER
IS
BEGIN
    DBMS_OUTPUT.PUT_LINE('Increase by 1');
    RETURN test_max(p_add + 1);
END;
BEGIN
    DBMS_OUTPUT.PUT_LINE(test_max(3));
END;

Subfunction test_max invokes subfunction add_one, which also invokes subfunction test_max, so a forward declaration is required for one of the subprograms, which is implemented for add_one at the beginning of the anonymous block declaration section.

The resulting output from the anonymous block is as follows:

Increase by 1
Increase by 1
Final value is 5

2.6.6 Overloading Subprograms

Generally, subprograms of the same type (subprocedure or subfunction) with the same name, and same formal parameter specification can appear multiple times within the same standalone program as long as they are not sibling blocks (that is, the subprograms are not declared in the same local block).

Each subprogram can be individually invoked depending upon the use of qualifiers and the location where the subprogram invocation is made as discussed in the previous sections.

It is however possible to declare subprograms, even as siblings, that are of the same subprogram type and name as long as certain aspects of the formal parameters differ. These characteristics (subprogram type, name, and formal parameter specification) is generally known as a program’s signature.

The declaration of multiple subprograms where the signatures are identical except for certain aspects of the formal parameter specification is referred to as subprogram overloading.
Thus, the determination of which particular overloaded subprogram is to be invoked is determined by a match of the actual parameters specified by the subprogram invocation and the formal parameter lists of the overloaded subprograms.

Any of the following differences permit overloaded subprograms:

- The number of formal parameters are different.
- At least one pair of data types of the corresponding formal parameters (that is, compared according to the same order of appearance in the formal parameter list) are different, but are not aliases. Data type aliases are discussed later in this section.

Note that the following differences alone do not permit overloaded subprograms:

- Different formal parameter names
- Different parameter modes (IN, IN OUT, OUT) for the corresponding formal parameters
- For subfunctions, different data types in the RETURN clause

As previously indicated, one of the differences allowing overloaded subprograms are different data types. However, certain data types have alternative names referred to as aliases, which can be used for the table definition.

For example, there are fixed length character data types that can be specified as CHAR or CHARACTER. There are variable length character data types that can be specified as CHAR VARYING, CHARACTER VARYING, VARCHAR, or VARCHAR2. For integers, there are BINARY_INTEGER, PLS_INTEGER, and INTEGER data types. For numbers, there are NUMBER, NUMERIC, DEC, and DECIMAL data types.

For detailed information about the data types supported by Advanced Server, see the Database Compatibility for Oracle Developers Reference Guide, available from EDB at:

https://www.enterprisedb.com/edb-docs

Thus, when attempting to create overloaded subprograms, the formal parameter data types are not considered different if the specified data types are aliases of each other.

It can be determined if certain data types are aliases of other types by displaying the table definition containing the data types in question.

For example, the following table definition contains some data types and their aliases.

```sql
CREATE TABLE data_type_aliases (  
dt_BLOB BLOB,  
dt_LONG_RAW LONG RAW,  
dt_RAW RAW(4),  
dt_BYTEA BYTEA,  
dt_INTEGER INTEGER,  
dt_BINARY_INTEGER BINARY_INTEGER,  
dt_PLS_INTEGER PLS_INTEGER,  
dt_REAL REAL,  
dt_DOUBLE_PRECISION DOUBLE PRECISION,  
dt_FLOAT FLOAT,  
dt_NUMBER NUMBER,  
dt_DECIMAL DECIMAL,
)`
Using the PSQL `\d` command to display the table definition, the Type column displays the data type internally assigned to each column based upon its data type in the table definition:

<table>
<thead>
<tr>
<th>Column</th>
<th>Type</th>
<th>Modifiers</th>
</tr>
</thead>
<tbody>
<tr>
<td>dt_blob</td>
<td>bytea</td>
<td></td>
</tr>
<tr>
<td>dt_long_raw</td>
<td>bytea</td>
<td></td>
</tr>
<tr>
<td>dt_raw</td>
<td>bytea(4)</td>
<td></td>
</tr>
<tr>
<td>dt_bytea</td>
<td>bytea</td>
<td></td>
</tr>
<tr>
<td>dt_integer</td>
<td>integer</td>
<td></td>
</tr>
<tr>
<td>dt_binary_integer</td>
<td>integer</td>
<td></td>
</tr>
<tr>
<td>dt_pls_integer</td>
<td>integer</td>
<td></td>
</tr>
<tr>
<td>dt_real</td>
<td>real</td>
<td></td>
</tr>
<tr>
<td>dt_double_precision</td>
<td>double precision</td>
<td></td>
</tr>
<tr>
<td>dt_float</td>
<td>double precision</td>
<td></td>
</tr>
<tr>
<td>dt_number</td>
<td>numeric</td>
<td></td>
</tr>
<tr>
<td>dt_decimal</td>
<td>numeric</td>
<td></td>
</tr>
<tr>
<td>dt_numeric</td>
<td>numeric</td>
<td></td>
</tr>
<tr>
<td>dt_char</td>
<td>character(1)</td>
<td></td>
</tr>
<tr>
<td>dt_character</td>
<td>character(1)</td>
<td></td>
</tr>
<tr>
<td>dt_vchar2</td>
<td>character varying(4)</td>
<td></td>
</tr>
<tr>
<td>dt_char_varying</td>
<td>character varying(4)</td>
<td></td>
</tr>
<tr>
<td>dt_vchar</td>
<td>character varying(4)</td>
<td></td>
</tr>
</tbody>
</table>

In the example, the base set of data types are `bytea`, `integer`, `real`, `double precision`, `numeric`, `character`, and `character varying`.

When attempting to declare overloaded subprograms, a pair of formal parameter data types that are aliases would not be sufficient to allow subprogram overloading. Thus, parameters with data types `INTEGER` and `PLS_INTEGER` cannot overload a pair of subprograms, but data types `INTEGER` and `REAL`, or `INTEGER` and `FLOAT`, or `INTEGER` and `NUMBER` can overload the subprograms.

**Note:** The overloading rules based upon formal parameter data types are not compatible with Oracle databases. Generally, the Advanced Server rules are more flexible, and certain combinations are allowed in Advanced Server that would result in an error when attempting to create the procedure or function in Oracle databases.

For certain pairs of data types used for overloading, casting of the arguments specified by the subprogram invocation may be required to avoid an error encountered during runtime of the subprogram. Invocation of a subprogram must include the actual parameter list that can specifically identify the data types. Certain
pairs of overloaded data types may require the CAST function to explicitly identify data types. For example, pairs of overloaded data types that may require casting during the invocation are CHAR and VARCHAR2, or NUMBER and REAL.

The following example shows a group of overloaded subfunctions invoked from within an anonymous block. The executable section of the anonymous block contains the use of the CAST function to invoke overloaded functions with certain data types.

```sql
DECLARE
  FUNCTION add_it (
    p_add_1 IN BINARY_INTEGER,
    p_add_2 IN BINARY_INTEGER ) RETURN VARCHAR2
IS
  BEGIN
    RETURN 'add_it BINARY_INTEGER: ' || TO_CHAR(p_add_1 + p_add_2, 9999.9999);
  END add_it;

  FUNCTION add_it (
    p_add_1 IN NUMBER,
    p_add_2 IN NUMBER ) RETURN VARCHAR2
IS
  BEGIN
    RETURN 'add_it NUMBER: ' || TO_CHAR(p_add_1 + p_add_2, 999.9999);
  END add_it;

  FUNCTION add_it (
    p_add_1 IN REAL,
    p_add_2 IN REAL ) RETURN VARCHAR2
IS
  BEGIN
    RETURN 'add_it REAL: ' || TO_CHAR(p_add_1 + p_add_2, 9999.9999);
  END add_it;

  FUNCTION add_it (
    p_add_1 IN DOUBLE PRECISION,
    p_add_2 IN DOUBLE PRECISION ) RETURN VARCHAR2
IS
  BEGIN
    RETURN 'add_it DOUBLE PRECISION: ' || TO_CHAR(p_add_1 + p_add_2, 9999.9999);
  END add_it;
BEGIN
  DBMS_OUTPUT.PUT_LINE(add_it (25, 50));
  DBMS_OUTPUT.PUT_LINE(add_it (25.3333, 50.3333));
  DBMS_OUTPUT.PUT_LINE(add_it (TO_NUMBER(25.3333), TO_NUMBER(50.3333)));
  DBMS_OUTPUT.PUT_LINE(add_it (CAST('25.3333' AS REAL), CAST('50.3333' AS REAL)));
  DBMS_OUTPUT.PUT_LINE(add_it (CAST('25.3333' AS DOUBLE PRECISION),
                                 CAST('50.3333' AS DOUBLE PRECISION)));
END;
```
The following is the output displayed from the anonymous block:

<table>
<thead>
<tr>
<th>Variable</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>add_it BINARY_INTEGER</td>
<td>75.0000</td>
</tr>
<tr>
<td>add_it NUMBER</td>
<td>75.6666</td>
</tr>
<tr>
<td>add_it NUMBER</td>
<td>75.6666</td>
</tr>
<tr>
<td>add_it REAL</td>
<td>75.6666</td>
</tr>
<tr>
<td>add_it DOUBLE PRECISION</td>
<td>75.6666</td>
</tr>
</tbody>
</table>

2.6.7 Accessing Subprogram Variables

Variable declared in blocks such as subprograms or anonymous blocks can be accessed from the executable section or the exception section of other blocks depending upon their relative location.

Accessing a variable means being able to reference it within a SQL statement or an SPL statement as is done with any local variable.

Note: If the subprogram signature contains formal parameters, these may be accessed in the same manner as local variables of the subprogram. In this section, all discussion related to variables of a subprogram also applies to formal parameters of the subprogram.

Access of variables not only includes those defined as a data type, but also includes others such as record types, collection types, and cursors.

The variable may be accessed by at most one qualifier, which is the name of the subprogram or labeled anonymous block in which the variable has been locally declared.

The syntax to reference a variable is shown by the following:

```sql
[[qualifier.]]<variable>
```

If specified, qualifier is the subprogram or labeled anonymous block in which variable has been declared in its declaration section (that is, it is a local variable).

Note: In Advanced Server, there is only one circumstance where two qualifiers are permitted. This scenario is for accessing public variables of packages where the reference can be specified in the following format:

```sql
schema_name.package_name.public_variable_name
```

For more information about supported package syntax, see the Database Compatibility for Oracle Developers Built-In Package Guide.

The following summarizes how variables can be accessed:

- Variables can be accessed as long as the block in which the variable has been locally declared is within the ancestor hierarchical path starting from the block containing the reference to the variable. Such variables declared in ancestor blocks are referred to as global variables.

- If a reference to an unqualified variable is made, the first attempt is to locate a local variable of that name. If such a local variable does not exist, then the search for the variable is made in the parent of
the current block, and so forth, proceeding up the ancestor hierarchy. If such a variable is not found, then an error occurs upon invocation of the subprogram.

- If a reference to a qualified variable is made, the same search process is performed as described in the previous bullet point, but searching for the first match of the subprogram or labeled anonymous block that contains the local variable. The search proceeds up the ancestor hierarchy until a match is found. If such a match is not found, then an error occurs upon invocation of the subprogram.

The following location of variables cannot be accessed relative to the block from where the reference to the variable is made:

- Variables declared in a descendent block cannot be accessed,
- Variables declared in a sibling block, a sibling block of an ancestor block, or any descendants within the sibling block cannot be accessed.

Note: The Advanced Server process for accessing variables is not compatible with Oracle databases. For Oracle, any number of qualifiers can be specified and the search is based upon the first match of the first qualifier in a similar manner to the Oracle matching algorithm for invoking subprograms.

The following example displays how variables in various blocks are accessed, with and without qualifiers. The lines that are commented out illustrate attempts to access variables that would result in an error.

```sql
CREATE OR REPLACE PROCEDURE level_0
IS
    v_level_0 VARCHAR2(20) := 'Value from level_0';
PROCEDURE level_1a
IS
    v_level_1a VARCHAR2(20) := 'Value from level_1a';
PROCEDURE level_2a
IS
    v_level_2a VARCHAR2(20) := 'Value from level_2a';
BEGIN
    DBMS_OUTPUT.PUT_LINE('...... BLOCK level_2a');
    DBMS_OUTPUT.PUT_LINE('........ v_level_2a: ' || v_level_2a);
    DBMS_OUTPUT.PUT_LINE('........ v_level_1a: ' || v_level_1a);
    DBMS_OUTPUT.PUT_LINE('........ level_1a.v_level_1a: ' || level_1a.v_level_1a);
    DBMS_OUTPUT.PUT_LINE('........ v_level_0: ' || v_level_0);
    DBMS_OUTPUT.PUT_LINE('........ level_0.v_level_0: ' || level_0.v_level_0);
    DBMS_OUTPUT.PUT_LINE('...... END BLOCK level_2a');
END level_2a;
BEGIN
    DBMS_OUTPUT.PUT_LINE('.. BLOCK level_1a');
    level_2a;
    -- DBMS_OUTPUT.PUT_LINE('.... v_level_2a: ' || v_level_2a);
    -- Error - Descendent block ----^
    -- DBMS_OUTPUT.PUT_LINE('.... level_2a.v_level_2a: ' || level_2a.v_level_2a);
    -- Error - Descendent block ---------------^
(continues on next page)
```
The following is the output showing the content of each variable when the procedure is invoked:

```
BEGIN
  level_0;
END;

BLOCK level_0
  .. v_level_0: Value from level_0
  .. BLOCK level_1a
  .... BLOCK level_2a
  ........ v_level_2a: Value from level_2a
  ........ v_level_1a: Value from level_1a
  ........ level_1a.v_level_1a: Value from level_1a
  ........ v_level_0: Value from level_0
  ........ level_0.v_level_0: Value from level_0
  .... END BLOCK level_2a
  .. END BLOCK level_1a
  .. BLOCK level_1b
  .... v_level_1b: Value from level_1b
  .... v_level_0 : Value from level_0
  .. END BLOCK level_1b
END level_0
```

The following example shows similar access attempts when all variables in all blocks have the same name:

```
CREATE OR REPLACE PROCEDURE level_0
```
IS
v_common VARCHAR2(20) := 'Value from level_0';
PROCEDURE level_1a
IS
v_common VARCHAR2(20) := 'Value from level_1a';
PROCEDURE level_2a
IS
v_common VARCHAR2(20) := 'Value from level_2a';
BEGIN
DBMS_OUTPUT.PUT_LINE('...... BLOCK level_2a');
DBMS_OUTPUT.PUT_LINE('........ v_common: ' || v_common);
DBMS_OUTPUT.PUT_LINE('........ level_2a.v_common: ' || level_2a.v_common);
DBMS_OUTPUT.PUT_LINE('........ level_1a.v_common: ' || level_1a.v_common);
DBMS_OUTPUT.PUT_LINE('........ level_0.v_common: ' || level_0.v_common);
END level_2a;
BEGIN
DBMS_OUTPUT.PUT_LINE('.. BLOCK level_1a');
DBMS_OUTPUT.PUT_LINE('.... v_common: ' || v_common);
level_2a;
DBMS_OUTPUT.PUT_LINE('.. END BLOCK level_1a');
END level_1a;
PROCEDURE level_1b
IS
v_common VARCHAR2(20) := 'Value from level_1b';
BEGIN
DBMS_OUTPUT.PUT_LINE('.. BLOCK level_1b');
DBMS_OUTPUT.PUT_LINE('.... v_common: ' || v_common);
level_2a;
DBMS_OUTPUT.PUT_LINE('.. END BLOCK level_1b');
END level_1b;
BEGIN
DBMS_OUTPUT.PUT_LINE('BLOCK level_0');
DBMS_OUTPUT.PUT_LINE('.. v_common: ' || v_common);
level_1a;
level_1b;
DBMS_OUTPUT.PUT_LINE('END BLOCK level_0');
END level_0;

The following is the output showing the content of each variable when the procedure is invoked:

BEGIN
  level_0;
END;

BLOCK level_0
.. v_common: Value from level_0
.. BLOCK level_1a

(continues on next page)
As previously discussed, the labels on anonymous blocks can also be used to qualify access to variables. The following example shows variable access within a set of nested anonymous blocks:

```sql
DECLARE
  v_common VARCHAR2(20) := 'Value from level_0';
BEGIN
  DBMS_OUTPUT.PUT_LINE('BLOCK level_0');
  DBMS_OUTPUT.PUT_LINE('.. v_common: ' || v_common);
  <<level_1a>>
  DECLARE
    v_common VARCHAR2(20) := 'Value from level_1a';
  BEGIN
    DBMS_OUTPUT.PUT_LINE('.. BLOCK level_1a');
    DBMS_OUTPUT.PUT_LINE('.... v_common: ' || v_common);
    <<level_2a>>
    DECLARE
      v_common VARCHAR2(20) := 'Value from level_2a';
    BEGIN
      DBMS_OUTPUT.PUT_LINE('...... BLOCK level_2a');
      DBMS_OUTPUT.PUT_LINE('........ v_common: ' || v_common);
      DBMS_OUTPUT.PUT_LINE('........ level_1a.v_common: ' || level_1a.v_common);
      DBMS_OUTPUT.PUT_LINE('...... END BLOCK level_2a');
    END;
  END;
  DBMS_OUTPUT.PUT_LINE('.. END BLOCK level_1a');
<<level_1b>>
  DECLARE
    v_common VARCHAR2(20) := 'Value from level_1b';
  BEGIN
    DBMS_OUTPUT.PUT_LINE('.. BLOCK level_1b');
    DBMS_OUTPUT.PUT_LINE('.... v_common: ' || v_common);
    DBMS_OUTPUT.PUT_LINE('.... level_1b.v_common: ' || level_1b.v_common);
    DBMS_OUTPUT.PUT_LINE('.. END BLOCK level_1b');
  END;
END;
```
The following is the output showing the content of each variable when the anonymous block is invoked:

```
BLOCK level_0
  .. v_common: Value from level_0
  .. BLOCK level_1a
    .... v_common: Value from level_1a
    ...... BLOCK level_2a
    ........ v_common: Value from level_2a
    ........ level_1a.v_common: Value from level_1a
    ....... END BLOCK level_2a
  .. END BLOCK level_1a
  .. BLOCK level_1b
    .... v_common: Value from level_1b
    .... level_1b.v_common: Value from level_1b
  .. END BLOCK level_1b
END BLOCK level_0
```

The following example is an object type whose object type method, `display_emp`, contains record type `emp_typ` and subprocedure `emp_sal_query`. Record variable `r_emp` declared locally to `emp_sal_query` is able to access the record type `emp_typ` declared in the parent block `display_emp`.

```
CREATE OR REPLACE TYPE emp_pay_obj_typ AS OBJECT
  (  
    empno NUMBER(4),  
    MEMBER PROCEDURE display_emp(SELF IN OUT emp_pay_obj_typ)  
  );

CREATE OR REPLACE TYPE BODY emp_pay_obj_typ AS
  MEMBER PROCEDURE display_emp (SELF IN OUT emp_pay_obj_typ)  
  IS
    TYPE emp_typ IS RECORD (  
      ename emp.ename%TYPE,  
      job emp.job%TYPE,  
      hiredate emp.hiredate%TYPE,  
      sal emp.sal%TYPE,  
      deptno emp.deptno%TYPE  
    );
    PROCEDURE emp_sal_query (  
      p_empno IN emp.empno%TYPE  
    )  
    IS
      r_emp emp_typ;  
      v_avgsal emp.sal%TYPE;  
      BEGIN  
        SELECT ename, job, hiredate, sal, deptno  
        INTO r_emp.ename, r_emp.job, r_emp.hiredate, r_emp.sal,  
        r_emp.deptno  
        FROM emp WHERE empno = p_empno;
```

(continues on next page)
DBMS_OUTPUT.PUT_LINE('Employee # : ' || p_empno);
DBMS_OUTPUT.PUT_LINE('Name : ' || r_emp.ename);
DBMS_OUTPUT.PUT_LINE('Job : ' || r_emp.job);
DBMS_OUTPUT.PUT_LINE('Hire Date : ' || r_emp.hiredate);
DBMS_OUTPUT.PUT_LINE('Salary : ' || r_emp.sal);
DBMS_OUTPUT.PUT_LINE('Dept # : ' || r_emp.deptno);

SELECT AVG(sal) INTO v_avgsal
FROM emp WHERE deptno = r_emp.deptno;
IF r_emp.sal > v_avgsal THEN
   DBMS_OUTPUT.PUT_LINE('Employee''s salary is more than the '
      || 'department average of ' || v_avgsal);
ELSE
   DBMS_OUTPUT.PUT_LINE('Employee''s salary does not exceed the '
      || 'department average of ' || v_avgsal);
END IF;
END;

BEGIN
emp_sal_query(SELF.empno);
END;
END;

The following is the output displayed when an instance of the object type is created and procedure display_emp is invoked:

DECLARE
   v_emp EMP_PAY_OBJ_TYP;
BEGIN
   v_emp := emp_pay_obj_typ(7900);
   v_emp.display_emp;
END;
Employee # : 7900
Name : JAMES
Job : CLERK
Hire Date : 03-DEC-81 00:00:00
Salary : 950.00
Dept # : 30
Employee's salary does not exceed the department average of 1566.67

The following example is a package with three levels of subprocedures. A record type, collection type, and cursor type declared in the upper level procedure can be accessed by the descendent subprocedure.

CREATE OR REPLACE PACKAGE emp_dept_pkg
IS
   PROCEDURE display_emp ( p_deptno NUMBER );
END;
(continues on next page)
CREATE OR REPLACE PACKAGE BODY emp_dept_pkg IS

PROCEDURE display_emp ( 
    p_deptno    NUMBER
) IS

    TYPE emp_rec_typ IS RECORD ( 
        empno    emp.empno%TYPE, 
        ename    emp.ename%TYPE 
    );
    TYPE emp_arr_typ IS TABLE OF emp_rec_typ INDEX BY BINARY_INTEGER;
    TYPE emp_cur_type IS REF CURSOR RETURN emp_rec_typ;

    PROCEDURE emp_by_dept ( 
        p_deptno    emp.deptno%TYPE 
    ) IS

        emp_arr    emp_arr_typ;
        emp_refcur emp_cur_type;
        i          BINARY_INTEGER := 0;

    PROCEDURE display_emp_arr
    IS BEGIN
        DBMS_OUTPUT.PUT_LINE('EMPNO ENAME');
        DBMS_OUTPUT.PUT_LINE('----- -------');
        FOR j IN emp_arr.FIRST .. emp_arr.LAST LOOP
            DBMS_OUTPUT.PUT_LINE(emp_arr(j).empno || ' ' || emp_arr(j).ename);
        END LOOP;
    END display_emp_arr;

BEGIN
    OPEN emp_refcur FOR SELECT empno, ename FROM emp WHERE deptno = p_deptno;
    LOOP
        i := i + 1;
        FETCH emp_refcur INTO emp_arr(i).empno, emp_arr(i).ename;
        EXIT WHEN emp_refcur%NOTFOUND;
    END LOOP;
    CLOSE emp_refcur;
    display_emp_arr;
END emp_by_dept;

BEGIN
    emp_by_dept(p_deptno);
END;
END;
END;

The following is the output displayed when the top level package procedure is invoked:

BEGIN
    emp_dept_pkg.display_emp(20);
END;
EMPNO ENAME

2.7 Compilation Errors in Procedures and Functions

When the Advanced Server parsers compile a procedure or function, they confirm that both the CREATE statement and the program body (that portion of the program that follows the AS keyword) conforms to the grammar rules for SPL and SQL constructs. By default, the server will terminate the compilation process if a parser detects an error. Note that the parsers detect syntax errors in expressions, but not semantic errors (i.e. an expression referencing a non-existent column, table, or function, or a value of incorrect type).

spl.max_error_count instructs the server to stop parsing if it encounters the specified number of errors in SPL code, or when it encounters an error in SQL code. The default value of spl.max_error_count is 10; the maximum value is 1000. Setting spl.max_error_count to a value of 1 instructs the server to stop parsing when it encounters the first error in either SPL or SQL code.

You can use the SET command to specify a value for spl.max_error_count for your current session. The syntax is:

```
SET spl.max_error_count = <number_of_errors>
```

Where number_of_errors specifies the number of SPL errors that may occur before the server halts the compilation process. For example:

```
SET spl.max_error_count = 6
```

The example instructs the server to continue past the first five SPL errors it encounters. When the server encounters the sixth error it will stop validating, and print six detailed error messages, and one error summary.

To save time when developing new code, or when importing existing code from another source, you may want to set the spl.max_error_count configuration parameter to a relatively high number of errors.

Please note that if you instruct the server to continue parsing in spite of errors in the SPL code in a program body, and the parser encounters an error in a segment of SQL code, there may still be errors in any SPL or SQL code that follows the erroneous SQL code. For example, the following function results in two errors:

```
CREATE FUNCTION computeBonus(baseSalary number) RETURN number AS 
BEGIN 
    bonus := baseSalary * 1.10;
    total := bonus + 100;

    RETURN bonus;
END;
```

```
ERROR: "bonus" is not a known variable
LINE 4: bonus := baseSalary * 1.10;
   ^
ERROR: "total" is not a known variable
LINE 5: total := bonus + 100;
   ^
ERROR: compilation of SPL function/procedure "computebonus" failed due to 2 errors
```

The following example adds a SELECT statement to the previous example. The error in the SELECT statement masks the other errors that follow:
CREATE FUNCTION computeBonus(employeeName number) RETURN number AS
BEGIN
    SELECT salary INTO baseSalary FROM emp
    WHERE ename = employeeName;

    bonus := baseSalary * 1.10;
    total := bonus + 100;

    RETURN bonus;
END;

ERROR: "basesalary" is not a known variable
LINE 3: SELECT salary INTO baseSalary FROM emp WHERE ename = emp...
2.8 Program Security

Security over what user may execute an SPL program and what database objects an SPL program may access for any given user executing the program is controlled by the following:

- Privilege to execute a program.
- Privileges granted on the database objects (including other SPL programs) which a program attempts to access.
- Whether the program is defined with definer’s rights or invoker’s rights.

These aspects are discussed in the following sections.

2.8.1 EXECUTE Privilege

An SPL program (function, procedure, or package) can begin execution only if any of the following are true:

- The current user is a superuser, or
- The current user has been granted EXECUTE privilege on the SPL program, or
- The current user inherits EXECUTE privilege on the SPL program by virtue of being a member of a group which does have such privilege, or
- EXECUTE privilege has been granted to the PUBLIC group.

Whenever an SPL program is created in Advanced Server, EXECUTE privilege is automatically granted to the PUBLIC group by default, therefore, any user can immediately execute the program.

This default privilege can be removed by using the REVOKE EXECUTE command. The following is an example:

```
REVOKE EXECUTE ON PROCEDURE list_emp FROM PUBLIC;
```

Explicit EXECUTE privilege on the program can then be granted to individual users or groups.

```
GRANT EXECUTE ON PROCEDURE list_emp TO john;
```

Now, user, john, can execute the list_emp program; other users who do not meet any of the conditions listed at the beginning of this section cannot.

Once a program begins execution, the next aspect of security is what privilege checks occur if the program attempts to perform an action on any database object including:

- Reading or modifying table or view data.
- Creating, modifying, or deleting a database object such as a table, view, index, or sequence.
- Obtaining the current or next value from a sequence.
- Calling another program (function, procedure, or package).

Each such action can be protected by privileges on the database object either allowed or disallowed for the user.
Note that it is possible for a database to have more than one object of the same type with the same name, but each such object belonging to a different schema in the database. If this is the case, which object is being referenced by an SPL program? This is the topic of the next section.

### 2.8.2 Database Object Name Resolution

A database object inside an SPL program may either be referenced by its qualified name or by an unqualified name. A qualified name is in the form of `schema.name` where `schema` is the name of the schema under which the database object with identifier, `name`, exists. An unqualified name does not have the `schema` portion. When a reference is made to a qualified name, there is absolutely no ambiguity as to exactly which database object is intended – it either does or does not exist in the specified schema.

Locating an object with an unqualified name, however, requires the use of the current user’s search path. When a user becomes the current user of a session, a default search path is always associated with that user. The search path consists of a list of schemas which are searched in left-to-right order for locating an unqualified database object reference. The object is considered non-existent if it can’t be found in any of the schemas in the search path. The default search path can be displayed in PSQL using the `SHOW search_path` command.

```sql
edb=# SHOW search_path;
   search_path
            -----------------     
         "$user", public       
(1 row)
```

$\texttt{user}$ in the above search path is a generic placeholder that refers to the current user so if the current user of the above session is `enterprisedb`, an unqualified database object would be searched for in the following schemas in this order – first, `enterprisedb`, then `public`.

Once an unqualified name has been resolved in the search path, it can be determined if the current user has the appropriate privilege to perform the desired action on that specific object.

**Note:** The concept of the search path is not compatible with Oracle databases. For an unqualified reference, Oracle simply looks in the schema of the current user for the named database object. It also important to note that in Oracle, a user and his or her schema is the same entity while in Advanced Server, a user and a schema are two distinct objects.

### 2.8.3 Database Object Privileges

Once an SPL program begins execution, any attempt to access a database object from within the program results in a check to ensure the current user has the authorization to perform the intended action against the referenced object. Privileges on database objects are bestowed and removed using the `GRANT` and `REVOKE` commands, respectively. If the current user attempts unauthorized access on a database object, then the program will throw an exception. See *Exception Handling* for information about exception handling.
2.8.4 Definer’s vs. Invokers Rights

When an SPL program is about to begin execution, a determination is made as to what user is to be associated with this process. This user is referred to as the current user. The current user’s database object privileges are used to determine whether or not access to database objects referenced in the program will be permitted. The current prevailing search path in effect when the program is invoked will be used to resolve any unqualified object references.

The selection of the current user is influenced by whether the SPL program was created with definer’s right or invoker’s rights. The AUTHID clause determines that selection. Appearance of the clause AUTHID DEFINER gives the program definer’s rights. This is also the default if the AUTHID clause is omitted. Use of the clause AUTHID CURRENT_USER gives the program invoker’s rights. The difference between the two is summarized as follows:

- If a program has definer’s rights, then the owner of the program becomes the current user when program execution begins. The program owner’s database object privileges are used to determine if access to a referenced object is permitted. In a definer’s rights program, it is irrelevant as to which user actually invoked the program.

- If a program has invoker’s rights, then the current user at the time the program is called remains the current user while the program is executing (but not necessarily within called subprograms – see the following bullet points). When an invoker’s rights program is invoked, the current user is typically the user that started the session (i.e., made the database connection) although it is possible to change the current user after the session has started using the SET ROLE command. In an invoker’s rights program, it is irrelevant as to which user actually owns the program.

From the previous definitions, the following observations can be made:

- If a definer’s rights program calls a definer’s rights program, the current user changes from the owner of the calling program to the owner of the called program during execution of the called program.

- If a definer’s rights program calls an invoker’s rights program, the owner of the calling program remains the current user during execution of both the calling and called programs.

- If an invoker’s rights program calls an invoker’s rights program, the current user of the calling program remains the current user during execution of the called program.

- If an invokers’ rights program calls a definer’s rights program, the current user switches to the owner of the definer’s rights program during execution of the called program.

The same principles apply if the called program in turn calls another program in the cases cited above.

2.8.5 Security Example

In the following example, a new database will be created along with two users – hr_mgr who will own a copy of the entire sample application in schema, hr_mgr; and sales_mgr who will own a schema named, sales_mgr, that will have a copy of only the emp table containing only the employees who work in sales.

The procedure list_emp, function hire_clerk, and package emp_admin will be used in this example. All of the default privileges that are granted upon installation of the sample application will be removed and then be explicitly re-granted so as to present a more secure environment in this example.
Programs list_emp and hire_clerk will be changed from the default of definer’s rights to invoker’s rights. It will be then illustrated that when sales_mgr runs these programs, they act upon the emp table in sales_mgr’s schema since sales_mgr’s search path and privileges will be used for name resolution and authorization checking.

Programs get_dept_name and hire_emp in the emp_admin package will then be executed by sales_mgr. In this case, the dept table and emp table in hr_mgr’s schema will be accessed as hr_mgr is the owner of the emp_admin package which is using definer’s rights. Since the default search path is in effect with the $user placeholder, the schema matching the user (in this case, hr_mgr) is used to find the tables.

Step 1 – Create Database and Users

As user enterprisedb, create the hr database:

```
CREATE DATABASE hr;
```

Switch to the hr database and create the users:

```
\c hr enterprisedb
CREATE USER hr_mgr IDENTIFIED BY password;
CREATE USER sales_mgr IDENTIFIED BY password;
```

Step 2 – Create the Sample Application

Create the entire sample application, owned by hr_mgr, in hr_mgr’s schema.

```
\c - hr_mgr
\i /usr/edb/as11/share/edb-sample.sql
BEGIN
CREATE TABLE
CREATE TABLE
CREATE TABLE
CREATE TABLE
CREATE VIEW
CREATE SEQUENCE
.
.
.
CREATE PACKAGE
CREATE PACKAGE BODY
COMMIT
```

Step 3 – Create the emp Table in Schema sales_mgr

Create a subset of the emp table owned by sales_mgr in sales_mgr’s schema.

```
\c - hr_mgr
GRANT USAGE ON SCHEMA hr_mgr TO sales_mgr;
\c - sales_mgr
CREATE TABLE emp AS SELECT * FROM hr_mgr.emp WHERE job = 'SALESMAN';
```

In the above example, the GRANT USAGE ON SCHEMA command is given to allow sales_mgr access into hr_mgr’s schema to make a copy of hr_mgr’s emp table. This step is required in Advanced Server
and is not compatible with Oracle databases since Oracle does not have the concept of a schema that is distinct from its user.

**Step 4 – Remove Default Privileges**

Remove all privileges to later illustrate the minimum required privileges needed.

```
c - hr_mgr
REVOKE USAGE ON SCHEMA hr_mgr FROM sales_mgr;
REVOKE ALL ON dept FROM PUBLIC;
REVOKE ALL ON emp FROM PUBLIC;
REVOKE ALL ON next_empno FROM PUBLIC;
REVOKE EXECUTE ON FUNCTION new_empno() FROM PUBLIC;
REVOKE EXECUTE ON PROCEDURE list_emp FROM PUBLIC;
REVOKE EXECUTE ON FUNCTION hire_clerk(VARCHAR2,NUMBER) FROM PUBLIC;
REVOKE EXECUTE ON PACKAGE emp_admin FROM PUBLIC;
```

**Step 5 – Change list_emp to Invoker’s Rights**

While connected as user, hr_mgr, add the AUTHID CURRENT_USER clause to the list_emp program and resave it in Advanced Server. When performing this step, be sure you are logged on as hr_mgr, otherwise the modified program may wind up in the public schema instead of in hr_mgr’s schema.

```
CREATE OR REPLACE PROCEDURE list_emp
AUTHID CURRENT_USER
IS
  v_empno NUMBER(4);
  v_ename VARCHAR2(10);
  CURSOR emp_cur IS
    SELECT empno, ename FROM emp ORDER BY empno;
BEGIN
  OPEN emp_cur;
  DBMS_OUTPUT.PUT_LINE('EMPNO ENAME');
  DBMS_OUTPUT.PUT_LINE('----- -------');
  LOOP
    FETCH emp_cur INTO v_empno, v_ename;
    EXIT WHEN emp_cur%NOTFOUND;
    DBMS_OUTPUT.PUT_LINE(v_empno || ' ' || v_ename);
  END LOOP;
  CLOSE emp_cur;
END;
```

**Step 6 – Change hire_clerk to Invoker’s Rights and Qualify Call to new_empno**

While connected as user, hr_mgr, add the AUTHID CURRENT_USER clause to the hire_clerk program.

Also, after the BEGIN statement, fully qualify the reference, new_empno, to hr_mgr.new_empno in order to ensure the hire_clerk function call to the new_empno function resolves to the hr_mgr schema.

When resaving the program, be sure you are logged on as hr_mgr, otherwise the modified program may wind up in the public schema instead of in hr_mgr’s schema.
CREATE OR REPLACE FUNCTION hire_clerk (  
    p_ename VARCHAR2,  
    p_deptno NUMBER  
) RETURN NUMBER  
AUTHID CURRENT_USER  
IS  
    v_empno NUMBER(4);  
    v_ename VARCHAR2(10);  
    v_job VARCHAR2(9);  
    v_mgr NUMBER(4);  
    v_hiredate DATE;  
    v_sal NUMBER(7,2);  
    v_comm NUMBER(7,2);  
    v_deptno NUMBER(2);  
BEGIN  
    v_empno := hr_mgr.new_empno;  
    INSERT INTO emp VALUES (v_empno, p_ename, 'CLERK', 7782,  
        TRUNC(SYSDATE), 950.00, NULL, p_deptno);  
    SELECT empno, ename, job, mgr, hiredate, sal, comm, deptno INTO  
        v_empno, v_ename, v_job, v_mgr, v_hiredate, v_sal, v_comm, v_deptno  
    FROM emp WHERE empno = v_empno;  
    DBMS_OUTPUT.PUT_LINE('Department : ' || v_deptno);  
    DBMS_OUTPUT.PUT_LINE('Employee No: ' || v_empno);  
    DBMS_OUTPUT.PUT_LINE('Name : ' || v_ename);  
    DBMS_OUTPUT.PUT_LINE('Job : ' || v_job);  
    DBMS_OUTPUT.PUT_LINE('Manager : ' || v_mgr);  
    DBMS_OUTPUT.PUT_LINE('Hire Date : ' || v_hiredate);  
    DBMS_OUTPUT.PUT_LINE('Salary : ' || v_sal);  
    DBMS_OUTPUT.PUT_LINE('Commission : ' || v_comm);  
    RETURN v_empno;  
EXCEPTION  
    WHEN OTHERS THEN  
        DBMS_OUTPUT.PUT_LINE('The following is SQLERRM:');  
        DBMS_OUTPUT.PUT_LINE(SQLERRM);  
        DBMS_OUTPUT.PUT_LINE('The following is SQLCODE:');  
        DBMS_OUTPUT.PUT_LINE(SQLCODE);  
    RETURN -1;  
END;

Step 7 – Grant Required Privileges

While connected as user hr_mgr, grant the privileges needed so sales_mgr can execute the list_emp procedure, hire_clerk function, and emp_admin package. Note that the only data object sales_mgr has access to is the emp table in the sales_mgr schema. sales_mgr has no privileges on any table in the hr_mgr schema.

GRANT USAGE ON SCHEMA hr_mgr TO sales_mgr;
GRANT EXECUTE ON PROCEDURE list_emp TO sales_mgr;
GRANT EXECUTE ON FUNCTION hire_clerk(VARCHAR2,NUMBER) TO sales_mgr;
GRANT EXECUTE ON FUNCTION new_empno() TO sales_mgr;
GRANT EXECUTE ON PACKAGE emp_admin TO sales_mgr;

Step 8 – Run Programs list_emp and hire_clerk

2.8. Program Security 63
Connect as user, sales_mgr, and run the following anonymous block:

```sql
\c - sales_mgr
DECLARE
  v_empno NUMBER(4);
BEGIN
  hr_mgr.list_emp;
  DBMS_OUTPUT.PUT_LINE('*** Adding new employee ***');
  v_empno := hr_mgr.hire_clerk('JONES',40);
  DBMS_OUTPUT.PUT_LINE('*** After new employee added ***');
  hr_mgr.list_emp;
END;

EMPNO ENAME  
---- -------
 7499   ALLEN  
 7521   WARD   
 7654   MARTIN 
 7844   TURNER
*** Adding new employee ***
Department : 40
Employee No: 8000
Name : JONES
Job : CLERK
Manager : 7782
Hire Date : 08-NOV-07 00:00:00
Salary : 950.00
*** After new employee added ***
EMPNO ENAME  
---- -------
 7499   ALLEN  
 7521   WARD   
 7654   MARTIN 
 7844   TURNER 
 8000   JONES
```

The table and sequence accessed by the programs of the anonymous block are illustrated in the following diagram. The gray ovals represent the schemas of sales_mgr and hr_mgr. The current user during each program execution is shown within parenthesis in bold red font.
Fig. 1: Invokers Rights Programs

Selecting from sales_mgr’s emp table shows that the update was made in this table.

```
SELECT empno, ename, hiredate, sal, deptno,
hr_mgr.emp_admin.get_dept_name(deptno) FROM sales_mgr.emp;
```

<table>
<thead>
<tr>
<th>empno</th>
<th>ename</th>
<th>hiredate</th>
<th>sal</th>
<th>deptno</th>
<th>get_dept_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>7499</td>
<td>ALLEN</td>
<td>20-FEB-81 00:00:00</td>
<td>1600.00</td>
<td>30</td>
<td>SALES</td>
</tr>
<tr>
<td>7521</td>
<td>WARD</td>
<td>22-FEB-81 00:00:00</td>
<td>1250.00</td>
<td>30</td>
<td>SALES</td>
</tr>
<tr>
<td>7654</td>
<td>MARTIN</td>
<td>28-SEP-81 00:00:00</td>
<td>1250.00</td>
<td>30</td>
<td>SALES</td>
</tr>
<tr>
<td>7844</td>
<td>TURNER</td>
<td>08-SEP-81 00:00:00</td>
<td>1500.00</td>
<td>30</td>
<td>SALES</td>
</tr>
<tr>
<td>8000</td>
<td>JONES</td>
<td>08-NOV-07 00:00:00</td>
<td>950.00</td>
<td>40</td>
<td>OPERATIONS</td>
</tr>
</tbody>
</table>

(5 rows)

The following diagram shows that the SELECT command references the emp table in the sales_mgr schema, but the dept table referenced by the get_dept_name function in the emp_admin package is from the hr_mgr schema since the emp_admin package has definer’s rights and is owned by hr_mgr. The default search path setting with the $user placeholder resolves the access by user hr_mgr to the dept table in the hr_mgr schema.
Step 9 – Run Program hire_emp in the emp_admin Package

While connected as user, sales_mgr, run the hire_emp procedure in the emp_admin package.

```sql
EXEC hr_mgr.emp_admin.hire_emp(9001, 'ALICE', 'SALESMAN', 8000, TRUNC(SYSDATE), 1000, 7369, 40);
```

This diagram illustrates that the hire_emp procedure in the emp_admin definer’s rights package updates the emp table belonging to hr_mgr since the object privileges of hr_mgr are used, and the default search path setting with the $user placeholder resolves to the schema of hr_mgr.

Now connect as user, hr_mgr. The following SELECT command verifies that the new employee was added to hr_mgr’s emp table since the emp_admin package has definer’s rights and hr_mgr is emp_admin’s owner.
```sql
\c hr_mgr
SELECT empno, ename, hiredate, sal, deptno,
hr_mgr.emp_admin.get_dept_name(deptno) FROM hr_mgr.emp;
```

<table>
<thead>
<tr>
<th>empno</th>
<th>ename</th>
<th>hiredate</th>
<th>sal</th>
<th>deptno</th>
<th>get_dept_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>7369</td>
<td>SMITH</td>
<td>17-DEC-80</td>
<td>800.00</td>
<td>20</td>
<td>RESEARCH</td>
</tr>
<tr>
<td>7499</td>
<td>ALLEN</td>
<td>20-FEB-81</td>
<td>1600.00</td>
<td>30</td>
<td>SALES</td>
</tr>
<tr>
<td>7521</td>
<td>WARD</td>
<td>22-FEB-81</td>
<td>1250.00</td>
<td>30</td>
<td>SALES</td>
</tr>
<tr>
<td>7566</td>
<td>JONES</td>
<td>02-APR-81</td>
<td>2975.00</td>
<td>20</td>
<td>RESEARCH</td>
</tr>

</tr>
</tbody>
</table>

(15 rows)
SPL is a block-structured language. The first section that can appear in a block is the declaration. The declaration contains the definition of variables, cursors, and other types that can be used in SPL statements contained in the block.

### 3.1 Declaring a Variable

Generally, all variables used in a block must be declared in the declaration section of the block. A variable declaration consists of a name that is assigned to the variable and its data type. Optionally, the variable can be initialized to a default value in the variable declaration.

The general syntax of a variable declaration is:

```
<name> <type> [ { := | DEFAULT } { <expression> | NULL } ];
```

- name is an identifier assigned to the variable.
- type is the data type assigned to the variable.
- [ := expression ], if given, specifies the initial value assigned to the variable when the block is entered. If the clause is not given then the variable is initialized to the SQL NULL value.

The default value is evaluated every time the block is entered. So, for example, assigning SYSDATE to a variable of type DATE causes the variable to have the time of the current invocation, not the time when the procedure or function was precompiled.

The following procedure illustrates some variable declarations that utilize defaults consisting of string and numeric expressions.
CREATE OR REPLACE PROCEDURE dept_salary_rpt (p_deptno NUMBER) IS
todays_date DATE := SYSDATE;
rpt_title VARCHAR2(60) := 'Report For Department # ' || p_deptno || ' on ' || todays_date;
base_sal INTEGER := 35525;
base_comm_rate NUMBER := 1.33333;
base_annual NUMBER := ROUND(base_sal * base_comm_rate, 2);
BEGIN
    DBMS_OUTPUT.PUT_LINE(rpt_title);
    DBMS_OUTPUT.PUT_LINE('Base Annual Salary: ' || base_annual);
END;

The following output of the above procedure shows that default values in the variable declarations are indeed assigned to the variables.

EXEC dept_salary_rpt(20);
Report For Department # 20 on 10-JUL-07 16:44:45
Base Annual Salary: 47366.55

3.2 Using %TYPE in Variable Declarations

Often, variables will be declared in SPL programs that will be used to hold values from tables in the database. In order to ensure compatibility between the table columns and the SPL variables, the data types of the two should be the same.

However, as quite often happens, a change might be made to the table definition. If the data type of the column is changed, the corresponding change may be required to the variable in the SPL program.

Instead of coding the specific column data type into the variable declaration the column attribute, %TYPE, can be used instead. A qualified column name in dot notation or the name of a previously declared variable must be specified as a prefix to %TYPE. The data type of the column or variable prefixed to %TYPE is assigned to the variable being declared. If the data type of the given column or variable changes, the new data type will be associated with the variable without the need to modify the declaration code.

Note: The %TYPE attribute can be used with formal parameter declarations as well.

<name> { { <table> | <view> }<.column> | <variable> }%TYPE;

name is the identifier assigned to the variable or formal parameter that is being declared. column is the name of a column in table or view. variable is the name of a variable that was declared prior to the variable identified by name.

Note: The variable does not inherit any of the column’s other attributes such as might be specified on the
column with the NOT NULL clause or the DEFAULT clause.

In the following example a procedure queries the emp table using an employee number, displays the employee’s data, finds the average salary of all employees in the department to which the employee belongs, and then compares the chosen employee’s salary with the department average.

```sql
CREATE OR REPLACE PROCEDURE emp_sal_query (
    p_empno IN NUMBER
) IS
    v_ename VARCHAR2(10);
    v_job VARCHAR2(9);
    v_hiredate DATE;
    v_sal NUMBER(7,2);
    v_deptno NUMBER(2);
    v_avgsal NUMBER(7,2);
BEGIN
    SELECT ename, job, hiredate, sal, deptno
        INTO v_ename, v_job, v_hiredate, v_sal, v_deptno
        FROM emp WHERE empno = p_empno;
    DBMS_OUTPUT.PUT_LINE('Employee # : ' || p_empno);
    DBMS_OUTPUT.PUT_LINE('Name : ' || v_ename);
    DBMS_OUTPUT.PUT_LINE('Job : ' || v_job);
    DBMS_OUTPUT.PUT_LINE('Hire Date : ' || v_hiredate);
    DBMS_OUTPUT.PUT_LINE('Salary : ' || v_sal);
    DBMS_OUTPUT.PUT_LINE('Dept # : ' || v_deptno);
    SELECT AVG(sal) INTO v_avgsal
        FROM emp WHERE deptno = v_deptno;
    IF v_sal > v_avgsal THEN
        DBMS_OUTPUT.PUT_LINE('Employee''s salary is more than the ' || v_avgsal);
    ELSE
        DBMS_OUTPUT.PUT_LINE('Employee''s salary does not exceed the ' || v_avgsal);
    END IF;
END;
```

Instead of the above, the procedure could be written as follows without explicitly coding the emp table data types into the declaration section of the procedure.

```sql
CREATE OR REPLACE PROCEDURE emp_sal_query (p_empno IN emp.empno%TYPE)
IS
    v_ename emp.ename%TYPE;
    v_job emp.job%TYPE;
    v_hiredate emp.hiredate%TYPE;
    v_sal emp.sal%TYPE;
    v_deptno emp.deptno%TYPE;
    v_avgsal v_sal%TYPE;
BEGIN
    SELECT ename, job, hiredate, sal, deptno
        INTO v_ename, v_job, v_hiredate, v_sal, v_deptno
        FROM emp WHERE empno = p_empno;
    DBMS_OUTPUT.PUT_LINE('Employee # : ' || p_empno);
    DBMS_OUTPUT.PUT_LINE('Name : ' || v_ename);
    DBMS_OUTPUT.PUT_LINE('Job : ' || v_job);
    DBMS_OUTPUT.PUT_LINE('Hire Date : ' || v_hiredate);
    DBMS_OUTPUT.PUT_LINE('Salary : ' || v_sal);
    DBMS_OUTPUT.PUT_LINE('Dept # : ' || v_deptno);
    SELECT AVG(sal) INTO v_avgsal
        FROM emp WHERE deptno = v_deptno;
    IF v_sal > v_avgsal THEN
        DBMS_OUTPUT.PUT_LINE('Employee''s salary is more than the ' || v_avgsal);
    ELSE
        DBMS_OUTPUT.PUT_LINE('Employee''s salary does not exceed the ' || v_avgsal);
    END IF;
END;
```

(continues on next page)
SELECT ename, job, hiredate, sal, deptno
    INTO v_ename, v_job, v_hiredate, v_sal, v_deptno
FROM emp WHERE empno = p_empno;
DBMS_OUTPUT.PUT_LINE('Employee # : ' || p_empno);
DBMS_OUTPUT.PUT_LINE('Name : ' || v_ename);
DBMS_OUTPUT.PUT_LINE('Job : ' || v_job);
DBMS_OUTPUT.PUT_LINE('Hire Date : ' || v_hiredate);
DBMS_OUTPUT.PUT_LINE('Salary : ' || v_sal);
DBMS_OUTPUT.PUT_LINE('Dept # : ' || v_deptno);

SELECT AVG(sal) INTO v_avgsal
FROM emp WHERE deptno = v_deptno;
IF v_sal > v_avgsal THEN
    DBMS_OUTPUT.PUT_LINE('Employee''s salary is more than the ' || 'department average of ' || v_avgsal);
ELSE
    DBMS_OUTPUT.PUT_LINE('Employee''s salary does not exceed the ' || 'department average of ' || v_avgsal);
END IF;
END;

Note: p_empno shows an example of a formal parameter defined using %TYPE.

v_avgsal illustrates the usage of %TYPE referring to another variable instead of a table column.

The following is sample output from executing this procedure.

EXEC emp_sal_query(7698);

Employee # : 7698
Name        : BLAKE
Job         : MANAGER
Hire Date   : 01-MAY-81 00:00:00
Salary      : 2850.00
Dept #      : 30
Employee's salary is more than the department average of 1566.67

3.3 Using %ROWTYPE in Record Declarations

The %TYPE attribute provides an easy way to create a variable dependent upon a column’s data type. Using the %ROWTYPE attribute, you can define a record that contains fields that correspond to all columns of a given table. Each field takes on the data type of its corresponding column. The fields in the record do not inherit any of the columns’ other attributes such as might be specified with the NOT NULL clause or the DEFAULT clause.

A record is a named, ordered collection of fields. A field is similar to a variable; it has an identifier and data type, but has the additional property of belonging to a record, and must be referenced using dot notation with the record name as its qualifier.
You can use the `%ROWTYPE` attribute to declare a record. The `%ROWTYPE` attribute is prefixed by a table name. Each column in the named table defines an identically named field in the record with the same data type as the column.

```sql
<record table>%ROWTYPE;
```

record is an identifier assigned to the record. table is the name of a table (or view) whose columns are to define the fields in the record. The following example shows how the `emp_sal_query` procedure from the prior section can be modified to use `emp%ROWTYPE` to create a record named `r_emp` instead of declaring individual variables for the columns in `emp`.

```sql
CREATE OR REPLACE PROCEDURE emp_sal_query (
   p_empno IN emp.empno%TYPE
) IS
   r_emp emp%ROWTYPE;
   v_avgsal emp.sal%TYPE;
BEGIN
   SELECT ename, job, hiredate, sal, deptno
   INTO r_emp.ename, r_emp.job, r_emp.hiredate, r_emp.sal, r_emp.deptno
   FROM emp WHERE empno = p_empno;
   DBMS_OUTPUT.PUT_LINE('Employee # : ' || p_empno);
   DBMS_OUTPUT.PUT_LINE('Name : ' || r_emp.ename);
   DBMS_OUTPUT.PUT_LINE('Job : ' || r_emp.job);
   DBMS_OUTPUT.PUT_LINE('Hire Date : ' || r_emp.hiredate);
   DBMS_OUTPUT.PUT_LINE('Salary : ' || r_emp.sal);
   DBMS_OUTPUT.PUT_LINE('Dept # : ' || r_emp.deptno);
   SELECT AVG(sal) INTO v_avgsal
   FROM emp WHERE deptno = r_emp.deptno;
   IF r_emp.sal > v_avgsal THEN
      DBMS_OUTPUT.PUT_LINE('Employee''s salary is more than the ' || 'department average of ' || v_avgsal);
   ELSE
      DBMS_OUTPUT.PUT_LINE('Employee''s salary does not exceed the ' || 'department average of ' || v_avgsal);
   END IF;
END;
```

### 3.4 User-Defined Record Types and Record Variables

Records can be declared based upon a table definition using the `%ROWTYPE` attribute as shown in [Using %ROWTYPE in Record Declarations](#). This section describes how a new record structure can be defined that is not tied to any particular table definition.

The `TYPE IS RECORD` statement is used to create the definition of a record type. A *record type* is a definition of a record comprised of one or more identifiers and their corresponding data types. A record type cannot, by itself, be used to manipulate data.

The syntax for a `TYPE IS RECORD` statement is:
**EDB Postgres™ Advanced Server, Release 13**

Where fields is a comma-separated list of one or more field definitions of the following form:

```
<field_name data_type> [NOT NULL][:= | DEFAULT] <default_value>
```

Where:

- **rec_type**
  - rec_type is an identifier assigned to the record type.
- **field_name**
  - field_name is the identifier assigned to the field of the record type.
- **data_type**
  - data_type specifies the data type of field_name.

**DEFAULT default_value**

The DEFAULT clause assigns a default data value for the corresponding field. The data type of the default expression must match the data type of the column. If no default is specified, then the default is NULL.

A record variable or simply put, a record, is an instance of a record type. A record is declared from a record type. The properties of the record such as its field names and types are inherited from the record type.

The following is the syntax for a record declaration.

```
<record rectype>
```

record is an identifier assigned to the record variable. rectype is the identifier of a previously defined record type. Once declared, a record can then be used to hold data.

Dot notation is used to make reference to the fields in the record.

```
<record.field>
```

record is a previously declared record variable and field is the identifier of a field belonging to the record type from which record is defined.

The emp_sal_query is again modified – this time using a user-defined record type and record variable.

```
CREATE OR REPLACE PROCEDURE emp_sal_query ( 
  p_empno IN emp.empno%TYPE 
) 
IS 
  TYPE emp_typ IS RECORD ( 
    ename emp.ename%TYPE, 
    job emp.job%TYPE, 
    hiredate emp.hiredate%TYPE, 
    sal emp.sal%TYPE, 
    deptno emp.deptno%TYPE 
  )
```

(continues on next page)
r_emp      emp_typ;
v_avgsal   emp.sal%TYPE;
BEGIN
    SELECT ename, job, hiredate, sal, deptno
    INTO r_emp.ename, r_emp.job, r_emp.hiredate, r_emp.sal, r_emp.deptno
    FROM emp WHERE empno = p_empno;
    DBMS_OUTPUT.PUT_LINE('Employee # : ' || p_empno);
    DBMS_OUTPUT.PUT_LINE('Name : ' || r_emp.ename);
    DBMS_OUTPUT.PUT_LINE('Job : ' || r_emp.job);
    DBMS_OUTPUT.PUT_LINE('Hire Date : ' || r_emp.hiredate);
    DBMS_OUTPUT.PUT_LINE('Salary : ' || r_emp.sal);
    DBMS_OUTPUT.PUT_LINE('Dept # : ' || r_emp.deptno);

    SELECT AVG(sal) INTO v_avgsal
    FROM emp WHERE deptno = r_emp.deptno;
    IF r_emp.sal > v_avgsal THEN
        DBMS_OUTPUT.PUT_LINE('Employee''s salary is more than the ' || 'department average of ' || v_avgsal);
    ELSE
        DBMS_OUTPUT.PUT_LINE('Employee''s salary does not exceed the ' || 'department average of ' || v_avgsal);
    END IF;
END;

Note that instead of specifying data type names, the %TYPE attribute can be used for the field data types in the record type definition.

The following is the output from executing this stored procedure.

EXEC emp_sal_query(7698);

Employee # : 7698
Name       : BLAKE
Job        : MANAGER
Hire Date  : 01-MAY-81 00:00:00
Salary     : 2850.00
Dept #     : 30
Employee's salary is more than the department average of 1566.67
This section begins the discussion of the programming statements that can be used in an SPL program.

### 4.1 Assignment

The assignment statement sets a variable or a formal parameter of mode OUT or IN OUT specified on the left side of the assignment, :=, to the evaluated expression specified on the right side of the assignment.

\[
\text{<variable> := <expression>};
\]

**variable** is an identifier for a previously declared variable, OUT formal parameter, or IN OUT formal parameter.

**expression** is an expression that produces a single value. The value produced by the expression must have a compatible data type with that of variable.

The following example shows the typical use of assignment statements in the executable section of the procedure.

```sql
CREATE OR REPLACE PROCEDURE dept_salary_rpt (  
p_deptno NUMBER  
)  
IS  
  todays_date DATE;  
  rpt_title VARCHAR2(60);  
  base_sal INTEGER;  
  base_comm_rate NUMBER;  
  base_annual NUMBER;  
BEGIN  
  todays_date := SYSDATE;  
END;
```
rpt_title := 'Report For Department # ' || p_deptno || ' on ' || todays_date;
base_sal := 35525;
base_comm_rate := 1.33333;
base_annual := ROUND(base_sal * base_comm_rate, 2);

DBMS_OUTPUT.PUT_LINE(rpt_title);
DBMS_OUTPUT.PUT_LINE('Base Annual Salary: ' || base_annual);
END;

4.2 DELETE

The DELETE command (available in the SQL language) can also be used in SPL programs.

An expression in the SPL language can be used wherever an expression is allowed in the SQL DELETE command. Thus, SPL variables and parameters can be used to supply values to the delete operation.

CREATE OR REPLACE PROCEDURE emp_delete (p_empno IN emp.empno%TYPE)
IS
BEGIN
DELETE FROM emp WHERE empno = p_empno;

IF SQL%FOUND THEN
   DBMS_OUTPUT.PUT_LINE('Deleted Employee # : ' || p_empno);
ELSE
   DBMS_OUTPUT.PUT_LINE('Employee # ' || p_empno || ' not found');
END IF;
END;

The SQL%FOUND conditional expression returns TRUE if a row is deleted, FALSE otherwise. See Obtaining the Result Status for a discussion of SQL%FOUND and other similar expressions.

The following shows the deletion of an employee using this procedure.

EXEC emp_delete(9503);

Deleted Employee # : 9503

SELECT * FROM emp WHERE empno = 9503;

empno | ename | job | mgr | hiredate | sal | comm | deptno
-------+-------+-----+-----+----------+-----+-------+-------
(0 rows)

Note: The DELETE command can be included in a FORALL statement. A FORALL statement allows a single DELETE command to delete multiple rows from values supplied in one or more collections. See 4.2. DELETE

76
Using the FORALL Statement for more information on the FORALL statement.

4.3 INSERT

The INSERT command available in the SQL language can also be used in SPL programs.

An expression in the SPL language can be used wherever an expression is allowed in the SQL INSERT command. Thus, SPL variables and parameters can be used to supply values to the insert operation.

The following is an example of a procedure that performs an insert of a new employee using data passed from a calling program.

```sql
CREATE OR REPLACE PROCEDURE emp_insert (  
  p_empno IN emp.empno%TYPE,  
  p_ename IN emp.ename%TYPE,  
  p_job IN emp.job%TYPE,  
  p_mgr IN emp.mgr%TYPE,  
  p_hiredate IN emp.hiredate%TYPE,  
  p_sal IN emp.sal%TYPE,  
  p_comm IN emp.comm%TYPE,  
  p_deptno IN emp.deptno%TYPE
) IS
BEGIN
  INSERT INTO emp VALUES (  
    p_empno,  
    p_ename,  
    p_job,  
    p_mgr,  
    p_hiredate,  
    p_sal,  
    p_comm,  
    p_deptno);

  DBMS_OUTPUT.PUT_LINE('Added employee...');
  DBMS_OUTPUT.PUT_LINE('Employee # : ' || p_empno);
  DBMS_OUTPUT.PUT_LINE('Name : ' || p_ename);
  DBMS_OUTPUT.PUT_LINE('Job : ' || p_job);
  DBMS_OUTPUT.PUT_LINE('Manager : ' || p_mgr);
  DBMS_OUTPUT.PUT_LINE('Hire Date : ' || p_hiredate);
  DBMS_OUTPUT.PUT_LINE('Salary : ' || p_sal);
  DBMS_OUTPUT.PUT_LINE('Commission : ' || p_comm);
  DBMS_OUTPUT.PUT_LINE('Dept # : ' || p_deptno);

EXCEPTION
  WHEN OTHERS THEN
    DBMS_OUTPUT.PUT_LINE('OTHERS exception on INSERT of employee # ' || p_empno);
    DBMS_OUTPUT.PUT_LINE('SQLCODE : ' || SQLCODE);
    DBMS_OUTPUT.PUT_LINE('SQLERRM : ' || SQLERRM);
END;
```

4.3. INSERT 77
If an exception occurs all database changes made in the procedure are automatically rolled back. In this example the EXCEPTION section with the WHEN OTHERS clause catches all exceptions. Two variables are displayed. SQLCODE is a number that identifies the specific exception that occurred. SQLERRM is a text message explaining the error. See Exception Handling for more information on exception handling.

The following shows the output when this procedure is executed.

```
EXEC emp_insert(9503,'PETERSON','ANALYST',7902,'31-MAR-05',5000,NULL,40);
```

Added employee...
Employee #: 9503
Name: PETERSON
Job: ANALYST
Manager: 7902
Hire Date: 31-MAR-05 00:00:00
Salary: 5000
Dept #: 40

----------------------
SELECT * FROM emp WHERE empno = 9503;

```
<table>
<thead>
<tr>
<th>empno</th>
<th>ename</th>
<th>job</th>
<th>mgr</th>
<th>hiredate</th>
<th>sal</th>
<th>comm</th>
<th>deptno</th>
</tr>
</thead>
<tbody>
<tr>
<td>9503</td>
<td>PETERSON</td>
<td>ANALYST</td>
<td>7902</td>
<td>31-MAR-05 00:00:00</td>
<td>5000.00</td>
<td></td>
<td>40</td>
</tr>
</tbody>
</table>
```

(1 row)

Note: The INSERT command can be included in a FORALL statement. A FORALL statement allows a single INSERT command to insert multiple rows from values supplied in one or more collections. See Using the FORALL Statement for more information on the FORALL statement.

### 4.4 NULL

The simplest statement is the NULL statement. This statement is an executable statement that does nothing.

```
NULL;
```

The following is the simplest, possible valid SPL program.

```
BEGIN
    NULL;
END;
```

The NULL statement can act as a placeholder where an executable statement is required such as in a branch of an IF-THEN-ELSE statement.

For example:
CREATE OR REPLACE PROCEDURE divide_it ( 
    p_numerator IN NUMBER, 
    p_denominator IN NUMBER, 
    p_result OUT NUMBER 
) IS 
BEGIN 
    IF p_denominator = 0 THEN 
        NULL; 
    ELSE 
        p_result := p_numerator / p_denominator; 
    END IF; 
END;

4.5 Using the RETURNING INTO Clause

The INSERT, UPDATE, and DELETE commands may be appended by the optional RETURNING INTO clause. This clause allows the SPL program to capture the newly added, modified, or deleted values from the results of an INSERT, UPDATE, or DELETE command, respectively.

The following is the syntax.

{ <insert> | <update> | <delete> } 
RETURNING { * | <expr_1> [ , <expr_2> ] ...} 
INTO { <record> | <field_1> [ , <field_2> ] ...} ;

insert is a valid INSERT command. update is a valid UPDATE command. delete is a valid DELETE command. If * is specified, then the values from the row affected by the INSERT, UPDATE, or DELETE command are made available for assignment to the record or fields to the right of the INTO keyword. (Note that the use of * is an Advanced Server extension and is not compatible with Oracle databases.) expr_1, expr_2... are expressions evaluated upon the row affected by the INSERT, UPDATE, or DELETE command. The evaluated results are assigned to the record or fields to the right of the INTO keyword. record is the identifier of a record that must contain fields that match in number and order, and are data type compatible with the values in the RETURNING clause. field_1, field_2,... are variables that must match in number and order, and are data type compatible with the set of values in the RETURNING clause.

If the INSERT, UPDATE, or DELETE command returns a result set with more than one row, then an exception is thrown with SQLCODE 01422, query returned more than one row. If no rows are in the result set, then the variables following the INTO keyword are set to null.

Note: There is a variation of RETURNING INTO using the BULK COLLECT clause that allows a result set of more than one row that is returned into a collection. See Using the BULK COLLECT Clause for more information on the BULK COLLECT clause.

The following example is a modification of the emp_comp_update procedure introduced in UPDATE, with the addition of the RETURNING INTO clause.
CREATE OR REPLACE PROCEDURE emp_comp_update (  
    p_empno IN emp.empno%TYPE,  
    p_sal IN emp.sal%TYPE,  
    p_comm IN emp.comm%TYPE  
) 
IS  
    v_empno emp.empno%TYPE;  
    v_ename emp.ename%TYPE;  
    v_job emp.job%TYPE;  
    v_sal emp.sal%TYPE;  
    v_comm emp.comm%TYPE;  
    v_deptno emp.deptno%TYPE;  
BEGIN  
    UPDATE emp SET sal = p_sal, comm = p_comm WHERE empno = p_empno  
    RETURNING  
        empno,  
        ename,  
        job,  
        sal,  
        comm,  
        deptno  
    INTO  
        v_empno,  
        v_ename,  
        v_job,  
        v_sal,  
        v_comm,  
        v_deptno;  
    IF SQL%FOUND THEN  
        DBMS_OUTPUT.PUT_LINE('Updated Employee # ' || v_empno);  
        DBMS_OUTPUT.PUT_LINE('Name ' || v_ename);  
        DBMS_OUTPUT.PUT_LINE('Job ' || v_job);  
        DBMS_OUTPUT.PUT_LINE('Department ' || v_deptno);  
        DBMS_OUTPUT.PUT_LINE('New Salary ' || v_sal);  
        DBMS_OUTPUT.PUT_LINE('New Commission ' || v_comm);  
    ELSE  
        DBMS_OUTPUT.PUT_LINE('Employee # ' || p_empno || ' not found');  
    END IF;  
END;  
END;

The following is the output from this procedure (assuming employee 9503 created by the emp_insert procedure still exists within the table).

EXEC emp_comp_update(9503, 6540, 1200);

Updated Employee # : 9503
Name : PETERSON
Job : ANALYST
Department : 40
New Salary : 6540.00
New Commission : 1200.00

4.5. Using the RETURNING INTO Clause 80
The following example is a modification of the emp_delete procedure, with the addition of the RETURNING INTO clause using record types.

```sql
CREATE OR REPLACE PROCEDURE emp_delete (p_empno IN emp.empno%TYPE)
IS
    r_emp emp%ROWTYPE;
BEGIN
    DELETE FROM emp WHERE empno = p_empno
    RETURNING * INTO r_emp;
    IF SQL%FOUND THEN
        DBMS_OUTPUT.PUT_LINE('Deleted Employee # : ' || r_emp.empno);
        DBMS_OUTPUT.PUT_LINE('Name : ' || r_emp.ename);
        DBMS_OUTPUT.PUT_LINE('Job : ' || r_emp.job);
        DBMS_OUTPUT.PUT_LINE('Manager : ' || r_emp.mgr);
        DBMS_OUTPUT.PUT_LINE('Hire Date : ' || r_emp.hiredate);
        DBMS_OUTPUT.PUT_LINE('Salary : ' || r_emp.sal);
        DBMS_OUTPUT.PUT_LINE('Commission : ' || r_emp.comm);
        DBMS_OUTPUT.PUT_LINE('Department : ' || r_emp.deptno);
    ELSE
        DBMS_OUTPUT.PUT_LINE('Employee # ' || p_empno || ' not found');
    END IF;
END;
```

The following is the output from this procedure.

```
EXEC emp_delete(9503);

Deleted Employee # : 9503
Name : PETERSON
Job : ANALYST
Manager : 7902
Hire Date : 31-MAR-05 00:00:00
Salary : 6540.00
Commission : 1200.00
Department : 40
```

### 4.6 SELECT INTO

The SELECT INTO statement is an SPL variation of the SQL SELECT command, the differences being:

- That SELECT INTO is designed to assign the results to variables or records where they can then be used in SPL program statements.
- The accessible result set of SELECT INTO is at most one row.
Other than the above, all of the clauses of the \texttt{SELECT} command such as \texttt{WHERE}, \texttt{ORDER BY}, \texttt{GROUP BY}, \texttt{HAVING}, etc. are valid for \texttt{SELECT INTO}. The following are the two variations of \texttt{SELECT INTO}.

\begin{center}
\begin{tabular}{|l|}
\hline
\texttt{SELECT <select_expressions> INTO <target> FROM ...;}
\hline
\end{tabular}
\end{center}

\texttt{target} is a comma-separated list of simple variables. \texttt{select_expressions} and the remainder of the statement are the same as for the \texttt{SELECT} command. The selected values must exactly match in data type, number, and order the structure of the target or a runtime error occurs.

\begin{center}
\begin{tabular}{|l|}
\hline
\texttt{SELECT * INTO <record> FROM <table> ...;}
\hline
\end{tabular}
\end{center}

\texttt{record} is a record variable that has previously been declared.

If the query returns zero rows, null values are assigned to the target(s). If the query returns multiple rows, the first row is assigned to the target(s) and the rest are discarded. (Note that “the first row” is not well-defined unless you’ve used \texttt{ORDER BY}.)

\textbf{Note:} In either cases, where no row is returned or more than one row is returned, SPL throws an exception.

\textbf{Note:} There is a variation of \texttt{SELECT INTO} using the \texttt{BULK COLLECT} clause that allows a result set of more than one row that is returned into a collection. See \texttt{SELECT BULK COLLECT} for more information on using the \texttt{BULK COLLECT} clause with the \texttt{SELECT INTO} statement.

You can use the \texttt{WHEN NO_DATA_FOUND} clause in an \texttt{EXCEPTION} block to determine whether the assignment was successful (that is, at least one row was returned by the query).

This version of the \texttt{emp_sal_query} procedure uses the variation of \texttt{SELECT INTO} that returns the result set into a record. Also note the addition of the \texttt{EXCEPTION} block containing the \texttt{WHEN NO_DATA_FOUND} conditional expression.

\begin{center}
\begin{tabular}{|l|}
\hline
\texttt{CREATE OR REPLACE PROCEDURE emp_sal_query (}
\hspace{1cm} \texttt{p_empno IN emp.empno\%TYPE}
\texttt{)}
\hspace{1cm} \texttt{IS}
\texttt{r_emp emp\%ROWTYPE;}
\texttt{v_avgsal emp.sal\%TYPE;}
\texttt{BEGIN}
\texttt{SELECT * INTO r_emp}
\hspace{1.5cm} \texttt{FROM emp WHERE empno = p_empno;}
\hspace{1.5cm} \texttt{DBMS_OUTPUT.PUT_LINE('Employee # : ' || p_empno);}  
\hspace{1.5cm} \texttt{DBMS_OUTPUT.PUT_LINE('Name : ' || r_emp.ename);}  
\hspace{1.5cm} \texttt{DBMS_OUTPUT.PUT_LINE('Job : ' || r_emp.job);}  
\hspace{1.5cm} \texttt{DBMS_OUTPUT.PUT_LINE('Hire Date : ' || r_emp.hiredate);}  
\hspace{1.5cm} \texttt{DBMS_OUTPUT.PUT_LINE('Salary : ' || r_emp.sal);}  
\hspace{1.5cm} \texttt{DBMS_OUTPUT.PUT_LINE('Dept # : ' || r_emp.deptno);}  
\hspace{1.5cm} \texttt{SELECT AVG(sal) INTO v_avgsal}
\hspace{1.5cm} \texttt{FROM emp WHERE deptno = r_emp.deptno;}
\end{tabular}
\end{center}

(continues on next page)
IF r_emp.sal > v_avgsal THEN
    DBMS_OUTPUT.PUT_LINE('Employee''s salary is more than the ' || 'department average of ' || v_avgsal);
ELSE
    DBMS_OUTPUT.PUT_LINE('Employee''s salary does not exceed the ' || 'department average of ' || v_avgsal);
END IF;

EXCEPTION
    WHEN NO_DATA_FOUND THEN
        DBMS_OUTPUT.PUT_LINE('Employee # ' || p_empno || ' not found');
END;

If the query is executed with a non-existent employee number the results appear as follows.

EXEC emp_sal_query(0);
Employee # 0 not found

Another conditional clause of use in the EXCEPTION section with SELECT INTO is the TOO_MANY_ROWS exception. If more than one row is selected by the SELECT INTO statement an exception is thrown by SPL.

When the following block is executed, the TOO_MANY_ROWS exception is thrown since there are many employees in the specified department.

DECLARE
    v_ename emp.ename%TYPE;
BEGIN
    SELECT ename INTO v_ename FROM emp WHERE deptno = 20 ORDER BY ename;
EXCEPTION
    WHEN TOO_MANY_ROWS THEN
        DBMS_OUTPUT.PUT_LINE('More than one employee found');
        DBMS_OUTPUT.PUT_LINE('First employee returned is ' || v_ename);
END;

More than one employee found
First employee returned is ADAMS

Note: See Exception Handling for more information on exception handling.
4.7 UPDATE

The UPDATE command available in the SQL language can also be used in SPL programs.

An expression in the SPL language can be used wherever an expression is allowed in the SQL UPDATE command. Thus, SPL variables and parameters can be used to supply values to the update operation.

```sql
CREATE OR REPLACE PROCEDURE emp_comp_update (  
p_empno IN emp.empno%TYPE,  
p_sal IN emp.sal%TYPE,  
p_comm IN emp.comm%TYPE  
)  
IS  
BEGIN  
  UPDATE emp SET sal = p_sal, comm = p_comm WHERE empno = p_empno;
  
  IF SQL%FOUND THEN
    DBMS_OUTPUT.PUT_LINE('Updated Employee # : ' || p_empno);
    DBMS_OUTPUT.PUT_LINE('New Salary : ' || p_sal);
    DBMS_OUTPUT.PUT_LINE('New Commission : ' || p_comm);
  ELSE
    DBMS_OUTPUT.PUT_LINE('Employee # ' || p_empno || ' not found');
  END IF;
END;
```

The SQL%FOUND conditional expression returns TRUE if a row is updated, FALSE otherwise. See Obtaining the Result Status for a discussion of SQL%FOUND and other similar expressions.

The following shows the update on the employee using this procedure.

```sql
EXEC emp_comp_update(9503, 6540, 1200);

Updated Employee # : 9503
New Salary : 6540
New Commission : 1200

SELECT * FROM emp WHERE empno = 9503;

empno | ename | job | mgr | hiredate | sal | comm | deptno
------|-------|-----|-----|----------+-----+-------+-------
9503 | PETERSON | ANALYST | 7902 | 31-MAR-05 00:00:00 | 6540.00 | 1200.00 | 40

(1 row)
```

Note: The UPDATE command can be included in a FORALL statement. A FORALL statement allows a single UPDATE command to update multiple rows from values supplied in one or more collections. See Using the FORALL Statement for more information on the FORALL statement.
4.8 Obtaining the Result Status

There are several attributes that can be used to determine the effect of a command. *SQL%FOUND* is a Boolean that returns **TRUE** if at least one row was affected by an **INSERT**, **UPDATE** or **DELETE** command or a **SELECT INTO** command retrieved one or more rows.

The following anonymous block inserts a row and then displays the fact that the row has been inserted.

```
BEGIN
    INSERT INTO emp (empno, ename, job, sal, deptno) VALUES (9001, 'JONES', 'CLERK', 850.00, 40);
    IF SQL%FOUND THEN
        DBMS_OUTPUT.PUT_LINE('Row has been inserted');
    END IF;
END;
Row has been inserted
```

*SQL%ROWCOUNT* provides the number of rows affected by an **INSERT**, **UPDATE**, **DELETE**, or **SELECT INTO** command. The *SQL%ROWCOUNT* value is returned as a **BIGINT** data type. The following example updates the row that was just inserted and displays *SQL%ROWCOUNT*.

```
BEGIN
    UPDATE emp SET hiredate = '03-JUN-07' WHERE empno = 9001;
    DBMS_OUTPUT.PUT_LINE('# rows updated: ' || SQL%ROWCOUNT);
END;
# rows updated: 1
```

*SQL%NOTFOUND* is the opposite of *SQL%FOUND*. *SQL%NOTFOUND* returns **TRUE** if no rows were affected by an **INSERT**, **UPDATE** or **DELETE** command or a **SELECT INTO** command retrieved no rows.

```
BEGIN
    UPDATE emp SET hiredate = '03-JUN-07' WHERE empno = 9000;
    IF SQL%NOTFOUND THEN
        DBMS_OUTPUT.PUT_LINE('No rows were updated');
    END IF;
END;
No rows were updated
```
The programming statements in SPL that make it a full procedural complement to SQL are described in this section.

5.1 IF Statement

IF statements let you execute commands based on certain conditions. SPL has four forms of IF:

- IF ... THEN
- IF ... THEN ... ELSE
- IF ... THEN ... ELSE IF
- IF ... THEN ... ELSIF ... THEN ... ELSE

5.1.1 IF-THEN

```plaintext
IF boolean-expression THEN
    <statements>
END IF;
```

IF-THEN statements are the simplest form of IF. The statements between THEN and END IF will be executed if the condition is TRUE. Otherwise, they are skipped.

In the following example an IF-THEN statement is used to test and display employees who have a commission.
DECLARE
    v_empno emp.empno%TYPE;
    v_comm emp.comm%TYPE;
CURSOR emp_cursor IS SELECT empno, comm FROM emp;
BEGIN
    OPEN emp_cursor;
    DBMS_OUTPUT.PUT_LINE('EMPNO COMM');
    DBMS_OUTPUT.PUT_LINE('----- -------');
    LOOP
        FETCH emp_cursor INTO v_empno, v_comm;
        EXIT WHEN emp_cursor%NOTFOUND;
        -- Test whether or not the employee gets a commission
        IF v_comm IS NOT NULL AND v_comm > 0 THEN
            DBMS_OUTPUT.PUT_LINE(v_empno || ' ' ||
                    TO_CHAR(v_comm,'$99999.99'));
        END IF;
    END LOOP;
    CLOSE emp_cursor;
END;

The following is the output from this program.

EMPNO COMM
----- -------
7499 $300.00
7521 $500.00
7654 $1400.00

5.1.2 IF-THEN-ELSE

IF boolean-expression THEN
    <statements>
ELSE
    <statements>
END IF;

IF-THEN-ELSE statements add to IF-THEN by letting you specify an alternative set of statements that should be executed if the condition evaluates to false.

The previous example is modified so an IF-THEN-ELSE statement is used to display the text Non-commission if the employee does not get a commission.

DECLARE
    v_empno emp.empno%TYPE;
    v_comm emp.comm%TYPE;
CURSOR emp_cursor IS SELECT empno, comm FROM emp;
BEGIN
    OPEN emp_cursor;
(continues on next page)
```sql
DBMS_OUTPUT.PUT_LINE('EMPNO COMM');
DBMS_OUTPUT.PUT_LINE('----- -------');
LOOP
    FETCH emp_cursor INTO v_empno, v_comm;
    EXIT WHEN emp_cursor%NOTFOUND;
    -- Test whether or not the employee gets a commission
    --
    IF v_comm IS NOT NULL AND v_comm > 0 THEN
        DBMS_OUTPUT.PUT_LINE(v_empno || ' ' ||
                              TO_CHAR(v_comm,'$99999.99'));
    ELSE
        DBMS_OUTPUT.PUT_LINE(v_empno || ' ' || 'Non-commission');
    END IF;
END LOOP;
CLOSE emp_cursor;
END;
```

The following is the output from this program.

<table>
<thead>
<tr>
<th>EMPNO</th>
<th>COMM</th>
</tr>
</thead>
<tbody>
<tr>
<td>7369</td>
<td>Non-commission</td>
</tr>
<tr>
<td>7499</td>

<tr>
<td>7934</td>
<td>Non-commission</td>
</tr>
</tbody>
</table>

5.1.3 IF-THEN-ELSE IF

IF statements can be nested so that alternative IF statements can be invoked once it is determined whether or not the conditional of an outer IF statement is TRUE or FALSE.

In the following example the outer IF-THEN-ELSE statement tests whether or not an employee has a commission. The inner IF-THEN-ELSE statements then test whether the employee’s total compensation exceeds or is less than the company average.

```sql
DECLARE
    v_empno     emp.empno%TYPE;
    v_sal       emp.sal%TYPE;
    v_comm      emp.comm%TYPE;
```

---

5.1. IF Statement 88
v_avg NUMBER(7,2);
CURSOR emp_cursor IS SELECT empno, sal, comm FROM emp;
BEGIN
  -- Calculate the average yearly compensation in the company
  SELECT AVG((sal + NVL(comm,0)) * 24) INTO v_avg FROM emp;
  DBMS_OUTPUT.PUT_LINE('Average Yearly Compensation: ' ||
    TO_CHAR(v_avg,'$999,999.99'));
  OPEN emp_cursor;
  DBMS_OUTPUT.PUT_LINE('EMPNO YEARLY COMP');
  DBMS_OUTPUT.PUT_LINE('----- -----------');
  LOOP
    FETCH emp_cursor INTO v_empno, v_sal, v_comm;
    EXIT WHEN emp_cursor%NOTFOUND;
    -- Test whether or not the employee gets a commission
    IF v_comm IS NOT NULL AND v_comm > 0 THEN
      -- Test if the employee's compensation with commission exceeds the average
      IF (v_sal + v_comm) * 24 > v_avg THEN
        DBMS_OUTPUT.PUT_LINE(v_empno || ' ' ||
          TO_CHAR((v_sal + v_comm) * 24,'$999,999.99') ||
          ' Exceeds Average');
      ELSE
        DBMS_OUTPUT.PUT_LINE(v_empno || ' ' ||
          TO_CHAR((v_sal + v_comm) * 24,'$999,999.99') ||
          ' Below Average');
      END IF;
    ELSE
      -- Test if the employee's compensation without commission exceeds the average
      IF v_sal * 24 > v_avg THEN
        DBMS_OUTPUT.PUT_LINE(v_empno || ' ' ||
          TO_CHAR(v_sal * 24,'$999,999.99') || ' Exceeds Average');
      ELSE
        DBMS_OUTPUT.PUT_LINE(v_empno || ' ' ||
          TO_CHAR(v_sal * 24,'$999,999.99') || ' Below Average');
      END IF;
    END IF;
  END LOOP;
  CLOSE emp_cursor;
END;

Note: The logic in this program can be simplified considerably by calculating the employee’s yearly compensation using the NVL function within the SELECT command of the cursor declaration, however, the

5.1. IF Statement
The purpose of this example is to demonstrate how IF statements can be used.

The following is the output from this program.

```plaintext
Average Yearly Compensation: $ 53,528.57
EMPNO    YEARLY COMP
-----    -----------
 7369 $ 19,200.00 Below Average
 7499 $ 45,600.00 Below Average
 7521 $ 42,000.00 Below Average
 7566 $ 71,400.00 Exceeds Average
 7654 $ 63,600.00 Exceeds Average
 7698 $ 68,400.00 Exceeds Average
 7782 $ 58,800.00 Exceeds Average
 7788 $ 72,000.00 Exceeds Average
 7839 $120,000.00 Exceeds Average
 7844 $ 36,000.00 Below Average
 7876 $ 26,400.00 Below Average
 7900 $ 22,800.00 Below Average
 7902 $ 72,000.00 Exceeds Average
 7934 $ 31,200.00 Below Average
```

When you use this form, you are actually nesting an IF statement inside the ELSE part of an outer IF statement. Thus you need one END IF statement for each nested IF and one for the parent IF-ELSE.

### 5.1.4 IF-THEN-ELSIF-ELSE

```plaintext
IF boolean-expression THEN
    <statements>
[ ELSIF boolean-expression THEN
    <statements>
[ ELSIF boolean-expression THEN
    <statements> ] ...]
[ ELSE
    <statements> ]
END IF;
```

IF-THEN-ELSIF-ELSE provides a method of checking many alternatives in one statement. Formally it is equivalent to nested IF-THEN-ELSE-IF-THEN commands, but only one END IF is needed.

The following example uses an IF-THEN-ELSIF-ELSE statement to count the number of employees by compensation ranges of $25,000.

```plaintext
DECLARE
  v_empno emp.empno%TYPE;
  v_comp NUMBER(8,2);
  v_1t_25K SMALLINT := 0;
  v_25K_50K SMALLINT := 0;
  v_50K_75K SMALLINT := 0;
  v_75K_100K SMALLINT := 0;
```

(continues on next page)
v_ge_100K  SMALLINT := 0;
CURSOR emp_cursor IS SELECT empno, (sal + NVL(comm,0)) * 24 FROM emp;
BEGIN
  OPEN emp_cursor;
  LOOP
    FETCH emp_cursor INTO v_empno, v_comp;
    EXIT WHEN emp_cursor%NOTFOUND;
    IF v_comp < 25000 THEN
      v_lt_25K := v_lt_25K + 1;
    ELSIF v_comp < 50000 THEN
      v_25K_50K := v_25K_50K + 1;
    ELSIF v_comp < 75000 THEN
      v_50K_75K := v_50K_75K + 1;
    ELSIF v_comp < 100000 THEN
      v_75K_100K := v_75K_100K + 1;
    ELSE
      v_ge_100K := v_ge_100K + 1;
    END IF;
  END LOOP;
  CLOSE emp_cursor;
  DBMS_OUTPUT.PUT_LINE('Number of employees by yearly compensation');
  DBMS_OUTPUT.PUT_LINE('Less than 25,000 : ' || v_lt_25K);
  DBMS_OUTPUT.PUT_LINE('25,000 - 49,999 : ' || v_25K_50K);
  DBMS_OUTPUT.PUT_LINE('50,000 - 74,999 : ' || v_50K_75K);
  DBMS_OUTPUT.PUT_LINE('75,000 - 99,999 : ' || v_75K_100K);
  DBMS_OUTPUT.PUT_LINE('100,000 and over : ' || v_ge_100K);
END;

The following is the output from this program.

Number of employees by yearly compensation
Less than 25,000 : 2
25,000 - 49,999 : 5
50,000 - 74,999 : 6
75,000 - 99,999 : 0
100,000 and over : 1

5.2 RETURN Statement

The RETURN statement terminates the current function, procedure or anonymous block and returns control to the caller.

There are two forms of the RETURN Statement. The first form of the RETURN statement is used to terminate a procedure or function that returns void. The syntax of the first form is:

RETURN;

The second form of RETURN returns a value to the caller. The syntax of the second form of the RETURN statement is:
RETURN <expression>;

expression must evaluate to the same data type as the return type of the function.

The following example uses the RETURN statement returns a value to the caller:

```sql
CREATE OR REPLACE FUNCTION emp_comp (p_sal NUMBER, p_comm NUMBER) RETURN NUMBER IS BEGIN RETURN (p_sal + NVL(p_comm, 0)) * 24; END emp_comp;
```

### 5.3 GOTO Statement

The GOTO statement causes the point of execution to jump to the statement with the specified label. The syntax of a GOTO statement is:

```
GOTO <label>
```

<label> is a name assigned to an executable statement. <label> must be unique within the scope of the function, procedure or anonymous block.

To label a statement, use the syntax:

```
<<label>> <statement>
```

<statement> is the point of execution that the program jumps to.

You can label assignment statements, any SQL statement (like INSERT, UPDATE, CREATE, etc.) and selected procedural language statements. The procedural language statements that can be labeled are:

- IF
- EXIT
- RETURN
- RAISE
- EXECUTE
- PERFORM
- GET DIAGNOSTICS
- OPEN
- FETCH
- MOVE
Please note that `exit` is considered a keyword, and cannot be used as the name of a label.

**GOTO** statements cannot transfer control into a conditional block or sub-block, but can transfer control from a conditional block or sub-block.

The following example verifies that an employee record contains a name, job description, and employee hire date; if any piece of information is missing, a **GOTO** statement transfers the point of execution to a statement that prints a message that the employee is not valid.

```sql
CREATE OR REPLACE PROCEDURE verify_emp (p_empno NUMBER) IS
  v_ename emp.ename%TYPE;
  v_job emp.job%TYPE;
  v_hiredate emp.hiredate%TYPE;
BEGIN
  SELECT ename, job, hiredate
    INTO v_ename, v_job, v_hiredate
    FROM emp
    WHERE empno = p_empno;
  IF v_ename IS NULL THEN
    GOTO invalid_emp;
  END IF;
  IF v_job IS NULL THEN
    GOTO invalid_emp;
  END IF;
  IF v_hiredate IS NULL THEN
    GOTO invalid_emp;
  END IF;
  DBMS_OUTPUT.PUT_LINE('Employee ' || p_empno || ' validated without errors.');
  RETURN;
<<invalid_emp>> DBMS_OUTPUT.PUT_LINE('Employee ' || p_empno || ' is not a valid employee.');
END;
```

**GOTO** statements have the following restrictions:

- A **GOTO** statement cannot jump to a declaration.
5.3. GOTO Statement

- A GOTO statement cannot transfer control to another function or procedure.
- A label should not be placed at the end of a block, function or procedure.
5.4 CASE Expression

The CASE expression returns a value that is substituted where the CASE expression is located within an expression.

There are two formats of the CASE expression - one that is called a searched CASE and the other that uses a selector.

5.4.1 Selector CASE Expression

The selector CASE expression attempts to match an expression called the selector to the expression specified in one or more WHEN clauses. result is an expression that is type-compatible in the context where the CASE expression is used. If a match is found, the value given in the corresponding THEN clause is returned by the CASE expression. If there are no matches, the value following ELSE is returned. If ELSE is omitted, the CASE expression returns null.

```
CASE <selector-expression>
  WHEN <match-expression> THEN <result>
  [ WHEN <match-expression> THEN <result>
  [ WHEN <match-expression> THEN <result> ] ...]
  [ ELSE <result> ]
END;
```

match-expression is evaluated in the order in which it appears within the CASE expression. result is an expression that is type-compatible in the context where the CASE expression is used. When the first match-expression is encountered that equals selector-expression, result in the corresponding THEN clause is returned as the value of the CASE expression. If none of match-expression equals selector-expression then result following ELSE is returned. If no ELSE is specified, the CASE expression returns null.

The following example uses a selector CASE expression to assign the department name to a variable based upon the department number.

```
DECLARE
  v_empno   emp.empno%TYPE;
  v_ename   emp.ename%TYPE;
  v_deptno  emp.deptno%TYPE;
  v_dname   dept.dname%TYPE;
CURSOR emp_cursor IS SELECT empno, ename, deptno FROM emp;
BEGIN
  OPEN emp_cursor;
  DBMS_OUTPUT.PUT_LINE('EMPNO ENAME DEPTNO DNAME');
  DBMS_OUTPUT.PUT_LINE('----- ------- ------ ----------');
  LOOP
    FETCH emp_cursor INTO v_empno, v_ename, v_deptno;
    EXIT WHEN emp_cursor%NOTFOUND;
    END;
END;
```

(continues on next page)
v_dname :=
CASE v_deptno
    WHEN 10 THEN 'Accounting'
    WHEN 20 THEN 'Research'
    WHEN 30 THEN 'Sales'
    WHEN 40 THEN 'Operations'
    ELSE 'unknown'
END;

DBMS_OUTPUT.PUT_LINE(v_empno || ' ' || RPAD(v_ename, 10) ||
                      ' ' || v_deptno || ' ' || v_dname);
END LOOP;
CLOSE emp_cursor;
END;

The following is the output from this program.

<table>
<thead>
<tr>
<th>EMPNO</th>
<th>ENAME</th>
<th>DEPTNO</th>
<th>DNAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>7369</td>
<td>SMITH</td>
<td>20</td>

</tr>
</tbody>
</table>

5.4.2 Searched CASE Expression

A searched CASE expression uses one or more Boolean expressions to determine the resulting value to return.

```
CASE WHEN <boolean-expression> THEN
    <result>
[ WHEN <boolean-expression> THEN
    <result>
    [ WHEN <boolean-expression> THEN
    <result> ] ...]
[ ELSE
    <result> ]
END;
```

boolean-expression is evaluated in the order in which it appears within the CASE expression. result is an expression that is type-compatible in the context where the CASE expression is used. When
the first boolean-expression is encountered that evaluates to TRUE, result in the corresponding THEN clause is returned as the value of the CASE expression. If none of boolean-expression evaluates to true then result following ELSE is returned. If no ELSE is specified, the CASE expression returns null.

The following example uses a searched CASE expression to assign the department name to a variable based upon the department number.

```
DECLARE
  v_empno emp.empno%TYPE;
  v_ename emp.ename%TYPE;
  v_deptno emp.deptno%TYPE;
  v_dname dept.dname%TYPE;
  CURSOR emp_cursor IS SELECT empno, ename, deptno FROM emp;
BEGIN
  OPEN emp_cursor;
  DBMS_OUTPUT.PUT_LINE('EMPNO ENAME DEPTNO DNAME');
  DBMS_OUTPUT.PUT_LINE('----- ------- ------ ----------');
  LOOP
    FETCH emp_cursor INTO v_empno, v_ename, v_deptno;
    EXIT WHEN emp_cursor%NOTFOUND;
    v_dname :=
      CASE
        WHEN v_deptno = 10 THEN 'Accounting'
        WHEN v_deptno = 20 THEN 'Research'
        WHEN v_deptno = 30 THEN 'Sales'
        WHEN v_deptno = 40 THEN 'Operations'
        ELSE 'unknown'
      END;
    DBMS_OUTPUT.PUT_LINE(v_empno || ' ' || RPAD(v_ename, 10) ||
      ' ' || v_deptno || ' ' || v_dname);
  END LOOP;
  CLOSE emp_cursor;
END;
```

The following is the output from this program.

<table>
<thead>
<tr>
<th>EMPNO</th>
<th>ENAME</th>
<th>DEPTNO</th>
<th>DNAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>7369</td>
<td>SMITH</td>
<td>20</td>

5.4. CASE Expression
5.5 CASE Statement

The CASE statement executes a set of one or more statements when a specified search condition is TRUE. The CASE statement is a stand-alone statement in itself while the previously discussed CASE expression must appear as part of an expression.

There are two formats of the CASE statement - one that is called a searched CASE and the other that uses a selector.

5.5.1 Selector CASE Statement

The selector CASE statement attempts to match an expression called the selector to the expression specified in one or more WHEN clauses. When a match is found one or more corresponding statements are executed.

```
CASE <selector-expression>
  WHEN <match-expression> THEN
    <statements>
  [ WHEN <match-expression> THEN
    <statements>
  [ WHEN <match-expression> THEN
    <statements> ] ...]
  [ ELSE
    <statements> ]
END CASE;
```

selector-expression returns a value type-compatible with each match-expression. match-expression is evaluated in the order in which it appears within the CASE statement. statements are one or more SPL statements, each terminated by a semi-colon. When the value of selector-expression equals the first match-expression, the statement(s) in the corresponding THEN clause are executed and control continues following the END CASE keywords. If there are no matches, the statement(s) following ELSE are executed. If there are no matches and there is no ELSE clause, an exception is thrown.

The following example uses a selector CASE statement to assign a department name and location to a variable based upon the department number.

```
DECLARE
  v_empno        emp.empno%TYPE;
  v_ename        emp.ename%TYPE;
  v_deptno       emp.deptno%TYPE;
  v_dname        dept.dname%TYPE;
  v_loc          dept.loc%TYPE;
  CURSOR emp_cursor IS SELECT empno, ename, deptno FROM emp;
BEGIN
  OPEN emp_cursor;
  DBMS_OUTPUT.PUT_LINE('EMPNO ENAME DEPTNO DNAME ' || ' LOC');
  DBMS_OUTPUT.PUT_LINE('----- ------- ------ -------- ----------');
  LOOP
    [ ... ]
  END LOOP;
END;
```

(continues on next page)
FETCH emp_cursor INTO v_empno, v_ename, v_deptno;
EXIT WHEN emp_cursor%NOTFOUND;
CASE v_deptno
  WHEN 10 THEN v_dname := 'Accounting';
       v_loc := 'New York';
  WHEN 20 THEN v_dname := 'Research';
       v_loc := 'Dallas';
  WHEN 30 THEN v_dname := 'Sales';
       v_loc := 'Chicago';
  WHEN 40 THEN v_dname := 'Operations';
       v_loc := 'Boston';
  ELSE v_dname := 'unknown';
       v_loc := '';
END CASE;
DBMS_OUTPUT.PUT_LINE(v_empno || ' ' || RPAD(v_ename, 10) ||
                     ' ' || v_deptno || ' ' || RPAD(v_dname, 14) || ' ' ||
                     v_loc);
END LOOP;
CLOSE emp_cursor;
END;

The following is the output from this program.

<table>
<thead>
<tr>
<th>EMPNO</th>
<th>ENAME</th>
<th>DEPTNO</th>
<th>DNAME</th>
<th>LOC</th>

</tbody>
</table>

5.5.2 Searched CASE Statement

A searched CASE statement uses one or more Boolean expressions to determine the resulting set of statements to execute.

```
CASE WHEN <boolean-expression> THEN
  <statements>
  [ WHEN <boolean-expression> THEN
    <statements>
  [ WHEN <boolean-expression> THEN
```

(continues on next page)
boolean-expression is evaluated in the order in which it appears within the CASE statement. When the first boolean-expression is encountered that evaluates to TRUE, the statement(s) in the corresponding THEN clause are executed and control continues following the END CASE keywords. If none of boolean-expression evaluates to TRUE, the statement(s) following ELSE are executed. If none of boolean-expression evaluates to TRUE and there is no ELSE clause, an exception is thrown.

The following example uses a searched CASE statement to assign a department name and location to a variable based upon the department number.

```sql
DECLARE
  v_empno emp.empno%TYPE;
  v_ename emp.ename%TYPE;
  v_deptno emp.deptno%TYPE;
  v_dname dept.dname%TYPE;
  v_loc dept.loc%TYPE;
CURSOR emp_cursor IS SELECT empno, ename, deptno FROM emp;
BEGIN
  OPEN emp_cursor;
  DBMS_OUTPUT.PUT_LINE('EMPNO ENAME DEPTNO DNAME ' || ' LOC');
  DBMS_OUTPUT.PUT_LINE('----- ------- ------ ----------' || ' ---------');
  LOOP
    FETCH emp_cursor INTO v_empno, v_ename, v_deptno;
    EXIT WHEN emp_cursor%NOTFOUND;
    CASE
    WHEN v_deptno = 10 THEN v_dname := 'Accounting';
      v_loc := 'New York';
    WHEN v_deptno = 20 THEN v_dname := 'Research';
      v_loc := 'Dallas';
    WHEN v_deptno = 30 THEN v_dname := 'Sales';
      v_loc := 'Chicago';
    WHEN v_deptno = 40 THEN v_dname := 'Operations';
      v_loc := 'Boston';
    ELSE v_dname := 'unknown';
      v_loc := '';
    END CASE;
    DBMS_OUTPUT.PUT_LINE(v_empno || ' ' || RPAD(v_ename, 10) ||
                         ' ' || v_deptno || ' ' || RPAD(v_dname, 14) || ' ' ||
                         v_loc);
  END LOOP;
  CLOSE emp_cursor;
END;
```

The following is the output from this program.
<table>
<thead>
<tr>
<th>EMPNO</th>

5.6 Loops

With the **LOOP**, **EXIT**, **CONTINUE**, **WHILE**, and **FOR** statements, you can arrange for your SPL program to repeat a series of commands.

### 5.6.1 LOOP

```
LOOP
  <statements>
END LOOP;
```

**LOOP** defines an unconditional loop that is repeated indefinitely until terminated by an **EXIT** or **RETURN** statement.

### 5.6.2 EXIT

```
EXIT [ WHEN <expression> ];
```

The innermost loop is terminated and the statement following **END LOOP** is executed next.

If **WHEN** is present, loop exit occurs only if the specified condition is **TRUE**, otherwise control passes to the statement after **EXIT**.

**EXIT** can be used to cause early exit from all types of loops; it is not limited to use with unconditional loops.

The following is a simple example of a loop that iterates ten times and then uses the **EXIT** statement to terminate.

```
DECLARE
  v_counter NUMBER(2);
BEGIN
  v_counter := 1;
  LOOP
    EXIT WHEN v_counter > 10;
    DBMS_OUTPUT.PUT_LINE('Iteration # ' || v_counter);
    v_counter := v_counter + 1;
  END LOOP;
END;
```

The following is the output from this program.

Iteration # 1
Iteration # 2
Iteration # 3
Iteration # 4
Iteration # 5
Iteration # 6
Iteration # 7

(continues on next page)
5.6.3 CONTINUE

The CONTINUE statement provides a way to proceed with the next iteration of a loop while skipping intervening statements.

When the CONTINUE statement is encountered, the next iteration of the innermost loop is begun, skipping all statements following the CONTINUE statement until the end of the loop. That is, control is passed back to the loop control expression, if any, and the body of the loop is re-evaluated.

If the WHEN clause is used, then the next iteration of the loop is begun only if the specified expression in the WHEN clause evaluates to TRUE. Otherwise, control is passed to the next statement following the CONTINUE statement.

The CONTINUE statement may not be used outside of a loop.

The following is a variation of the previous example that uses the CONTINUE statement to skip the display of the odd numbers.

```sql
DECLARE
  v_counter NUMBER(2);
BEGIN
  v_counter := 0;
  LOOP
    v_counter := v_counter + 1;
    EXIT WHEN v_counter > 10;
    CONTINUE WHEN MOD(v_counter,2) = 1;
    DBMS_OUTPUT.PUT_LINE('Iteration # ' || v_counter);
  END LOOP;
END;
```

The following is the output from above program.

```
Iteration # 2
Iteration # 4
Iteration # 6
Iteration # 8
Iteration # 10
```
5.6.4 WHILE

```
WHILE <expression> LOOP
    <statements>
END LOOP;
```

The WHILE statement repeats a sequence of statements so long as the condition expression evaluates to TRUE. The condition is checked just before each entry to the loop body.

The following example contains the same logic as in the previous example except the WHILE statement is used to take the place of the EXIT statement to determine when to exit the loop.

**Note:** The conditional expression used to determine when to exit the loop must be altered. The EXIT statement terminates the loop when its conditional expression is true. The WHILE statement terminates (or never begins the loop) when its conditional expression is false.

```
DECLARE
    v_counter NUMBER(2);
BEGIN
    v_counter := 1;
    WHILE v_counter <= 10 LOOP
        DBMS_OUTPUT.PUT_LINE('Iteration # ' || v_counter);
        v_counter := v_counter + 1;
    END LOOP;
END;
```

The same result is generated by this example as in the prior example.

```
Iteration # 1
Iteration # 2
Iteration # 3
Iteration # 4
Iteration # 5
Iteration # 6
Iteration # 7
Iteration # 8
Iteration # 9
Iteration # 10
```

5.6.5 FOR (integer variant)

```
FOR <name> IN [REVERSE] <expression .. expression> LOOP
    <statements>
END LOOP;
```

This form of FOR creates a loop that iterates over a range of integer values. The variable name is automatically defined as type INTEGER and exists only inside the loop. The two expressions giving the loop range are evaluated once when entering the loop. The iteration step is +1 and name begins with the value
of expression to the left of .. and terminates once name exceeds the value of expression to the right of ... Thus the two expressions take on the following roles: start-value.. end-value.

The optional REVERSE clause specifies that the loop should iterate in reverse order. The first time through the loop, name is set to the value of the right-most expression; the loop terminates when the name is less than the left-most expression.

The following example simplifies the WHILE loop example even further by using a FOR loop that iterates from 1 to 10.

```sql
BEGIN
  FOR i IN 1 .. 10 LOOP
    DBMS_OUTPUT.PUT_LINE('Iteration # ' || i);
    END LOOP;
END;
```

Here is the output using the FOR statement.

Iteration # 1
Iteration # 2
Iteration # 3
Iteration # 4
Iteration # 5
Iteration # 6
Iteration # 7
Iteration # 8
Iteration # 9
Iteration # 10

If the start value is greater than the end value the loop body is not executed at all. No error is raised as shown by the following example.

```sql
BEGIN
  FOR i IN 10 .. 1 LOOP
    DBMS_OUTPUT.PUT_LINE('Iteration # ' || i);
    END LOOP;
END;
```

There is no output from this example as the loop body is never executed.

**Note:** SPL also supports CURSOR FOR loops (see Cursor FOR Loop).
5.7 Exception Handling

By default, any error occurring in an SPL program aborts execution of the program. You can trap errors and recover from them by using a BEGIN block with an EXCEPTION section. The syntax is an extension of the normal syntax for a BEGIN block:

```
[ DECLARE <declarations> ]
BEGIN
  <statements>
EXCEPTION
  WHEN <condition> [ OR <condition> ]... THEN
  <handler_statements>
  [ WHEN <condition> [ OR <condition> ]... THEN
    <handler_statements> ]...
END;
```

If no error occurs, this form of block simply executes all the statements, and then control passes to the next statement after END. If an error occurs within the statements, further processing of the statements is abandoned, and control passes to the EXCEPTION list. The list is searched for the first condition matching the error that occurred. If a match is found, the corresponding handler_statements are executed, and then control passes to the next statement after END. If no match is found, the error propagates out as though the EXCEPTION clause were not there at all. The error can be caught by an enclosing block with EXCEPTION; if there is no enclosing block, it aborts processing of the subprogram.

The special condition name OTHERS matches every error type. Condition names are not case-sensitive.

If a new error occurs within the selected handler_statements, it cannot be caught by this EXCEPTION clause, but is propagated out. A surrounding EXCEPTION clause could catch it.

The following table lists the condition names that may be used:
<table>
<thead>
<tr>
<th>Condition Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CASE_NOT_FOUND</td>
<td>The application has encountered a situation where none of the cases in a CASE statement evaluates to TRUE and there is no ELSE condition.</td>
</tr>
<tr>
<td>COLLECTION_IS_NULL</td>
<td>The application has attempted to invoke a collection method on a null collection such as an uninitialized nested table.</td>
</tr>
<tr>
<td>CURSOR_ALREADY_OPEN</td>
<td>The application has attempted to open a cursor that is already open.</td>
</tr>
<tr>
<td>DUP_VAL_ON_INDEX</td>
<td>The application has attempted to store a duplicate value that currently exists within a constrained column.</td>
</tr>
<tr>
<td>INVALID_CURSOR</td>
<td>The application has attempted to access an unopened cursor.</td>
</tr>
<tr>
<td>INVALID_NUMBER</td>
<td>The application has encountered a data exception (equivalent to SQLSTATE class code 22). INVALID_NUMBER is an alias for VALUE_ERROR.</td>
</tr>
<tr>
<td>NO_DATA_FOUND</td>
<td>No rows satisfy the selection criteria.</td>
</tr>
<tr>
<td>OTHERS</td>
<td>The application has encountered an exception that hasn’t been caught by a prior condition in the exception section.</td>
</tr>
<tr>
<td>SUBSCRIPT_BEYOND_COUNT</td>
<td>The application has attempted to reference a subscript of a nested table or varray beyond its initialized or extended size.</td>
</tr>
<tr>
<td>SUBSCRIPT_OUTSIDE_LIMIT</td>
<td>The application has attempted to reference a subscript or extend a varray beyond its maximum size limit.</td>
</tr>
<tr>
<td>TOO_MANY_ROWS</td>
<td>The application has encountered more than one row that satisfies the selection criteria (where only one row is allowed to be returned).</td>
</tr>
<tr>
<td>VALUE_ERROR</td>
<td>The application has encountered a data exception (equivalent to SQLSTATE class code 22). VALUE_ERROR is an alias for INVALID_NUMBER.</td>
</tr>
<tr>
<td>ZERO_DIVIDE</td>
<td>The application has tried to divide by zero.</td>
</tr>
<tr>
<td>User-defined Exception</td>
<td>See User-defined Exceptions.</td>
</tr>
</tbody>
</table>

**Note:** Condition names INVALID_NUMBER and VALUE_ERROR are not compatible with Oracle databases for which these condition names are for exceptions resulting only from a failed conversion of a string to a numeric literal. In addition, for Oracle databases, an INVALID_NUMBER exception is applicable only to SQL statements while a VALUE_ERROR exception is applicable only to procedural statements.
5.8 User-defined Exceptions

Any number of errors (referred to in PL/SQL as exceptions) can occur during program execution. When an exception is thrown, normal execution of the program stops, and control of the program transfers to the error-handling portion of the program. An exception may be a pre-defined error that is generated by the server, or may be a logical error that raises a user-defined exception.

User-defined exceptions are never raised by the server; they are raised explicitly by a RAISE statement. A user-defined exception is raised when a developer-defined logical rule is broken; a common example of a logical rule being broken occurs when a check is presented against an account with insufficient funds. An attempt to cash a check against an account with insufficient funds will provoke a user-defined exception.

You can define exceptions in functions, procedures, packages or anonymous blocks. While you cannot declare the same exception twice in the same block, you can declare the same exception in two different blocks.

Before implementing a user-defined exception, you must declare the exception in the declaration section of a function, procedure, package or anonymous block. You can then raise the exception using the RAISE statement:

```sql
DECLARE
    <exception_name> EXCEPTION;
BEGIN
    ...
    RAISE <exception_name>;
    ...
END;
```

(exception_name) is the name of the exception.

Unhandled exceptions propagate back through the call stack. If the exception remains unhandled, the exception is eventually reported to the client application.

User-defined exceptions declared in a block are considered to be local to that block, and global to any nested blocks within the block. To reference an exception that resides in an outer block, you must assign a label to the outer block; then, preface the name of the exception with the block name:

```
block_name.exception_name
```

Conversely, outer blocks cannot reference exceptions declared in nested blocks.

The scope of a declaration is limited to the block in which it is declared unless it is created in a package, and when referenced, qualified by the package name. For example, to raise an exception named out_of_stock that resides in a package named inventory_control a program must raise an error named:

```
inventory_control.out_of_stock
```

The following example demonstrates declaring a user-defined exception in a package. The user-defined exception does not require a package-qualifier when it is raised in check_balance, since it resides in the same package as the exception:
CREATE OR REPLACE PACKAGE ar AS
  overdrawn EXCEPTION;
  PROCEDURE check_balance(p_balance NUMBER, p_amount NUMBER);
END;

CREATE OR REPLACE PACKAGE BODY ar AS
  PROCEDURE check_balance(p_balance NUMBER, p_amount NUMBER)
  IS
    BEGIN
      IF (p_amount > p_balance) THEN
        RAISE overdrawn;
      END IF;
    END;
END;

The following procedure (purchase) calls the check_balance procedure. If p_amount is greater than p_balance, check_balance raises an exception; purchase catches the ar.overdrawn exception. purchase must refer to the exception with a package-qualified name (ar.overdrawn) because purchase is not defined within the ar package.

CREATE PROCEDURE purchase(customerID INT, amount NUMERIC) AS
  BEGIN
    ar.check_balance(getcustomerbalance(customerid), amount);
    record_purchase(customerid, amount);
  EXCEPTION
    WHEN ar.overdrawn THEN
      raise_credit_limit(customerid, amount*1.5);
  END;

When ar.check_balance raises an exception, execution jumps to the exception handler defined in purchase:

EXCEPTION
  WHEN ar.overdrawn THEN
    raise_credit_limit(customerid, amount*1.5);

The exception handler raises the customer’s credit limit and ends. When the exception handler ends, execution resumes with the statement that follows ar.check_balance.
5.9 PRAGMA EXCEPTION_INIT

PRAGMA EXCEPTION_INIT associates a user-defined error code with an exception. A PRAGMA EXCEPTION_INIT declaration may be included in any block, sub-block or package. You can only assign an error code to an exception (using PRAGMA EXCEPTION_INIT) after declaring the exception. The format of a PRAGMA EXCEPTION_INIT declaration is:

```
PRAGMA EXCEPTION_INIT(<exception_name>,
    (<exception_number> | <exception_code>))
```

Where:

- **exception_name** is the name of the associated exception.
- **exception_number** is a user-defined error code associated with the pragma. If you specify an unmapped exception_number, the server will return a warning.
- **exception_code** is the name of a pre-defined exception. For a complete list of valid exceptions, see the Postgres core documentation available at:

  [https://www.postgresql.org/docs/current/static/errcodes-appendix.html](https://www.postgresql.org/docs/current/static/errcodes-appendix.html)

The previous section (User-defined Exceptions) included an example that demonstrates declaring a user-defined exception in a package. The following example uses the same basic structure, but adds a PRAGMA EXCEPTION_INIT declaration:

```sql
CREATE OR REPLACE PACKAGE ar AS
    overdrawn EXCEPTION;
    PRAGMA EXCEPTION_INIT (overdrawn, -20100);
    PROCEDURE check_balance(p_balance NUMBER, p_amount NUMBER);
END;
CREATE OR REPLACE PACKAGE BODY ar AS
    PROCEDURE check_balance(p_balance NUMBER, p_amount NUMBER)
    IS
        BEGIN
            IF (p_amount > p_balance) THEN
                RAISE overdrawn;
            END IF;
        END;
    END;
```

The following procedure (purchase) calls the check_balance procedure. If p_amount is greater than p_balance, check_balance raises an exception; purchase catches the ar.overdrawn exception.

```sql
CREATE PROCEDURE purchase(customerID int, amount NUMERIC)
AS
    BEGIN
        ar.check_balance(getcustomerbalance(customerid), amount);
        record_purchase(customerid, amount);
    EXCEPTION
        WHEN ar.overdrawn THEN
```

(continues on next page)
When `ar.check_balance` raises an exception, execution jumps to the exception handler defined in `purchase`.

```sql
EXCEPTION
  WHEN ar.overdrawn THEN
    DBMS_OUTPUT.PUT_LINE ('This account is overdrawn.');
    DBMS_OUTPUT.PUT_LINE ('SQLCode :'||SQLCODE||' '||SQLERRM );
END;
```

The exception handler returns an error message, followed by `SQLCODE` information:

```
This account is overdrawn.
SQLCODE: -20100 User-Defined Exception
```

The following example demonstrates using a pre-defined exception. The code creates a more meaningful name for the `no_data_found` exception: if the given customer does not exist, the code catches the exception, calls `DBMS_OUTPUT.PUT_LINE` to report the error, and then re-raises the original exception:

```sql
CREATE OR REPLACE PACKAGE ar AS
  overdrawn EXCEPTION;
  PRAGMA EXCEPTION_INIT (unknown_customer, no_data_found);
  PROCEDURE check_balance(p_customer_id NUMBER);
END;

CREATE OR REPLACE PACKAGE BODY ar AS
  PROCEDURE check_balance(p_customer_id NUMBER)
  IS
    v_balance NUMBER;
    BEGIN
      SELECT balance INTO v_balance FROM customer
      WHERE cust_id = p_customer_id;
      EXCEPTION WHEN unknown_customer THEN
        DBMS_OUTPUT.PUT_LINE('invalid customer id');
        RAISE;
      END;
END;
```
5.10 RAISE_APPLICATION_ERROR

The procedure, RAISE_APPLICATION_ERROR, allows a developer to intentionally abort processing within an SPL program from which it is called by causing an exception. The exception is handled in the same manner as described in Exception Handling. In addition, the RAISE_APPLICATION_ERROR procedure makes a user-defined code and error message available to the program which can then be used to identify the exception.

```sql
RAISE_APPLICATION_ERROR(<error_number>, <message>);
```

Where:

- `error_number` is an integer value or expression that is returned in a variable named SQLCODE when the procedure is executed. `error_number` must be a value between -20000 and -20999.
- `message` is a string literal or expression that is returned in a variable named SQLERRM.

For additional information on the SQLCODE and SQLERRM variables, see Errors and Messages.

The following example uses the RAISE_APPLICATION_ERROR procedure to display a different code and message depending upon the information missing from an employee.

```sql
CREATE OR REPLACE PROCEDURE verify_emp (
    p_empno NUMBER
) IS
    v_ename emp.ename%TYPE;
    v_job emp.job%TYPE;
    v_mgr emp.mgr%TYPE;
    v_hiredate emp.hiredate%TYPE;
BEGIN
    SELECT ename, job, mgr, hiredate
    INTO v_ename, v_job, v_mgr, v_hiredate FROM emp
    WHERE empno = p_empno;
    IF v_ename IS NULL THEN
        RAISE_APPLICATION_ERROR(-20010, 'No name for ' || p_empno);
    END IF;
    IF v_job IS NULL THEN
        RAISE_APPLICATION_ERROR(-20020, 'No job for ' || p_empno);
    END IF;
    IF v_mgr IS NULL THEN
        RAISE_APPLICATION_ERROR(-20030, 'No manager for ' || p_empno);
    END IF;
    IF v_hiredate IS NULL THEN
        RAISE_APPLICATION_ERROR(-20040, 'No hire date for ' || p_empno);
    END IF;
    DBMS_OUTPUT.PUT_LINE('Employee ' || p_empno || ' validated without errors');
EXCEPTION
    WHEN OTHERS THEN
        DBMS_OUTPUT.PUT_LINE('SQLCODE: ' || SQLCODE);
```

(continues on next page)
The following shows the output in a case where the manager number is missing from an employee record.

```
EXEC verify_emp(7839);
SQLCODE: -20030
SQLERRM: EDB-20030: No manager for 7839
```
CHAPTER 6

Transaction Control

There may be circumstances where it is desired that all updates to a database are to occur successfully, or none are to occur at all if any error occurs. A set of database updates that are to all occur successfully as a single unit, or are not to occur at all, is said to be a transaction.

A common example in banking is a funds transfer between two accounts. The two parts of the transaction are the withdrawal of funds from one account, and the deposit of the funds in another account. Both parts of this transaction must occur otherwise the bank’s books will be out of balance. The deposit and withdrawal are one transaction.

An SPL application can be created that uses a style of transaction control compatible with Oracle databases if the following conditions are met:

- The `edb_stmt_level_tx` parameter must be set to `TRUE`. This prevents the action of unconditionally rolling back all database updates within the `BEGIN/END` block if any exception occurs.
- The application must not be running in autocommit mode. If autocommit mode is on, each successful database update is immediately committed and cannot be undone. The manner in which autocommit mode is turned on or off is application dependent.

A transaction begins when the first SQL command is encountered in the SPL program. All subsequent SQL commands are included as part of that transaction. The transaction ends when one of the following occurs:

- An unhandled exception occurs in which case the effects of all database updates made during the transaction are rolled back and the transaction is aborted.
- A `COMMIT` command is encountered in which case the effect of all database updates made during the transaction become permanent.
- A `ROLLBACK` command is encountered in which case the effects of all database updates made during the transaction are rolled back and the transaction is aborted. If a new SQL command is encountered, a new transaction begins.
• Control returns to the calling application (such as Java, PSQL, etc.) in which case the action of the application determines whether the transaction is committed or rolled back unless the transaction is within a block in which `PRAGMA AUTONOMOUS_TRANSACTION` has been declared in which case the commitment or rollback of the transaction occurs independently of the calling program.

**Note:** Unlike Oracle, DDL commands such as `CREATE TABLE` do not implicitly occur within their own transaction. Therefore, DDL commands do not automatically cause an immediate database commit as in Oracle, and DDL commands may be rolled back just like DML commands.

A transaction may span one or more `BEGIN/END` blocks, or a single `BEGIN/END` block may contain one or more transactions.

The following sections discuss the `COMMIT` and `ROLLBACK` commands in more detail.

### 6.1 COMMIT

The `COMMIT` command makes all database updates made during the current transaction permanent, and ends the current transaction.

```sql
COMMIT [ WORK ];
```

The `COMMIT` command may be used within anonymous blocks, stored procedures, or functions. Within an SPL program, it may appear in the executable section and/or the exception section.

In the following example, the third `INSERT` command in the anonymous block results in an error. The effect of the first two `INSERT` commands are retained as shown by the first `SELECT` command. Even after issuing a `ROLLBACK` command, the two rows remain in the table as shown by the second `SELECT` command verifying that they were indeed committed.

**Note:** The `edb_stmt_level_tx` configuration parameter shown in the example below can be set for the entire database using the `ALTER DATABASE` command, or it can be set for the entire database server by changing it in the `postgresql.conf` file.

```sql
\set AUTOCOMMIT off
SET edb_stmt_level_tx TO on;
BEGIN
    INSERT INTO dept VALUES (50, 'FINANCE', 'DALLAS');
    INSERT INTO dept VALUES (60, 'MARKETING', 'CHICAGO');
    COMMIT;
    INSERT INTO dept VALUES (70, 'HUMAN RESOURCES', 'CHICAGO');
EXCEPTION
    WHEN OTHERS THEN
        DBMS_OUTPUT.PUT_LINE('SQLERRM: ' || SQLERRM);
        DBMS_OUTPUT.PUT_LINE('SQLCODE: ' || SQLCODE);
END;
```

(continues on next page)
SQLERRM: value too long for type character varying(14)
SQLCODE: 22001

SELECT * FROM dept;

deptno | dname    | loc
-------+----------+--------
10    | ACCOUNTING | NEW YORK
20    | RESEARCH  | DALLAS
30    | SALES     | CHICAGO
40    | OPERATIONS | BOSTON
50    | FINANCE   | DALLAS
60    | MARKETING | CHICAGO
(6 rows)

ROLLBACK;

SELECT * FROM dept;

deptno | dname    | loc
-------+----------+--------
10    | ACCOUNTING | NEW YORK
20    | RESEARCH  | DALLAS
30    | SALES     | CHICAGO
40    | OPERATIONS | BOSTON
50    | FINANCE   | DALLAS
60    | MARKETING | CHICAGO
(6 rows)

6.2 ROLLBACK

The ROLLBACK command undoes all database updates made during the current transaction, and ends the current transaction.

ROLLBACK [ WORK ];

The ROLLBACK command may be used within anonymous blocks, stored procedures, or functions. Within an SPL program, it may appear in the executable section and/or the exception section.

In the following example, the exception section contains a ROLLBACK command. Even though the first two INSERT commands are executed successfully, the third results in an exception that results in the rollback of all the INSERT commands in the anonymous block.

\set AUTOCOMMIT off
SET edb_stmt_level_tx TO on;
BEGIN
   INSERT INTO dept VALUES (50, 'FINANCE', 'DALLAS');
   INSERT INTO dept VALUES (60, 'MARKETING', 'CHICAGO');
   INSERT INTO dept VALUES (70, 'HUMAN RESOURCES', 'CHICAGO');
EXCEPTION
  WHEN OTHERS THEN
    ROLLBACK;
    DBMS_OUTPUT.PUT_LINE('SQLERRM: ' || SQLERRM);
    DBMS_OUTPUT.PUT_LINE('SQLCODE: ' || SQLCODE);
END;

SQLERRM: value too long for type character varying(14)
SQLCODE: 22001

SELECT * FROM dept;

deptho | dname | loc
---------+----------+--------
  10 | ACCOUNTING | NEW YORK
  20 | RESEARCH | DALLAS
  30 | SALES | CHICAGO
  40 | OPERATIONS | BOSTON
(4 rows)

The following is a more complex example using both COMMIT and ROLLBACK. First, the following stored procedure is created which inserts a new employee.

\set AUTOCOMMIT off
SET edb_stmt_level_tx TO on;

CREATE OR REPLACE PROCEDURE emp_insert (p_empno IN emp.empno%TYPE,
  p_ename IN emp.ename%TYPE,
  p_job IN emp.job%TYPE,
  p_mgr IN emp.mgr%TYPE,
  p_hiredate IN emp.hiredate%TYPE,
  p_sal IN emp.sal%TYPE,
  p_comm IN emp.comm%TYPE,
  p_deptno IN emp.deptno%TYPE)
IS
BEGIN
  INSERT INTO emp VALUES (p_empno,
    p_ename,
    p_job,
    p_mgr,
    p_hiredate,
    p_sal,
    p_comm,
    p_deptno);

  DBMS_OUTPUT.PUT_LINE('Added employee...');
  DBMS_OUTPUT.PUT_LINE('Employee #: ' || p_empno);
  DBMS_OUTPUT.PUT_LINE('Name: ' || p_ename);
END;
(continues on next page)
Note that this procedure has no exception section so any error that may occur is propagated up to the calling program.

The following anonymous block is run. Note the use of the COMMIT command after all calls to the \texttt{emp_insert} procedure and the ROLLBACK command in the exception section.

```sql
BEGIN
    emp_insert(9601, 'FARRELL', 'ANALYST', 7902, '03-MAR-08', 5000, NULL, 40);
    emp_insert(9602, 'TYLER', 'ANALYST', 7900, '25-JAN-08', 4800, NULL, 40);
    COMMIT;
EXCEPTION
    WHEN OTHERS THEN
        DBMS_OUTPUT.PUT_LINE('SQLERRM: ' || SQLERRM);
        DBMS_OUTPUT.PUT_LINE('An error occurred - roll back inserts');
        ROLLBACK;
END;
```

The following \texttt{SELECT} command shows that employees Farrell and Tyler were successfully added.

```sql
SELECT * FROM emp WHERE empno > 9600;
```
Now, execute the following anonymous block:

```
BEGIN
    emp_insert(9603,'HARRISON','SALESMAN',7902,'13-DEC-07',5000,3000,20);
    emp_insert(9604,'JARVIS','SALESMAN',7902,'05-MAY-08',4800,4100,11);
    COMMIT;
EXCEPTION
    WHEN OTHERS THEN
        DBMS_OUTPUT.PUT_LINE('SQLERRM: ' || SQLERRM);
        DBMS_OUTPUT.PUT_LINE('An error occurred - roll back inserts');
        ROLLBACK;
END;
```

Added employee...
Employee #: 9603
Name: HARRISON
Job: SALESMAN
Manager: 7902
Hire Date: 13-DEC-07 00:00:00
Salary: 5000
Commission: 3000
Dept #: 20

SQLERRM: insert or update on table "emp" violates foreign key constraint "emp_ref_dept_fk"
An error occurred - roll back inserts

A SELECT command run against the table yields the following:

```
SELECT * FROM emp WHERE empno > 9600;
```

<table>
<thead>
<tr>
<th>empno</th>
<th>ename</th>
<th>job</th>
<th>mgr</th>
<th>hiredate</th>
<th>sal</th>
<th>comm</th>
<th>deptno</th>
</tr>
</thead>
<tbody>
<tr>
<td>9601</td>
<td>FARRELL</td>
<td>ANALYST</td>
<td>7902</td>
<td>03-MAR-08 00:00:00</td>
<td>5000.00</td>
<td></td>
<td>40</td>
</tr>
<tr>
<td>9602</td>
<td>TYLER</td>
<td>ANALYST</td>
<td>7900</td>
<td>25-JAN-08 00:00:00</td>
<td>4800.00</td>
<td></td>
<td>40</td>
</tr>
</tbody>
</table>
(2 rows)

The ROLLBACK command in the exception section successfully undoes the insert of employee Harrison. Also note that employees Farrell and Tyler are still in the table as their inserts were made permanent by the COMMIT command in the first anonymous block.

Note: Executing a COMMIT or ROLLBACK in a plpgsql procedure will throw an error if there is an Oracle-style SPL procedure on the runtime stack.
6.3 PRAGMA AUTONOMOUS_TRANSACTION

An SPL program can be declared as an autonomous transaction by specifying the following directive in the declaration section of the SPL block:

```
PRAGMA AUTONOMOUS_TRANSACTION;
```

An autonomous transaction is an independent transaction started by a calling program. A commit or rollback of SQL commands within the autonomous transaction has no effect on the commit or rollback in any transaction of the calling program. A commit or rollback in the calling program has no effect on the commit or rollback of SQL commands in the autonomous transaction.

The following SPL programs can include PRAGMA AUTONOMOUS_TRANSACTION:

- Standalone procedures and functions
- Anonymous blocks
- Procedures and functions declared as subprograms within packages and other calling procedures, functions, and anonymous blocks
- Triggers
- Object type methods

The following are issues and restrictions related to autonomous transactions:

- Each autonomous transaction consumes a connection slot for as long as it is in progress. In some cases, this may mean that the `max_connections` parameter in the `postgresql.conf` file should be raised.

- In most respects, an autonomous transaction behaves exactly as if it was a completely separate session, but GUCs (that is, settings established with `SET`) are a deliberate exception. Autonomous transactions absorb the surrounding values and can propagate values they commit to the outer transaction.

- Autonomous transactions can be nested, but there is a limit of 16 levels of autonomous transactions within a single session.

- Parallel query is not supported within autonomous transactions.

- The Advanced Server implementation of autonomous transactions is not entirely compatible with Oracle databases in that the Advanced Server autonomous transaction does not produce an ERROR if there is an uncommitted transaction at the end of an SPL block.

The following set of examples illustrates the usage of autonomous transactions. This first set of scenarios show the default behavior when there are no autonomous transactions.

Before each scenario, the `dept` table is reset to the following initial values:

```
SELECT * FROM dept;
```

```
depno | dname     | loc
--------+------------+----------
10     | ACCOUNTING | NEW YORK
20     | RESEARCH   | DALLAS
```

(continues on next page)
Scenario 1a – No autonomous transactions with only a final COMMIT

This first set of scenarios show the insertion of three rows starting just after the initial BEGIN command of the transaction, then from within an anonymous block within the starting transaction, and finally from a stored procedure executed from within the anonymous block.

The stored procedure is the following:

```sql
CREATE OR REPLACE PROCEDURE insert_dept_70 IS
    BEGIN
        INSERT INTO dept VALUES (70,'MARKETING','LOS ANGELES');
    END;
```

The PSQL session is the following:

```sql
BEGIN;
    INSERT INTO dept VALUES (50,'HR','DENVER');
    BEGIN
        INSERT INTO dept VALUES (60,'FINANCE','CHICAGO');
        insert_dept_70;
    END;
COMMIT;
```

After the final commit, all three rows are inserted:

```sql
SELECT * FROM dept ORDER BY 1;
```

<table>
<thead>
<tr>
<th>deptno</th>
<th>dname</th>
<th>loc</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>ACCOUNTING</td>
<td>NEW YORK</td>
</tr>
<tr>
<td>20</td>
<td>RESEARCH</td>
<td>DALLAS</td>
</tr>
<tr>
<td>30</td>
<td>SALES</td>
<td>CHICAGO</td>
</tr>
<tr>
<td>40</td>
<td>OPERATIONS</td>
<td>BOSTON</td>
</tr>
<tr>
<td>50</td>
<td>HR</td>
<td>DENVER</td>
</tr>
<tr>
<td>60</td>
<td>FINANCE</td>
<td>CHICAGO</td>
</tr>
<tr>
<td>70</td>
<td>MARKETING</td>
<td>LOS ANGELES</td>
</tr>
</tbody>
</table>

(7 rows)

Scenario 1b – No autonomous transactions, but a final ROLLBACK

The next scenario shows that a final ROLLBACK command after all inserts results in the rollback of all three insertions:

```sql
BEGIN;
    INSERT INTO dept VALUES (50,'HR','DENVER');
    BEGIN
        INSERT INTO dept VALUES (60,'FINANCE','CHICAGO');
        insert_dept_70;
    END;
```

(continues on next page)
Scenario 1c – No autonomous transactions, but anonymous block ROLLBACK

A ROLLBACK command given at the end of the anonymous block also eliminates all three prior insertions:

BEGIN;
INSERT INTO dept VALUES (50,'HR','DENVER');
BEGIN
  INSERT INTO dept VALUES (60,'FINANCE','CHICAGO');
  insert_dept_70;
ROLLBACK;
END;
COMMIT;

SELECT * FROM dept ORDER BY 1;

| deptno | dname      | loc        |
|--------+------------|------------|
| 10     | ACCOUNTING | NEW YORK  |
| 20     | RESEARCH   | DALLAS     |
| 30     | SALES      | CHICAGO    |
| 40     | OPERATIONS | BOSTON     |

(4 rows)

This next set of scenarios shows the effect of using autonomous transactions with PRAGMA AUTONOMOUS_TRANSACTION in various locations.

Scenario 2a – Autonomous transaction of anonymous block with COMMIT

The procedure remains as initially created:

CREATE OR REPLACE PROCEDURE insert_dept_70 IS
BEGIN
  INSERT INTO dept VALUES (70,'MARKETING','LOS ANGELES');
END;

Now, the PRAGMA AUTONOMOUS_TRANSACTION is given with the anonymous block along with the COMMIT command at the end of the anonymous block.
BEGIN;
INSERT INTO dept VALUES (50,'HR','DENVER');
DECLARE
    PRAGMA AUTONOMOUS_TRANSACTION;
BEGIN
    INSERT INTO dept VALUES (60,'FINANCE','CHICAGO');
    insert_dept_70;
    COMMIT;
END;
ROLLBACK;

After the ROLLBACK at the end of the transaction, only the first row insertion at the very beginning of the transaction is discarded. The other two row insertions within the anonymous block with PRAGMA AUTONOMOUS_TRANSACTION have been independently committed.

SELECT * FROM dept ORDER BY 1;

<table>
<thead>
<tr>
<th>deptno</th>
<th>dname</th>
<th>loc</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>ACCOUNTING</td>
<td>NEW YORK</td>
</tr>
<tr>
<td>20</td>
<td>RESEARCH</td>
<td>DALLAS</td>
</tr>
<tr>
<td>30</td>
<td>SALES</td>
<td>CHICAGO</td>
</tr>
<tr>
<td>40</td>
<td>OPERATIONS</td>
<td>BOSTON</td>
</tr>
<tr>
<td>60</td>
<td>FINANCE</td>
<td>CHICAGO</td>
</tr>
<tr>
<td>70</td>
<td>MARKETING</td>
<td>LOS ANGELES</td>
</tr>
</tbody>
</table>

(6 rows)

Scenario 2b – Autonomous transaction anonymous block with COMMIT including procedure with ROLLBACK, but not an autonomous transaction procedure

Now, the procedure has the ROLLBACK command at the end. Note, however, that the PRAGMA AUTONOMOUS_TRANSACTION is not included in this procedure.

CREATE OR REPLACE PROCEDURE insert_dept_70 IS
BEGIN
    INSERT INTO dept VALUES (70,'MARKETING','LOS ANGELES');
    ROLLBACK;
END;

Now, the rollback within the procedure removes the two rows inserted within the anonymous block (deptno 60 and 70) before the final COMMIT command within the anonymous block.

BEGIN;
INSERT INTO dept VALUES (50,'HR','DENVER');
DECLARE
    PRAGMA AUTONOMOUS_TRANSACTION;
BEGIN
    INSERT INTO dept VALUES (60,'FINANCE','CHICAGO');
    insert_dept_70;
    COMMIT;
END;
COMMIT;
After the final commit at the end of the transaction, the only row inserted is the first one from the beginning of the transaction. Since the anonymous block is an autonomous transaction, the rollback within the enclosed procedure has no effect on the insertion that occurs before the anonymous block is executed.

```
SELECT * FROM dept ORDER by 1;

<table>
<thead>
<tr>
<th>deptno</th>
<th>dname</th>
<th>loc</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>ACCOUNTING</td>
<td>NEW YORK</td>
</tr>
<tr>
<td>20</td>
<td>RESEARCH</td>
<td>DALLAS</td>
</tr>
<tr>
<td>30</td>
<td>SALES</td>
<td>CHICAGO</td>
</tr>
<tr>
<td>40</td>
<td>OPERATIONS</td>
<td>BOSTON</td>
</tr>
<tr>
<td>50</td>
<td>HR</td>
<td>DENVER</td>
</tr>
</tbody>
</table>

(5 rows)
```

**Scenario 2c – Autonomous transaction anonymous block with COMMIT including procedure with ROLLBACK that is also an autonomous transaction procedure**

Now, the procedure with the `ROLLBACK` command at the end also has `PRAGMA AUTONOMOUS_TRANSACTION` included. This isolates the effect of the `ROLLBACK` command within the procedure.

```
CREATE OR REPLACE PROCEDURE insert_dept_70 IS
    PRAGMA AUTONOMOUS_TRANSACTION;
BEGIN
    INSERT INTO dept VALUES (70,'MARKETING','LOS ANGELES');
    ROLLBACK;
END;
```

Now, the rollback within the procedure removes the row inserted by the procedure, but not the other row inserted within the anonymous block.

```
BEGIN;
INSERT INTO dept VALUES (50,'HR','DENVER');
DECLARE
    PRAGMA AUTONOMOUS_TRANSACTION;
BEGIN
    INSERT INTO dept VALUES (60,'FINANCE','CHICAGO');
    insert_dept_70;
    COMMIT;
END;
COMMIT;
```

After the final commit at the end of the transaction, the row inserted is the first one from the beginning of the transaction as well as the row inserted at the beginning of the anonymous block. The only insertion rolled back is the one within the procedure.

```
SELECT * FROM dept ORDER by 1;

<table>
<thead>
<tr>
<th>deptno</th>
<th>dname</th>
<th>loc</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>ACCOUNTING</td>
<td>NEW YORK</td>
</tr>
</tbody>
</table>

(continues on next page)```
The following sections now show examples of `PRAGMA AUTONOMOUS_TRANSACTION` in a couple of other SPL program types.

**Autonomous Transaction Trigger**

The following example shows the effect of declaring a trigger with `PRAGMA AUTONOMOUS_TRANSACTION`.

The following table is created to log changes to the `emp` table:

```sql
CREATE TABLE empauditlog (
    audit_date DATE,
    audit_user VARCHAR2(20),
    audit_desc VARCHAR2(20)
);
```

The trigger attached to the `emp` table that inserts these changes into the `empauditlog` table is the following. Note the inclusion of `PRAGMA AUTONOMOUS_TRANSACTION` in the declaration section.

```sql
CREATE OR REPLACE TRIGGER emp_audit_trig
    AFTER INSERT OR UPDATE OR DELETE ON emp
DECLARE
    PRAGMA AUTONOMOUS_TRANSACTION;
    v_action VARCHAR2(20);
BEGIN
    IF INSERTING THEN
        v_action := 'Added employee(s)';
    ELSIF UPDATING THEN
        v_action := 'Updated employee(s)';
    ELSIF DELETING THEN
        v_action := 'Deleted employee(s)';
    END IF;
    INSERT INTO empauditlog VALUES (SYSDATE, USER, v_action);
END;
```

The following two inserts are made into the `emp` table within a transaction started by the `BEGIN` command.

```sql
BEGIN;
INSERT INTO emp VALUES (9001,'SMITH','ANALYST',7782,SYSDATE,NULL,NULL,10);
INSERT INTO emp VALUES (9002,'JONES','CLERK',7782,SYSDATE,NULL,NULL,10);
```

The following shows the two new rows in the `emp` table as well as the two entries in the `empauditlog` table:
### SELECT * FROM emp WHERE empno > 9000;

<table>
<thead>
<tr>
<th>empno</th>
<th>ename</th>
<th>job</th>
<th>mgr</th>
<th>hiredate</th>
<th>sal</th>
<th>comm</th>
<th>deptno</th>
</tr>
</thead>
<tbody>
<tr>
<td>9001</td>
<td>SMITH</td>
<td>ANALYST</td>
<td>7782</td>
<td>23-AUG-18 07:12:27</td>
<td></td>
<td></td>
<td>10</td>
</tr>
<tr>
<td>9002</td>
<td>JONES</td>
<td>CLERK</td>
<td>7782</td>
<td>23-AUG-18 07:12:27</td>
<td></td>
<td></td>
<td>10</td>
</tr>
</tbody>
</table>

(2 rows)

### SELECT TO_CHAR(AUDIT_DATE,'DD-MON-YY HH24:MI:SS') AS "audit date", audit_user, audit_desc FROM empauditlog ORDER BY 1 ASC;

<table>
<thead>
<tr>
<th>audit date</th>
<th>audit_user</th>
<th>audit_desc</th>
</tr>
</thead>
<tbody>
<tr>
<td>23-AUG-18 07:12:27</td>
<td>enterprisedb</td>
<td>Added employee(s)</td>
</tr>
<tr>
<td>23-AUG-18 07:12:27</td>
<td>enterprisedb</td>
<td>Added employee(s)</td>
</tr>
</tbody>
</table>

(2 rows)

But then the ROLLBACK command is given during this session. The emp table no longer contains the two rows, but the empauditlog table still contains its two entries as the trigger implicitly performed a commit and PRAGMA AUTONOMOUS_TRANSACTION commits those changes independent from the rollback given in the calling transaction.

**Autonomous Transaction Object Type Method**

The following example shows the effect of declaring an object method with PRAGMA AUTONOMOUS_TRANSACTION.

The following object type and object type body are created. The member procedure within the object type body contains the PRAGMA AUTONOMOUS_TRANSACTION in the declaration section along with COMMIT at the end of the procedure.

```sql
CREATE OR REPLACE TYPE insert_dept_typ AS OBJECT (
    deptno NUMBER(2),
    dname VARCHAR2(14),
    loc VARCHAR2(13),

(continues on next page)```
MEMBER PROCEDURE insert_dept
);

CREATE OR REPLACE TYPE BODY insert_dept_typ AS
  MEMBER PROCEDURE insert_dept
  IS
    PRAGMA AUTONOMOUS_TRANSACTION;
  BEGIN
    INSERT INTO dept VALUES (SELF.deptno,SELF.dname,SELF.loc);
    COMMIT;
  END;
END;

In the following anonymous block, an insert is performed into the \texttt{dept} table, followed by invocation of the \texttt{insert_dept} method of the object, ending with a \texttt{ROLLBACK} command in the anonymous block.

\begin{verbatim}
BEGIN;
DECLARE
  v_dept INSERT_DEPT_TYP :=
    insert_dept_typ(60,'FINANCE','CHICAGO');
BEGIN
  INSERT INTO dept VALUES (50,'HR','DENVER');
  v_dept.insert_dept;
  ROLLBACK;
END;
\end{verbatim}

Since \texttt{insert_dept} has been declared as an autonomous transaction, its insert of department number 60 remains in the table, but the rollback removes the insertion of department 50.

\begin{verbatim}
SELECT * FROM dept ORDER BY 1;
\end{verbatim}

\begin{verbatim}
depthno | dname    | loc
---------+-----------+----------
  10     | ACCOUNTING | NEW YORK
  20     | RESEARCH   | DALLAS
  30     | SALES      | CHICAGO
  40     | OPERATIONS | BOSTON
  60     | FINANCE    | CHICAGO
\end{verbatim}

(5 rows)
Dynamic SQL is a technique that provides the ability to execute SQL commands that are not known until the commands are about to be executed. Up to this point, the SQL commands that have been illustrated in SPL programs have been static SQL - the full command (with the exception of variables) must be known and coded into the program before the program, itself, can begin to execute. Thus using dynamic SQL, the executed SQL can change during program runtime.

In addition, dynamic SQL is the only method by which data definition commands, such as CREATE TABLE, can be executed from within an SPL program.

Note, however, that the runtime performance of dynamic SQL will be slower than static SQL.

The EXECUTE IMMEDIATE command is used to run SQL commands dynamically.

```sql
EXECUTE IMMEDIATE '<sql_expression>;'  
[ INTO { <variable> [, ...] | <record> } ]  
[ USING <expression> [, ...] ]
```

*sql_expression* is a string expression containing the SQL command to be dynamically executed. *variable* receives the output of the result set, typically from a SELECT command, created as a result of executing the SQL command in sql_expression. The number, order, and type of variables must match the number, order, and be type-compatible with the fields of the result set. Alternatively, a record can be specified as long as the record’s fields match the number, order, and are type-compatible with the result set. When using the INTO clause, exactly one row must be returned in the result set, otherwise an exception occurs. When using the USING clause the value of expression is passed to a placeholder. Placeholders appear embedded within the SQL command in sql_expression where variables may be used. Placeholders are denoted by an identifier with a colon (:) prefix - :name. The number, order, and resultant data types of the evaluated expressions must match the number, order and be type-compatible with the placeholders in sql_expression. Note that placeholders are not declared anywhere in the SPL program – they only appear in sql_expression.

The following example shows basic dynamic SQL commands as string literals.
DECLARE
    v_sql VARCHAR2(50);
BEGIN
    EXECUTE IMMEDIATE 'CREATE TABLE job (jobno NUMBER(3),' ||
        ' jname VARCHAR2(9))';
    v_sql := 'INSERT INTO job VALUES (100, "ANALYST")';
    EXECUTE IMMEDIATE v_sql;
    v_sql := 'INSERT INTO job VALUES (200, "CLERK")';
    EXECUTE IMMEDIATE v_sql;
END;

The following example illustrates the USING clause to pass values to placeholders in the SQL string.

DECLARE
    v_sql VARCHAR2(50) := 'INSERT INTO job VALUES ' ||
        '(:p_jobno, :p_jname)';
    v_jobno job.jobno%TYPE;
    v_jname job.jname%TYPE;
BEGIN
    v_jobno := 300;
    v_jname := "MANAGER";
    EXECUTE IMMEDIATE v_sql USING v_jobno, v_jname;
    v_jobno := 400;
    v_jname := "SALESMAN";
    EXECUTE IMMEDIATE v_sql USING v_jobno, v_jname;
    v_jobno := 500;
    v_jname := "PRESIDENT";
    EXECUTE IMMEDIATE v_sql USING v_jobno, v_jname;
END;

The following example shows both the INTO and USING clauses. Note the last execution of the SELECT command returns the results into a record instead of individual variables.

DECLARE
    v_sql VARCHAR2(60);
    v_jobno job.jobno%TYPE;
    v_jname job.jname%TYPE;
    r_job job%ROWTYPE;
BEGIN
    DBMS_OUTPUT.PUT_LINE('JOBNO JNAME');
    DBMS_OUTPUT.PUT_LINE('----- -------');
    v_sql := 'SELECT jobno, jname FROM job WHERE jobno = :p_jobno';
    EXECUTE IMMEDIATE v_sql INTO v_jobno, v_jname USING 100;
    DBMS_OUTPUT.PUT_LINE(v_jobno || ' ' || v_jname);
    EXECUTE IMMEDIATE v_sql INTO v_jobno, v_jname USING 200;
    DBMS_OUTPUT.PUT_LINE(v_jobno || ' ' || v_jname);
    EXECUTE IMMEDIATE v_sql INTO v_jobno, v_jname USING 300;
    DBMS_OUTPUT.PUT_LINE(v_jobno || ' ' || v_jname);
    EXECUTE IMMEDIATE v_sql INTO v_jobno, v_jname USING 400;
    DBMS_OUTPUT.PUT_LINE(v_jobno || ' ' || v_jname);
    EXECUTE IMMEDIATE v_sql INTO r_job USING 500;
    DBMS_OUTPUT.PUT_LINE(r_job.jobno || ' ' || r_job.jname);
end;
The following is the output from the previous anonymous block:

<table>
<thead>
<tr>
<th>JOBNO</th>
<th>JNAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>100</td>
<td>ANALYST</td>
</tr>
<tr>
<td>200</td>
<td>CLERK</td>
</tr>
<tr>
<td>300</td>
<td>MANAGER</td>
</tr>
<tr>
<td>400</td>
<td>SALESMAN</td>
</tr>
<tr>
<td>500</td>
<td>PRESIDENT</td>
</tr>
</tbody>
</table>

You can use the `BULK COLLECT` clause to assemble the result set from an `EXECUTE IMMEDIATE` statement into a named collection. See *Using the BULK COLLECT Clause*, `EXECUTE IMMEDIATE BULK COLLECT` for information about using the `BULK COLLECT` clause.
Rather than executing a whole query at once, it is possible to set up a cursor that encapsulates the query, and then read the query result set one row at a time. This allows the creation of SPL program logic that retrieves a row from the result set, does some processing on the data in that row, and then retrieves the next row and repeats the process.

Cursors are most often used in the context of a FOR or WHILE loop. A conditional test should be included in the SPL logic that detects when the end of the result set has been reached so the program can exit the loop.

### 8.1 Declaring a Cursor

In order to use a cursor, it must first be declared in the declaration section of the SPL program. A cursor declaration appears as follows:

```sql
CURSOR <name> IS <query>;
```

name is an identifier that will be used to reference the cursor and its result set later in the program. query is a SQL SELECT command that determines the result set retrievable by the cursor.

**Note:** An extension of this syntax allows the use of parameters. This is discussed in more detail in *Parameterized Cursors*.

The following are some examples of cursor declarations:

```sql
CREATE OR REPLACE PROCEDURE cursor_example
IS
```

(continues on next page)
8.2 Opening a Cursor

Before a cursor can be used to retrieve rows, it must first be opened. This is accomplished with the \texttt{OPEN} statement.

\begin{verbatim}
OPEN <name>;
\end{verbatim}

\texttt{name} is the identifier of a cursor that has been previously declared in the declaration section of the SPL program. The \texttt{OPEN} statement must not be executed on a cursor that has already been, and still is open.

The following shows an \texttt{OPEN} statement with its corresponding cursor declaration.

\begin{verbatim}
CREATE OR REPLACE PROCEDURE cursor_example
IS
  CURSOR emp_cur_3 IS SELECT empno, ename FROM emp WHERE deptno = 10
  ORDER BY empno;
BEGIN
  OPEN emp_cur_3;
  ...
END;
\end{verbatim}

8.3 Fetching Rows From a Cursor

Once a cursor has been opened, rows can be retrieved from the cursor's result set by using the \texttt{FETCH} statement.

\begin{verbatim}
FETCH <name> INTO { <record> | <variable> [, <variable_2> ]... };
\end{verbatim}

\texttt{name} is the identifier of a previously opened cursor. \texttt{record} is the identifier of a previously defined record (for example, using \texttt{table\%ROWTYPE}). \texttt{variable}, \texttt{variable_2}... are SPL variables that will receive the field data from the fetched row. The fields in \texttt{record} or \texttt{variable}, \texttt{variable_2}... must match in number and order, the fields returned in the \texttt{SELECT} list of the query given in the cursor declaration. The data types of the fields in the \texttt{SELECT} list must match, or be implicitly convertible to the data types of the fields in \texttt{record} or the data types of \texttt{variable}, \texttt{variable_2}...

\begin{itemize}
  \item \textbf{Note:} There is a variation of \texttt{FETCH INTO} using the \texttt{BULK COLLECT} clause that can return multiple rows at a time into a collection. See Section \textit{Using the BULK COLLECT Clause} for more information on
\end{itemize}
using the BULK COLLECT clause with the FETCH INTO statement.

The following shows the FETCH statement.

```sql
CREATE OR REPLACE PROCEDURE cursor_example
IS
    v_empno NUMBER(4);
    v_ename VARCHAR2(10);
    CURSOR emp_cur_3 IS SELECT empno, ename FROM emp WHERE deptno = 10
        ORDER BY empno;
BEGIN
    OPEN emp_cur_3;
    FETCH emp_cur_3 INTO v_empno, v_ename;
    ...
END;
```

Instead of explicitly declaring the data type of a target variable, %TYPE can be used instead. In this way, if the data type of the database column is changed, the target variable declaration in the SPL program does not have to be changed. %TYPE will automatically pick up the new data type of the specified column.

```sql
CREATE OR REPLACE PROCEDURE cursor_example
IS
    v_empno emp.empno%TYPE;
    v_ename emp.ename%TYPE;
    CURSOR emp_cur_3 IS SELECT empno, ename FROM emp WHERE deptno = 10
        ORDER BY empno;
BEGIN
    OPEN emp_cur_3;
    FETCH emp_cur_3 INTO v_empno, v_ename;
    ...
END;
```

If all the columns in a table are retrieved in the order defined in the table, %ROWTYPE can be used to define a record into which the FETCH statement will place the retrieved data. Each field within the record can then be accessed using dot notation.

```sql
CREATE OR REPLACE PROCEDURE cursor_example
IS
    v_emp_rec emp%ROWTYPE;
    CURSOR emp_cur_1 IS SELECT * FROM emp;
BEGIN
    OPEN emp_cur_1;
    FETCH emp_cur_1 INTO v_emp_rec;
    DBMS_OUTPUT.PUT_LINE('Employee Number: ' || v_emp_rec.empno);
    DBMS_OUTPUT.PUT_LINE('Employee Name : ' || v_emp_rec.ename);
    ...
END;
```
8.4 Closing a Cursor

Once all the desired rows have been retrieved from the cursor result set, the cursor must be closed. Once closed, the result set is no longer accessible. The `CLOSE` statement appears as follows:

```
CLOSE <name>;
```

`name` is the identifier of a cursor that is currently open. Once a cursor is closed, it must not be closed again. However, once the cursor is closed, the `OPEN` statement can be issued again on the closed cursor and the query result set will be rebuilt after which the `FETCH` statement can then be used to retrieve the rows of the new result set.

The following example illustrates the use of the `CLOSE` statement:

```
CREATE OR REPLACE PROCEDURE cursor_example
IS
  v_emp_rec emp%ROWTYPE;
  CURSOR emp_cur_1 IS SELECT * FROM emp;
BEGIN
  OPEN emp_cur_1;
  FETCH emp_cur_1 INTO v_emp_rec;
  DBMS_OUTPUT.PUT_LINE('Employee Number: ' || v_emp_rec.empno);
  DBMS_OUTPUT.PUT_LINE('Employee Name: ' || v_emp_rec.ename);
  CLOSE emp_cur_1;
END;
```

This procedure produces the following output when invoked. Employee number 7369, SMITH is the first row of the result set.

```
EXEC cursor_example;
Employee Number: 7369
Employee Name: SMITH
```

8.5 Using %ROWTYPE With Cursors

Using the `%ROWTYPE` attribute, a record can be defined that contains fields corresponding to all columns fetched from a cursor or cursor variable. Each field takes on the data type of its corresponding column. The `%ROWTYPE` attribute is prefixed by a cursor name or cursor variable name.

```
<record> <cursor>%ROWTYPE;
```

`record` is an identifier assigned to the record. `cursor` is an explicitly declared cursor within the current scope.

The following example shows how you can use a cursor with `%ROWTYPE` to get information about which employee works in which department.
CREATE OR REPLACE PROCEDURE emp_info
IS
    CURSOR empcur IS SELECT ename, deptno FROM emp;
    myvar empcur%ROWTYPE;
BEGIN
    OPEN empcur;
    LOOP
        FETCH empcur INTO myvar;
        EXIT WHEN empcur%NOTFOUND;
        DBMS_OUTPUT.PUT_LINE( myvar.ename || ' works in department ' || myvar.deptno );
    END LOOP;
    CLOSE empcur;
END;

The following is the output from this procedure.

EXEC emp_info;

SMITH works in department 20
ALLEN works in department 30
WARD works in department 30
JONES works in department 20
MARTIN works in department 30
BLAKE works in department 30
CLARK works in department 10
SCOTT works in department 20
KING works in department 10
TURNER works in department 30
ADAMS works in department 20
JAMES works in department 30
FORD works in department 20
MILLER works in department 10
8.6 Cursor Attributes

Each cursor has a set of attributes associated with it that allows the program to test the state of the cursor. These attributes are %ISOPEN, %FOUND, %NOTFOUND, and %ROWCOUNT. These attributes are described in the following sections.

8.6.1 %ISOPEN

The %ISOPEN attribute is used to test whether or not a cursor is open.

```
<cursor_name>%ISOPEN
```

cursor_name is the name of the cursor for which a BOOLEAN data type of TRUE will be returned if the cursor is open, FALSE otherwise.

The following is an example of using %ISOPEN.

```
CREATE OR REPLACE PROCEDURE cursor_example
IS
  ...
  CURSOR emp_cur_1 IS SELECT * FROM emp;
  ...
BEGIN
  ...
  IF emp_cur_1%ISOPEN THEN
    NULL;
  ELSE
    OPEN emp_cur_1;
  END IF;
  FETCH emp_cur_1 INTO ... 
  ...
END;
```

8.6.2 %FOUND

The %FOUND attribute is used to test whether or not a row is retrieved from the result set of the specified cursor after a FETCH on the cursor.

```
<cursor_name>%FOUND
```

cursor_name is the name of the cursor for which a BOOLEAN data type of TRUE will be returned if a row is retrieved from the result set of the cursor after a FETCH.

After the last row of the result set has been fetched the next FETCH results in %FOUND returning FALSE. FALSE is also returned after the first FETCH if there are no rows in the result set to begin with.

Referencing %FOUND on a cursor before it is opened or after it is closed results in an INVALID_CURSOR exception being thrown.

%FOUND returns null if it is referenced when the cursor is open, but before the first FETCH.
The following example uses %FOUND.

```sql
CREATE OR REPLACE PROCEDURE cursor_example
IS
    v_emp_rec emp%ROWTYPE;
    CURSOR emp_cur_1 IS SELECT * FROM emp;
BEGIN
    OPEN emp_cur_1;
    DBMS_OUTPUT.PUT_LINE('EMPNO ENAME');
    DBMS_OUTPUT.PUT_LINE('----- -------');
    FETCH emp_cur_1 INTO v_emp_rec;
    WHILE emp_cur_1%FOUND LOOP
        DBMS_OUTPUT.PUT_LINE(v_emp_rec.empno || ' ' || v_emp_rec.ename);
        FETCH emp_cur_1 INTO v_emp_rec;
    END LOOP;
    CLOSE emp_cur_1;
END;
```

When the previous procedure is invoked, the output appears as follows:

```sql
EXEC cursor_example;

EMPNO  ENAME
-----  -------
7369   SMITH
7499   ALLEN
7521   WARD
7566   JONES
7654   MARTIN
7698   BLAKE
7782   CLARK
7788   SCOTT
7839   KING
7844   TURNER
7876   ADAMS
7900   JAMES
7902   FORD
7934   MILLER
```

### 8.6.3 %NOTFOUND

The %NOTFOUND attribute is the logical opposite of %FOUND.

```sql
<cursor_name>%NOTFOUND
```

cursor_name is the name of the cursor for which a BOOLEAN data type of FALSE will be returned if a row is retrieved from the result set of the cursor after a FETCH.

After the last row of the result set has been fetched the next FETCH results in %NOTFOUND returning TRUE. TRUE is also returned after the first FETCH if there are no rows in the result set to begin with.

Referencing %NOTFOUND on a cursor before it is opened or after it is closed, results in an
INVALID_CURSOR exception being thrown.

%NOTFOUND returns null if it is referenced when the cursor is open, but before the first FETCH.

The following example uses %NOTFOUND.

```sql
CREATE OR REPLACE PROCEDURE cursor_example
IS
    v_emp_rec emp%ROWTYPE;
    CURSOR emp_cur_1 IS SELECT * FROM emp;
BEGIN
    OPEN emp_cur_1;
    DBMS_OUTPUT.PUT_LINE('EMPNO ENAME');
    DBMS_OUTPUT.PUT_LINE('----- -------');
    LOOP
        FETCH emp_cur_1 INTO v_emp_rec;
        EXIT WHEN emp_cur_1%NOTFOUND;
        DBMS_OUTPUT.PUT_LINE(v_emp_rec.empno || ' ' || v_emp_rec.ename);
    END LOOP;
    CLOSE emp_cur_1;
END;
```

Similar to the prior example, this procedure produces the same output when invoked.

```sql
EXEC cursor_example;
```

<table>
<thead>
<tr>
<th>EMPNO</th>
<th>ENAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>7369</td>
<td>SMITH</td>
</tr>
<tr>
<td>7499</td>
<td>ALLEN</td>
</tr>
<tr>
<td>7521</td>
<td>WARD</td>
</tr>
<tr>
<td>7566</td>
<td>JONES</td>
</tr>
<tr>
<td>7654</td>
<td>MARTIN</td>
</tr>
<tr>
<td>7698</td>
<td>BLAKE</td>
</tr>
<tr>
<td>7782</td>
<td>CLARK</td>
</tr>
<tr>
<td>7788</td>
<td>SCOTT</td>
</tr>
<tr>
<td>7839</td>
<td>KING</td>
</tr>
<tr>
<td>7844</td>
<td>TURNER</td>
</tr>
<tr>
<td>7876</td>
<td>ADAMS</td>
</tr>
<tr>
<td>7900</td>
<td>JAMES</td>
</tr>
<tr>
<td>7902</td>
<td>FORD</td>
</tr>
<tr>
<td>7934</td>
<td>MILLER</td>
</tr>
</tbody>
</table>

### 8.6.4 %ROWCOUNT

The %ROWCOUNT attribute returns an integer showing the number of rows fetched so far from the specified cursor.

```sql
<cursor_name>%ROWCOUNT
```

cursor_name is the name of the cursor for which %ROWCOUNT returns the number of rows retrieved thus far. After the last row has been retrieved, %ROWCOUNT remains set to the total number of rows returned until
the cursor is closed at which point %ROWCOUNT will throw an INVALID_CURSOR exception if referenced. Referencing %ROWCOUNT on a cursor before it is opened or after it is closed, results in an INVALID_CURSOR exception being thrown.

%ROWCOUNT returns 0 if it is referenced when the cursor is open, but before the first FETCH. %ROWCOUNT also returns 0 after the first FETCH when there are no rows in the result set to begin with.

The following example uses %ROWCOUNT.

```sql
CREATE OR REPLACE PROCEDURE cursor_example
IS
    v_emp_rec emp%ROWTYPE;
    CURSOR emp_cur_1 IS SELECT * FROM emp;
BEGIN
    OPEN emp_cur_1;
    DBMS_OUTPUT.PUT_LINE('EMPNO ENAME');
    DBMS_OUTPUT.PUT_LINE('----- -------');
    LOOP
        FETCH emp_cur_1 INTO v_emp_rec;
        EXIT WHEN emp_cur_1%NOTFOUND;
        DBMS_OUTPUT.PUT_LINE(v_emp_rec.empno || ' ' || v_emp_rec.ename);
    END LOOP;
    DBMS_OUTPUT.PUT_LINE('**********************');
    DBMS_OUTPUT.PUT_LINE(emp_cur_1%ROWCOUNT || ' rows were retrieved');
    CLOSE emp_cur_1;
END;
```

This procedure prints the total number of rows retrieved at the end of the employee list as follows:

```
EXEC cursor_example;
EMPNO  ENAME
-----  -------
 7369   SMITH
 7499   ALLEN
 7521   WARD
 7566   JONES
 7654   MARTIN
 7698   BLAKE
 7782   CLARK
 7788   SCOTT
 7839   KING
 7844   TURNER
 7876   ADAMS
 7900   JAMES
 7902   FORD
 7934   MILLER
**********************
14 rows were retrieved
```
8.6.5 Summary of Cursor States and Attributes

The following table summarizes the possible cursor states and the values returned by the cursor attributes.

<table>
<thead>
<tr>
<th>Cursor State</th>
<th>%ISOPEN</th>
<th>%FOUND</th>
<th>%NOTFOUND</th>
<th>%ROWCOUNT</th>
</tr>
</thead>
<tbody>
<tr>
<td>Before OPEN</td>
<td>False</td>
<td>INVALID_CURSOR</td>
<td>INVALID_CURSOR</td>
<td>INVALID_CURSOR</td>
</tr>
<tr>
<td>After OPEN &amp; Before 1st FETCH</td>
<td>True</td>
<td>Null</td>
<td>Null</td>
<td>0</td>
</tr>
<tr>
<td>After 1st Successful FETCH</td>
<td>True</td>
<td>True</td>
<td>False</td>
<td>1</td>
</tr>
<tr>
<td>After nth Successful FETCH (last row)</td>
<td>True</td>
<td>True</td>
<td>False</td>
<td>n</td>
</tr>
<tr>
<td>After n+1st FETCH (after last row)</td>
<td>True</td>
<td>False</td>
<td>True</td>
<td>n</td>
</tr>
<tr>
<td>After CLOSE</td>
<td>False</td>
<td>INVALID_CURSOR</td>
<td>INVALID_CURSOR</td>
<td>INVALID_CURSOR</td>
</tr>
</tbody>
</table>

8.7 Cursor FOR Loop

In the cursor examples presented so far, the programming logic required to process the result set of a cursor included a statement to open the cursor, a loop construct to retrieve each row of the result set, a test for the end of the result set, and finally a statement to close the cursor. The cursor FOR loop is a loop construct that eliminates the need to individually code the statements just listed.

The cursor FOR loop opens a previously declared cursor, fetches all rows in the cursor result set, and then closes the cursor.

The syntax for creating a cursor FOR loop is as follows.

```sql
FOR <record> IN <cursor>
LOOP
   <statements>
END LOOP;
```

*record* is an identifier assigned to an implicitly declared record with definition, *cursor%ROWTYPE*. *cursor* is the name of a previously declared cursor. *statements* are one or more SPL statements. There must be at least one statement.

The following example shows the example from %NOTFOUND, modified to use a cursor FOR loop.
CREATE OR REPLACE PROCEDURE cursor_example
IS
    CURSOR emp_cur_1 IS SELECT * FROM emp;
BEGIN
    DBMS_OUTPUT.PUT_LINE('EMPNO ENAME');
    DBMS_OUTPUT.PUT_LINE('----- -------');
    FOR v_emp_rec IN emp_cur_1 LOOP
        DBMS_OUTPUT.PUT_LINE(v_emp_rec.empno || ' ' || v_emp_rec.ename);
    END LOOP;
END;

The same results are achieved as shown in the output below.

EXEC cursor_example;

EMPNO   ENAME
-----   -------
7369    SMITH
7499    ALLEN
7521    WARD
7566    JONES
7654    MARTIN
7698    BLAKE
7782    CLARK
7788    SCOTT
7839    KING
7844    TURNER
7876    ADAMS
7900    JAMES
7902    FORD
7934    MILLER

8.8 Parameterized Cursors

A user can also declare a static cursor that accepts parameters, and can pass values for those parameters when opening that cursor. In the following example we have created a parameterized cursor which will display the name and salary of all employees from the emp table that have a salary less than a specified value which is passed as a parameter.

DECLARE
    my_record emp%ROWTYPE;
    CURSOR c1 (max_wage NUMBER) IS
        SELECT * FROM emp WHERE sal < max_wage;
BEGIN
    OPEN c1(2000);
    LOOP
        FETCH c1 INTO my_record;
        EXIT WHEN c1%NOTFOUND;
        DBMS_OUTPUT.PUT_LINE('Name = ' || my_record.ename || ', salary = ' || my_record.sal);
    END LOOP;
END;
So for example if we pass the value 2000 as \texttt{max\_wage}, then we will only be shown the name and salary of all employees that have a salary less than 2000. The result of the above query is the following:

<table>
<thead>
<tr>
<th>Name</th>
<th>salary</th>
</tr>
</thead>
<tbody>
<tr>
<td>SMITH</td>
<td>800.00</td>
</tr>
<tr>
<td>ALLEN</td>
<td>1600.00</td>
</tr>
<tr>
<td>WARD</td>
<td>1250.00</td>
</tr>
<tr>
<td>MARTIN</td>
<td>1250.00</td>
</tr>
<tr>
<td>TURNER</td>
<td>1500.00</td>
</tr>
<tr>
<td>ADAMS</td>
<td>1100.00</td>
</tr>
<tr>
<td>JAMES</td>
<td>950.00</td>
</tr>
<tr>
<td>MILLER</td>
<td>1300.00</td>
</tr>
</tbody>
</table>
This section discusses another type of cursor that provides far greater flexibility than the previously discussed static cursors.

### 9.1 REF CURSOR Overview

A cursor variable is a cursor that actually contains a pointer to a query result set. The result set is determined by the execution of the `OPEN FOR` statement using the cursor variable.

A cursor variable is not tied to a single particular query like a static cursor. The same cursor variable may be opened a number of times with `OPEN FOR` statements containing different queries. Each time, a new result set is created from that query and made available via the cursor variable.

REF CURSOR types may be passed as parameters to or from stored procedures and functions. The return type of a function may also be a REF CURSOR type. This provides the capability to modularize the operations on a cursor into separate programs by passing a cursor variable between programs.

### 9.2 Declaring a Cursor Variable

SPL supports the declaration of a cursor variable using both the `SYS_REFCURSOR` built-in data type as well as creating a type of `REF CURSOR` and then declaring a variable of that type. `SYS_REFCURSOR` is a `REF CURSOR` type that allows any result set to be associated with it. This is known as a weakly-typed `REF CURSOR`.

Only the declaration of `SYS_REFCURSOR` and user-defined `REF CURSOR` variables are different. The remaining usage like opening the cursor, selecting into the cursor and closing the cursor is the same across both the cursor types. For the rest of this chapter our examples will primarily be making use of...
the **SYS_REFCURSOR** cursors. All you need to change in the examples to make them work for user defined **REF CURSORs** is the declaration section.

**Note:** *Strongly-typed* **REF CURSORs** require the result set to conform to a declared number and order of fields with compatible data types and can also optionally return a result set.

### 9.2.1 Declaring a **SYS_REFCURSOR** Cursor Variable

The following is the syntax for declaring a **SYS_REFCURSOR** cursor variable:

```sql
<name> SYS_REFCURSOR;
```

*name* is an identifier assigned to the cursor variable.

The following is an example of a **SYS_REFCURSOR** variable declaration.

```sql
DECLARE
    emp_refcur SYS_REFCURSOR;
```

### 9.2.2 Declaring a User Defined **REF CURSOR** Type Variable

You must perform two distinct declaration steps in order to use a user defined **REF CURSOR** variable:

- Create a referenced cursor **TYPE**
- Declare the actual cursor variable based on that **TYPE**

The syntax for creating a user defined **REF CURSOR** type is as follows:

```sql
TYPE <cursor_type_name> IS REF CURSOR [RETURN <return_type>];
```

The following is an example of a cursor variable declaration.

```sql
DECLARE
    TYPE emp_cur_type IS REF CURSOR RETURN emp%ROWTYPE;
    my_rec emp_cur_type;
    ...
```
9.3 Opening a Cursor Variable

Once a cursor variable is declared, it must be opened with an associated SELECT command. The OPEN FOR statement specifies the SELECT command to be used to create the result set.

```sql
OPEN <name> FOR query;
```

`name` is the identifier of a previously declared cursor variable. `query` is a SELECT command that determines the result set when the statement is executed. The value of the cursor variable after the OPEN FOR statement is executed identifies the result set.

In the following example, the result set is a list of employee numbers and names from a selected department. Note that a variable or parameter can be used in the SELECT command anywhere an expression can normally appear. In this case a parameter is used in the equality test for department number.

```sql
CREATE OR REPLACE PROCEDURE emp_by_dept (p_deptno emp.deptno%TYPE)
IS
    emp_refcur SYS_REFCURSOR;
BEGIN
    OPEN emp_refcur FOR SELECT empno, ename FROM emp WHERE deptno = p_deptno;
    ...
END;
```

9.4 Fetching Rows From a Cursor Variable

After a cursor variable is opened, rows may be retrieved from the result set using the FETCH statement. See Fetching Rows From a Cursor for details on using the FETCH statement to retrieve rows from a result set.

In the example below, a FETCH statement has been added to the previous example so now the result set is returned into two variables and then displayed. Note that the cursor attributes used to determine cursor state of static cursors can also be used with cursor variables. See Cursor Attributes for details on cursor attributes.

```sql
CREATE OR REPLACE PROCEDURE emp_by_dept (p_deptno emp.deptno%TYPE)
IS
    emp_refcur SYS_REFCURSOR;
    v_empno emp.empno%TYPE;
    v_ename emp.ename%TYPE;
BEGIN
    OPEN emp_refcur FOR SELECT empno, ename FROM emp WHERE deptno = p_deptno;
    DBMS_OUTPUT.PUT_LINE('EMPNO ENAME');
    DBMS_OUTPUT.PUT_LINE('----- -------');
    LOOP
        FETCH emp_refcur INTO v_empno, v_ename;
        EXIT WHEN emp_refcur%NOTFOUND;
        DBMS_OUTPUT.PUT_LINE(v_empno || ' ' || v_ename);
    END LOOP;
    ...
END;
```

9.3. Opening a Cursor Variable
9.5 Closing a Cursor Variable

Use the `CLOSE` statement described in Closing a Cursor to release the result set.

**Note:** Unlike static cursors, a cursor variable does not have to be closed before it can be re-opened again. The result set from the previous open will be lost.

The example is completed with the addition of the `CLOSE` statement.

```sql
CREATE OR REPLACE PROCEDURE emp_by_dept (  
    p_deptno emp.deptno%TYPE  
) IS  
    emp_refcur SYS_REFCURSOR;  
    v_empno emp.empno%TYPE;  
    v_ename emp.ename%TYPE;  
BEGIN  
    OPEN emp_refcur FOR SELECT empno, ename FROM emp WHERE deptno = p_deptno;  
    DBMS_OUTPUT.PUT_LINE('EMPNO ENAME');  
    DBMS_OUTPUT.PUT_LINE('----- -------');  
    LOOP  
        FETCH emp_refcur INTO v_empno, v_ename;  
        EXIT WHEN emp_refcur%NOTFOUND;  
        DBMS_OUTPUT.PUT_LINE(v_empno || ' ' || v_ename);  
    END LOOP;  
    CLOSE emp_refcur;  
END;
```

The following is the output when this procedure is executed.

```
EXEC emp_by_dept(20)

EMPNO   ENAME  
-----   -------  
7369    SMITH  
7566    JONES  
7788    SCOTT  
7876    ADAMS  
7902    FORD  
```

9.6 Usage Restrictions

The following are restrictions on cursor variable usage.

- Comparison operators cannot be used to test cursor variables for equality, inequality, null, or not null
- Null cannot be assigned to a cursor variable
- The value of a cursor variable cannot be stored in a database column
• Static cursors and cursor variables are not interchangeable. For example, a static cursor cannot be used in an `OPEN FOR` statement.

In addition the following table shows the permitted parameter modes for a cursor variable used as a procedure or function parameter depending upon the operations on the cursor variable within the procedure or function.

<table>
<thead>
<tr>
<th>Operation</th>
<th>IN</th>
<th>IN OUT</th>
<th>OUT</th>
</tr>
</thead>
<tbody>
<tr>
<td>OPEN</td>
<td>No</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>FETCH</td>
<td>Yes</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>CLOSE</td>
<td>Yes</td>
<td>Yes</td>
<td>No</td>
</tr>
</tbody>
</table>

So for example, if a procedure performs all three operations, `OPEN FOR`, `FETCH`, and `CLOSE` on a cursor variable declared as the procedure’s formal parameter, then that parameter must be declared with `IN OUT` mode.
9.7 Examples

The following examples demonstrate cursor variable usage.

9.7.1 Returning a REF CURSOR From a Function

In the following example the cursor variable is opened with a query that selects employees with a given job. Note that the cursor variable is specified in this function’s RETURN statement so the result set is made available to the caller of the function.

```sql
CREATE OR REPLACE FUNCTION emp_by_job (p_job VARCHAR2) RETURN SYS_REFCURSOR IS emp_refcur SYS_REFCURSOR;
BEGIN
  OPEN emp_refcur FOR SELECT empno, ename FROM emp WHERE job = p_job;
  RETURN emp_refcur;
END;
```

This function is invoked in the following anonymous block by assigning the function’s return value to a cursor variable declared in the anonymous block’s declaration section. The result set is fetched using this cursor variable and then it is closed.

```sql
DECLARE
  v_empno emp.empno%TYPE;
  v_ename emp.ename%TYPE;
  v_job emp.job%TYPE := 'SALESMAN';
  v_emp_refcur SYS_REFCURSOR;
BEGIN
  DBMS_OUTPUT.PUT_LINE('EMPLOYEES WITH JOB ' || v_job);
  DBMS_OUTPUT.PUT_LINE('EMPNO ENAME ');
  DBMS_OUTPUT.PUT_LINE('----- ------- ');
  v_emp_refcur := emp_by_job(v_job);
  LOOP
    FETCH v_emp_refcur INTO v_empno, v_ename;
    EXIT WHEN v_emp_refcur%NOTFOUND;
    DBMS_OUTPUT.PUT_LINE(v_empno || ' ' || v_ename);
  END LOOP;
  CLOSE v_emp_refcur;
END;
```

The following is the output when the anonymous block is executed.

```
EMPLOYEES WITH JOB SALESMAN
EMPNO  ENAME
------  -------
7499    ALLEN
7521    WARD
7654    MARTIN
7844    TURNER
```
9.7.2 Modularizing Cursor Operations

The following example illustrates how the various operations on cursor variables can be modularized into separate programs.

The following procedure opens the given cursor variable with a SELECT command that retrieves all rows.

```sql
CREATE OR REPLACE PROCEDURE open_all_emp (p_emp_refcur IN OUT SYS_REFCURSOR)
IS
BEGIN
  OPEN p_emp_refcur FOR SELECT empno, ename FROM emp;
END;
```

This variation opens the given cursor variable with a SELECT command that retrieves all rows, but of a given department.

```sql
CREATE OR REPLACE PROCEDURE open_emp_by_dept (p_emp_refcur IN OUT SYS_REFCURSOR,
                                                p_deptno emp.deptno%TYPE)
IS
BEGIN
  OPEN p_emp_refcur FOR SELECT empno, ename FROM emp
    WHERE deptno = p_deptno;
END;
```

This third variation opens the given cursor variable with a SELECT command that retrieves all rows, but from a different table. Also note that the function’s return value is the opened cursor variable.

```sql
CREATE OR REPLACE FUNCTION open_dept (p_dept_refcur IN OUT SYS_REFCURSOR) RETURN SYS_REFCURSOR
IS
  v_dept_refcur SYS_REFCURSOR;
BEGIN
  v_dept_refcur := p_dept_refcur;
  OPEN v_dept_refcur FOR SELECT deptno, dname FROM dept;
  RETURN v_dept_refcur;
END;
```

This procedure fetches and displays a cursor variable result set consisting of employee number and name.

```sql
CREATE OR REPLACE PROCEDURE fetch_emp (p_emp_refcur IN OUT SYS_REFCURSOR)
IS
  v_empno emp.empno%TYPE;
  v_ename emp.ename%TYPE;
BEGIN
  DBMS_OUTPUT.PUT_LINE('EMPNO ENAME');
  (continues on next page)
```
This procedure fetches and displays a cursor variable result set consisting of department number and name.

```
CREATE OR REPLACE PROCEDURE fetch_dept (
  p_dept_refcur IN SYS_REFCURSOR
) IS
  v_deptno dept.deptno%TYPE;
  v_dname dept.dname%TYPE;
BEGIN
  DBMS_OUTPUT.PUT_LINE('DEPT  DNAME');
  DBMS_OUTPUT.PUT_LINE('----  ---------');
  LOOP
    FETCH p_dept_refcur INTO v_deptno, v_dname;
    EXIT WHEN p_dept_refcur%NOTFOUND;
    DBMS_OUTPUT.PUT_LINE(v_deptno || ' ' || v_dname);
  END LOOP;
END;
```

This procedure closes the given cursor variable.

```
CREATE OR REPLACE PROCEDURE close_refcur (p_refcur IN OUT SYS_REFCURSOR)
IS
BEGIN
  CLOSE p_refcur;
END;
```

The following anonymous block executes all the previously described programs.

```
DECLARE
  gen_refcur SYS_REFCURSOR;
BEGIN
  DBMS_OUTPUT.PUT_LINE('ALL EMPLOYEES');
  open_all_emp(gen_refcur);
  fetch_emp(gen_refcur);
  DBMS_OUTPUT.PUT_LINE('****************');

  DBMS_OUTPUT.PUT_LINE('EMPLOYEES IN DEPT #10');
  open_emp_by_dept(gen_refcur, 10);
  fetch_emp(gen_refcur);
  DBMS_OUTPUT.PUT_LINE('****************');
```

(continues on next page)
```sql
DBMS_OUTPUT.PUT_LINE('DEPARTMENTS');
fetch_dept(open_dept(gen_refcur));
DBMS_OUTPUT.PUT_LINE('*****************');

close_refcur(gen_refcur);
END;
```

The following is the output from the anonymous block.

<table>
<thead>
<tr>
<th>EMPNO</th>
<th>ENAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>7369</td>
<td>SMITH</td>
</tr>
<tr>
<td>7499</td>

</tr>
</tbody>
</table>

***************

9.7. Examples
9.8 Dynamic Queries With REF CURSORs

Advanced Server also supports dynamic queries via the `OPEN FOR USING` statement. A string literal or string variable is supplied in the `OPEN FOR USING` statement to the `SELECT` command.

```
OPEN <name> FOR <dynamic_string>
   [ USING <bind_arg> [, <bind_arg_2> ] ...];
```

`name` is the identifier of a previously declared cursor variable. `dynamic_string` is a string literal or string variable containing a `SELECT` command (without the terminating semi-colon). `bind_arg`, `bind_arg_2`... are bind arguments that are used to pass variables to corresponding placeholders in the `SELECT` command when the cursor variable is opened. The placeholders are identifiers prefixed by a colon character.

The following is an example of a dynamic query using a string literal.

```
CREATE OR REPLACE PROCEDURE dept_query
IS
   emp_refcur SYS_REFCURSOR;
   v_empno emp.empno%TYPE;
   v_ename emp.ename%TYPE;
BEGIN
   OPEN emp_refcur FOR 'SELECT empno, ename FROM emp WHERE deptno = 30' ||
   ' AND sal >= 1500';
   DBMS_OUTPUT.PUT_LINE('EMPNO ENAME');
   DBMS_OUTPUT.PUT_LINE('----- -------');
   LOOP
      FETCH emp_refcur INTO v_empno, v_ename;
      EXIT WHEN emp_refcur%NOTFOUND;
      DBMS_OUTPUT.PUT_LINE(v_empno || ' ' || v_ename);
   END LOOP;
   CLOSE emp_refcur;
END;
```

The following is the output when the procedure is executed.

```
EXEC dept_query;

EMPNO   ENAME
------   -------
7499     ALLEN
7698     BLAKE
7844     TURNER
```

In the next example, the previous query is modified to use bind arguments to pass the query parameters.

```
CREATE OR REPLACE PROCEDURE dept_query (p_deptno emp.deptno%TYPE,
   p_sal emp.sal%TYPE)
IS
   emp_refcur SYS_REFCURSOR;
```
v_empno emp.empno%TYPE;
v_ename emp.ename%TYPE;
BEGIN
OPEN emp_refcur FOR 'SELECT empno, ename FROM emp WHERE deptno = :dept'
|| ' AND sal >= :sal' USING p_deptno, p_sal;
DBMS_OUTPUT.PUT_LINE('EMPNO ENAME');
DBMS_OUTPUT.PUT_LINE('----- -------');
LOOP
FETCH emp_refcur INTO v_empno, v_ename;
EXIT WHEN emp_refcur%NOTFOUND;
DBMS_OUTPUT.PUT_LINE(v_empno || ' ' || v_ename);
END LOOP;
CLOSE emp_refcur;
END;

The following is the resulting output.

EXEC dept_query(30, 1500);
EMPNO  ENAME
-----  -------
7499  ALLEN
7698  BLAKE
7844  TURNER

Finally, a string variable is used to pass the SELECT providing the most flexibility.

CREATE OR REPLACE PROCEDURE dept_query ( p_deptno emp.deptno%TYPE,
                                         p_sal emp.sal%TYPE )
IS
emp_refcur SYS_REFCURSOR;
v_empno emp.empno%TYPE;
v_ename emp.ename%TYPE;
p_query_string VARCHAR2(100);
BEGIN
p_query_string := 'SELECT empno, ename FROM emp WHERE ' ||
'deptno = :dept AND sal >= :sal';
OPEN emp_refcur FOR p_query_string USING p_deptno, p_sal;
DBMS_OUTPUT.PUT_LINE('EMPNO ENAME');
DBMS_OUTPUT.PUT_LINE('----- -------');
LOOP
FETCH emp_refcur INTO v_empno, v_ename;
EXIT WHEN emp_refcur%NOTFOUND;
DBMS_OUTPUT.PUT_LINE(v_empno || ' ' || v_ename);
END LOOP;
CLOSE emp_refcur;
END;
EXEC dept_query(20, 1500);

</tbody>
</table>
A collection is a set of ordered data items with the same data type. Generally, the data item is a scalar field, but may also be a user-defined type such as a record type or an object type as long as the structure and the data types that comprise each field of the user-defined type are the same for each element in the set. Each particular data item in the set is referenced by using subscript notation within a pair of parentheses.

Note: Multilevel collections (that is, where the data item of a collection is another collection) are not supported.

The most commonly known type of collection is an array. In Advanced Server, the supported collection types are associative arrays (formerly called index-by-tables in Oracle), nested tables, and varrays.

The general steps for using a collection are the following:

- A collection of the desired type must be defined. This can be done in the declaration section of an SPL program, which results in a local type that is accessible only within that program. For nested table and varray types this can also be done using the CREATE TYPE command, which creates a persistent, standalone type that can be referenced by any SPL program in the database.

- Variables of the collection type are declared. The collection associated with the declared variable is said to be uninitialized at this point if there is no value assignment made as part of the variable declaration.

- Uninitialized collections of nested tables and varrays are null. A null collection does not yet exist. Generally, a COLLECTION_IS_NULL exception is thrown if a collection method is invoked on a null collection.

- Uninitialized collections of associative arrays exist, but have no elements. An existing collection with no elements is called an empty collection.
• To initialize a null collection, you must either make it an empty collection or assign a non-null value to it. Generally, a null collection is initialized by using its constructor.

• To add elements to an empty associative array, you can simply assign values to its keys. For nested tables and varrays, generally its constructor is used to assign initial values to the nested table or varray. For nested tables and varrays, the EXTEND method is then used to grow the collection beyond its initial size established by the constructor.

The specific process for each collection type is described in the following sections.

10.1 Associative Arrays

An associative array is a type of collection that associates a unique key with a value. The key does not have to be numeric, but can be character data as well.

An associative array has the following characteristics:

• An associative array type must be defined after which array variables can be declared of that array type. Data manipulation occurs using the array variable.

• When an array variable is declared, the associative array is created, but it is empty - just start assigning values to key values.

• The key can be any negative integer, positive integer, or zero if INDEX BY BINARY_INTEGER or PLS_INTEGER is specified.

• The key can be character data if INDEX BY VARCHAR2 is specified.

• There is no pre-defined limit on the number of elements in the array - it grows dynamically as elements are added.

• The array can be sparse - there may be gaps in the assignment of values to keys.

• An attempt to reference an array element that has not been assigned a value will result in an exception.

The TYPE IS TABLE OF ... INDEX BY statement is used to define an associative array type.

```
TYPE <assoctype> IS TABLE OF { <datatype> | <rectype> | <objtype> } 
INDEX BY { BINARY_INTEGER | PLS_INTEGER | VARCHAR2(<n>) };
```

assoctype is an identifier assigned to the array type. datatype is a scalar data type such as VARCHAR2 or NUMBER. rectype is a previously defined record type. objtype is a previously defined object type. n is the maximum length of a character key.

In order to make use of the array, a variable must be declared with that array type. The following is the syntax for declaring an array variable.

```
<array assoctype>
```

array is an identifier assigned to the associative array. assoctype is the identifier of a previously defined array type.

An element of the array is referenced using the following syntax.

10.1. Associative Arrays
array is the identifier of a previously declared array. \( n \) is the key value, type-compatible with the data type given in the \texttt{INDEX BY} clause. If the array type of \texttt{array} is defined from a record type or object type, then \texttt{[.field \]} must reference an individual field within the record type or attribute within the object type from which the array type is defined. Alternatively, the entire record can be referenced by omitting \texttt{[.field \]}.

The following example reads the first ten employee names from the \texttt{emp} table, stores them in an array, then displays the results from the array.

```sql
DECLARE
    TYPE emp_arr_typ IS TABLE OF VARCHAR2(10) INDEX BY BINARY_INTEGER;
    emp_arr emp_arr_typ;
    CURSOR emp_cur IS SELECT ename FROM emp WHERE ROWNUM <= 10;
    i INTEGER := 0;
BEGIN
    FOR r_emp IN emp_cur LOOP
        i := i + 1;
        emp_arr(i) := r_emp.ename;
    END LOOP;
    FOR j IN 1..10 LOOP
        DBMS_OUTPUT.PUT_LINE(emp_arr(j));
    END LOOP;
END;
```

The above example produces the following output:

```
SMITH
ALLEN
WARD
JONES
MARTIN
BLAKE
CLARK
SCOTT
KING
TURNER
```

The previous example is now modified to use a record type in the array definition.

```sql
DECLARE
    TYPE emp_rec_typ IS RECORD (
        empno NUMBER(4),
        ename VARCHAR2(10)
    );
    TYPE emp_arr_typ IS TABLE OF emp_rec_typ INDEX BY BINARY_INTEGER;
    emp_arr emp_arr_typ;
    CURSOR emp_cur IS SELECT empno, ename FROM emp WHERE ROWNUM <= 10;
    i INTEGER := 0;
BEGIN
    DBMS_OUTPUT.PUT_LINE('EMPNO ENAME');
    (continues on next page)
```
The following is the output from this anonymous block.

<table>
<thead>
<tr>
<th>EMPNO</th>
<th>ENAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>------</td>
<td>-------</td>
</tr>
<tr>
<td>7369</td>
<td>SMITH</td>
</tr>
<tr>
<td>7499</td>
<td>ALLEN</td>
</tr>
<tr>
<td>7521</td>
<td>WARD</td>
</tr>
<tr>
<td>7566</td>
<td>JONES</td>
</tr>
<tr>
<td>7654</td>
<td>MARTIN</td>
</tr>
<tr>
<td>7698</td>
<td>BLAKE</td>
</tr>
<tr>
<td>7782</td>
<td>CLARK</td>
</tr>
<tr>
<td>7788</td>
<td>SCOTT</td>
</tr>
<tr>
<td>7839</td>
<td>KING</td>
</tr>
<tr>
<td>7844</td>
<td>TURNER</td>
</tr>
</tbody>
</table>

The EMPNO%ROWTYPE attribute could be used to define emp_arr_typ instead of using the emp_rec_typ record type as shown in the following.

```sql
DECLARE
    TYPE emp_arr_typ IS TABLE OF emp%ROWTYPE INDEX BY BINARY_INTEGER;
    emp_arr emp_arr_typ;
    CURSOR emp_cur IS SELECT empno, ename FROM emp WHERE ROWNUM <= 10;
    i INTEGER := 0;
BEGIN
    DBMS_OUTPUT.PUT_LINE('EMPNO ENAME');
    DBMS_OUTPUT.PUT_LINE('----- -------');
    FOR r_emp IN emp_cur LOOP
        i := i + 1;
        emp_arr(i).empno := r_emp.empno;
        emp_arr(i).ename := r_emp.ename;
    END LOOP;
    FOR j IN 1..10 LOOP
        DBMS_OUTPUT.PUT_LINE(emp_arr(j).empno || ' ' || emp_arr(j).ename);
    END LOOP;
END;
```

The results are the same as in the prior example.

Instead of assigning each field of the record individually, a record level assignment can be made from `r_emp`...
The key of an associative array can be character data as shown in the following example.

DECLARE
    TYPE job_arr_typ IS TABLE OF NUMBER INDEX BY VARCHAR2(9);
    job_arr   job_arr_typ;
BEGIN
    job_arr('ANALYST') := 100;
    job_arr('CLERK') := 200;
    job_arr('MANAGER') := 300;
    job_arr('SALESMAN') := 400;
    job_arr('PRESIDENT') := 500;
    DBMS_OUTPUT.PUT_LINE('ANALYST : '  || job_arr('ANALYST'));
    DBMS_OUTPUT.PUT_LINE('CLERK : '  || job_arr('CLERK'));
    DBMS_OUTPUT.PUT_LINE('MANAGER : '  || job_arr('MANAGER'));
    DBMS_OUTPUT.PUT_LINE('SALESMAN : '  || job_arr('SALESMAN'));
    DBMS_OUTPUT.PUT_LINE('PRESIDENT : '  || job_arr('PRESIDENT'));
END;

ANALYST : 100
CLERK : 200
MANAGER : 300
SALESMAN : 400
PRESIDENT: 500
10.2 Nested Tables

A nested table is a type of collection that associates a positive integer with a value. A nested table has the following characteristics:

- A nested table type must be defined after which nested table variables can be declared of that nested table type. Data manipulation occurs using the nested table variable, or simply, “table” for short.

- When a nested table variable is declared, the nested table initially does not exist (it is a null collection). The null table must be initialized with a constructor. You can also initialize the table by using an assignment statement where the right-hand side of the assignment is an initialized table of the same type. **Note:** Initialization of a nested table is mandatory in Oracle, but optional in SPL.

- The key is a positive integer.

- The constructor establishes the number of elements in the table. The EXTEND method adds additional elements to the table. See Collection Methods for information on collection methods. **Note:** Usage of the constructor to establish the number of elements in the table and usage of the EXTEND method to add additional elements to the table are mandatory in Oracle, but optional in SPL.

- The table can be sparse - there may be gaps in the assignment of values to keys.

- An attempt to reference a table element beyond its initialized or extended size will result in a SUBSCRIPT_BEYOND_COUNT exception.

The **TYPE IS TABLE** statement is used to define a nested table type within the declaration section of an SPL program.

```plaintext
TYPE <tbltype> IS TABLE OF { <datatype> | <rectype> | <objtype> };
```

`tbltype` is an identifier assigned to the nested table type. `datatype` is a scalar data type such as VARCHAR2 or NUMBER. `rectype` is a previously defined record type. `objtype` is a previously defined object type.

**Note:** You can use the CREATE TYPE command to define a nested table type that is available to all SPL programs in the database. See the Database Compatibility for Oracle Developers Reference Guide for more information about the CREATE TYPE command.

In order to make use of the table, a variable must be declared of that nested table type. The following is the syntax for declaring a table variable.

```plaintext
<table tbltype>
```

table is an identifier assigned to the nested table. `tbltype` is the identifier of a previously defined nested table type.

A nested table is initialized using the nested table type’s constructor.

```plaintext
<tbltype> ([ { <expr1> | NULL } [, { <expr2> | NULL } ] [, ...] ])
```
tbltype is the identifier of the nested table type’s constructor, which has the same name as the nested table type. expr1, expr2, ... are expressions that are type-compatible with the element type of the table. If NULL is specified, the corresponding element is set to null. If the parameter list is empty, then an empty nested table is returned, which means there are no elements in the table. If the table is defined from an object type, then exprn must return an object of that object type. The object can be the return value of a function or the object type’s constructor, or the object can be an element of another nested table of the same type.

If a collection method other than EXISTS is applied to an uninitialized nested table, a COLLECTION_IS_NULL exception is thrown. See Collection Methods for information on collection methods.

The following is an example of a constructor for a nested table:

```
DECLARE
    TYPE nested_typ IS TABLE OF CHAR(1);
    v_nested nested_typ := nested_typ('A','B');
```

An element of the table is referenced using the following syntax.

```
<table>(<n>)[<.element> ]
```

table is the identifier of a previously declared table. n is a positive integer. If the table type of table is defined from a record type or object type, then [.element ] must reference an individual field within the record type or attribute within the object type from which the nested table type is defined. Alternatively, the entire record or object can be referenced by omitting [.element ].

The following is an example of a nested table where it is known that there will be four elements.

```
DECLARE
    TYPE dname_tbl_typ IS TABLE OF VARCHAR2(14);
    dname_tbl dname_tbl_typ;
    CURSOR dept_cur IS SELECT dname FROM dept ORDER BY dname;
    i INTEGER := 0;
BEGIN
    dname_tbl := dname_tbl_typ(NULL, NULL, NULL, NULL);
    FOR r_dept IN dept_cur LOOP
        i := i + 1;
        dname_tbl(i) := r_dept.dname;
    END LOOP;
    DBMS_OUTPUT.PUT_LINE('DNAME');
    DBMS_OUTPUT.PUT_LINE('----------');
    FOR j IN 1..i LOOP
        DBMS_OUTPUT.PUT_LINE(dname_tbl(j));
    END LOOP;
END;
```

The above example produces the following output:

```
DNAME
----------
ACCOUNTING
```

(continues on next page)
The following example reads the first ten employee names from the emp table, stores them in a nested table, then displays the results from the table. The SPL code is written to assume that the number of employees to be returned is not known beforehand.

```sql
DECLARE
    TYPE emp_rec_typ IS RECORD (
        empno NUMBER(4),
        ename VARCHAR2(10)
    );
    TYPE emp_tbl_typ IS TABLE OF emp_rec_typ;
    emp_tbl emp_tbl_typ;
    CURSOR emp_cur IS SELECT empno, ename FROM emp WHERE ROWNUM <= 10;
    i INTEGER := 0;
BEGIN
    emp_tbl := emp_tbl_typ();
    DBMS_OUTPUT.PUT_LINE('EMPNO ENAME');
    DBMS_OUTPUT.PUT_LINE('----- -------');
    FOR r_emp IN emp_cur LOOP
        i := i + 1;
        emp_tbl.EXTEND;
        emp_tbl(i) := r_emp;
    END LOOP;
    FOR j IN 1..10 LOOP
        DBMS_OUTPUT.PUT_LINE(emp_tbl(j).empno || ' ' || emp_tbl(j).ename);
    END LOOP;
END;
```

Note the creation of an empty table with the constructor emp_tbl_typ() as the first statement in the executable section of the anonymous block. The EXTEND collection method is then used to add an element to the table for each employee returned from the result set. See Extend for information on EXTEND.

The following is the output.

<table>
<thead>
<tr>
<th>EMPNO</th>
<th>ENAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>7369</td>
<td>SMITH</td>
</tr>
<tr>
<td>7499</td>
<td>ALLEN</td>
</tr>
<tr>
<td>7521</td>
<td>WARD</td>
</tr>
<tr>
<td>7566</td>
<td>JONES</td>
</tr>
<tr>
<td>7654</td>
<td>MARTIN</td>
</tr>
<tr>
<td>7698</td>
<td>BLAKE</td>
</tr>
<tr>
<td>7782</td>
<td>CLARK</td>
</tr>
<tr>
<td>7788</td>
<td>SCOTT</td>
</tr>
<tr>
<td>7839</td>
<td>KING</td>
</tr>
<tr>
<td>7844</td>
<td>TURNER</td>
</tr>
</tbody>
</table>

The following example shows how a nested table of an object type can be used. First, an object type is
created with attributes for the department name and location.

```
CREATE TYPE dept_obj_typ AS OBJECT {
    dname VARCHAR2(14),
    loc VARCHAR2(13)
};
```

The following anonymous block defines a nested table type whose element consists of the `dept_obj_typ` object type. A nested table variable is declared, initialized, and then populated from the `dept` table. Finally, the elements from the nested table are displayed.

```
DECLARE
    TYPE dept_tbl_typ IS TABLE OF dept_obj_typ;
    dept_tbl dept_tbl_typ;
    CURSOR dept_cur IS SELECT dname, loc FROM dept ORDER BY dname;
    i INTEGER := 0;
BEGIN
    dept_tbl := dept_tbl_typ(
        dept_obj_typ(NULL,NULL),
        dept_obj_typ(NULL,NULL),
        dept_obj_typ(NULL,NULL),
        dept_obj_typ(NULL,NULL)
    );
    FOR r_dept IN dept_cur LOOP
        i := i + 1;
        dept_tbl(i).dname := r_dept.dname;
        dept_tbl(i).loc := r_dept.loc;
    END LOOP;
    DBMS_OUTPUT.PUT_LINE('DNAME LOC');
    DBMS_OUTPUT.PUT_LINE('---------- ----------');
    FOR j IN 1..i LOOP
        DBMS_OUTPUT.PUT_LINE(RPAD(dept_tbl(j).dname,14) || ' ' ||
                             dept_tbl(j).loc);
    END LOOP;
END;
```

The parameters comprising the nested table’s constructor, `dept_tbl_typ`, are calls to the object type’s constructor `dept_obj_typ`. The following is the output from the anonymous block:

```
<table>
<thead>
<tr>
<th>DNAME</th>
<th>LOC</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACCOUNTING</td>
<td>NEW YORK</td>
</tr>
<tr>
<td>OPERATIONS</td>
<td>BOSTON</td>
</tr>
<tr>
<td>RESEARCH</td>
<td>DALLAS</td>
</tr>
<tr>
<td>SALES</td>
<td>CHICAGO</td>
</tr>
</tbody>
</table>
```

10.2. Nested Tables
10.3 Varrays

A **varray** or **variable-size array** is a type of collection that associates a positive integer with a value. In many respects, it is similar to a nested table.

A varray has the following characteristics:

- A **varray type** must be defined along with a maximum size limit. After the varray type is defined, **varray variables** can be declared of that varray type. Data manipulation occurs using the varray variable, or simply, “varray” for short. The number of elements in the varray cannot exceed the maximum size limit established in the varray type definition.

- When a varray variable is declared, the varray initially does not exist (it is a null collection). The null varray must be initialized with a **constructor**. You can also initialize the varray by using an assignment statement where the right-hand side of the assignment is an initialized varray of the same type.

- The key is a positive integer.

- The constructor establishes the number of elements in the varray, which must not exceed the maximum size limit. The **EXTEND** method can add additional elements to the varray up to the maximum size limit. See **Collection Methods** for information on collection methods.

- Unlike a nested table, a varray cannot be sparse - there are no gaps in the assignment of values to keys.

- An attempt to reference a varray element beyond its initialized or extended size, but within the maximum size limit will result in a **SUBSCRIPT_BEYOND_COUNT** exception.

- An attempt to reference a varray element beyond the maximum size limit or extend a varray beyond the maximum size limit will result in a **SUBSCRIPT_OUTSIDE_LIMIT** exception.

The **TYPE IS VARRAY** statement is used to define a varray type within the declaration section of an SPL program.

```sql
TYPE <varraytype> IS { VARRAY | VARYING ARRAY }(<maxsize>)
   OF { <datatype> | <objtype> };
```

- **varraytype** is an identifier assigned to the varray type. **datatype** is a scalar data type such as VARCHAR2 or NUMBER. **maxsize** is the maximum number of elements permitted in varrays of that type. **objtype** is a previously defined object type.

The **CREATE TYPE** command can be used to define a varray type that is available to all SPL programs in the database. In order to make use of the varray, a **variable** must be declared of that varray type. The following is the syntax for declaring a varray variable:

```sql
<varray vararraytype>
```

- **varray** is an identifier assigned to the varray. **vararraytype** is the identifier of a previously defined varray type.

A varray is initialized using the varray type's constructor.

```sql
<varraytype> ([ { <expr1> | NULL } [, { <expr2> | NULL } ] ...
```

10.3. Varrays 164
varraytype is the identifier of the varray type’s constructor, which has the same name as the varray type. expr1, expr2, ... are expressions that are type-compatible with the element type of the varray. If NULL is specified, the corresponding element is set to null. If the parameter list is empty, then an empty varray is returned, which means there are no elements in the varray. If the varray is defined from an object type, then exprn must return an object of that object type. The object can be the return value of a function or the return value of the object type’s constructor. The object can also be an element of another varray of the same varray type.

If a collection method other than EXISTS is applied to an uninitialized varray, a COLLECTION_IS_NULL exception is thrown. See Collection Methods for information on collection methods.

The following is an example of a constructor for a varray:

```
DECLARE
    TYPE varray_typ IS VARRAY(2) OF CHAR(1);
    v_varray varray_typ := varray_typ('A','B');
```

An element of the varray is referenced using the following syntax.

```
<vvarray>(<n>)[<.element> ]
```

vvarray is the identifier of a previously declared varray. n is a positive integer. If the varray type of vvarray is defined from an object type, then [.element ] must reference an attribute within the object type from which the varray type is defined. Alternatively, the entire object can be referenced by omitting [.element ].

The following is an example of a varray where it is known that there will be four elements.

```
DECLARE
    TYPE dname_varray_typ IS VARRAY(4) OF VARCHAR2(14);
    dname_varray dname_varray_typ;
    CURSOR dept_cur IS SELECT dname FROM dept ORDER BY dname;
    i INTEGER := 0;
BEGIN
    dname_varray := dname_varray_typ(NULL, NULL, NULL, NULL);
    FOR r_dept IN dept_cur LOOP
        i := i + 1;
        dname_varray(i) := r_dept.dname;
    END LOOP;
    DBMS_OUTPUT.PUT_LINE('DNAME');
    DBMS_OUTPUT.PUT_LINE('----------');
    FOR j IN 1..i LOOP
        DBMS_OUTPUT.PUT_LINE(dname_varray(j));
    END LOOP;
END;
```

The above example produces the following output:

```
DNAME
----------
ACCOUNTING
OPERATIONS
```

(continues on next page)
CHAPTER 11

Collection Methods

Collection methods are functions and procedures that provide useful information about a collection that can aid in the processing of data in the collection. The following sections discuss the collection methods supported by Advanced Server.

11.1 COUNT

COUNT is a method that returns the number of elements in a collection. The syntax for using COUNT is as follows:

```
<collection>.COUNT
```

collection is the name of a collection.

For a varray, COUNT always equals LAST.

The following example shows that an associative array can be sparsely populated (i.e., there are “gaps” in the sequence of assigned elements). COUNT includes only the elements that have been assigned a value.

```java
DECLARE
    TYPE sparse_arr_typ IS TABLE OF NUMBER INDEX BY BINARY_INTEGER;
    sparse_arr sparse_arr_typ;
BEGIN
    sparse_arr(-100) := -100;
    sparse_arr(-10)  := -10;
    sparse_arr(0)    := 0;
    sparse_arr(10)   := 10;
    sparse_arr(100)  := 100;
    DBMS_OUTPUT.PUT_LINE('COUNT: ' || sparse_arr.COUNT);
END;
```
The following output shows that there are five populated elements included in COUNT.

| COUNT: 5 |

### 11.2 DELETE

The DELETE method deletes entries from a collection. You can call the DELETE method in three different ways.

Use the first form of the DELETE method to remove all entries from a collection:

```sql
<collection>.DELETE
```

Use the second form of the DELETE method to remove the specified entry from a collection:

```sql
<collection>.DELETE(<subscript>)
```

Use the third form of the DELETE method to remove the entries that are within the range specified by `first_subscript` and `last_subscript` (including the entries for the `first_subscript` and the `last_subscript`) from a collection.

```sql
<collection>.DELETE(<first_subscript>, <last_subscript>)
```

If `first_subscript` and `last_subscript` refer to non-existent elements, elements that are in the range between the specified subscripts are deleted. If `first_subscript` is greater than `last_subscript`, or if you specify a value of NULL for one of the arguments, DELETE has no effect.

Note that when you delete an entry, the subscript remains in the collection; you can re-use the subscript with an alternate entry. If you specify a subscript that does not exist in the call to the DELETE method, DELETE does not raise an exception.

The following example demonstrates using the DELETE method to remove the element with subscript 0 from the collection:

```sql
DECLARE
    TYPE sparse_arr_typ IS TABLE OF NUMBER INDEX BY BINARY_INTEGER;
    sparse_arr sparse_arr_typ;
    v_results VARCHAR2(50);
    v_sub NUMBER;
BEGIN
    sparse_arr(-100) := -100;
    sparse_arr(-10) := -10;
    sparse_arr(0) := 0;
    sparse_arr(10) := 10;
    sparse_arr(100) := 100;
    DBMS_OUTPUT.PUT_LINE('COUNT: ' || sparse_arr.COUNT);
    sparse_arr.DELETE(0);
    DBMS_OUTPUT.PUT_LINE('COUNT: ' || sparse_arr.COUNT);
    v_sub := sparse_arr.FIRST;
    WHILE v_sub IS NOT NULL LOOP
(continues on next page)
IF sparse_arr(v_sub) IS NULL THEN
    v_results := v_results || 'NULL '; 
ELSE
    v_results := v_results || sparse_arr(v_sub) || ' '; 
END IF;

v_sub := sparse_arr.NEXT(v_sub);
END LOOP;

DBMS_OUTPUT.PUT_LINE('Results: ' || v_results);

COUNT: 5
COUNT: 4
Results: -100 -10 10 100

COUNT indicates that before the DELETE method, there were 5 elements in the collection; after the DELETE method was invoked, the collection contains 4 elements.

11.3 EXISTS

The EXISTS method verifies that a subscript exists within a collection. EXISTS returns TRUE if the subscript exists; if the subscript does not exist, EXISTS returns FALSE. The method takes a single argument; the subscript that you are testing for. The syntax is:

<collection>.EXISTS(<subscript>)

collection is the name of the collection.

subscript is the value that you are testing for. If you specify a value of NULL, EXISTS returns false.

The following example verifies that subscript number 10 exists within the associative array:

DECLARE
    TYPE sparse_arr_typ IS TABLE OF NUMBER INDEX BY BINARY_INTEGER;
    sparse_arr sparse_arr_typ;
BEGIN
    sparse_arr(-100) := -100;
    sparse_arr(-10) := -10;
    sparse_arr(0) := 0;
    sparse_arr(10) := 10;
    sparse_arr(100) := 100;
    DBMS_OUTPUT.PUT_LINE('The index exists: ' || CASE WHEN sparse_arr.exists(10) = TRUE THEN 'true' ELSE 'false' END);
END;

The index exists: true

Some collection methods raise an exception if you call them with a subscript that does not exist within the specified collection. Rather than raising an error, the EXISTS method returns a value of FALSE.
11.4 EXTEND

The EXTEND method increases the size of a collection. There are three variations of the EXTEND method. The first variation appends a single NULL element to a collection; the syntax for the first variation is:

```sql
<collection>.EXTEND
```

collection is the name of a collection.

The following example demonstrates using the EXTEND method to append a single, null element to a collection:

```sql
DECLARE
   TYPE sparse_arr_typ IS TABLE OF NUMBER;
   sparse_arr sparse_arr_typ := sparse_arr_typ(-100,-10,0,10,100);
   v_results VARCHAR2(50);
BEGIN
   DBMS_OUTPUT.PUT_LINE('COUNT: ' || sparse_arr.COUNT);
   sparse_arr.EXTEND;
   DBMS_OUTPUT.PUT_LINE('COUNT: ' || sparse_arr.COUNT);
   FOR i IN sparse_arr.FIRST .. sparse_arr.LAST LOOP
      IF sparse_arr(i) IS NULL THEN
         v_results := v_results || 'NULL ';
      ELSE
         v_results := v_results || sparse_arr(i) || ' ';
      END IF;
   END LOOP;
   DBMS_OUTPUT.PUT_LINE('Results: ' || v_results);
END;
COUNT: 5
COUNT: 6
Results: -100 -10 0 10 100 NULL
```

COUNT indicates that before the EXTEND method, there were 5 elements in the collection; after the EXTEND method was invoked, the collection contains 6 elements.

The second variation of the EXTEND method appends a specified number of elements to the end of a collection.

```sql
<collection>.EXTEND(<count>)
```

collection is the name of a collection.

count is the number of null elements added to the end of the collection.

The following example demonstrates using the EXTEND method to append multiple null elements to a collection:

```sql
DECLARE
   TYPE sparse_arr_typ IS TABLE OF NUMBER;
   sparse_arr sparse_arr_typ := sparse_arr_typ(-100,-10,0,10,100);
   v_results VARCHAR2(50);
BEGIN
   DBMS_OUTPUT.PUT_LINE('COUNT: ' || sparse_arr.COUNT);
   sparse_arr.EXTEND(5);
   DBMS_OUTPUT.PUT_LINE('COUNT: ' || sparse_arr.COUNT);
   FOR i IN sparse_arr.FIRST .. sparse_arr.LAST LOOP
      IF sparse_arr(i) IS NULL THEN
         v_results := v_results || 'NULL ';
      ELSE
         v_results := v_results || sparse_arr(i) || ' ';
      END IF;
   END LOOP;
   DBMS_OUTPUT.PUT_LINE('Results: ' || v_results);
END;
COUNT: 5
COUNT: 10
Results: -100 -10 0 10 100 NULL NULL NULL NULL
```
COUNT indicates that before the EXTEND method, there were 5 elements in the collection; after the EXTEND method was invoked, the collection contains 8 elements.

The third variation of the EXTEND method appends a specified number of copies of a particular element to the end of a collection.

\[
\text{<collection>}.\text{EXTEND(<count>, <index_number>)}
\]

collection is the name of a collection.

count is the number of elements added to the end of the collection.

index_number is the subscript of the element that is being copied to the collection.

The following example demonstrates using the EXTEND method to append multiple copies of the second element to the collection:

```sql
DECLARE
    TYPE sparse_arr_typ IS TABLE OF NUMBER;
    sparse_arr sparse_arr_typ := sparse_arr_typ(-100,-10,0,10,100);
    v_results VARCHAR2(50);
BEGIN
    DBMS_OUTPUT.PUT_LINE('COUNT: ' || sparse_arr.COUNT);
    sparse_arr.EXTEND(3);
    DBMS_OUTPUT.PUT_LINE('COUNT: ' || sparse_arr.COUNT);
    FOR i IN sparse_arr.FIRST .. sparse_arr.LAST LOOP
        IF sparse_arr(i) IS NULL THEN
            v_results := v_results || 'NULL ';
        ELSE
            v_results := v_results || sparse_arr(i) || ' ';
        END IF;
    END LOOP;
    DBMS_OUTPUT.PUT_LINE('Results: ' || v_results);
END;
COUNT: 5
COUNT: 8
Results: -100 -10 0 10 100 NULL NULL NULL
```
COUNT indicates that before the EXTEND method, there were 5 elements in the collection; after the EXTEND method was invoked, the collection contains 8 elements.

Note: The EXTEND method cannot be used on a null or empty collection.

### 11.5 FIRST

FIRST is a method that returns the subscript of the first element in a collection. The syntax for using FIRST is as follows:

```
<collection>.FIRST
```

collection is the name of a collection.

The following example displays the first element of the associative array.

```
DECLARE
  TYPE sparse_arr_typ IS TABLE OF NUMBER INDEX BY BINARY_INTEGER;
  sparse_arr sparse_arr_typ;
BEGIN
  sparse_arr(-100) := -100;
  sparse_arr(-10) := -10;
  sparse_arr(0) := 0;
  sparse_arr(10) := 10;
  sparse_arr(100) := 100;
  DBMS_OUTPUT.PUT_LINE('FIRST element: ' || sparse_arr(sparse_arr.FIRST));
END;
```

FIRST element: -100

### 11.6 LAST

LAST is a method that returns the subscript of the last element in a collection. The syntax for using LAST is as follows:

```
<collection>.LAST
```

collection is the name of a collection.

The following example displays the last element of the associative array.

```
```
DECLARE
    TYPE sparse_arr_typ IS TABLE OF NUMBER INDEX BY BINARY_INTEGER;
    sparse_arr sparse_arr_typ;
BEGIN
    sparse_arr(-100) := -100;
    sparse_arr(-10)  := -10;
    sparse_arr(0)   := 0;
    sparse_arr(10)  := 10;
    sparse_arr(100) := 100;
    DBMS_OUTPUT.PUT_LINE('LAST element: ' || sparse_arr(sparse_arr.LAST));
END;

LAST element: 100

11.7 LIMIT

LIMIT is a method that returns the maximum number of elements permitted in a collection. LIMIT is applicable only to varrays. The syntax for using LIMIT is as follows:

<collection>.LIMIT

collection is the name of a collection.

For an initialized varray, LIMIT returns the maximum size limit determined by the varray type definition. If the varray is uninitialized (that is, it is a null varray), an exception is thrown.

For an associative array or an initialized nested table, LIMIT returns NULL. If the nested table is uninitialized (that is, it is a null nested table), an exception is thrown.

11.8 NEXT

NEXT is a method that returns the subscript that follows a specified subscript. The method takes a single argument; the subscript that you are testing for.

<collection>.NEXT(<subscript>)

collection is the name of the collection.

If the specified subscript is less than the first subscript in the collection, the function returns the first subscript. If the subscript does not have a successor, NEXT returns NULL. If you specify a NULL subscript, PRIOR does not return a value.

The following example demonstrates using NEXT to return the subscript that follows subscript 10 in the associative array, sparse_arr:

DECLARE
    TYPE sparse_arr_typ IS TABLE OF NUMBER INDEX BY BINARY_INTEGER;
    sparse_arr sparse_arr_typ;
(continues on next page)
BEGIN
    sparse_arr(-100) := -100;
    sparse_arr(-10)  := -10;
    sparse_arr(0)    := 0;
    sparse_arr(10)   := 10;
    sparse_arr(100)  := 100;
    DBMS_OUTPUT.PUT_LINE('NEXT element: ' || sparse_arr.next(10));
END;
NEXT element: 100

11.9 PRIOR

The PRIOR method returns the subscript that precedes a specified subscript in a collection. The method takes a single argument; the subscript that you are testing for. The syntax is:

\[ \text{<collection>}.\text{PRIOR(<subscript>)} \]

collection is the name of the collection.

If the subscript specified does not have a predecessor, PRIOR returns NULL. If the specified subscript is greater than the last subscript in the collection, the method returns the last subscript. If you specify a NULL subscript, PRIOR does not return a value.

The following example returns the subscript that precedes subscript 100 in the associative array, sparse_arr:

DECLARE
    TYPE sparse_arr_typ IS TABLE OF NUMBER INDEX BY BINARY_INTEGER;
    sparse_arr sparse_arr_typ;
BEGIN
    sparse_arr(-100) := -100;
    sparse_arr(-10)  := -10;
    sparse_arr(0)    := 0;
    sparse_arr(10)   := 10;
    sparse_arr(100)  := 100;
    DBMS_OUTPUT.PUT_LINE('PRIOR element: ' || sparse_arr.prior(100));
END;
PRIOR element: 10
11.10 TRIM

The TRIM method removes an element or elements from the end of a collection. The syntax for the TRIM method is:

```sql
<collection>.TRIM[<count>]
```

collection is the name of a collection.

count is the number of elements removed from the end of the collection. Advanced Server will return an error if count is less than 0 or greater than the number of elements in the collection.

The following example demonstrates using the TRIM method to remove an element from the end of a collection:

```sql
DECLARE
  TYPE sparse_arr_typ IS TABLE OF NUMBER;
  sparse_arr sparse_arr_typ := sparse_arr_typ(-100,-10,0,10,100);
BEGIN
  DBMS_OUTPUT.PUT_LINE('COUNT: ' || sparse_arr.COUNT);
  sparse_arr.TRIM;
  DBMS_OUTPUT.PUT_LINE('COUNT: ' || sparse_arr.COUNT);
END;
COUNT: 5
COUNT: 4
```

COUNT indicates that before the TRIM method, there were 5 elements in the collection; after the TRIM method was invoked, the collection contains 4 elements.

You can also specify the number of elements to remove from the end of the collection with the TRIM method:

```sql
DECLARE
  TYPE sparse_arr_typ IS TABLE OF NUMBER;
  sparse_arr sparse_arr_typ := sparse_arr_typ(-100,-10,0,10,100);
  v_results VARCHAR2(50);
BEGIN
  DBMS_OUTPUT.PUT_LINE('COUNT: ' || sparse_arr.COUNT);
  sparse_arr.TRIM(2);
  DBMS_OUTPUT.PUT_LINE('COUNT: ' || sparse_arr.COUNT);
  FOR i IN sparse_arr.FIRST .. sparse_arr.LAST LOOP
    IF sparse_arr(i) IS NULL THEN
      v_results := v_results || 'NULL ';
    ELSE
      v_results := v_results || sparse_arr(i) || ' ';  
    END IF;
  END LOOP;
  DBMS_OUTPUT.PUT_LINE('Results: ' || v_results);
END;
COUNT: 5
COUNT: 3
Results: -100 -10 0
```
`COUNT` indicates that before the `TRIM` method, there were 5 elements in the collection; after the `TRIM` method was invoked, the collection contains 3 elements.
CHAPTER 12

Working with Collections

Collection operators allow you to transform, query and manipulate the contents of a collection.

12.1 TABLE()

Use the TABLE() function to transform the members of an array into a set of rows. The signature is:

```
TABLE(<collection_value>)
```

Where:

`collection_value`

- `collection_value` is an expression that evaluates to a value of collection type.

The TABLE() function expands the nested contents of a collection into a table format. You can use the TABLE() function anywhere you use a regular table expression.

The TABLE() function returns a SETOF ANYELEMENT (a set of values of any type). For example, if the argument passed to this function is an array of dates, TABLE() will return a SETOF dates. If the argument passed to this function is an array of paths, TABLE() will return a SETOF paths.

You can use the TABLE() function to expand the contents of a collection into table form:

```
postgres=# SELECT * FROM TABLE(monthly_balance(445.00, 980.20, 552.00));

monthly_balance
---------------
 445.00
 980.20
```

(continues on next page)
12.2 Using the MULTISET UNION Operator

The MULTISET UNION operator combines two collections to form a third collection. The signature is:

```
<coll_1> MULTISET UNION [ ALL | DISTINCT | UNIQUE ] <coll_2>
```

Where `coll_1` and `coll_2` specify the names of the collections to combine.

Include the ALL keyword to specify that duplicate elements (elements that are present in both `coll_1` and `coll_2`) should be represented in the result, once for each time they are present in the original collections. This is the default behavior of MULTISET UNION.

Include the DISTINCT or UNIQUE keyword to specify that duplicate elements should be included in the result only once. The DISTINCT and UNIQUE keywords are synonymous.

The following example demonstrates using the MULTISET UNION operator to combine two collections (`collection_1` and `collection_2`) into a third collection (`collection_3`):

```sql
DECLARE
    TYPE int_arr_typ IS TABLE OF NUMBER(2);
    collection_1 int_arr_typ;
    collection_2 int_arr_typ;
    collection_3 int_arr_typ;
    v_results VARCHAR2(50);
BEGIN
    collection_1 := int_arr_typ(10,20,30);
    collection_2 := int_arr_typ(30,40);
    collection_3 := collection_1 MULTISET UNION ALL collection_2;
    DBMS_OUTPUT.PUT_LINE('COUNT: ' || collection_3.COUNT);
    FOR i IN collection_3.FIRST .. collection_3.LAST LOOP
        IF collection_3(i) IS NULL THEN
            v_results := v_results || 'NULL ';
        ELSE
            v_results := v_results || collection_3(i) || ' ';
        END IF;
    END LOOP;
    DBMS_OUTPUT.PUT_LINE('Results: ' || v_results);
END;
```

```
COUNT: 5
Results: 10 20 30 30 40
```

The resulting collection includes one entry for each element in `collection_1` and `collection_2`. If the DISTINCT keyword is used, the results are as follows:
DECLARE
    TYPE int_arr_typ IS TABLE OF NUMBER(2);
    collection_1 int_arr_typ;
    collection_2 int_arr_typ;
    collection_3 int_arr_typ;
    v_results VARCHAR2(50);
BEGIN
    collection_1 := int_arr_typ(10,20,30);
    collection_2 := int_arr_typ(30,40);
    collection_3 := collection_1 MULTISET UNION DISTINCT collection_2;
    DBMS_OUTPUT.PUT_LINE('COUNT: ' || collection_3.COUNT);
    FOR i IN collection_3.FIRST .. collection_3.LAST LOOP
        IF collection_3(i) IS NULL THEN
            v_results := v_results || 'NULL ';
        ELSE
            v_results := v_results || collection_3(i) || ' ';
        END IF;
    END LOOP;
    DBMS_OUTPUT.PUT_LINE('Results: ' || v_results);
END;
COUNT: 4
Results: 10 20 30 40

The resulting collection includes only those members with distinct values. Note in the following example that the MULTISET UNION DISTINCT operator also removes duplicate entries that are stored within the same collection:

DECLARE
    TYPE int_arr_typ IS TABLE OF NUMBER(2);
    collection_1 int_arr_typ;
    collection_2 int_arr_typ;
    collection_3 int_arr_typ;
    v_results VARCHAR2(50);
BEGIN
    collection_1 := int_arr_typ(10,20,30,30);
    collection_2 := int_arr_typ(40,50);
    collection_3 := collection_1 MULTISET UNION DISTINCT collection_2;
    DBMS_OUTPUT.PUT_LINE('COUNT: ' || collection_3.COUNT);
    FOR i IN collection_3.FIRST .. collection_3.LAST LOOP
        IF collection_3(i) IS NULL THEN
            v_results := v_results || 'NULL ';
        ELSE
            v_results := v_results || collection_3(i) || ' ';
        END IF;
    END LOOP;
    DBMS_OUTPUT.PUT_LINE('Results: ' || v_results);
END;
COUNT: 5
Results: 10 20 30 40 50

12.2. Using the MULTISET UNION Operator
12.3 Using the FORALL Statement

Collections can be used to more efficiently process DML commands by passing all the values to be used for repetitive execution of a DELETE, INSERT, or UPDATE command in one pass to the database server rather than re-iteratively invoking the DML command with new values. The DML command to be processed in such a manner is specified with the FORALL statement. In addition, one or more collections are given in the DML command where different values are to be substituted each time the command is executed.

```
FORALL <index> IN <lower_bound> .. <upper_bound>
  { <insert_stmt> | <update_stmt> | <delete_stmt> };
```

index is the position in the collection given in the insert_stmt, update_stmt, or delete_stmt DML command that iterates from the integer value given as lower_bound up to and including upper_bound.

If an exception occurs during any iteration of the FORALL statement, all updates that occurred since the start of the execution of the FORALL statement are automatically rolled back. This behavior is not compatible with Oracle databases. Oracle allows explicit use of the COMMIT or ROLLBACK commands to control whether or not to commit or roll back updates that occurred prior to the exception.

The FORALL statement creates a loop—each iteration of the loop increments the index variable (you typically use the index within the loop to select a member of a collection). The number of iterations is controlled by the lower_bound .. upper_bound clause. The loop is executed once for each integer between the lower_bound and upper_bound (inclusive) and the index is incremented by one for each iteration. For example:

```
FORALL i IN 2 .. 5
```

Creates a loop that executes four times—in the first iteration, the index (i) is set to the value 2; in the second iteration, the index is set to the value 3, and so on. The loop executes for the value 5 and then terminates.

The following example creates a table (emp_copy) that is an empty copy of the emp table. The example declares a type (emp_tbl) that is an array where each element in the array is of composite type, composed of the column definitions used to create the table, emp. The example also creates an index on the emp_tbl type.

```
t_emp is an associative array, of type emp_tbl. The SELECT statement uses the BULK COLLECT INTO command to populate the t_emp array. After the t_emp array is populated, the FORALL statement iterates through the values (i) in the t_emp array index and inserts a row for each record into emp_copy.
```

```
CREATE TABLE emp_copy(LIKE emp);
DECLARE
  TYPE emp_tbl IS TABLE OF emp%ROWTYPE INDEX BY BINARY_INTEGER;
  t_emp emp_tbl;
BEGIN
  SELECT * FROM emp BULK COLLECT INTO t_emp;
```

(continues on next page)
FORALL i IN t_emp.FIRST .. t_emp.LAST
    INSERT INTO emp_copy VALUES t_emp(i);
END;

The following example uses a FORALL statement to update the salary of three employees:

DECLARE
    TYPE empno_tbl IS TABLE OF emp.empno%TYPE INDEX BY BINARY_INTEGER;
    TYPE sal_tbl IS TABLE OF emp.ename%TYPE INDEX BY BINARY_INTEGER;
    t_empno EMPNO_TBL;
    t_sal SAL_TBL;
BEGIN
    t_empno(1) := 9001;
    t_sal(1) := 3350.00;
    t_empno(2) := 9002;
    t_sal(2) := 2000.00;
    t_empno(3) := 9003;
    t_sal(3) := 4100.00;
    FORALL i IN t_empno.FIRST..t_empno.LAST
        UPDATE emp SET sal = t_sal(i) WHERE empno = t_empno(i);
END;

SELECT * FROM emp WHERE empno > 9000;

empno | ename | job | mgr | hiredate | sal | comm | deptno
-------+--------+---------+-----+----------+---------+------+--------
9001 | JONES | ANALYST | | | 3350.00 | | 40
9002 | LARSEN | CLERK | | | 2000.00 | | 40
9003 | WILSON | MANAGER | | | 4100.00 | | 40
(3 rows)

The following example deletes three employees in a FORALL statement:

DECLARE
    TYPE empno_tbl IS TABLE OF emp.empno%TYPE INDEX BY BINARY_INTEGER;
    t_empno EMPNO_TBL;
BEGIN
    t_empno(1) := 9001;
    t_empno(2) := 9002;
    t_empno(3) := 9003;
    FORALL i IN t_empno.FIRST..t_empno.LAST
        DELETE FROM emp WHERE empno = t_empno(i);
END;

SELECT * FROM emp WHERE empno > 9000;

empno | ename | job | mgr | hiredate | sal | comm | deptno
-------+-------+-----+-----+----------+-----+------+

(0 rows)
12.4 Using the BULK COLLECT Clause

SQL commands that return a result set consisting of a large number of rows may not be operating as efficiently as possible due to the constant context switching that must occur between the database server and the client in order to transfer the entire result set. This inefficiency can be mitigated by using a collection to gather the entire result set in memory which the client can then access. The **BULK COLLECT** clause is used to specify the aggregation of the result set into a collection.

The **BULK COLLECT** clause can be used with the **SELECT INTO**, **FETCH INTO** and **EXECUTE IMMEDIATE** commands, and with the RETURNING INTO clause of the **DELETE**, **INSERT**, and **UPDATE** commands. Each of these is illustrated in the following sections.

12.4.1 SELECT BULK COLLECT

The **BULK COLLECT** clause can be used with the **SELECT INTO** statement as follows. (Refer to **SELECT INTO** for additional information on the **SELECT INTO** statement.)

```sql
SELECT <select_expressions> BULK COLLECT INTO <collection> [, ...] FROM ...;
```

If a single collection is specified, then `collection` may be a collection of a single field, or it may be a collection of a record type. If more than one collection is specified, then each `collection` must consist of a single field. `select_expressions` must match in number, order, and type-compatibility all fields in the target collections.

The following example shows the use of the **BULK COLLECT** clause where the target collections are associative arrays consisting of a single field.

```sql
DECLARE
    TYPE empno_tbl IS TABLE OF emp.empno%TYPE INDEX BY BINARY_INTEGER;
    TYPE ename_tbl IS TABLE OF emp.ename%TYPE INDEX BY BINARY_INTEGER;
    TYPE job_tbl IS TABLE OF emp.job%TYPE INDEX BY BINARY_INTEGER;
    TYPE hiredate_tbl IS TABLE OF emp.hiredate%TYPE INDEX BY BINARY_INTEGER;
    TYPE sal_tbl IS TABLE OF emp.sal%TYPE INDEX BY BINARY_INTEGER;
    TYPE comm_tbl IS TABLE OF emp.comm%TYPE INDEX BY BINARY_INTEGER;
    TYPE deptno_tbl IS TABLE OF emp.deptno%TYPE INDEX BY BINARY_INTEGER;
    t_empno EMPNO_TBL;
    t_ename ENAME_TBL;
    t_job JOB_TBL;
    t_hiredate HIREDATE_TBL;
    t_sal SAL_TBL;
    t_comm COMM_TBL;
    t_deptno DEPTNO_TBL;
BEGIN
    SELECT empno, ename, job, hiredate, sal, comm, deptno BULK COLLECT INTO t_empno, t_ename, t_job, t_hiredate, t_sal, t_comm, t_deptno FROM emp;
    DBMS_OUTPUT.PUT_LINE('EMPNO ENAME JOB HIREDATE SAL COMM DEPTNO');
    DBMS_OUTPUT.PUT_LINE('----- ------- --------- --------- ' ||
        ' || ' ' || ' --- --- --- --- --- --- --- --- ' ||
    );
END;
```

(continues on next page)
The following example produces the same result, but uses an associative array on a record type defined with the %ROWTYPE attribute.

```sql
DECLARE
  TYPE emp_tbl IS TABLE OF emp%ROWTYPE INDEX BY BINARY_INTEGER;
  t_emp EMP_TBL;
BEGIN
  SELECT * BULK COLLECT INTO t_emp FROM emp;
  DBMS_OUTPUT.PUT_LINE('EMPNO ENAME JOB HIREDATE SAL COMM DEPTNO ' ||
                        '-------- ------- --------- --------- -------- -------- -----' ||
                        '-------- ------');
  FOR i IN 1..t_emp.COUNT LOOP
    DBMS_OUTPUT.PUT_LINE(t_emp(i).empno || ' ' ||
                         RPAD(t_emp(i).ename,8) || ' ' ||
                         RPAD(t_emp(i).job,10) || ' ' ||
                         TO_CHAR(t_emp(i).hiredate,'DD-MON-YY') || ' ' ||
                         TO_CHAR(t_emp(i).sal,'99,999.99') || ' ' ||
                         TO_CHAR(NVL(t_emp(i).comm,0),'99,999.99') || ' ' ||
                         t_emp(i).deptno);
  END LOOP;
END;
```

12.4. Using the BULK COLLECT Clause
### 12.4.2 FETCH BULK COLLECT

The `BULK COLLECT` clause can be used with a `FETCH` statement. (See *Fetching Rows From a Cursor* for information on the `FETCH` statement.) Instead of returning a single row at a time from the result set, the `FETCH BULK COLLECT` will return all rows at once from the result set into the specified collection unless restricted by the `LIMIT` clause.

```
FETCH <name> BULK COLLECT INTO <collection> [, ...] [ LIMIT <n> ];
```

If a single collection is specified, then `collection` may be a collection of a single field, or it may be a collection of a record type. If more than one collection is specified, then each `collection` must consist of a single field. The expressions in the `SELECT` list of the cursor identified by `name` must match in number, order, and type-compatibility all fields in the target collections. If `LIMIT n` is specified, the number of rows returned into the collection on each `FETCH` will not exceed $n$.

The following example uses the `FETCH BULK COLLECT` statement to retrieve rows into an associative array.

```
DECLARE
    TYPE emp_tbl IS TABLE OF emp%ROWTYPE INDEX BY BINARY_INTEGER;
    t_emp      EMP_TBL;
    CURSOR emp_cur IS SELECT * FROM emp;
BEGIN
    OPEN emp_cur;
    FETCH emp_cur BULK COLLECT INTO t_emp;
    CLOSE emp_cur;
    DBMS_OUTPUT.PUT_LINE('EMPNO ENAME JOB HIREDATE SAL COMM DEPTNO ' ||
                         '----- ------- --------- --------- -------- -------- ------
                         7369 SMITH CLERK 17-DEC-80 800.00 .00 20
                         7499 ALLEN SALESMAN 20-FEB-81 1,600.00 300.00 30
                         7521 WARD SALESMAN 22-FEB-81 1,250.00 500.00 30
                         7566 JONES MANAGER 02-APR-81 2,975.00 .00 20
                         7654 MARTIN SALESMAN 28-SEP-81 1,250.00 1,400.00 30
                         7698 BLAKE MANAGER 01-MAY-81 2,850.00 .00 30
                         7782 CLARK MANAGER 09-JUN-81 2,450.00 .00 10
                         7788 SCOTT ANALYST 19-APR-87 3,000.00 .00 20
                         7839 KING PRESIDENT 17-NOV-81 5,000.00 .00 10
                         7844 TURNER SALESMAN 08-SEP-81 1,500.00 .00 30
                         7876 ADAMS CLERK 23-MAY-87 1,100.00 .00 20
                         7900 JAMES CLERK 03-DEC-81 950.00 .00 30
                         7902 FORD ANALYST 03-DEC-81 3,000.00 .00 20
                         7934 MILLER CLERK 23-JAN-82 1,300.00 .00 10
    FOR i IN 1..t_emp.COUNT LOOP
        DBMS_OUTPUT.PUT_LINE('EMPNO ENAME JOB HIREDATE ' ||
                              'SAL ' || 'COMM DEPTNO ' ||
                              '----- ------- --------- --------- -------- -------- ------');
    END LOOP;
    CLOSE emp_cur;
END;
```

(continues on next page)
12.4.3 EXECUTE IMMEDIATE BULK COLLECT

The BULK COLLECT clause can be used with a EXECUTE IMMEDIATE statement to specify a collection to receive the returned rows.

```sql
EXECUTE IMMEDIATE '<sql_expression>;'  
    BULK COLLECT INTO <collection> [,...]  
    [USING {[<bind_type>] <bind_argument>} [...]];
```

collection specifies the name of a collection.

bind_type specifies the parameter mode of the bind_argument.

- A bind_type of IN specifies that the bind_argument contains a value that is passed to the sql_expression.
- A bind_type of OUT specifies that the bind_argument receives a value from the sql_expression.
- A bind_type of IN OUT specifies that the bind_argument is passed to sql_expression, and then stores the value returned by sql_expression.

bind_argument specifies a parameter that contains a value that is either passed to the sql_expression (specified with a bind_type of IN), or that receives a value from the
sql_expression (specified with a bind_type of OUT), or both (specified with a bind_type of IN OUT).

If a single collection is specified, then collection may be a collection of a single field, or a collection of a record type; if more than one collection is specified, each collection must consist of a single field.

12.4.4 RETURNING BULK COLLECT

The BULK COLLECT clause can be added to the RETURNING INTO clause of a DELETE, INSERT, or UPDATE command. (See Using the RETURNING INTO Clause for information on the RETURNING INTO clause.)

```sql
{ <insert> | <update> | <delete> }
RETURNING { * | <expr_1> [, <expr_2> ] ...}
   BULK COLLECT INTO <collection> [, ...];
```

insert, update, and delete are the INSERT, UPDATE, and DELETE commands as described in INSERT, UPDATE, and DELETE, respectively. If a single collection is specified, then collection may be a collection of a single field, or it may be a collection of a record type. If more than one collection is specified, then each collection must consist of a single field. The expressions following the RETURNING keyword must match in number, order, and type-compatibility all fields in the target collections. If * is specified, then all columns in the affected table are returned. (Note that the use of * is an Advanced Server extension and is not compatible with Oracle databases.)

The clerkemp table created by copying the emp table is used in the remaining examples in this section as shown below.

```
CREATE TABLE clerkemp AS SELECT * FROM emp WHERE job = 'CLERK';
```

<table>
<thead>
<tr>
<th>empno</th>
<th>ename</th>
<th>job</th>
<th>mgr</th>
<th>hiredate</th>
<th>sal</th>
<th>comm</th>
<th>deptno</th>
</tr>
</thead>
<tbody>
<tr>
<td>7369</td>
<td>SMITH</td>
<td>CLERK</td>
<td>7902</td>
<td>17-DEC-80 00:00:00</td>
<td>800.00</td>
<td></td>
<td>20</td>
</tr>
<tr>
<td>7876</td>
<td>ADAMS</td>
<td>CLERK</td>
<td>7788</td>
<td>23-MAY-87 00:00:00</td>
<td>1100.00</td>
<td></td>
<td>20</td>
</tr>
<tr>
<td>7900</td>
<td>JAMES</td>
<td>CLERK</td>
<td>7698</td>
<td>03-DEC-81 00:00:00</td>
<td>950.00</td>
<td></td>
<td>30</td>
</tr>
<tr>
<td>7934</td>
<td>MILLER</td>
<td>CLERK</td>
<td>7782</td>
<td>23-JAN-82 00:00:00</td>
<td>1300.00</td>
<td></td>
<td>10</td>
</tr>
</tbody>
</table>

(4 rows)

The following example increases everyone’s salary by 1.5, stores the employees’ numbers, names, and new salaries in three associative arrays, and finally, displays the contents of these arrays.

```
DECLARE
   TYPE empno_tbl IS TABLE OF emp.empno%TYPE INDEX BY BINARY_INTEGER;
   TYPE ename_tbl IS TABLE OF emp.ename%TYPE INDEX BY BINARY_INTEGER;
   TYPE sal_tbl IS TABLE OF emp.sal%TYPE INDEX BY BINARY_INTEGER;
   t_empno EMPNO_TBL;
   t_ename ENAME_TBL;
   t_sal SAL_TBL;
BEGIN
   (continues on next page)
```
UPDATE clerkemp SET sal = sal * 1.5 RETURNING empno, ename, sal
  BULK COLLECT INTO t_empno, t_ename, t_sal;
DBMS_OUTPUT.PUT_LINE('EMPNO ENAME SAL ');
DBMS_OUTPUT.PUT_LINE('----- ------- -------- ');
FOR i IN 1..t_empno.COUNT LOOP
  DBMS_OUTPUT.PUT_LINE(t_empno(i) || ' ' || RPAD(t_ename(i),8) ||
                       ' ' || TO_CHAR(t_sal(i),'99,999.99'));
END LOOP;
END;

EMPNO  ENAME   SAL
------  ------  --------
7369   SMITH  1,200.00
7876   ADAMS  1,650.00
7900   JAMES  1,425.00
7934   MILLER 1,950.00

The following example performs the same functionality as the previous example, but uses a single collection
defined with a record type to store the employees’ numbers, names, and new salaries.

DECLARE
  TYPE emp_rec IS RECORD (.empno emp.empno%TYPE,
                           ename emp.ename%TYPE,
                           sal emp.sal%TYPE);TYPE emp_tbl IS TABLE OF emp_rec INDEX BY BINARY_INTEGER;
t_emp EMP_TBL;
BEGIN
  UPDATE clerkemp SET sal = sal * 1.5 RETURNING empno, ename, sal
    BULK COLLECT INTO t_emp;
  DBMS_OUTPUT.PUT_LINE('EMPNO ENAME SAL ');
  DBMS_OUTPUT.PUT_LINE('----- ------- -------- ');
  FOR i IN 1..t_emp.COUNT LOOP
    DBMS_OUTPUT.PUT_LINE(t_emp(i).empno || ' ' ||
                          RPAD(t_emp(i).ename,8) ||
                          ' ' || TO_CHAR(t_emp(i).sal,'99,999.99'));
  END LOOP;
END;

EMPNO  ENAME   SAL
------  ------  --------
7369   SMITH  1,200.00
7876   ADAMS  1,650.00
7900   JAMES  1,425.00
7934   MILLER 1,950.00

The following example deletes all rows from the clerkemp table, and returns information on the deleted
rows into an associative array, which is then displayed.

DECLARE

12.4. Using the BULK COLLECT Clause 187
TYPE emp_rec IS RECORD(
  empno emp.empno%TYPE,
  ename emp.ename%TYPE,
  job emp.job%TYPE,
  hiredate emp.hiredate%TYPE,
  sal emp.sal%TYPE,
  comm emp.comm%TYPE,
  deptno emp.deptno%TYPE
);

TYPE emp_tbl IS TABLE OF emp_rec INDEX BY BINARY_INTEGER;
r_emp EMP_TBL;

BEGIN
  DELETE FROM clerkemp RETURNING empno, ename, job, hiredate, sal,
      comm, deptno BULK COLLECT INTO r_emp;
  DBMS_OUTPUT.PUT_LINE('EMPNO ENAME JOB HIREDATE SAL COMM DEPTNO');
  DBMS_OUTPUT.PUT_LINE('----- ------- --------- --------- -------- -------- -----
  ---- ---- ---- ---- ---- ---- ---- --
  FOR i IN 1..r_emp.COUNT LOOP
    DBMS_OUTPUT.PUT_LINE(r_emp(i).empno || ' ' ||
      RPAD(r_emp(i).ename,8) || ' ' ||
      RPAD(r_emp(i).job,10) || ' ' ||
      TO_CHAR(r_emp(i).hiredate,'DD-MON-YY') || ' ' ||
      TO_CHAR(r_emp(i).sal,'99,999.99') || ' ' ||
      TO_CHAR(NVL(r_emp(i).comm,0),'99,999.99') || ' ' ||
      r_emp(i).deptno);
  END LOOP;
END;

EMPNO ENAME JOB HIREDATE SAL COMM DEPTNO
----- ------- --------- --------- -------- -------- -----
7369 SMITH CLERK 17-DEC-80 1,200.00 .00 20
7876 ADAMS CLERK 23-MAY-87 1,650.00 .00 20
7900 JAMES CLERK 03-DEC-81 1,425.00 .00 30
7934 MILLER CLERK 23-JAN-82 1,950.00 .00 10
12.5 Errors and Messages

Use the DBMS_OUTPUT.PUT_LINE statement to report messages.

```
DBMS_OUTPUT.PUT_LINE ( <message> );
```

message is any expression evaluating to a string.

This example displays the message on the user’s output display:

```
DBMS_OUTPUT.PUT_LINE('My name is John');
```

The special variables SQLCODE and SQLERRM contain a numeric code and a text message, respectively, that describe the outcome of the last SQL command issued. If any other error occurs in the program such as division by zero, these variables contain information pertaining to the error.
CHAPTER 13

Triggers

This chapter describes Advanced Server triggers. As with procedures and functions, triggers are written in the SPL language.

13.1 Overview

A trigger is a named SPL code block that is associated with a table and stored in the database. When a specified event occurs on the associated table, the SPL code block is executed. The trigger is said to be fired when the code block is executed.

The event that causes a trigger to fire can be any combination of an insert, update, or deletion carried out on the table, either directly or indirectly. If the table is the object of a SQL \texttt{INSERT}, \texttt{UPDATE}, \texttt{DELETE}, or \texttt{TRUNCATE} command the trigger is directly fired assuming that the corresponding insert, update, delete, or truncate event is defined as a \textit{triggering event}. The events that fire the trigger are defined in the \texttt{CREATE TRIGGER} command.

A trigger can be fired indirectly if a triggering event occurs on the table as a result of an event initiated on another table. For example, if a trigger is defined on a table containing a foreign key defined with the \texttt{ON DELETE CASCADE} clause and a row in the parent table is deleted, all children of the parent would be deleted as well. If deletion is a triggering event on the child table, deletion of the children will cause the trigger to fire.
13.2 Types of Triggers

Advanced Server supports both row-level and statement-level triggers. A row-level trigger fires once for each row that is affected by a triggering event. For example, if deletion is defined as a triggering event on a table and a single DELETE command is issued that deletes five rows from the table, then the trigger will fire five times, once for each row.

In contrast, a statement-level trigger fires once per triggering statement regardless of the number of rows affected by the triggering event. In the prior example of a single DELETE command deleting five rows, a statement-level trigger would fire only once.

The sequence of actions can be defined regarding whether the trigger code block is executed before or after the triggering statement, itself, in the case of statement-level triggers; or before or after each row is affected by the triggering statement in the case of row-level triggers.

In a before row-level trigger, the trigger code block is executed before the triggering action is carried out on each affected row. In a before statement-level trigger, the trigger code block is executed before the action of the triggering statement is carried out.

In an after row-level trigger, the trigger code block is executed after the triggering action is carried out on each affected row. In an after statement-level trigger, the trigger code block is executed after the action of the triggering statement is carried out.

In a compound trigger, a statement-level and a row-level trigger can be defined in a single trigger and can be fired at more than one timing point see, Compound Triggers for information about compound triggers.
13.3 Creating Triggers

The CREATE TRIGGER command defines and names a trigger that will be stored in the database.

Name

CREATE TRIGGER -- define a simple trigger

Synopsis

CREATE [ OR REPLACE ] TRIGGER <name>
{ BEFORE | AFTER | INSTEAD OF }
{ INSERT | UPDATE | DELETE | TRUNCATE }
[ OR { INSERT | UPDATE | DELETE | TRUNCATE } ] [, ...]
ON <table>
[ REFERENCING { OLD AS <old> | NEW AS <new> } ...]
[ FOR EACH ROW ]
[ WHEN <condition> ]
[ DECLARE
  [ PRAGMA AUTONOMOUS_TRANSACTION; ]
  <declaration>; [, ...] ]
BEGIN
  <statement>; [, ...]
[ EXCEPTION
  { WHEN <exception> [ OR <exception> ] [...] THEN
  <statement>; [, ...] } [, ...] ]
]
END

Name

CREATE TRIGGER -- define a compound trigger

Synopsis

CREATE [ OR REPLACE ] TRIGGER <name>
FOR { INSERT | UPDATE | DELETE | TRUNCATE }
[ OR { INSERT | UPDATE | DELETE | TRUNCATE } ] [, ...]
ON <table>
[ REFERENCING { OLD AS <old> | NEW AS <new> } ...]
[ WHEN <condition> ]
COMPOUND TRIGGER
[ <private_declaration>; ] ...
[ <procedure_or_function_definition> ] ...
<compound_trigger_definition>
END

Where private_declaration is an identifier of a private variable that can be accessed by any procedure or function. There can be zero, one, or more private variables. private_declaration can be any of the following:

- Variable Declaration
- Record Declaration
- Collection Declaration
- REF CURSOR and Cursor Variable Declaration
- TYPE Definitions for Records, Collections, and REF CURSORs
- Exception
- Object Variable Declaration

Where `procedure_or_function_definition :=`

```
procedure_definition | function_definition
```

Where `procedure_definition :=`

```
PROCEDURE proc_name[ argument_list ]
[ options_list ]
{ IS | AS }
  procedure_body
END [ proc_name ] ;
```

Where `procedure_body :=`

```
[ declaration; ] [, ...]
BEGIN
  statement; [...]  
[ EXCEPTION
    { WHEN exception [OR exception] [...] THEN statement; }
[ ...
]
```

Where `function_definition :=`

```
FUNCTION func_name [ argument_list ]
  RETURN rettype [ DETERMINISTIC ]
[ options_list ]
{ IS | AS }
  function_body
END [ func_name ] ;
```

Where `function_body :=`

```
[ declaration; ] [, ...]
BEGIN
  statement; [...]  
[ EXCEPTION
    { WHEN exception [ OR exception ] [...] THEN statement; }
[ ...
]
```

Where `compound_trigger_definition` is:
CREATE TRIGGER defines a new trigger. CREATE OR REPLACE TRIGGER will either create a new trigger, or replace an existing definition.

If you are using the CREATE TRIGGER keywords to create a new trigger, the name of the new trigger must not match any existing trigger defined on the same table. New triggers will be created in the same schema as the table on which the triggering event is defined.

If you are updating the definition of an existing trigger, use the CREATE OR REPLACE TRIGGER keywords.

When you use syntax compatible with Oracle databases to create a trigger, the trigger runs as a SECURITY DEFINER function.

Parameters

name

The name of the trigger to create.

BEFORE | AFTER

Determine whether the trigger is fired before or after the triggering event.

INSTEAD OF

INSTEAD OF trigger modifies an updatable view; the trigger will execute to update the underlying table(s) appropriately. The INSTEAD OF trigger is executed for each row of the view that is updated or modified.

INSERT | UPDATE | DELETE | TRUNCATE

Defines the triggering event.

table
The name of the table or view on which the triggering event occurs.

condition

condition is a Boolean expression that determines if the trigger will actually be executed; if condition evaluates to TRUE, the trigger will fire.

If the simple trigger definition includes the FOR EACH ROW keywords, the WHEN clause can refer to columns of the old and/or new row values by writing OLD.column_name or NEW.column_name respectively. INSERT triggers cannot refer to OLD and DELETE triggers cannot refer to NEW.

If the compound trigger definition includes a statement-level trigger having a WHEN clause, then the trigger is executed without evaluating the expression in the WHEN clause. Similarly, if a compound trigger definition includes a row-level trigger having a WHEN clause, then the trigger is executed if the expression evaluates to TRUE.

If the trigger includes the INSTEAD OF keywords, it may not include a WHEN clause. A WHEN clause cannot contain subqueries.

REFERENCING { OLD AS old | NEW AS new } ...

REFERENCING clause to reference old rows and new rows, but restricted in that old may only be replaced by an identifier named old or any equivalent that is saved in all lowercase (for example, REFERENCING OLD AS old, REFERENCING OLD AS OLD, or REFERENCING OLD AS "old"). Also, new may only be replaced by an identifier named new or any equivalent that is saved in all lowercase (for example, REFERENCING NEW AS new, REFERENCING NEW AS NEW, or REFERENCING NEW AS "new").

Either one, or both phrases OLD AS old and NEW AS new may be specified in the REFERENCING clause (for example, REFERENCING NEW AS New OLD AS Old). This clause is not compatible with Oracle databases in that identifiers other than old or new may not be used.

FOR EACH ROW

Determines whether the trigger should be fired once for every row affected by the triggering event, or just once per SQL statement. If specified, the trigger is fired once for every affected row (row-level trigger), otherwise the trigger is a statement-level trigger.

PRAGMA AUTONOMOUS_TRANSACTION

PRAGMA AUTONOMOUS_TRANSACTION is the directive that sets the trigger as an autonomous transaction.

declaration

A variable, type, REF CURSOR, or subprogram declaration. If subprogram declarations are included, they must be declared after all other variable, type, and REF CURSOR declarations.

statement

An SPL program statement. Note that a DECLARE - BEGIN - END block is considered an SPL statement unto itself. Thus, the trigger body may contain nested blocks.

exception
An exception condition name such as NO_DATA_FOUND, OTHERS, etc.

13.4 Trigger Variables

In the trigger code block, several special variables are available for use.

NEW

NEW is a pseudo-record name that refers to the new table row for insert and update operations in row-level triggers. This variable is not applicable in statement-level triggers and in delete operations of row-level triggers.

Its usage is: :NEW.column where column is the name of a column in the table on which the trigger is defined.

The initial content of :NEW.column is the value in the named column of the new row to be inserted or of the new row that is to replace the old one when used in a before row-level trigger. When used in an after row-level trigger, this value has already been stored in the table since the action has already occurred on the affected row.

In the trigger code block, :NEW.column can be used like any other variable. If a value is assigned to :NEW.column, in the code block of a before row-level trigger, the assigned value will be used in the new inserted or updated row.

OLD

OLD is a pseudo-record name that refers to the old table row for update and delete operations in row-level triggers. This variable is not applicable in statement-level triggers and in insert operations of row-level triggers.

Its usage is: :OLD.column where column is the name of a column in the table on which the trigger is defined.

The initial content of :OLD.column is the value in the named column of the row to be deleted or of the old row that is to be replaced by the new one when used in a before row-level trigger. When used in an after row-level trigger, this value is no longer stored in the table since the action has already occurred on the affected row.

In the trigger code block, :OLD.column can be used like any other variable. Assigning a value to :OLD.column, has no effect on the action of the trigger.

INSERTING

INSERTING is a conditional expression that returns TRUE if an insert operation fired the trigger, otherwise it returns FALSE.

UPDATING

UPDATING is a conditional expression that returns TRUE if an update operation fired the trigger, otherwise it returns FALSE.

DELETING

13.4. Trigger Variables 196
DELETING is a conditional expression that returns TRUE if a delete operation fired the trigger, otherwise it returns FALSE.

13.5 Transactions and Exceptions

A trigger is always executed as part of the same transaction within which the triggering statement is executing. When no exceptions occur within the trigger code block, the effects of any triggering commands within the trigger are committed if and only if the transaction containing the triggering statement is committed. Therefore, if the transaction is rolled back, the effects of any triggering commands within the trigger are also rolled back.

If an exception does occur within the trigger code block, but it is caught and handled in an exception section, the effects of any triggering commands within the trigger are still rolled back nonetheless. The triggering statement itself, however, is not rolled back unless the application forces a roll back of the encapsulating transaction.

If an unhandled exception occurs within the trigger code block, the transaction that encapsulates the trigger is aborted and rolled back. Therefore, the effects of any triggering commands within the trigger and the triggering statement, itself are all rolled back.

13.6 Compound Triggers

Advanced Server has added compatible syntax to support compound triggers. A compound trigger combines all the triggering timings under one trigger body that can be invoked at one or more timing points. A timing point is a point in time related to a triggering statement (an INSERT, UPDATE, DELETE or TRUNCATE statement that modifies data). The supported timing points are:

- BEFORE STATEMENT: Before the triggering statement executes.
- BEFORE EACH ROW: Before each row that the triggering statement affects.
- AFTER EACH ROW: After each row that the triggering statement affects.
- AFTER STATEMENT: After the triggering statement executes.
- INSTEAD OF EACH ROW: Trigger fires once for every row affected by the triggering statement.

A compound trigger may include any combination of timing points defined in a single trigger.

The optional declaration section in a compound trigger allows you to declare trigger-level variables and subprograms. The content of the declaration is accessible to all timing points referenced by the trigger definition. The variables and subprograms created by the declaration persist only for the duration of the triggering statement.

A compound trigger contains a declaration, followed by a PL block for each timing point:

```sql
CREATE OR REPLACE TRIGGER compound_trigger_name
FOR INSERT OR UPDATE OR DELETE ON table_name
COMPOUND TRIGGER
    -- Global Declaration Section (optional)
```

(continues on next page)
-- Variables declared here can be used inside any timing-point blocks.

BEFORE STATEMENT IS
BEGIN
  NULL;
END BEFORE STATEMENT;

BEFORE EACH ROW IS
BEGIN
  NULL;
END BEFORE EACH ROW;

AFTER EACH ROW IS
BEGIN
  NULL;
END AFTER EACH ROW;

AFTER STATEMENT IS
BEGIN
  NULL;
END AFTER STATEMENT;
END compound_trigger_name;
/
Trigger created.

Note: It is not mandatory to have all the four timing blocks; you can create a compound trigger for any of the required timing-points.

A Compound Trigger has the following restrictions:

- A compound trigger body is comprised of a compound trigger block.
- A compound trigger can be defined on a table or a view.
- Exceptions are non-transferable to other timing-point section and must be handled separately in that section only by each compound trigger block.
- If a GOTO statement is specified in a timing-point section, then the target of the GOTO statement must also be specified in the same timing-point section.
- :OLD and :NEW variable identifiers cannot exist in the declarative section, the BEFORE STATEMENT section, or the AFTER STATEMENT section.
- :NEW values can only be modified by the BEFORE EACH ROW block.
- The sequence of compound trigger timing-point execution is specific, but if a simple trigger exists within the same timing-point then the simple trigger is fired first, followed by the firing of compound triggers.
13.7 Trigger Examples

The following sections illustrate an example of each type of trigger.

13.7.1 Before Statement-Level Trigger

The following is an example of a simple before statement-level trigger that displays a message prior to an insert operation on the emp table.

```sql
CREATE OR REPLACE TRIGGER emp_alert_trig
    BEFORE INSERT ON emp
BEGIN
    DBMS_OUTPUT.PUT_LINE('New employees are about to be added');
END;
```

The following INSERT is constructed so that several new rows are inserted upon a single execution of the command. For each row that has an employee id between 7900 and 7999, a new row is inserted with an employee id incremented by 1000. The following are the results of executing the command when three new rows are inserted.

```sql
INSERT INTO emp (empno, ename, deptno) SELECT empno + 1000, ename, 40
    FROM emp WHERE empno BETWEEN 7900 AND 7999;
```

```
New employees are about to be added
```

```
SELECT empno, ename, deptno FROM emp WHERE empno BETWEEN 8900 AND 8999;
```

<table>
<thead>
<tr>
<th>EMPNO</th>
<th>ENAME</th>
<th>DEPTNO</th>
</tr>
</thead>
<tbody>
<tr>
<td>8900</td>
<td>JAMES</td>
<td>40</td>
</tr>
<tr>
<td>8902</td>
<td>FORD</td>
<td>40</td>
</tr>
<tr>
<td>8934</td>
<td>MILLER</td>
<td>40</td>
</tr>
</tbody>
</table>

The message, New employees are about to be added, is displayed once by the firing of the trigger even though the result is the addition of three new rows.

13.7.2 After Statement-Level Trigger

The following is an example of an after statement-level trigger. Whenever an insert, update, or delete operation occurs on the emp table, a row is added to the empauditlog table recording the date, user, and action.

```sql
CREATE TABLE empauditlog (
    audit_date DATE,
    audit_user VARCHAR2(20),
    audit_desc VARCHAR2(20)
);
CREATE OR REPLACE TRIGGER emp_audit_trig
    AFTER INSERT OR UPDATE OR DELETE ON emp
DECLARE
```

(continues on next page)
v_action VARCHAR2(20);
BEGIN
  IF INSERTING THEN
    v_action := 'Added employee(s)';
  ELSIF UPDATING THEN
    v_action := 'Updated employee(s)';
  ELSIF DELETING THEN
    v_action := 'Deleted employee(s)';
  END IF;
  INSERT INTO empauditlog VALUES (SYSDATE, USER, v_action);
END;

In the following sequence of commands, two rows are inserted into the emp table using two INSERT commands. The sal and comm columns of both rows are updated with one UPDATE command. Finally, both rows are deleted with one DELETE command.

INSERT INTO emp VALUES (9001,'SMITH','ANALYST',7782,SYSDATE,NULL,NULL,10);
INSERT INTO emp VALUES (9002,'JONES','CLERK',7782,SYSDATE,NULL,NULL,10);
UPDATE emp SET sal = 4000.00, comm = 1200.00 WHERE empno IN (9001, 9002);
DELETE FROM emp WHERE empno IN (9001, 9002);

SELECT TO_CHAR(AUDIT_DATE,'DD-MON-YY HH24:MI:SS') AS "AUDIT DATE",
       audit_user, audit_desc FROM empauditlog ORDER BY 1 ASC;

The contents of the empauditlog table show how many times the trigger was fired - once each for the two inserts, once for the update (even though two rows were changed) and once for the deletion (even though two rows were deleted).

### 13.7.3 Before Row-Level Trigger

The following example is a before row-level trigger that calculates the commission of every new employee belonging to department 30 that is inserted into the emp table.

```
CREATE OR REPLACE TRIGGER emp_comm_trig
  BEFORE INSERT ON emp
  FOR EACH ROW
BEGIN
  IF :NEW.deptno = 30 THEN
```

(continues on next page)
NEW.comm := :NEW.sal * .4;
END IF;
END;

The listing following the addition of the two employees shows that the trigger computed their commissions and inserted it as part of the new employee rows.

<table>
<thead>
<tr>
<th>EMPNO</th>
<th>ENAME</th>
<th>JOB</th>
<th>MGR</th>
<th>HIREDATE</th>
<th>SAL</th>
<th>COMM</th>
<th>DEPTNO</th>
</tr>
</thead>
<tbody>
<tr>
<td>9005</td>
<td>ROBERS</td>
<td>SALESMAN</td>
<td>7782</td>
<td>01-APR-05</td>
<td>3000</td>
<td>1200</td>
<td>30</td>
</tr>
<tr>
<td>9006</td>
<td>ALLEN</td>
<td>SALESMAN</td>
<td>7782</td>
<td>01-APR-05</td>
<td>4500</td>
<td>1800</td>
<td>30</td>
</tr>
</tbody>
</table>

**13.7.4 After Row-Level Trigger**

The following example is an after row-level trigger. When a new employee row is inserted, the trigger adds a new row to the jobhist table for that employee. When an existing employee is updated, the trigger sets the enddate column of the latest jobhist row (assumed to be the one with a null enddate) to the current date and inserts a new jobhist row with the employee’s new information.

Finally, trigger adds a row to the empchglog table with a description of the action.
v_action := 'Updated';
v_empno := :NEW.empno;
v_deptno := :NEW.deptno;
v_chgdesc := ''; IF NVL(:OLD.ename, '-null-') != NVL(:NEW.ename, '-null-') THEN
v_chgdesc := v_chgdesc || 'name, ';
END IF;
IF NVL(:OLD.job, '-null-') != NVL(:NEW.job, '-null-') THEN
v_chgdesc := v_chgdesc || 'job, ';
END IF;
IF NVL(:OLD.sal, -1) != NVL(:NEW.sal, -1) THEN
v_chgdesc := v_chgdesc || 'salary, ';
END IF;
IF NVL(:OLD.comm, -1) != NVL(:NEW.comm, -1) THEN
v_chgdesc := v_chgdesc || 'commission, ';
END IF;
IF NVL(:OLD.deptno, -1) != NVL(:NEW.deptno, -1) THEN
v_chgdesc := v_chgdesc || 'department, ';
END IF;
v_chgdesc := 'Changed ' || RTRIM(v_chgdesc, ', ');
UPDATE jobhist SET enddate = SYSDATE WHERE empno = :OLD.empno
AND enddate IS NULL;
INSERT INTO jobhist VALUES (:NEW.empno, SYSDATE, NULL,
:NEW.job, :NEW.sal, :NEW.comm, :NEW.deptno, v_chgdesc);
ELSIF DELETING THEN
v_action := 'Deleted';
v_empno := :OLD.empno;
v_deptno := :OLD.deptno;
END IF;

INSERT INTO empchglog VALUES (SYSDATE,
v_action || ' employee # ' || v_empno);

END;

In the first sequence of commands shown below, two employees are added using two separate INSERT commands and then both are updated using a single UPDATE command. The contents of the jobhist table shows the action of the trigger for each affected row - two new hire entries for the two new employees and two changed commission records for the updated commissions on the two employees. The empchglog table also shows the trigger was fired a total of four times, once for each action on the two rows.

**Records added to the emp table**

<table>
<thead>
<tr>
<th>EMPNO</th>
<th>STARTDATE</th>
<th>ENDDATE</th>
<th>JOB</th>
<th>SAL</th>
<th>COMM</th>
<th>DEPTNO</th>
</tr>
</thead>
<tbody>
<tr>
<td>9003</td>
<td>7782</td>
<td></td>
<td>ANALYST</td>
<td>5000.00</td>
<td></td>
<td>40</td>
</tr>
<tr>
<td>9004</td>
<td>7782</td>
<td></td>
<td>ANALYST</td>
<td>4500.00</td>
<td></td>
<td>40</td>
</tr>
</tbody>
</table>

**Records added to the jobhist table**

<table>
<thead>
<tr>
<th>EMPNO</th>
<th>STARTDATE</th>
<th>ENDDATE</th>
<th>JOB</th>
<th>SAL</th>
<th>COMM</th>
<th>DEPTNO</th>
</tr>
</thead>
<tbody>
<tr>
<td>9003</td>
<td>7782</td>
<td></td>
<td>ANALYST</td>
<td>5000.00</td>
<td></td>
<td>40</td>
</tr>
<tr>
<td>9004</td>
<td>7782</td>
<td></td>
<td>ANALYST</td>
<td>4500.00</td>
<td></td>
<td>40</td>
</tr>
</tbody>
</table>

**Records added to the empchglog table**

<table>
<thead>
<tr>
<th>STARTDATE</th>
<th>ACTION</th>
<th>EMPNO</th>
</tr>
</thead>
<tbody>
<tr>
<td>7782</td>
<td>Insert</td>
<td>9003</td>
</tr>
<tr>
<td>7782</td>
<td>Update</td>
<td>9004</td>
</tr>
</tbody>
</table>
---
9003 31-MAR-05 31-MAR-05 ANALYST 5000 40 New Hire
9004 31-MAR-05 31-MAR-05 ANALYST 4500 40 New Hire
9003 31-MAR-05 ANALYST 5000 5500 40 Changed commission
9004 31-MAR-05 ANALYST 4500 4950 40 Changed commission

SELECT * FROM empchglog;

<table>
<thead>
<tr>
<th>CHG_DATE</th>
<th>CHG_DESC</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-MAR-05</td>
<td>Added employee # 9003</td>
</tr>
<tr>
<td>31-MAR-05</td>
<td>Added employee # 9004</td>
</tr>
<tr>
<td>31-MAR-05</td>
<td>Updated employee # 9003</td>
</tr>
<tr>
<td>31-MAR-05</td>
<td>Updated employee # 9004</td>
</tr>
</tbody>
</table>

Finally, both employees are deleted with a single DELETE command. The empchglog table now shows the trigger was fired twice, once for each deleted employee.

DELETE FROM emp WHERE empno IN (9003, 9004);

SELECT * FROM empchglog;

<table>
<thead>
<tr>
<th>CHG_DATE</th>
<th>CHG_DESC</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-MAR-05</td>
<td>Added employee # 9003</td>
</tr>
<tr>
<td>31-MAR-05</td>
<td>Added employee # 9004</td>
</tr>
<tr>
<td>31-MAR-05</td>
<td>Updated employee # 9003</td>
</tr>
<tr>
<td>31-MAR-05</td>
<td>Updated employee # 9004</td>
</tr>
<tr>
<td>31-MAR-05</td>
<td>Deleted employee # 9003</td>
</tr>
<tr>
<td>31-MAR-05</td>
<td>Deleted employee # 9004</td>
</tr>
</tbody>
</table>

### 13.7.5 INSTEAD OF Trigger

The following example shows an INSTEAD OF trigger for inserting new employee row into the emp_vw view. The CREATE VIEW statement creates the emp_vw view by joining the two tables. The trigger adds the corresponding new rows into the emp and dept table respectively for a specific employee.

```
CREATE VIEW emp_vw AS SELECT * FROM emp e JOIN dept d USING(deptno);
CREATE VIEW
CREATE OR REPLACE TRIGGER empvw_instead_of_trig
    INSTEAD OF INSERT ON emp_vw
    FOR EACH ROW
DECLARE
    v_empno          emp.empno%TYPE;
```
EDB Postgres™ Advanced Server, Release 13

(continued from previous page)

v_ename emp.ename%TYPE;
v_deptno emp.deptno%TYPE;
v_dname dept.dname%TYPE;
v_loc dept.loc%TYPE;
v_action VARCHAR2(7);
BEGIN
  v_empno := :NEW.empno;
  v_ename := :NEW.ename;
  v_deptno := :NEW.deptno;
  v_dname := :NEW.dname;
  v_loc := :NEW.loc;
  INSERT INTO emp(empno, ename, deptno) VALUES(v_empno, v_ename, v_deptno);
  INSERT INTO dept(deptno, dname, loc) VALUES(v_deptno, v_dname, v_loc);
END;

CREATE TRIGGER

Now, insert the values into the emp_vw view. The insert action inserts a new row and produces the following output:

INSERT INTO emp_vw (empno, ename, deptno, dname, loc) VALUES(1234, 'ASHTON', 50, 'IT', 'NEW JERSEY');

1 row

Similarly, if you specify UPDATE or DELETE statement, the trigger will perform the appropriate actions for UPDATE or DELETE events.

13.7.6 Compound Triggers

The following example of a compound trigger records a change to the employee salary by defining a compound trigger (named hr_trigger) on the emp table.

First, create a table named emp.

CREATE TABLE emp(EMPNO INT, ENAME TEXT, SAL INT, DEPTNO INT);
CREATE TABLE

13.7. Trigger Examples
Then, create a compound trigger named `hr_trigger`. The trigger utilizes each of the four timing-points to modify the salary with an `INSERT`, `UPDATE`, or `DELETE` statement. In the global declaration section, the initial salary is declared as 10,000.

```sql
CREATE OR REPLACE TRIGGER hr_trigger
    FOR INSERT OR UPDATE OR DELETE ON emp
    COMPOUND TRIGGER
-- Global declaration.
    var_sal NUMBER := 10000;

    BEFORE STATEMENT IS
    BEGIN
        var_sal := var_sal + 1000;
        DBMS_OUTPUT.PUT_LINE('Before Statement: ' || var_sal);
    END BEFORE STATEMENT;

    BEFORE EACH ROW IS
    BEGIN
        var_sal := var_sal + 1000;
        DBMS_OUTPUT.PUT_LINE('Before Each Row: ' || var_sal);
    END BEFORE EACH ROW;

    AFTER EACH ROW IS
    BEGIN
        var_sal := var_sal + 1000;
        DBMS_OUTPUT.PUT_LINE('After Each Row: ' || var_sal);
    END AFTER EACH ROW;

    AFTER STATEMENT IS
    BEGIN
        var_sal := var_sal + 1000;
        DBMS_OUTPUT.PUT_LINE('After Statement: ' || var_sal);
    END AFTER STATEMENT;

END hr_trigger;
```

Output: Trigger created.

```
INSERT the record into table emp.

INSERT INTO emp (EMPNO, ENAME, SAL, DEPTNO) VALUES(1111, 'SMITH', 10000, 20);
```

The `INSERT` statement produces the following output:

```
Before Statement: 11000
Before each row: 12000
After each row: 13000
After statement: 14000
```

The `UPDATE` statement will update the employee salary record, setting the salary to 15000 for a specific employee number.

```
The UPDATE statement will update the employee salary record, setting the salary to 15000 for a specific employee number.
```
UPDATE emp SET SAL = 15000 where EMPNO = 1111;

The UPDATE statement produces the following output:

Before Statement: 11000
Before each row: 120000
After each row: 13000
After statement: 14000
UPDATE 1

SELECT * FROM emp;
EMPNO | ENAME | SAL | DEPTNO
-------+-------+-------+--------
1111 | SMITH | 15000 | 20
(1 row)

The DELETE statement deletes the employee salary record.

DELETE from emp where EMPNO = 1111;

The DELETE statement produces the following output:

Before Statement: 11000
Before each row: 120000
After each row: 13000
After statement: 14000
DELETE 1

SELECT * FROM emp;
EMPNO | ENAME | SAL | DEPTNO
-------+-------+-----+--------
(0 rows)

The TRUNCATE statement removes all the records from the emp table.

CREATE OR REPLACE TRIGGER hr_trigger
  FOR TRUNCATE ON emp
  COMPOUND TRIGGER
  -- Global declaration.
  var_sal NUMBER := 10000;
  BEFORE STATEMENT IS
  BEGIN
    var_sal := var_sal + 1000;
    DBMS_OUTPUT.PUT_LINE('Before Statement: ' || var_sal);
  END BEFORE STATEMENT;

  AFTER STATEMENT IS
  BEGIN
    var_sal := var_sal + 1000;
    DBMS_OUTPUT.PUT_LINE('After Statement: ' || var_sal);
  END AFTER STATEMENT;

(continues on next page)
The TRUNCATE statement produces the following output:

```
TRUNCATE emp;
Before Statement: 11000
After statement: 12000
TRUNCATE TABLE
```

**Note:** The TRUNCATE statement may be used only at a BEFORE STATEMENT or AFTER STATEMENT timing-point.

The following example creates a compound trigger named `hr_trigger` on the `emp` table with a WHEN condition that checks and prints employee salary whenever a INSERT, UPDATE, or DELETE statement affects the `emp` table. The database evaluates the WHEN condition for a row-level trigger, and the trigger is executed once per row if the WHEN condition evaluates to TRUE. The statement-level trigger is executed irrespective of the WHEN condition.

```
CREATE OR REPLACE TRIGGER hr_trigger
  FOR INSERT OR UPDATE OR DELETE ON emp
  REFERENCING NEW AS new OLD AS old
  WHEN (old.sal > 5000 OR new.sal < 8000)
  COMPOUND TRIGGER

BEFORE STATEMENT IS
BEGIN
  DBMS_OUTPUT.PUT_LINE('Before Statement');
END BEFORE STATEMENT;

BEFORE EACH ROW IS
BEGIN
  DBMS_OUTPUT.PUT_LINE('Before Each Row: ' || :OLD.sal || '|| ' || :NEW.sal);
END BEFORE EACH ROW;

AFTER EACH ROW IS
BEGIN
  DBMS_OUTPUT.PUT_LINE('After Each Row: ' || :OLD.sal || '|| ' || :NEW.sal);
END AFTER EACH ROW;

AFTER STATEMENT IS
BEGIN
  DBMS_OUTPUT.PUT_LINE('After Statement');
END AFTER STATEMENT;

END hr_trigger;
```

Insert the record into table `emp`.
INSERT INTO emp (EMPNO, ENAME, SAL, DEPTNO) VALUES (1111, 'SMITH', 1600, 20);

The INSERT statement produces the following output:

<table>
<thead>
<tr>
<th>Before Statement</th>
<th>Before Each Row: 1600</th>
<th>After Each Row: 1600</th>
<th>After Statement</th>
</tr>
</thead>
<tbody>
<tr>
<td>INSERT 0 1</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The UPDATE statement will update the employee salary record, setting the salary to 7500.

UPDATE emp SET SAL = 7500 where EMPNO = 1111;

The UPDATE statement produces the following output:

<table>
<thead>
<tr>
<th>Before Statement</th>
<th>Before Each Row: 1600 7500</th>
<th>After Each Row: 1600 7500</th>
<th>After Statement</th>
</tr>
</thead>
<tbody>
<tr>
<td>UPDATE 1</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

SELECT * from emp;

empno | ename | sal | deptno
-------+-------+------|--------
1111 | SMITH | 7500 | 20
(1 row)

The DELETE statement deletes the employee salary record.

DELETE from emp where EMPNO = 1111;

The DELETE statement produces the following output:

<table>
<thead>
<tr>
<th>Before Statement</th>
<th>Before Each Row: 7500</th>
<th>After Each Row: 7500</th>
<th>After Statement</th>
</tr>
</thead>
<tbody>
<tr>
<td>DELETE 1</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

SELECT * from emp;

empno | ename | sal | deptno
-------+-------+-----|--------
(0 rows)
Advanced Server provides a collection of packages that provide compatibility with Oracle packages.

A package is a named collection of functions, procedures, variables, cursors, user-defined record types, and records that are referenced using a common qualifier – the package identifier. Packages have the following characteristics:

- Packages provide a convenient means of organizing the functions and procedures that perform a related purpose. Permission to use the package functions and procedures is dependent upon one privilege granted to the entire package. All of the package programs must be referenced with a common name.

- Certain functions, procedures, variables, types, etc. in the package can be declared as public. Public entities are visible and can be referenced by other programs that are given EXECUTE privilege on the package. For public functions and procedures, only their signatures are visible - the program names, parameters if any, and return types of functions. The SPL code of these functions and procedures is not accessible to others, therefore applications that utilize a package are dependent only upon the information available in the signature – not in the procedural logic itself.

- Other functions, procedures, variables, types, etc. in the package can be declared as private. Private entities can be referenced and used by function and procedures within the package, but not by other external applications. Private entities are for use only by programs within the package.

- Function and procedure names can be overloaded within a package. One or more functions/procedures can be defined with the same name, but with different signatures. This provides the capability to create identically named programs that perform the same job, but on different types of input.

For more information about the package support provided by Advanced Server, see the Database Compatibility for Oracle Developers Built-in Package Guide, available at:

https://www.enterprisedb.com/edb-docs
For a list of built-in packages, see the Table of Contents, of “Built-In Packages” of the Database Compatibility for Oracle Developers Built-in Package Guide.
This chapter discusses how object-oriented programming techniques can be exploited in SPL. Object-oriented programming as seen in programming languages such as Java and C++ centers on the concept of objects. An object is a representation of a real-world entity such as a person, place, or thing. The generic description or definition of a particular object such as a person for example, is called an object type. Specific people such as “Joe” or “Sally” are said to be objects of object type, person, or equivalently, instances of the object type, person, or simply, person objects.

Note: The terms “database objects” and “objects” that have been used in this document up to this point should not be confused with an object type and object as used in this chapter. The previous usage of these terms relates to the entities that can be created in a database such as tables, views, indexes, users, etc. Within the context of this chapter, object type and object refer to specific data structures supported by the SPL programming language to implement object-oriented concepts.

Note: In Oracle, the term abstract data type (ADT) is used to describe object types in PL/SQL. The SPL implementation of object types is intended to be compatible with Oracle abstract data types.

Note: Advanced Server has not yet implemented support for some features of object-oriented programming languages. This chapter documents only those features that have been implemented.
15.1 Basic Object Concepts

An object type is a description or definition of some entity. This definition of an object type is characterized by two components:

- **Attributes** – fields that describe particular characteristics of an object instance. For a person object, examples might be name, address, gender, date of birth, height, weight, eye color, occupation, etc.
- **Methods** – programs that perform some type of function or operation on, or related to an object. For a person object, examples might be calculating the person’s age, displaying the person’s attributes, changing the values assigned to the person’s attributes, etc.

The following sections elaborate on some basic object concepts.

15.1.1 Attributes

Every object type must contain at least one attribute. The data type of an attribute can be any of the following:

- A base data type such as `NUMBER`, `VARCHAR2`, etc.
- Another object type
- A globally defined collection type (created by the `CREATE TYPE` command) such as a nested table or varray

An attribute gets its initial value (which may be null) when an object instance is initially created. Each object instance has its own set of attribute values.

15.1.2 Methods

Methods are SPL procedures or functions defined within an object type. Methods can be categorized into three general types:

- **Member Methods** – procedures or functions that operate within the context of an object instance. Member methods have access to, and can change the attributes of the object instance on which they are operating.
- **Static Methods** – procedures or functions that operate independently of any particular object instance. Static methods do not have access to, and cannot change the attributes of an object instance.
- **Constructor Methods** – functions used to create an instance of an object type. A default constructor method is always provided when an object type is defined.
15.1.3 Overloading Methods

In an object type it is permissible to define two or more identically named methods of the same type (this is, either a procedure or function), but with different signatures. Such methods are referred to as overloaded methods.

A method’s signature consists of the number of formal parameters, the data types of its formal parameters, and their order.
15.2 Object Type Components

Object types are created and stored in the database by using the following two constructs of the SPL language:

- The object type specification - This is the public interface specifying the attributes and method signatures of the object type.
- The object type body - This contains the implementation of the methods specified in the object type specification.

The following sections describe the commands used to create the object type specification and the object type body.

15.2.1 Object Type Specification Syntax

The following is the syntax of the object type specification:

```
CREATE [ OR REPLACE ] TYPE <name>
  [ AUTHID { DEFINER | CURRENT_USER } ]
  { IS | AS } OBJECT
  ( { <attribute> { <datatype> | <objtype> | <collecttype> } }
    [, ...]
  [ <method_spec> ] [, ...]
  [ <constructor> ] [, ...]
) [ [ NOT ] { FINAL | INSTANTIABLE } ] ...;
```

where `method_spec` is the following:

```
[ [ NOT ] { FINAL | INSTANTIABLE } ] ...
[ OVERRIDING ]
  <subprogram_spec>
```

where `subprogram_spec` is the following:

```
{ MEMBER | STATIC }
{ PROCEDURE <proc_name>
  [ ( [ SELF [ IN | IN OUT ] <name> ]
    [, <parml> [ IN | IN OUT | OUT ] <datatype1>
      [ DEFAULT <value1> ] ]
    [, <parm2> [ IN | IN OUT | OUT ] <datatype2>
      [ DEFAULT <value2> ]
    ) ...]
  ] ...
  ]
|
| FUNCTION <func_name>
  [ ( [ SELF [ IN | IN OUT ] <name> ]
    [, <parml> [ IN | IN OUT | OUT ] <datatype1>
      [ DEFAULT <value1> ] ]
    [, <parm2> [ IN | IN OUT | OUT ] <datatype2>
      [ DEFAULT <value2> ]
    ) ...]
  ] ...
```
where constructor is the following:

```
CONSTRUCTOR <func_name>
  [ ( [ SELF [ IN | IN OUT ] <name> ]
    [, <parm1> [ IN | IN OUT | OUT ] <datatype1>
      [ DEFAULT <value1> ] ]
    [, <parm2> [ IN | IN OUT | OUT ] <datatype2>
      [ DEFAULT <value2> ]
    ] ...)]
RETURN self AS RESULT
```

**Note:** The OR REPLACE option cannot be currently used to add, delete, or modify the attributes of an existing object type. Use the DROP TYPE command to first delete the existing object type. The OR REPLACE option can be used to add, delete, or modify the methods in an existing object type.

**Note:** The PostgreSQL form of the ALTER TYPE ALTER ATTRIBUTE command can be used to change the data type of an attribute in an existing object type. However, the ALTER TYPE command cannot add or delete attributes in the object type.

name is an identifier (optionally schema-qualified) assigned to the object type.

If the AUTHID clause is omitted or DEFINER is specified, the rights of the object type owner are used to determine access privileges to database objects. If CURRENT_USER is specified, the rights of the current user executing a method in the object are used to determine access privileges.

attribute is an identifier assigned to an attribute of the object type.

datatype is a base data type.

objtype is a previously defined object type.

collecttype is a previously defined collection type.

Following the closing parenthesis of the CREATE TYPE definition, [ NOT ] FINAL specifies whether or not a subtype can be derived from this object type. FINAL, which is the default, means that no subtypes can be derived from this object type. Specify NOT FINAL if you want to allow subtypes to be defined under this object type.

**Note:** Even though the specification of NOT FINAL is accepted in the CREATE TYPE command, SPL does not currently support the creation of subtypes.

15.2. Object Type Components
Following the closing parenthesis of the `CREATE TYPE` definition, `[ NOT ] INSTANTIABLE` specifies whether or not an object instance can be created of this object type. `INSTANTIABLE`, which is the default, means that an instance of this object type can be created. Specify `NOT INSTANTIABLE` if this object type is to be used only as a parent “template” from which other specialized subtypes are to be defined. If `NOT INSTANTIABLE` is specified, then `NOT FINAL` must be specified as well. If any method in the object type contains the `NOT INSTANTIABLE` qualifier, then the object type, itself, must be defined with `NOT INSTANTIABLE` and `NOT FINAL`.

**Note:** Even though the specification of `NOT INSTANTIABLE` is accepted in the `CREATE TYPE` command, SPL does not currently support the creation of subtypes.

`method_spec` denotes the specification of a member method or static method.

Prior to the definition of a method, `[ NOT ] FINAL` specifies whether or not the method can be overridden in a subtype. `NOT FINAL` is the default meaning the method can be overridden in a subtype.

Prior to the definition of a method specify `OVERRIDING` if the method overrides an identically named method in a supertype. The overriding method must have the same number of identically named method parameters with the same data types and parameter modes, in the same order, and the same return type (if the method is a function) as defined in the supertype.

Prior to the definition of a method, `[ NOT ] INSTANTIABLE` specifies whether or not the object type definition provides an implementation for the method. If `INSTANTIABLE` is specified, then the `CREATE TYPE BODY` command for the object type must specify the implementation of the method. If `NOT INSTANTIABLE` is specified, then the `CREATE TYPE BODY` command for the object type must not contain the implementation of the method. In this latter case, it is assumed a subtype contains the implementation of the method, overriding the method in this object type. If there are any `NOT INSTANTIABLE` methods in the object type, then the object type definition itself, must specify `NOT INSTANTIABLE` and `NOT FINAL` following the closing parenthesis of the object type specification. The default is `INSTANTIABLE`.

`subprogram_spec` denotes the specification of a procedure or function and begins with the specification of either `MEMBER` or `STATIC`. A member subprogram must be invoked with respect to a particular object instance while a static subprogram is not invoked with respect to any object instance.

`proc_name` is an identifier of a procedure. If the `SELF` parameter is specified, `name` is the object type name given in the `CREATE TYPE` command. If specified, `parm1, parm2, ...` are the formal parameters of the procedure. `datatype1, datatype2, ...` are the data types of `parm1, parm2, ...` respectively. `IN, IN OUT, and OUT` are the possible parameter modes for each formal parameter. If none are specified, the default is `IN`. `value1, value2, ...` are default values that may be specified for `IN` parameters.

Include the `CONSTRUCTOR` keyword and function definition to define a constructor function.

`func_name` is an identifier of a function. If the `SELF` parameter is specified, `name` is the object type name given in the `CREATE TYPE` command. If specified, `parm1, parm2, ...` are the formal parameters of the function. `datatype1, datatype2, ...` are the data types of `parm1, parm2, ...` respectively. `IN, IN OUT, and OUT` are the possible parameter modes for each formal parameter. If none are specified, the default is `IN`. `value1, value2, ...` are default values that may be specified for `IN` parameters. `return_type` is the data type of the value the function returns.

The following points should be noted about an object type specification:

---

**15.2. Object Type Components**
• There must be at least one attribute defined in the object type.
• There may be none, one, or more methods defined in the object type.
• For each member method there is an implicit, built-in parameter named SELF, whose data type is that of the object type being defined.

**SELF** refers to the object instance that is currently invoking the method. **SELF** can be explicitly declared as an **IN** or **IN OUT** parameter in the parameter list (for example as **MEMBER FUNCTION** (SELF **IN OUT** object_type ...)).

If **SELF** is explicitly declared, **SELF** must be the first parameter in the parameter list. If **SELF** is not explicitly declared, its parameter mode defaults to **IN OUT** for member procedures and **IN** for member functions.

• A static method cannot be overridden (**OVERRIDING** and **STATIC** cannot be specified together in **method_spec**).
• A static method must be instantiable (**NOT INSTANTIABLE** and **STATIC** cannot be specified together in **method_spec**).

### 15.2.2 Object Type Body Syntax

The following is the syntax of the object type body:

```
CREATE [ OR REPLACE ] TYPE BODY <name>
 { IS | AS }
 <method_spec> [...]
 [ <constructor> ] [...]
END;
```

where **method_spec** is the following:

```
{ MEMBER | STATIC }
{ PROCEDURE <proc_name>
 [ { [ SELF [ IN | IN OUT ] <name> ] }
 [ , parm1 [ IN | IN OUT | OUT ] datatype1
 [ DEFAULT value1 ] ]
 [ , parm2 [ IN | IN OUT | OUT ] datatype2
 [ DEFAULT value2 ]
 ] ...]
 ]
{ IS | AS }
{ PRAGMA AUTONOMOUS_TRANSACTION; }
{ <declarations> }
BEGIN
 <statement>; ...
{ EXCEPTION
 WHEN ... THEN
```

(continues on next page)
where `constructor` is:

```
CONSTRUCTOR <func_name>
   [ ( [ SELF [ IN | IN OUT ] <name> ]
     [, parm1 [ IN | IN OUT | OUT ] datatype1
        [ DEFAULT value1 ] ]
     [, parm2 [ IN | IN OUT | OUT ] datatype2
        [ DEFAULT value2 ]
     ] ...)
]
RETURN self AS RESULT
( IS | AS )
[ <declarations> ]
BEGIN
  <statement>; ...
[ EXCEPTION
  WHEN ... THEN
  <statement>; ...
END;
```

`name` is an identifier (optionally schema-qualified) assigned to the object type.

`method_spec` denotes the implementation of an instantiable method that was specified in the `CREATE TYPE` command.

If `INSTANTIABLE` was specified or omitted in `method_spec` of the `CREATE TYPE` command, then there must be a `method_spec` for this method in the `CREATE TYPE BODY` command.

If `NOT INSTANTIABLE` was specified in `method_spec` of the `CREATE TYPE` command, then there must be no `method_spec` for this method in the `CREATE TYPE BODY` command.
subprogram_spec denotes the specification of a procedure or function and begins with the specification of either MEMBER or STATIC. The same qualifier must be used as was specified in subprogram_spec of the CREATE TYPE command.

proc_name is an identifier of a procedure specified in the CREATE TYPE command. The parameter declarations have the same meaning as described for the CREATE TYPE command, and must be specified in the CREATE TYPE BODY command in the same manner as specified in the CREATE TYPE command.

Include the CONSTRUCTOR keyword and function definition to define a constructor function.

func_name is an identifier of a function specified in the CREATE TYPE command. The parameter declarations have the same meaning as described for the CREATE TYPE command, and must be specified in the CREATE TYPE BODY command in the same manner as specified in the CREATE TYPE command.

return_type is the data type of the value the function returns and must match return_type given in the CREATE TYPE command.

PRAGMA AUTONOMOUS_TRANSACTION is the directive that sets the procedure or function as an autonomous transaction.

declarations are variable, cursor, type, or subprogram declarations. If subprogram declarations are included, they must be declared after all other variable, cursor, and type declarations.

statement is an SPL program statement.
15.3 Creating Object Types

You can use the CREATE TYPE command to create an object type specification, and the CREATE TYPE BODY command to create an object type body. This section provides some examples using the CREATE TYPE and CREATE TYPE BODY commands.

The first example creates the addr_object_type object type that contains only attributes and no methods:

```sql
CREATE OR REPLACE TYPE addr_object_type AS OBJECT
(
   street VARCHAR2(30),
   city VARCHAR2(20),
   state CHAR(2),
   zip NUMBER(5)
);
```

Since there are no methods in this object type, an object type body is not required. This example creates a composite type, which allows you to treat related objects as a single attribute.

### 15.3.1 Member Methods

A member method is a function or procedure that is defined within an object type and can only be invoked through an instance of that type. Member methods have access to, and can change the attributes of, the object instance on which they are operating.

The following object type specification creates the emp_obj_typ object type:

```sql
CREATE OR REPLACE TYPE emp_obj_typ AS OBJECT
(
   empno NUMBER(4),
   ename VARCHAR2(20),
   addr ADDR_OBJ_TYP,
   MEMBER PROCEDURE display_emp(SELF IN OUT emp_obj_typ)
);
```

Object type emp_obj_typ contains a member method named display_emp. display_emp uses a SELF parameter, which passes the object instance on which the method is invoked.

A SELF parameter is a parameter whose data type is that of the object type being defined. SELF always refers to the instance that is invoking the method. A SELF parameter is the first parameter in a member procedure or function regardless of whether it is explicitly declared in the parameter list.

The following code snippet defines an object type body for emp_obj_typ:

```sql
CREATE OR REPLACE TYPE BODY emp_obj_typ AS
   MEMBER PROCEDURE display_emp (SELF IN OUT emp_obj_typ)
   IS
   BEGIN
      DBMS_OUTPUT.PUT_LINE('Employee No : ' || empno);
      DBMS_OUTPUT.PUT_LINE('Name : ' || ename);
   (continues on next page)
```
You can also use the SELF parameter in an object type body. To illustrate how the SELF parameter would be used in the CREATE TYPE BODY command, the preceding object type body could be written as follows:

```
CREATE OR REPLACE TYPE BODY emp_obj_typ AS
  MEMBER PROCEDURE display_emp (SELF IN OUT emp_obj_typ)
  IS
    BEGIN
      DBMS_OUTPUT.PUT_LINE('Employee No : ' || SELF.empno);
      DBMS_OUTPUT.PUT_LINE('Name : ' || SELF.ename);
      DBMS_OUTPUT.PUT_LINE('Street : ' || SELF.addr.street);
      DBMS_OUTPUT.PUT_LINE('City/State/Zip: ' || SELF.addr.city || ', ' || SELF.addr.state || ' ' || LPAD(SELF.addr.zip,5,'0'));
    END;
END;
```

Both versions of the emp_obj_typ body are completely equivalent.

### 15.3.2 Static Methods

Like a member method, a static method belongs to a type. A static method, however, is invoked not by an instance of the type, but by using the name of the type. For example, to invoke a static function named `get_count`, defined within the `emp_obj_type` type, you can write:

```
emp_obj_type.get_count();
```

A static method does not have access to, and cannot change the attributes of an object instance, and does not typically work with an instance of the type.

The following object type specification includes a static function `get_dname` and a member procedure `display_dept`:

```
CREATE OR REPLACE TYPE dept_obj_typ AS OBJECT (
  deptno NUMBER(2),
  STATIC FUNCTION get_dname(p_deptno IN NUMBER) RETURN VARCHAR2,
  MEMBER PROCEDURE display_dept
);
```

The object type body for `dept_obj_typ` defines a static function named `get_dname` and a member procedure named `display_dept`:

```
CREATE OR REPLACE TYPE BODY dept_obj_typ AS
  STATIC FUNCTION get_dname(p_deptno IN NUMBER) RETURN VARCHAR2
  IS
    v_dname VARCHAR2(14); (continues on next page)
```
BEGIN
  CASE p_deptno
    WHEN 10 THEN v_dname := 'ACCOUNTING';
    WHEN 20 THEN v_dname := 'RESEARCH';
    WHEN 30 THEN v_dname := 'SALES';
    WHEN 40 THEN v_dname := 'OPERATIONS';
    ELSE v_dname := 'UNKNOWN';
  END CASE;
  RETURN v_dname;
END;

MEMBER PROCEDURE display_dept
IS
BEGIN
  DBMS_OUTPUT.PUT_LINE('Dept No : ' || SELF.deptno);
  DBMS_OUTPUT.PUT_LINE('Dept Name : ' ||
    dept_obj_typ.get_dname(SELF.deptno));
END;
END;

Within the static function get_dname, there can be no references to SELF. Since a static function is invoked independently of any object instance, it has no implicit access to any object attribute.

Member procedure display_dept can access the deptno attribute of the object instance passed in the SELF parameter. It is not necessary to explicitly declare the SELF parameter in the display_dept parameter list.

The last DBMS_OUTPUT.PUT_LINE statement in the display_dept procedure includes a call to the static function get_dname (qualified by its object type name dept_obj_typ).

### 15.3.3 Constructor Methods

A constructor method is a function that creates an instance of an object type, typically by assigning values to the members of the object. An object type may define several constructors to accomplish different tasks. A constructor method is a member function (invoked with a SELF parameter) whose name matches the name of the type.

For example, if you define a type named address, each constructor is named address. You may overload a constructor by creating one or more different constructor functions with the same name, but with different argument types.

The SPL compiler will provide a default constructor for each object type. The default constructor is a member function whose name matches the name of the type and whose argument list matches the type members (in order). For example, given an object type such as:

```
CREATE TYPE address AS OBJECT
  (street_address VARCHAR2(40),
   postal_code VARCHAR2(10),
   city VARCHAR2(40),

(continues on next page)
The SPL compiler will provide a default constructor with the following signature:

```sql
CONSTRUCTOR FUNCTION address
(
  street_address VARCHAR2(40),
  postal_code VARCHAR2(10),
  city VARCHAR2(40),
  state VARCHAR2(2)
)
```

The body of the default constructor simply sets each member to `NULL`.

To create a custom constructor, declare the constructor function (using the keyword `constructor`) in the `CREATE TYPE` command and define the construction function in the `CREATE TYPE BODY` command. For example, you may wish to create a custom constructor for the `address` type which computes the city and state given a `street_address` and `postal_code`:

```sql
CREATE TYPE address AS OBJECT
(
  street_address VARCHAR2(40),
  postal_code VARCHAR2(10),
  city VARCHAR2(40),
  state VARCHAR2(2),

  CONSTRUCTOR FUNCTION address
  (  
    street_address VARCHAR2,
    postal_code VARCHAR2
  ) RETURN self AS RESULT

) CREATE TYPE BODY address AS

CONSTRUCTOR FUNCTION address
(
  street_address VARCHAR2,
  postal_code VARCHAR2
) RETURN self AS RESULT
IS
BEGIN
  self.street_address := street_address;
  self.postal_code := postal_code;
  self.city := postal_code_to_city(postal_code);  
  self.state := postal_code_to_state(postal_code);
  RETURN;
END;
END;
```

To create an instance of an object type, you invoke one of the constructor methods for that type. For example:
DECLARE
  cust_addr address := address('100 Main Street', 02203);
BEGIN
  DBMS_OUTPUT.PUT_LINE(cust_addr.city); -- displays Boston
  DBMS_OUTPUT.PUT_LINE(cust_addr.state); -- displays MA
END;

Custom constructor functions are typically used to compute member values when given incomplete information. The preceding example computes the values for `city` and `state` when given a postal code.

Custom constructor functions are also used to enforce business rules that restrict the state of an object. For example, if you define an object type to represent a `payment`, you can use a custom constructor to ensure that no object of type `payment` can be created with an `amount` that is `NULL`, negative, or zero. The default constructor would set `payment.amount` to `NULL` so you must create a custom constructor (whose signature matches the default constructor) to prohibit `NULL` amounts.
15.4 Creating Object Instances

To create an instance of an object type, you must first declare a variable of the object type, and then initialize the declared object variable. The syntax for declaring an object variable is:

\[
<\text{object } \text{obj\_type}>
\]

\text{object} is an identifier assigned to the object variable.
\text{obj\_type} is the identifier of a previously defined object type.

After declaring the object variable, you must invoke a \textit{constructor method} to initialize the object with values. Use the following syntax to invoke the constructor method:

\[
[\text{NEW}] \ <\text{obj\_type}> \ ((\text{expr1} | \text{NULL}) \ [, \ (\text{expr2} | \text{NULL}) \ ] \ [, \ ...])
\]

\text{obj\_type} is the identifier of the object type’s constructor method; the constructor method has the same name as the previously declared object type.

\text{expr1}, \text{expr2}, \ldots \ are expressions that are type-compatible with the first attribute of the object type, the second attribute of the object type, etc. If an attribute is of an object type, then the corresponding expression can be \text{NULL}, an object initialization expression, or any expression that returns that object type.

The following anonymous block declares and initializes a variable:

\[
\text{DECLARE} \\
\text{v\_emp EMP\_OBJ\_TYP;} \\
\text{BEGIN} \\
\text{v\_emp := emp\_obj\_typ (9001,'JONES',} \\
\text{ addr\_obj\_typ('123 MAIN STREET','EDISON','NJ',08817));} \\
\text{END;} \\
\]

The variable (v\_emp) is declared with a previously defined object type named \text{EMP\_OBJ\_TYPE}. The body of the block initializes the variable using the \text{emp\_obj\_typ} and \text{addr\_obj\_type} constructors.

You can include the \text{NEW} keyword when creating a new instance of an object in the body of a block. The \text{NEW} keyword invokes the object constructor whose signature matches the arguments provided.

The following example declares two variables, named \text{mgr} and \text{emp}. The variables are both of \text{EMP\_OBJ\_TYPE}. The \text{mgr} object is initialized in the declaration, while the \text{emp} object is initialized to \text{NULL} in the declaration, and assigned a value in the body.

\[
\text{DECLARE} \\
\text{mgr EMP\_OBJ\_TYPE := (9002,'SMITH');} \\
\text{emp EMP\_OBJ\_TYPE;} \\
\text{BEGIN} \\
\text{emp := NEW EMP\_OBJ\_TYPE (9003,'RAY');} \\
\text{END;} \\
\]

\textbf{Note:} In Advanced Server, the following alternate syntax can be used in place of the constructor method.
ROW is an optional keyword if two or more terms are specified within the parenthesis-enclosed, comma-delimited list. If only one term is specified, then specification of the ROW keyword is mandatory.

### 15.5 Referencing an Object

Once an object variable is created and initialized, individual attributes can be referenced using dot notation of the form:

```
<object.attribute>
```

object is the identifier assigned to the object variable. attribute is the identifier of an object type attribute.

If attribute, itself, is of an object type, then the reference must take the form:

```
<object.attribute.attribute_inner>
```

attribute_inner is an identifier belonging to the object type to which attribute references in its definition of object.

The following example expands upon the previous anonymous block to display the values assigned to the `emp_obj_typ` object.

```sql
DECLARE
  v_emp EMP_OBJ_TYP;
BEGIN
  v_emp := emp_obj_typ(9001,'JONES',
     addr_obj_typ('123 MAIN STREET','EDISON','NJ',08817));
  DBMS_OUTPUT.PUT_LINE('Employee No : ' || v_emp.empno);
  DBMS_OUTPUT.PUT_LINE('Name : ' || v_emp.ename);
  DBMS_OUTPUT.PUT_LINE('Street : ' || v_emp.addr.street);
  DBMS_OUTPUT.PUT_LINE('City/State/Zip: ' || v_emp.addr.city || ', ' ||
      v_emp.addr.state || ' ' || LPAD(v_emp.addr.zip,5,'0'));
END;
```

The following is the output from this anonymous block.

<table>
<thead>
<tr>
<th>Employee No</th>
<th>9001</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>JONES</td>
</tr>
<tr>
<td>Street</td>
<td>123 MAIN STREET</td>
</tr>
<tr>
<td>City/State/Zip</td>
<td>EDISON, NJ 08817</td>
</tr>
</tbody>
</table>

Methods are called in a similar manner as attributes.

Once an object variable is created and initialized, member procedures or functions are called using dot notation of the form:
object is the identifier assigned to the object variable. prog_name is the identifier of the procedure or function.

Static procedures or functions are not called utilizing an object variable. Instead the procedure or function is called utilizing the object type name:

object_type is the identifier assigned to the object type. prog_name is the identifier of the procedure or function.

The results of the previous anonymous block can be duplicated by calling the member procedure display_emp:

```
DECLARE
  v_emp    EMP_OBJ_TYP;
BEGIN
  v_emp := emp_obj_typ(9001,'JONES',
                      addr_obj_typ('123 MAIN STREET','EDISON','NJ',08817));
  v_emp.display_emp;
END;
```

The following is the output from this anonymous block.

<table>
<thead>
<tr>
<th>Employee No</th>
<th>9001</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>JONES</td>
</tr>
<tr>
<td>Street</td>
<td>123 MAIN STREET</td>
</tr>
<tr>
<td>City/State/Zip</td>
<td>EDISON, NJ 08817</td>
</tr>
</tbody>
</table>

The following anonymous block creates an instance of dept_obj_typ and calls the member procedure display_dept:

```
DECLARE
  v_dept    DEPT_OBJ_TYP := dept_obj_typ (20);
BEGIN
  v_dept.display_dept;
END;
```

The following is the output from this anonymous block.

<table>
<thead>
<tr>
<th>Dept No</th>
<th>20</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dept Name</td>
<td>RESEARCH</td>
</tr>
</tbody>
</table>

The static function defined in dept_obj_typ can be called directly by qualifying it by the object type name as follows:

```
BEGIN
  DBMS_OUTPUT.PUT_LINE(dept_obj_typ.get_dname(20));
END;
```
15.6 Dropping an Object Type

The syntax for deleting an object type is as follows.

```sql
DROP TYPE <objtype>;
```

`objtype` is the identifier of the object type to be dropped. If the definition of `objtype` contains attributes that are themselves object types or collection types, these nested object types or collection types must be dropped last.

If an object type body is defined for the object type, the `DROP TYPE` command deletes the object type body as well as the object type specification. In order to recreate the complete object type, both the `CREATE TYPE` and `CREATE TYPE BODY` commands must be reissued.

The following example drops the `emp_obj_typ` and the `addr_obj_typ` object types created earlier in this chapter. `emp_obj_typ` must be dropped first since it contains `addr_obj_typ` within its definition as an attribute.

```sql
DROP TYPE emp_obj_typ;
DROP TYPE addr_obj_typ;
```

The syntax for deleting an object type body, but not the object type specification is as follows.

```sql
DROP TYPE BODY <objtype>;
```

The object type body can be recreated by issuing the `CREATE TYPE BODY` command.

The following example drops only the object type body of the `dept_obj_typ`.

```sql
DROP TYPE BODY dept_obj_typ;
```
